- Draft of the UR has been reviewed by Survey Panel without major comments by qualified majority.

- Some later modifications were made based on GPG comments to specify that the requirement applies to the aftmost propeller shaft bearing, ensuring clarity for all readers. MP members agreed that the content of the UR is applicable to the aftmost propeller shaft bearing.

- The aftmost propeller shaft bearing is the bearing positioned immediately adjacent to and supporting the propeller. This critical bearing can either be located within the stern tube or mounted in a strut.

UR M86 "Monitoring and Safety Functions for Exhaust Gas Cleaning (SOx) Systems"

Summary

This Resolution provides the minimum requirements as regards monitoring and safety functions of exhaust gas cleaning (SOx) systems (EGCS).

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
New (Nov 2024)	27 November 2024	01 January 2026

- **New (Nov 2024)**

1 Origin of Change:

None

2 Main Reason for Change:

None

3 Surveyability review of UR and Auditability review of PR

None, no surveyability items has been found by Machinery Panel.

4 Human Element issues assessment

Not applicable.

5 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None

6 History of Decisions Made:

The topic of alarms and safeguards for Exhaust Gas Cleaning Systems (EGCS) was brought up to the Panel by a member society based on clients' concerns regarding the issue of water leakage from EGC units located in the engine room. The development of a new UR was in this regard was suggested to the Panel. It was agreed that the new UR should better look holistically at alarms and safeguards for EGC units, and not only at the issue of water leakage.

As safety is a crucial aspect to the operation of EGCS, the benefit of preparation of an IACS UR is to offer unification among member societies requirements for the design and installation of such equipment.

7 Other Resolutions Changes:

Technical Background (TB) document for UR M86 (New Nov 2024)

1. Scope and objectives

The objective of this new UR is to provide minimum requirements as regards the monitoring and safety functions of exhaust gas cleaning systems (SOx Scrubbers).

2. Engineering background for technical basis and rationale

Critical amongst the exhaust emissions regulations are the measures to reduce sulfur oxide (SOx) emissions inherent to the relatively high sulfur content of traditional marine fuels. Installation of an Exhaust Gas Cleaning System (EGCS) as an after-treatment device is one of a number of different routes to achieve SOx regulatory compliance.

There are current IMO guidelines covering the testing, survey and certification of EGCS, which generally cover the performance and emissions compliance aspects, leaving classification societies to develop further requirements primarily relating to safety issues.

The issue of engine room flooding in case of EGCS water leakage and associated detection arrangements needs special consideration as to whether engine room bilge detector under SOLAS Reg. II-1/48.1 can be accepted for EGCS shutdown; or a high-high bilge level alarm sensor together with an automatic EGCS shutdown function activated by the high-high level alarm is to be provided in the bilge well.

2a. Specification of the data utilised in the development/revision of the proposed IACS Resolution, if any

None

3. Source/derivation of the proposed IACS Resolution

- SOLAS Reg. II-1/ 48.1.
- Res. MEPC.340(77) 2021 Guidelines for Exhaust Gas Cleaning Systems.
- Member Societies' Rules and Guides.

4. Summary of Changes intended for the revised Resolution

None

5. Points of discussions or possible discussions

1) Section 1 General, A member suggested to add "*All systems outlined in this document are to be in compliance with applicable international regulations, including IMO MARPOL Annex VI and related guidelines*" at the end of paragraph. The qualified majority found that the meaning of sentence is obvious to readers, making it unnecessary to add if there are no specific requirement of the international regulations to be mentioned.

2) Section 2 Exhaust Bypass:

A member suggested adding a requirement for permanent soot cleaning arrangement as follows: The bypass arrangement may be omitted, provided the EGCS is designed for dry operation and has permanent soot cleaning arrangement. The qualified majority preferred the expression "and the lack of the bypass arrangement does not interfere with the continuous operation of the engine" (suggested by another member) in lieu of that one for soot arrangements. Moreover, the following alternatives were suggested for the second paragraph of section 2:

- In installations with individually controlled bypass- and uptake dampers per each fuel consumer, an interlock is required to prevent both dampers from being closed at the same time. The interlock shall be provided to prevent closing valve(s) on bypass and EGCS streams simultaneously.

- It shall not be possible to close the bypass damper unless the corresponding uptake damper is confirmed open. It shall also not be possible to close the uptake damper unless the corresponding bypass damper is confirmed open. Where the individual bypass- and uptake dampers for multiple engines are controlled by a common scrubber control system, the bypass dampers shall open automatically in case of high back pressure. This shall be controlled by a system arranged independent of the common scrubber control system. This does not apply for scrubber installations with either a 3-way damper or dampers with other mechanical interlock.

A member suggested introducing a risk assessment to be conducted demonstrating that EGC is designed for dry operation under all operating conditions.
The qualified majority found that conducting risk assessment isn't suitable means for ensuring that an EGCS is designed for dry operation under all operating conditions.

The Manufacturers must submit evidence demonstrating that the EGCS is designed for dry operation.

A member suggested the interlock system is to be designed to prevent single-point failures and automatically opening the bypass damper.
The qualified majority did not agree with the proposal for single point failures in the interlock system and found the initial text below provided by the Panel is clear and sufficient.

"In installations with individually controlled bypass- and uptake dampers, an interlock is required to prevent both dampers from being closed at the same time. The interlock can comprise a pressure sensor upstream of the dampers, interfaced to the EGCS safety system, opening the bypass damper in case of high back pressure."

3) Section 3 Control and Monitoring System: With regard to the FMEA and the requirement "when the control system is connected to an integrated control system of a vessel" a member expressed the view that EGCS manufacturers may not recognize the configuration of integrated control system in which the EGCS will be installed, therefore, they may not be able to submit an FMEA.

4) Section 4 Safety Shutdown System:

a) A discussion was held on the expression "as far as is practicable" and the independent operation of the safety system from the control and alarm systems:

b) The expression "as far as is practicable" was initially deleted, however after further discussion it was reinstated, following a discussion on a member's comment that there are some designs in which safety systems and control & monitoring systems share a control device (PLC).

c) A clarification was requested by a member for the expression "independently". The following views were offered:

   i) In general systems are considered independent where they do not share components such that a single failure in any one component in a system will not render the other systems inoperative.
   ii) ..a failure in one of the systems concerned should not render the other one inoperative.
   iii) Considering the possible consequence of failure in an exhaust gas scrubber installation (flooding, exhaust gas blocked), one of the Member's opinions is that scrubber safety shall be arranged independent of the scrubber control system. Perhaps the wording "safety system" in the proposed text can be misunderstood, as e.g. independent exhaust gas damper safety may be maintained through simple hardwired circuitry and did not agree that a common PLC covering both scrubber control and safety is acceptable. An explanation on EGCS arrangements where members accept combined scrubber safety and control/alarm is requested for further discussion within the MP.
   iv) .. Process sensors for safety and the belonging cables shall be separate from the control system.
   v) ..at least sensors and wires should be separate.
   vi) ..concerning the comment for PLC, the Member requires redundancy if the system cannot be designed independently.
   vii) ..the word "independently" means that the Control and Monitoring Systems have no influence for the Safety Shutdown System.
   viii) ..the safety system is to be independent from control and alarm systems, by means of separate power supply, cables and sensors.

d) A new discussion following the previous one on redundancy and independence was held, with the following views:

   i) ….understanding is that redundancy and independence are two different things and that a requirement for independence cannot be substituted with a requirement on redundancy.
   ii) There would be the case that control and safety system of EGCS is connected to a ship's integrated system or a standalone system. In either case, a separate PLC for EGCS will be required, but not required to arrange each dedicated PLC for control and safety system of EGCS. Each dedicated PLC may be required for an integrated system comprising different kinds of systems such as a combined system of FA/FD, PA, GA, etc. but not required between safety system and control system of a single system EGCS.
   iii) … "redundancy" in general cannot substitute "independency". "Redundancy" may be applied only on specific / individual parts of the system, and the system would still be vulnerable to several failure modes affecting both the control and the safety functions at the same time.

iv) The Member appreciated comments on the common PLC and noted that some members do not believe such a design is acceptable.

5) Section 4, Table with alarms and safeguards:

a) The term "Display" in the second column of the Table has been replaced by "Remote Indication", which, after further discussion, has been replaced with the expression "Indication at control positions". It has been also clarified that there is no need for devices for continuous monitoring.

b) The meaning of "X" was discussed, which is "to be provided".

c) A comment that wet emissions abatement systems are to be shutdown automatically in the event of closure of the overboard discharge valve, has not been considered for an explicit additional requirement in the Table.

d) A proposal to include "a self-check facility" for the safety system did not receive the qualified majority's support.

e) High temperature alarm:

i) The high temperature alarm before the unit was changed to same alarm after the unit based on the following justification offered by a member and accepted by the qualified majority: Temperature before the scrubber is irrelevant as long as the scrubber is working (temperature is quenched as part of the first stage of the scrubbing process) and shutting down water supply/opening bypass in this condition could aggravate the problem upstream of the unit. Temperature increase after the scrubber indicates a fault in the scrubber, e.g. defective nozzles, and should lead to shutdown.

ii) A proposal was made for relaxation of "Exhaust gas temperature after EGC unit (high-high)" to take measures in case of fire in the EGC unit by operating the washwater pump. The excessive operation of washwater pump could be prevented based on the water level monitoring. The proposal has not received the support from the majority.

f) With regard to the high-pressure alarm initially suggested for the differential pressure across the unit, a high-pressure alarm for high pressure before the unit has been introduced on the following basis offered by a member:

i) Pressure before the unit is what is relevant in order to protect the consumers connected to the cleaning unit and adding a sensor after the unit to monitor pressure drop just increases complexity without adding safety. Further, the unit is pretty much always the last item in the exhaust line (economizers and SCR are always fitted before the scrubber) so the pressure after the scrubber is basically always atmospheric or close to it. If there is equipment fitted after the scrubber unit which may clog, a differential pressure monitoring setup across the scrubber unit would hide a problem in the equipment downstream (differential pressure would be unchanged while actual backpressure to the connected consumers would increase).

ii) After further discussion, high pressure alarm for high pressure before the unit "and/or" high differential pressure across EGC unit has been stated in the Table.

iii) Another member suggested the following comment: When differential pressure across EGC unit is wired to the independent safety system, the pressure sensor before the unit shall be wired to the control & monitoring system (i.e. NOT the safety system)

g) Bilge level alarm: After lengthy discussions and various proposals in many rounds, the qualified majority supported the suggestion to not implement the automatic shutdown at high-high bilge level alarm (even though which was the main reason for the initiation of the work on this UR, ref. section 4 of the HF and section 2 above).

i) Based on inconsistencies with other seawater pumps, such as CSW pumps and ballast pumps, which do not require shutdown, as well as the various reasons for bilge generation in the engine room.
ii) In case the machinery space is manned, the crew will identify any leakage without any need for a dedicated alarm.
iii) Taking into account the above reasons in i) and ii), the panel decided to delete the parameter of bilge level alarm in Table 1 of the UR.
iv) During the discussion in the 40th Machinery Panel meeting, it was agreed that the work should proceed by addressing the essential parameters for indication, alarms and safety functions in Table 1 of the UR.

h) Water level in wet EGC: A suggestion for relaxation of the "water level in wet EGC unit" as this is not included in para. 4.4.7 of the EGCS Guidelines did not find support. Furthermore, the initial requirement "X" in the column for "indication" with a Footnote clarifying that a level switch is acceptable has been removed.

i) In Note 1 the expression "all EGCS pumps" has replaced the previous expression "wash water pumps" to also cover pumps in closed loop and treatment fluid systems.

j) A member suggested to adding definition of "X", "High/High-High" and "Low/Low-Low" for table 1 in section 5.
The Panel found that the presentation of control and monitoring in Table 1 aligns with other IACS URs, as alarms and functions have been introduced, and the content of Table 1 is self-explanatory.

6) A member proposed an additional clause, numbered 4, in the draft UR for Cyber Resilience, which includes the following requirements.
"Appropriate cyber resilience measures are to be implemented for the control and monitoring systems of the EGCS to protect against cyber threats".
The qualified majority in the Panel don't support this suggestion since Cyber security is addressed properly by IACS in a separate UR, which is applicable to all relevant systems and its not necessary to consider nor suitable to addressing this additional cluse in the individual URs.

UR M87 “Certification Scheme for Reciprocating Internal Combustion Engines”

Summary

This UR provides the Engine Certification Scheme based on engine type approval, including the requirements for issuing a type approval certificate, design evaluation certificate, and product certificate for individual engines.

It outlines the process and associated URs for engine certification, intended for shipboard applications such as propulsion, electrical power generation, or other auxiliary purposes.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
New (Apr 2025)	20 April 2025	01 January 2027

- **New (Apr 2025)**

1 Origin of Change:

☒ Request by non-IACS entity (CIMAC)

2 Main Reason for Change:

CIMAC WG2 is of the opinion that the existing UR M51 and UR M71 need to be revised and updated. They propose the development of a new UR titled 'Certification Scheme for Engines,' in line with technological advancements and considering operational aspects.
The Machinery Panel has decided to assess these proposals and improve the URs related to Internal Combustion (I.C.) Engines.

3 Surveyability review of UR and Auditability review of PR

Draft document UR has been reviewed by Survey Panel for surevability items.

4 Human Element issues assessment

Not applicable.

5 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None.

6 History of Decisions Made:

CIMAC proposed a revision of the existing UR M51 and UR M71 involving the followings.

- The revision of the existing UR M51 to cover only the Factory acceptance test of I.C Engines
- The revision of the existing UR M71 to cover only the Type approval test of I.C Engines
- The development of a new UR M87 on "Certification Scheme for Type Approval of I.C engines" providing requirements regarding the scheme for type approval of I.C Engines
- The development of a new UR M88 on "Shipboard Trials of I.C engines" providing requirements regarding the tests of I.C engines to be conducted when engine is installed on board ship.

The Machinery Panel reviewed CIMAC's proposals at its 30th meeting (2019) and decided that a dedicated PT was necessary to consider these proposals.

In particular, the Machinery Panel decided to improve the URs related to I.C. Engines, by developing a 'core' standard that describes the certification process and amending other applicable URs as needed.

Consequently, five URs, including UR M87 'Certification Scheme for Reciprocating Internal Combustion Engines,' were drafted at the second workshop of the PT in 2021 and submitted to the Machinery Panel for review. From 2021 to 2023, the URs were discussed and revised based on the Machinery Panel's comments
.

7 Other Resolutions Changes:

The following additional URs have been amended in parallel:
- M44 Documents for Approval of Reciprocating Internal Combustion Engines (revision)
- M71 Type Testing of Reciprocating Internal Combustion Engines (revision)
- M51 Factory Acceptance Test of Reciprocating Internal Combustion Engines (revision)
- M88 Shipboard Trials of Reciprocating Internal Combustion Engines (new)

8 Any hinderance to MASS, including any other new technologies:

None, the UR addresses the process of certification but has no requirement on the engine as a product, and therefore there is no hinderance to MASS.

9 Dates:

Original Proposal	: 05 September 2019	(Made by: PM19102_IMa)
Panel Approval	: 09 January 2025	(Ref: PM19102_IMzzk)
GPG Approval	: 20 April 2025	(Ref:24205_IGc)

****

Part B. Technical Background

List of Technical Background (TB) documents for UR M87:

Annex 1. **TB for New (Apr 2025)**

See separate TB document in Annex 1.

Technical Background (TB) document for UR M87 (New Apr 2025)

1. Scope and objectives

This UR provides the Engine Certification Scheme based on engine type approval, including the requirements for issuing a type approval certificate, design evaluation certificate, and product certificate for individual engines.

It outlines the process and associated URs for the certification of engines intended for shipboard applications, such as propulsion, electrical power generation, or other auxiliary purposes
.

2. Engineering background for technical basis and rationale

CIMAC proposed a revision of the URs relating I.C. Engines, so a new UR M87 is developed as a “core” standard of engine certification referring to other URs for the particulars.

The certification process outlined in UR M87 reflects the requirements previously included in UR M44 Rev.10 Corr.1 Feb 2022, but re-organized according to a logical and chronological process flow, and introduces some innovations in particular concerning:

- Clarification that Certification of engines is a process to be based on a type approval or on a similar process including drawing approval, type test and factory acceptance test
- Clarification that a Type Approval Certificate can only be issued to the engine designer
- Introduction of the possibility of issuance of a “Design evaluation certificate” to a Designer who is not a manufacturer.
- Introduction of the concept and definition of (engine) sub-systems, and the process for approval of new sub-systems to be included as extension of the scope of an existing engine type approval.

2a. Specification of the data utilised in the development/revision of the proposed IACS Resolution, if any

None

3. Source/derivation of the proposed IACS Resolution

CIMAC WG2 20180919, Subject: CERTIFICATION SCHEME FOR TYPE APPROVAL OF I.C ENGINES.

IACS UR M44 (Rev.10 Corr.1 Feb 2022)

4. Summary of Changes intended for the revised Resolution:

5.2.1 Deleted “- cylinder power, speed and cylinder pressures” in engine type definition in respect of previous content of UR M71.
The engine with different cylinder power could be defined in same engine type, but an extension of the scope of type approval may be required as 5.2.3.

5. Points of discussions or possible discussions

A) M87 2: The provisions of this UR may be incorporated into the society's Type Approval scheme.
IACS URs provide minimum unified requirements. Considering that individual classification societies have their own general certification schemes for marine products, UR M87 does not affect the right of each Class to establish its own approval program. The procedures not covered by this UR can be defined by each Society

B) M87 2: Scope covers Engines which are intend for propulsion and directly related to the safety operation of the ship (essential services).
A simplified scheme for engines has been introduced for power thresholds of 110 kW or less, concerning UR M44 and M71.

C) Definition of sub-system

A clear definition of a sub-system is undoubtedly helpful and important for its application. However, providing a concise and accurate definition, particularly for the technical approval requirements of sub-systems, is challenging due to their diversity.

Even though the current definition of sub-systems is general and may lead to some non-uniform application (e.g., one society may consider equipment as a sub-system and allow an extension of the engine type approval based on the requirements in Appendix 2, while another society may require a complete engine type approval), IACS still believes that the current definition of 'sub-system' is appropriate at present, based on the following considerations,

- The concept of a sub-system is flexible and can consist of an assembly of components belonging to an engine, intended to achieve a defined function and engine performance.
- The type approval of a sub-system can be required by the Society or be on a voluntary (optional) basis to simplify the certification process.
- The Society may supplement requirements (e.g., IACS UR or Class rules) for specific sub-systems when necessary.
- It is not possible to establish a prescribed standard, so general requirements are provided in M87, M44, M51, M71, and M88, as far as practicable.

D) Design evaluation certificate

A Design Evaluation report or letter may be issued instead of a Type Approval Certificate, with the engine designer as the applicant, in cases where the manufacturer assessment in section 5.5 cannot be carried out.
This is proposed where the issuance of a Design Evaluation Report or letter is part of the certification process of the Society.

The UR allows for the issuance of a 'Design Evaluation Report,' but some Societies may use an alternative document title, provided it is not confusing with a Type Approval Certificate.
Considering that the term 'Design Evaluation Report' is used in the current M44, UR M87 still recommends issuing the 'Design Evaluation Report' where its issuance is part of the certification process of the Society.

E) 5.2.1 the definition of engine type

F) Reference to Otto cycle or Diesel Cycle proposes by some Societies was not introduced because it is not so easy to distinguish the thermal cycles, like miller or mixing cycle and the definition of engine type given in M71 Corr.1 does not include Diesel or Otto Cycle.

G) Its has been introduced that Engines with the same type characteristics as defined in the UR can be included in the same engine type for a type approval.

H) Engines that use alternative fuels lead to the introduction of a note in the UR stating that, where the same engine type (as defined) is capable of using different fuels, its (engines) suitability must be demonstrated through integration testing for each new fuel type.

Additionally, if an engine has varying parameters, new functions, or alternative sub-systems beyond those listed above, it may still be defined as the same engine type. However, an extended approval is required in accordance with sections 5.2.2 to 5.2.3 and Appendix 2

I) Draft of document has been reviewed by SuP without major comments.

J) The draft document has been reviewed by CIMAC, and the Machinery Panel has carefully considered CIMAC's feedback, incorporating their views were deemed appropriate and relevant.

6. Attachments if any

None.

UR M88 "Shipboard Trials of Reciprocating Internal Combustion Engines"

Summary

This UR is derived from UR M51 and provides requirements for the shipboard tests of reciprocating internal combustion engines to be conducted upon installation on board.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
New (Apr 2025)	20 April 2025	01 January 2027

- **New (Apr 2025)**

1 Origin of Change:

X Request by non-IACS entity (Suggestion by CIMAC)

2 Main Reason for Change:

CIMAC WG2 believes that the existing UR M51 and UR M71 need to be revised and updated to reflect technological developments and operational considerations.
The Machinery Panel has decided to assess these proposals and improve URs related to internal combustion (I.C.) engine.

3 Surveyability review of UR and Auditability review of PR

Draft UR has been reviewed by Survey Panel without comments.

4 Human Element issues assessment

Not applicable.

5 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

X CIMAC WG2

6 History of Decisions Made:

CIMAC proposed a revision of the URs related to I.C. engines. The Machinery Panel reviewed CIMAC's proposals at its 30th meeting (2019) and decided that a dedicated PT was necessary to consider these proposals.

In 2020, PT PM19102 established principles for developing or amending IACS URs related to I.C. engines at its first workshop. The development of these URs primarily relied on members' knowledge and experience, with consideration of CIMAC's proposals.

Consequently, five URs, including UR M88, were drafted at the second PT workshop in 2021 and submitted to the Machinery Panel for review. UR M51, split as per CIMAC's proposal, now covers only FAT, while the new UR M88 on 'Shipboard Trials of I.C. Engines' was drafted from M51.

From 2021 to 2024, the URs were discussed and revised based on comments from the Machinery Panel. Several amendments were accepted, including tests for engines driving controllable pitch propellers and integration tests for subsystems, and requirements for Torsional vibrations including allowable time to transit the barred speed ranges.

7 Other Resolutions Changes:

The following other URs have been amended in parallel:

- M87 Certification Scheme for Reciprocating Internal Combustion Engines(new)
- M44 Documents for the Approval of Reciprocating Internal Combustion Engines (revision)
- M71 Type Testing of Reciprocating Internal Combustion Engines (revision)
- M51 Factory Acceptance Test of Reciprocating Internal Combustion Engines (revision)

8 Any hinderance to MASS, including any other new technologies:

None.

9 Dates:

Part B. Technical Background

List of Technical Background (TB) documents for UR M88:

Annex 1. **TB for New (Apr 2025)**

See separate TB document in Annex 1.

Technical Background (TB) document for UR M88 (new Apr 2025)

1. Scope and objectives

To develop a new Unified Requirement (UR) on shipboard trials of reciprocating internal combustion engines in alignment with CIMAC proposals, based on the requirements for shipboard trials specified in IACS UR M51 (Corr.1, Oct 2018).

New ship designs with limited engine power motivated by EEDI and EEXI have resulted in longer passing times through the BSR than what has traditionally been considered as “rapid”, which could have implications for the service life of the main propulsion shafting and associated components.

This concern was supported by correspondence from the Union of Greek Shipowners to IACS, which highlighted examples of extended BSR transit times and requested the establishment of a new Unified Requirement.

Issues related to BSR passage and system stability were initially addressed through IACS UR M51, 'Factory Acceptance Test and Shipboard Trials of I.C. Engines,' Rev.4, February 2015, section 4.5 on Torsional Vibrations, specifically 4.5.1 on the Barred Speed Range. This update also coincided with the implementation of the EEDI initiative.

Since the adoption of IACS UR M51 Rev.4, it has become evident that uncertainty remains regarding the BSR transit time. Consequently, concerns have emerged over how these uncertainties might affect confidence within the marine industry in predicting and, where necessary, achieving a satisfactory service life for main propulsion shafting and associated components.

The updated requirements were included in this UR M88 covering the shipboard trials of Reciprocating Internal Combustion Engines.

2. Engineering background for technical basis and rationale

CIMAC Working Group 2 (WG2) believes that the existing UR M51 and UR M71 require revision and updates to reflect technological advancements and consider operational aspects.
CIMAC submitted proposed documents to the Machinery Panel (MP) for review, including revised versions of M51 and M71, as well as two new URs.

PM19102 was tasked with organizing URs related to internal combustion (I.C.) engine approval, drawing primarily on members’ expertise and experience, and taking CIMAC’s proposals into consideration.

In line with CIMAC’s recommendations, the existing UR M51, which now only covers factory acceptance tests (FAT), was divided, resulting in the creation of a new UR, M88, titled 'Shipboard Trials of I.C. Engines.'
The structures of the revised UR M51 and the new UR M88 are aligned with URs M87, M44, and M71, where applicable.

Additional amendments were made based on experience gained through the implementation of existing UR M71 and M51. These include tests for propulsion engines driving power take-off (PTO) generators and extended testing for engines with subsystems.

The technical requirement with respect to Torsional vibrations and Barred speed range have been transferred from UR M51 and included in this UR M88 5.4.

2a. Specification of the data utilised in the development/revision of the proposed IACS Resolution, if any

None.

3. Source/derivation of the proposed IACS Resolution

CIMAC WG2 20180919, Subject: CERTIFICATION SCHEME FOR TYPE APPROVAL OF I.C ENGINES.
IACS UR M51 (Rev.4 Corr.1 Oct. 2018)

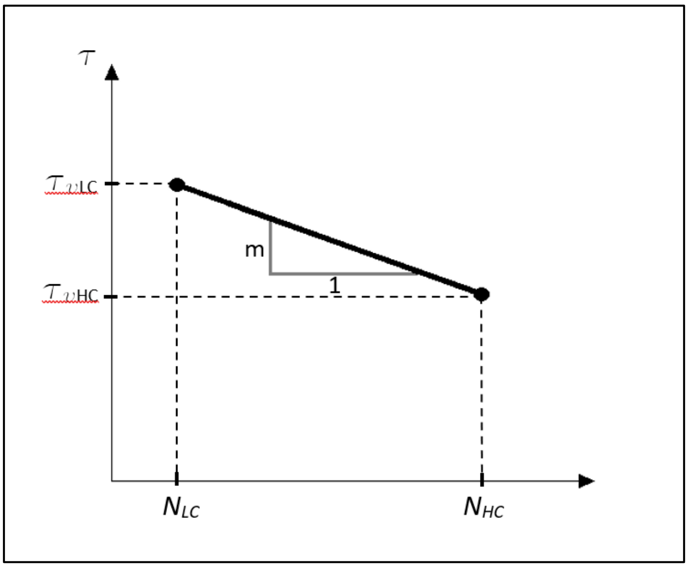
<u>3a.1 Requirement for BSR Passage Time Estimation</u>

The proposed formulation for the required Barred speed range passing time is based on principles of material fatigue, i.e. the higher the stress the lower the fatigue life, implying that for low stress levels it is possible to accumulate a higher number of cycles without fatigue cracks being generated. This is implemented by allowing a longer Tbsr when the stress on the shaft within the BSR (calculated for steady state conditions) is lower than the maximum allowable transient stress. the lower the stress the longer the allowed Tbsr, using a formula that refers to the slope of the S-N fatigue curve, i.e. the typical relation between stress and number of cycles to failure.

The method for establishing the allowable transit time across the BSR was based on the CIMAC method, developed by two engine manufacturers and one CS. This was seen to be an elegant solution which avoided the need for extensive calculation and could be applied from an early stage of the design process as well as confirmation from sea trials measurements.

The CIMAC method was adjusted in order to align it with the limits for low ($1x10^4$) and high ($1x10^7$) cycle fatigue. A factor of safety of 2.0 was used:
For stress levels between the allowable stresses for transient conditions (τ_T or τ_{vLC}) and the allowable stresses for continuous conditions (τ_C or τ_{vHC}), the allowed passage time is defined by the slope parameter of the S-N curve. The number of stress cycles N with an amplitude of τ_v resulting in Miner's sum or Miner Damage Rule (MDR) MDR=1, can be expressed as slope parameter 1/m in the S-N curve:

$$N(\tau_v) \propto \tau_v^{\frac{1}{m}} \quad where \quad \frac{1}{m} = \frac{log\left(\frac{N_{LC}}{N_{HC}}\right)}{log\left(\frac{\tau_{vLC}}{\tau_{vHC}}\right)}$$



Assuming:

- $\tau_v(N)$ is independent of the acceleration
- 5 seconds passage time when $\tau_v=\tau_T$ results in MDR=1

Then, the permissible passage time, T_{bsr}, for a stress amplitude between τ_T and τ_C can be expressed as:

$$T_{bsr}(\tau_v) = 5\left(\frac{\tau_v}{\tau_T}\right)^{\frac{1}{m}}$$

Using: $\frac{\tau_{vLC}}{\tau_{vHC}} = \frac{\tau_T}{\tau_C} = \frac{1.7}{\sqrt{C_k}}$

This results in a simple relation between τ_T and τ_C only influenced by C_k. Aligning with UR M68 (N_{LC} =1x10^4, N_{HC}=1x10^7) and, for intermediate shafts with C_k=1:

$$\frac{1}{m} = \frac{\log\frac{10^4}{10^7}}{\log\frac{1.7}{\sqrt{1}}} = -13$$

Using a factor of safety of 2, the definition of the slope becomes $\frac{1}{m} = -6.5$ and, therefore:

$$T_{bsr}(\tau_v) = 5\left(\frac{\tau_v}{\tau_T}\right)^{-6.5}$$

This was later reconsidered (see paragraph 5: **Points of discussions or possible discussions)** using 3x10^6 (i.e. the knuckle point of the S-N curve of relevant steel qualities) as N_{HC} and applying a factor of safety of 1.5, resulting in:

$$T_{bsr}(\tau_v) = 5\left(\frac{\tau_v}{\tau_T}\right)^{-7.2}$$

No special consideration is needed to propeller shafts (C_k=0.55) due to the starting point being τ_T, which already accounts for the influence of the C_k value.
The formula developed was based on 5 seconds being the smallest amount of maximum allowable value for T_{bsr}. Historically, it is understood that the requirements for vibratory torsional shear stress have used an implicit understanding that the transit across the BSR would be ‘rapid’, for which experience of ship operation has shown that a time, typically, in the order of 5 seconds has been acceptable and achievable.

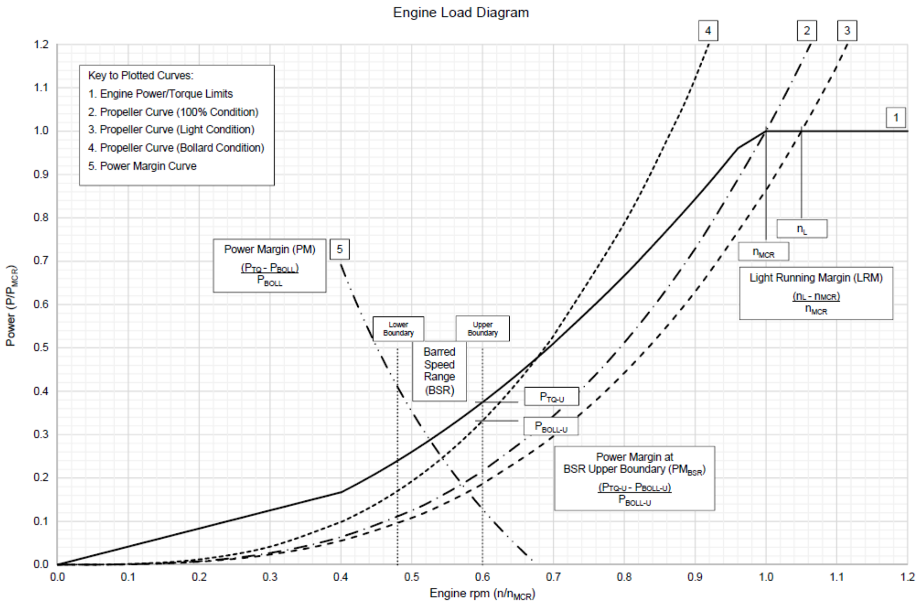
The proposed formulation is not expected to lead to consequences hampering safety, because the longer passing times only apply for low τ_{max}, e.g. for a τ_{max}/τ_t ratio of 0.6, the maximum Tbsr is of 198 seconds, i.e. about 3 minutes, but for τ_{max}/τ_t ratio lower than about 0.588 (=1/1.7), UR M68 does not require any BSR to be established, indicating that no fatigue cracks is expected, even in case of continuous operation in such a condition.

With 198 seconds of barred speed range passing time, in a typical system with 2-stroke 6 cylinder engine, having a 6th order harmonic that is critical at about 50 rpm and passing the BSR 4 times per week, it would take 25 years to accumulate 1.5x10^6 cycles (that is the typical value considered suitable to generate a crack), but the limitation of the transient stresses will prevent the crack being generated.

Further, although the Tbsr-formula will specify a safe transition time, the BSR shall still be passed as rapidly as possible and the recommended 10% M/E power margin at the upper BSR border will enable a quicker passing time than what would be specified by the Tbsr-formula.

3a.2 Requirements for fatigue estimations

Discussions took place with engine designers with extensive experience on the shortcomings arising from reduced main propulsive power in the same vessel size. Among the solutions available, the 'power reserve/excess of power' ensured there was sufficient available torque to satisfactorily accelerate the engine and propeller through the BSR, thereby avoiding excessive accumulation of damaging fatigue cycles. Based on these discussions, their recommended value of 10% for the Power Margin at the upper boundary of the BSR was accepted based on the evidence presented.



3a.3 Requirements for measurement of BSR Passage time

Panel members agreed that BSR can be passed in four ways: accelerating ahead, decelerating ahead, accelerating astern (negative rpm) and decelerating astern (negative rpm). Acceleration is dependent of engine power, while deceleration is mainly dependent of hull resistance. Consideration within the PT indicated a need to confirm the BSR transit time when the engine is developing power in the ahead and

astern directions and, as such, no requirement to measure the transit time during engine/vessel deceleration. During a vessel's life, the main propulsion shafting will experience manoeuvres which traverse the BSR in the ahead and astern directions. For this reason, it was considered relevant to measure T_{bsr} in both conditions. Accelerating astern was not considered so relevant as a BSR at low rpm range is passed within short time, and most manoeuvring are under the BSR range where BSR is at a high rpm range. Therefore, the only acceptance criterion is that passing BSR accelerating ahead shall be within calculated T_{bsr}, while the other modes are to be measured for information.
The requirement for measurement by the strain gauge technique if the calculated peak torsional shear stress exceeds 85% of the allowable transient stress was agreed by Panel members due to the greater accuracy of this technique compared to measuring angular vibration.

4. Summary of Changes intended for the revised Resolution:

The new UR M88 contains nearly the same requirements as UR M51.4, with only a few clarifications and amendments.

A) The structure was harmonized with other URs, incorporating CIMAC's proposals where feasible. Sections such as 'General,' 'Scope,' and 'Definitions' were added to ensure consistency with other URs.
B) 2. Scope
A reference to UR M78 was added to clarify that this UR provides common requirements for shipboard trials but does not cover requirements specific to dual-fuel (DF) and gas-fuelled (GF) engines.
C) 5.3.3, A note 2 is added for the engine load to be applied for the reverse direction which refers to UR M25.1
D) 5.3.6, Propulsion engines also driving power take off (PTO) generator.
Updating the expression «at engine speed n0» in provision C) for 100% PTO branch power to «at the designed engine speed (maximum possible engine speed) », taking into account of cases when PTO such as shaft generator is arranged in FPP shaft line.
E) 5.4 Inclusion of mandatory criteria for barred range transit time and a recommendation concerning power margin in the barred range, to ensure the capability of the system to pass the barred range "rapidly" as required in UR M68.5
F) 5.5, Extended test for engines with multi-operation mode or sub-systems
The requirements are aligned with integration tests of sub-system during FAT in IACS UR M51.7.4.

5. Points of discussions or possible discussions

Structure of UR
CIMAC proposed dividing the currently conducted tests into three formal stages A, B, and C, similar to the structure of type approval tests. However, the Project Team (PT) did not consider that CIMAC's proposed stages would bring any improvements to the UR. Therefore, the CIMAC proposal was not adopted.

3. Objectives
The 'Objectives' proposed by CIMAC for UR M88 include 'Demonstration of Economy,' 'Demonstration of Energy Efficiency Design Index (EEDI),' and 'Demonstration of Controllability.' However, since these demonstration items pertain to the overall

performance of the ship rather than specifically to the internal combustion engine, the Project Team (PT) does not support including these objectives.

5.2 The monitoring and alarm systems

The IACS UR M51 stipulates the relevant requirements as follows.

> *4.3 Monitoring and alarm system*
> *The monitoring and alarm systems are to be checked to the full extent for all engines, except items already verified during the works trials.*

In cases where Factory Acceptance Tests (FAT) are conducted using test bed equipment rather than the actual equipment intended for onboard installation, it may still be necessary to re-check certain items onboard to verify the effectiveness of the actual installation. Accordingly, M88.5.2 was drafted with the understanding that the decision to omit specific check items should be made by each Society based on individual circumstances.

5.4 Torsional vibrations

The torsional vibration including barred speed range have been transfer from UR M51 7.7 to UR M88 5.4.

CIMAC raised concern about T_{bsr} criteria and formula since exponent (^-6.5) in their opinion is too conservative and proposed to be replaced by (^-7.2).

5.4.1 The CIMAC proposal for T_{bsr} criteria and formula with respect to exponent (^-6.5) has been discussed within Panel.

5.4.2 Two members recall that the issue of exponent (^-6.5) has been addressed by the relevant Panel's Project team.

5.4.3 A member provides clarifications regarding the application of the exponent (^-7.2) by addressing:

Typical SN-curves (and TN curves) for steel has a knuckle point around 10^6 cycles (see illustration from Wikipedia). Member has carried out studies and identified knuckle point for relevant steel qualities to be approx. $3 \cdot 10^6$ cycles, which could be applied.

IACS UR-M68 specifies a continuous stress level t_C to be at a level relevant for >>1e7 cycles (see UR-M68.7 Note 2). This was wrongly interpreted as being a a knuckle point when the 1st draft of UR M88 was developed.

The slope (1/m) of the SN-curve without correction is calculated to be:

SN-curve	**cycles**	**1/m**
Wikipedia	$1 \cdot 10^6$	-8.68
CIMAC [1)]	$3 \cdot 10^6$	-10.75
Draft IACS UR-M88	$1 \cdot 10^7$	-13.02

Typical slope for relevant steel qualities is in the range (-5) to (-7). IACS UR M-68 is an empiric stress criterion; to correct for the deviation it was implemented a correction factor, let's call it Safety factor S.

The slope (1/m) of the SN-curve with correction is calculated to be:

SN-curve	cycles	S=1.5	S=2.0
Wikipedia	$1 \cdot 10^6$	-5.8	-4.3
CIMAC	$3 \cdot 10^6$	-7.2	-5.4
1st Draft IACS UR-M88	$1 \cdot 10^7$	-8.7	-6.5

As stated above considering that:

- The slope (1/m) should be in the range (-5) to (-7), where -5 is stricter than -7.
- 10^7 is not a knuckle point.

it could be finally agreed with CIMAC that S=1.5 and 3×10^6 cycles should be applied, considering also that the background of the formula has been used by the industry for 6 years without problems and a new industry standard should be implemented only if based on further scientific documentation.

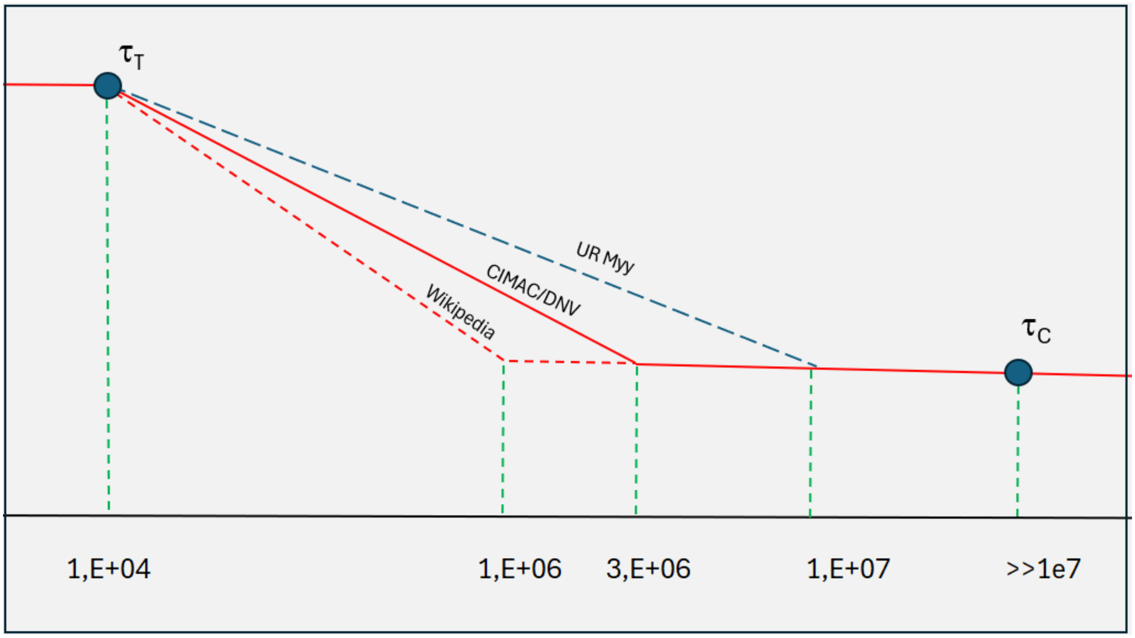


Illustration of various S-N curves and respective knuckle points.

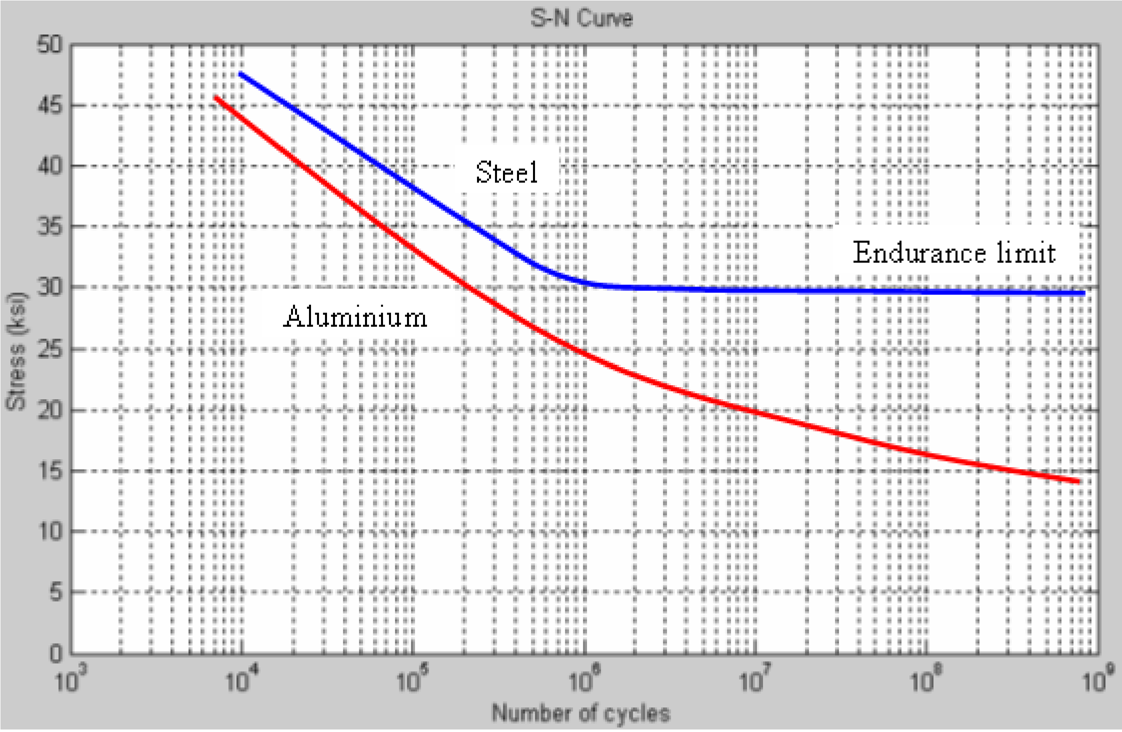
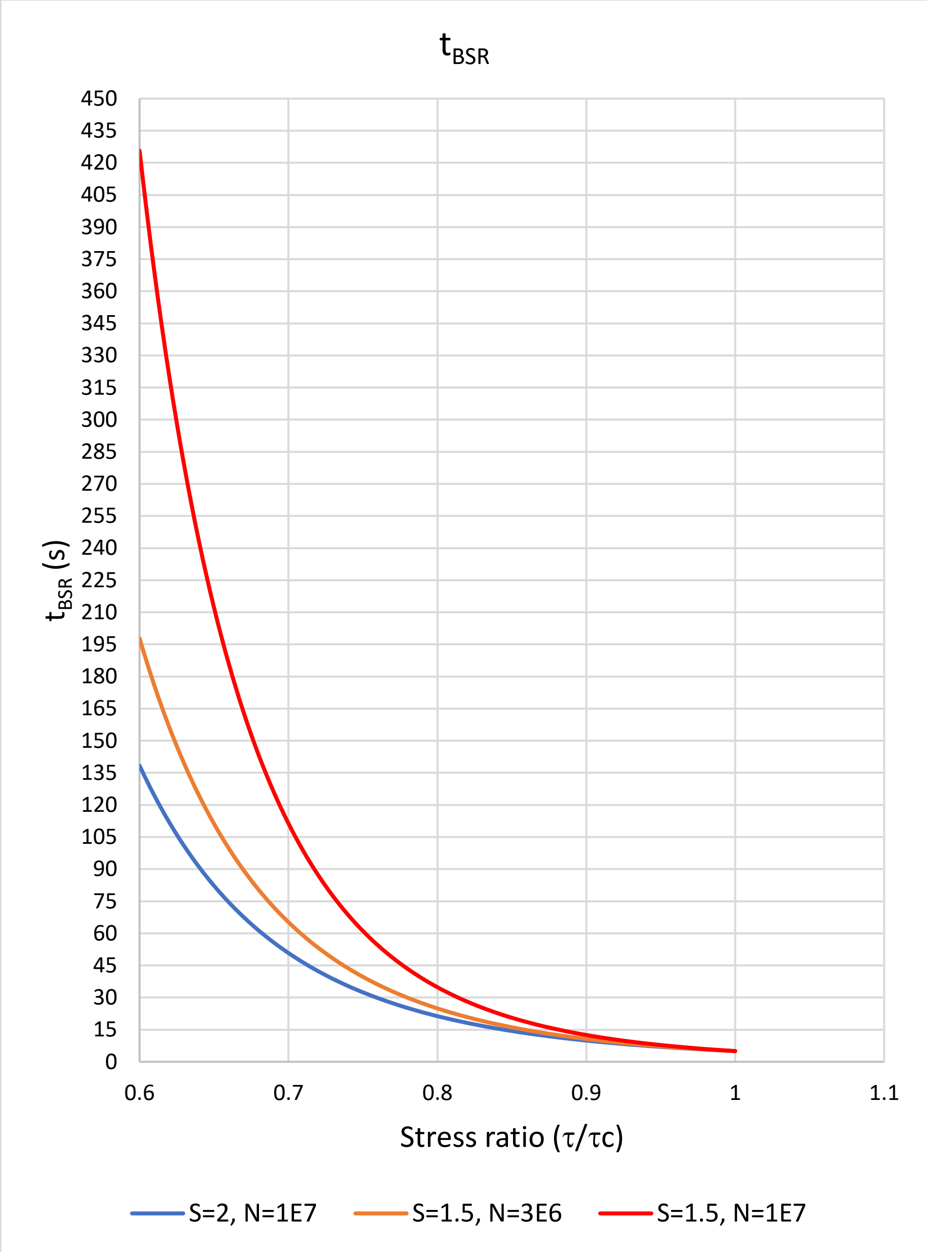


S-N curve for steel found at Wikipedia as an illustration example



Calculated allowed passing time based on suggested formula and the proposed draft document.

1) VBFEh 1983 Bericht Nr. ABF 11; Berechnung von Wöhlerlinien für Bauteile aus Stahl, Stahlguss und Grauguss Synthetische Wöhlerlinien.

Multiradii fillets

M68.6 specifies the lowest C_K factor to 1.0 and M68.7.2 formulates C_K=1.45/scf, where scf is the specific stress concentration factor. For a multi radii flange is *scf* approximate 1.05. This design has a substantial increased fatigue resistance. The member wants to stimulate good design and gives 10s extra passing time for such designs with *scf* ≤ 1.1.

It is argued that this is not within scope of M68 and disagreed that M68.2 opens for alternative methods.

Based on this, the Member suggest the Panel re-consider the exponent within the formula for T_{bsr}.

5.4.4 Based on clause 5.4.3 above, the majority of the Panel's members agreed that exponent (^-6.5) should be replaced with (^-7.2).

5.5 CIMAC proposes if an indirect measurement method is used (such as angular velocity), it is important that the mass-elastic system of shafting system is to be tuned to get the same natural frequencies before the transfer function (rad/s to MPa) is calculated.

5.5.1 Machinery Panel noted the CIMAC proposal however found its necessary to establish and develop the relevant guidance or acceptance criterial for calibration/tuning.

The Panel intends to initiate the incorporation of the CIMAC proposal within its development process to establish relevant guidance or acceptance criteria for calibration/tuning in the next revision of the UR.

5.6 Draft document has been reviewed by SuP without comment.

5.7 The Machinery Panel reviewed CIMAC's comments and agreed to incorporate them into the draft UR, as outlined above.

March 2021

History Files (HF) and Technical Background (TB) documents for URs concerning Navigation (UR N)

Res. No.	Title	Current Rev.	HF/TB?
UR N1	One man bridge operated (OMBO) ships	Deleted Mar 2021	HF

UR N1 “One man bridge operated (OMBO) ships”

Summary

A review of the contents of UR N1 concluded that the UR should be deleted as the majority of the requirements have been included in the other statutory instruments.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Del (Mar 2021)	25 March 2021	-
New (1992)	1992	1992

- **Del (Mar 2021)**

1 Origin of Change:

☐ Suggestion by IACS member

2 Main Reason for Change:

Following a detailed gap analysis and careful review, it was concluded that the contents of the UR are now contained in other statutory instruments and the UR could be deleted.

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None

4 History of Decisions Made:

Safety Panel agreed that UR N1 should be deleted in 2017.

GPG requested Safety Panel to review the decision (20081_IGb).

A one-man project team was established (PT PS44/2020) to carry out a detailed gap analysis to determine the relevance of requirements in UR N1 in light of new and/or updated standards/instruments (see PT PS44/2020 Form A and Form 1).

The Safety Panel reviewed the outcome of the gap analysis and comments received from EG/MASS and unanimously concluded that UR N1 could be deleted.

5 Other Resolutions Changes:

None

6 Any hinderance to MASS, including any other new technologies:

The basic principles relating to MASS have been taken into account when reaching the conclusion to delete UR N1.

7 Dates:

Original Proposal:	15 January 2021 (Made by: *PT PS44/2020*)
Panel Approval:	9 March 2021 (Ref: PS17010pISo)
GPG Approval:	25 March 2021 (Ref: 20081_IGh)

- **New (1992)**

No details are available.

****

Part B. Technical Background

List of Technical Background (TB) documents:

Annex 1. **TB for Deleted (Mar 2021)**

See separate TB document in Annex 1.

◄▼►

Note: *There is no technical background document available for New (1992).*

Technical Background (TB) document for UR N1 (Del Mar 2021)

1. Scope and objectives

A detailed gap analysis was required to determine the relevance of requirements in UR N1 in light of new and/or updated standards/instruments.

To review UR N1 to assess the continuing relevance of the requirements taking into account:

Current SOLAS requirements
Contents of IACS recommendation 95
Updates to IEC standards
Updates to ISO standards
Updates to IACS E10

Other relevant documents developed since 1992 relating to bridge operations.

To list the UR N1 requirements and state if and where they are replicated in other instruments.

To determine extent of revision needed for UR N1.

2. Engineering background for technical basis and rationale

In general most of the UR N 1 requirements are covered by other instruments, except for "OMBO Notation" and minor items. Therefore, it is recommended that the UR N 1 can be deleted as a result of this gap analysis between IACS UR N1 and other applicable instruments. For reference, requirements or parts of which are not possible to be covered by other instruments are highlighted in yellow in Appendix 1.

See Appendix 1 for the detailed gap analysis.

See Appendix 2 for the list of relevant instruments.

3. Source/derivation of the proposed IACS Resolution

Not applicable

4. Summary of Changes intended for the revised Resolution:

The whole of UR N1 is to be deleted.

5. Points of discussions or possible discussions

The following points were taken into consideration during the review:

1. Paragraph 15 of STCW Code Part A Chapter VIII/2 still allows that the officer in charge of the navigational watch to be the sole look-out in daylight under certain conditions.

2. Based on the provisions in UR N1, some ships have been certified of relevant optional notations under individual class Society's rules for concerned classes to allow the sole look-out on ship's wheel house.

3. Since the adoption of UR N1, new navigational systems, e.g. AIS, ECDIS, BNWAS, etc., have been introduced under SOLAS Chapter V.

The detailed gap analysis (Appendix 1) details where each part of the UR has been superseded by other statutory requirements and is therefore no longer needed.

6. Attachments if any

Appendix 1 – Gap Analysis.xlsx – the detailed paragraph by paragraph assessment of UR N1

Appendix 2 – Other relevant instruments since UR N1 (Nov 1992).docx – a list of relevant instruments.

Appendix 1

Gap Analysis of IACS UR N 1			
Text (UR N 1)	**Related instruments**	**Comment**	**Possible to be covered by other instruments (Yes/No)**
Part A-General			
Preamble It is technologically possible to operate the bridge with an officer of the navigational watch alone, acting as the sole lookout. However, the design, performance and maintenance of the equipment can have considerable effects on the safety of one man bridge operation. The aim of these rules is to provide technical requirements for the functionality of the bridge design and layout, the range of equipment to be installed, its performance and reliability. The composition and qualification of the personnel on watch remain the responsibility of the shipping companies and national authorities.	N/A	General description	N/A
1. Application			
1.1. The following requirements apply to the classification of sea-going ships for the assignment of an optional class notation for one man bridge operation and are intended to cover all the normal sailing conditions as authorized by the relevant National Authority.	N/A	No other instruments for class notation for one man bridge operation	No
1.2 These requirements may be applied to new and existing ships.	N/A	N/A	N/A
2. Operational Assumptions The requirements are framed on the following assumptions:			
2.1 **Plans for emergencies** are specified and the conditions under which a one man watch is permitted are clearly defined in an operations manual, which is acceptable to the Administration with which the ship is registered.	**STCW Code Part A Chapter VIII/2** 16 ... The officer in charge of the navigational watch may be the sole lookout in daylight provided that, on each such occasion: .1 the situation has been carefully assessed and it has been established without doubt that it is safe to do so; .2 full account has been taken of all relevant factors, including, but not limited to: – state of weather; – visibility; – traffic density; – proximity of dangers to navigation; and – the attention necessary when navigating in or near traffic separation schemes; and .3 assistance is immediately available to be summoned to the bridge when any change in the situation so requires.	STCW allows OOW to sole lookout under normal operating daylight conditions.	Yes
2.2 The manning of the bridge watch is in accordance with the **National Regulations** in the country of registration and for the waters in which the ship is operating.		General requirement	Yes
2.3 The requirements of the International Convention on Standards of Training Certification and Watchkeeping for seafarers **(STCW)** and other applicable statutory regulations are complied with.		N/A	Yes
3. Regulations, Guidelines, Standards			
3.1 IMO – The requirements are based on the understanding that the **applicable regulations and guidelines** issued by the International Maritime Organization are complied with and, in particular:	N/A	N/A	N/A
3.1.1 Regulation 12, chapter V of the 1974 "International Convention for the Safety of Life at Sea" **(SOLAS)** and applicable amendments;	N/A	SOLAS chapter V had been completely revised by Res.MSC.99(73) which entered into force on 1 July 2002 and this regulation moved to Regulation 19. It needs to be updated, if necessary.	N/A

3.1.2 the **international Regulations for Preventing Collisions at Sea** and all other relevant Regulations relating to Radiotelegraphy, Radiotelephony and Safety of Navigation required by Chapters **IV and V of SOLAS** 1974, as amended;	N/A	General requirement	N/A
3.1.3 the Provisional Guidelines for the Conduct of Trials in which the Officer of the Navigational Watch acts as the sole Lookout in Periods of Darkness (**MSC Circular 566** of 2 July 1991);	N/A	Considering the result of MSC 66, it confirmed that these trials had been terminated in 1997. Therefore, it seems no more effective instrument.	N/A
3.1.4 **IMO Assembly Resolution A708** on Navigation Bridge Visibility and Functions;	N/A	Applicable IMO resolutions or circulars could be referred in Appendix 2.	N/A
3.1.5 the **Performance Standards for navigational equipment** applicable to: – magnetic compasses (Resolution A382), – gyro-compasses (Resolution A424), – radar equipment (Resolutions A222, A278, A477), – ARPA (Resolution A422), – speed and distance measuring equipment (Resolution A478) – echo sounding equipment (Resolution A224), – radio direction finder (Resolution A223), – electronic navigational aids – general requirements (Resolution A574), – VHF Radio installation (Resolution A609), – automatic pilots (Resolution A342), – rate-of-turn indicators (Resolution A526).	N/A	Since this UR released, applicable performance standards have been updated in accordance with SOLAS IV and V, as amended. It needs to be updated referring to SOLAS IV/Reg.14 and V/Reg.18, if necessary.	N/A
3.2 **IEC, ISO Standards** – The requirements and guidelines of the following international standards are applicable: – ISO 8468 "Ships bridge layout and associated equipment – Requirements and guidelines"; – IEC 872: ARPA – Operational and performance requirements – Methods of testing and required test results; – IEC 936: Shipborne radar – Operational and performance requirements – Methods of testing and required test results; – IEC 1023: Marine speed and distance measuring equipment (SDME) – Operational and performance requirements – Methods of testing and required test results; – IEC Document 18 (Central Office) 534: Special features – Control and instrumentation.	N/A	Since this UR released, applicable international standards(ISO, IEC) have been updated. Following standards may newly include in this para, but not limited to; (refer to Appendix 2) - ISO 14612 - IEC 60945 - IEC 61209 - IEC 61924 - IEC 60533	N/A
3.3 **National Authorities** – Additional requirements may be imposed by the National Authority with whom the ship is registered and/or by the administration within whose territorial jurisdiction it is intended to operate.	N/A	General requirement	N/A
3.4 **IACS** – The requirements of UR E10 'Unified environmental test specification for testing procedure for electrical control and instrumentation equipment, marine computers and peripherals covered by classification' are applicable.	N/A	UR E 10 rev.7 is in force.	N/A
4. Definitions			
Terms used in the requirements are defined below:			
Acquisition: the selection of those target ships requiring a tracking procedure and the initiation of their tracking.	N/A	General definition	N/A
Alarm: a visual and audible signal indicating an abnormal situation.	**Res.A.1021(26) Code on alerts and indicator, 2009 :** Refer to 3.1.2 **MSC/Circ.982** : Refer to Appendix 1 "Definitions" **IACS Rec.95** : Refer to A.5.1 **ISO 8468** : Refer to 3.1.3	N/A	Yes
ARPA: automatic radar plotting aid.	**Resolution A.823(19)** **ISO 8468** : Refer to 3.2 Abbreviations	Commonly used definition in acronym. It is referenced in many instruments such as Performance standards.	Yes
Back-up navigator: any individual, generally an officer, who has been designated by the ship master to be on call if assistance is needed on the navigation bridge.	**MSC/Circ.566** **ISO 8468** : Refer to 3.1.6	N/A	Yes
Bridge: that area from which the navigation and control of the ship is exercised, including the wheelhouse and bridge wings.	**IACS Rec.95** : Refer to A.5.2 **ISO 8468** : 3.1.7	N/A	Yes
Bridge wings: those parts of the bridge on both sides of the ship's wheelhouse which, in general, extend to the ship's side.	**Res.A.468(12) :** Refer to 3.4.19 **IACS Rec.95** : Refer to A.5.2.1 **ISO 8468** : Refer to 3.1.13	Commonly used in various instruments.	Yes
CPA: closest point of approach, i.e. the shortest target ship-own ship calculated distance that will occur in case of no change in course and speed data.	N/A	Commonly used definition in acronym. It is referenced in many instruments such as IMO Resolutions and circulars.	N/A
Display: means by which a device presents visual information to the navigator, including conventional instrumentation.	**MSC/Circ.982** : Refer to Appendix 1 "Definitions" **ISO 8468** : Refer to 3.1.20		Yes

Ergonomics: application of the human factor in the analysis and design of equipment, work and working environment.	**MSC/Circ.982** : Refer to Appendix 1 "Definitions" **ISO 8468** : Refer to 3.1.25	General definition	Yes
Field of vision: angular size of a scene that can be observed from a position on the ship's bridge.	**MSC/Circ.982** : Refer to Appendix 1 "Definitions" **ISO 8468** : Refer to 3.1.27		Yes
Lookout: activity carried out by sight and hearing as well as by all available means appropriate in the prevailing circumstances and conditions so as to make a full appraisal of the situation and of the risk of collision.	**ISO 8468** : Refer to 3.1.32		Yes
Navigation: all tasks relevant for deciding, executing and maintaining course and speed in relation to waters and traffic.	**ISO 8468** : Refer to 3.1.38		Yes
Navigator: person navigating, operating bridge equipment and manoeuvring the ship.	**ISO 8468** : Refer to 3.1.41(operator)		Yes
Normal conditions: when all systems and equipment related to navigation operate within design limits, and environmental conditions such as weather and traffic do not cause excessive workload to the officer of the watch.	**ISO 8468** : Refer to 3.1.43		Yes
Officer of the watch: person responsible for safe navigating, operating of bridge equipment and manoeuvring of the ship.	N/A		N/A
OMBO: one man bridge operation.	**MSC/Circ.1014** Bridge Layout and Navigation Equipment IACS Unified N1 requirements for One Man Bridge Operated (OMBO) Ships. International Association of Classification Societies. 1992	It was superseded by MSC.1/Circ.1598 resulting in deletion of OMBO	Yes
OMBO ship: one man bridge operated ship.			Yes
Radar plotting: the whole process of target detection, tracking, calculation of parameters and display of information.	**ISO 8468** : Refer to 3.1.46	General definition	Yes
Sea-going ship: ship navigating on the high seas, i.e. areas along coasts and from coast to coast.	**ISO 8468** : Refer to 3.1.50		Yes
TCPA: time to closest point of approach.	**Resolution A.823(19)**	Common definition in acronym. It is referenced in many instruments such as Performance standards.	Yes
Tracking: is the process of observing the sequential changes in the position of a target, to establish its motion.	**ISO 8468** : Refer to 3.1.55	General definition	Yes
Watch alarm: alarm that is transferred from the bridge to the master and the back-up navigator in case of any officer of the watch deficiency (absence, lack of alertness, no response to another alarm/warning, etc.).	N/A		N/A
Wheelhouse: enclosed area of the bridge.	**IACS Rec.95** : Refer to A.5.2.4 **ISO 8468** : Refer to 3.1.61		Yes
Workstation: position at which one, or several tasks constituting a particular activity are carried out.	**MSC/Circ.982** : Refer to Appendix 1 "Definitions" **IACS Rec.95** : Refer to A.5.17 **ISO 8468** : Refer to 3.1.61		Yes
Part B – Technical Requirements			
1. Bridge Layout			
1.1 The **bridge configuration, the arrangement of consoles and equipment location** shall enable the officer of the watch to perform navigational duties and other functions allocated to the bridge as well as maintain a proper lookout from a convenient position on the bridge, hereafter referred to as a 'workstation'.	**SOLAS V/Reg.15** All decisions which are made for the purpose of applying the requirements of regulations 19, 22, 24, 25, 27, and 28 of this chapter and which affect bridge design, the design and arrangement of navigational systems and equipment on the bridge and bridge procedures** shall be taken with the aim of: ... **MSC/Circ.982** Refer to 5.1 Bridge Layout **IACS Rec.95** B 5 Workstation arrangements and required fields of vision The bridge should be designed and arranged with the aim of: ... **ISO 8468** : Refer to 5.2.3	General requirement	Yes
1.2 A workstation for navigation and traffic surveillance/manoeuvring shall be arranged to enable		Except for MSC/Circ.566, other instuments	

efficient operation **by one person** under normal operating conditions. All relevant instrumentation and controls shall be easily visible, audible and accessible from the workstation.	**MSC/Circ.566** 11 A workstation for navigation and traffic surveillance/manoeuvring should be arranged to enable efficient operation **by one person** under normal operating conditions. All relevant instrumentation should be easily accessible from the workstation. **MSC/Circ.982** 5.1.3.3 Passageway Dimensions The distance from the bridge front bulkhead, or from any consoles or installations placed against the front bulkhead, to any consoles or installations placed away from the bridge front should be sufficient for **two persons** to pass each other. The distance of a passageway between the front bulkhead and any consoles should preferably be at least 1 000 mm, and not less than 800 mm. 5.3.1.1 Workstation Area The workstations for navigating and manoeuvring, monitoring and for the bridge wings should be planned, designed and placed within an area spacious enough for not less than **two operators**, but close enough for the workstations to be operated by one person. **IACS Rec.95** B 5.1 Workstations for navigating and manoeuvring and for monitoring should be arranged within an area spacious enough for **two persons** to carry out the tasks in close cooperation, but sufficiently close together to enable the watch officer to control and safely carry out all the tasks from one working area under normal operating conditions.	has no assumption that the task could be carried out by one person under normal operating conditions. This paragraph is same as para.11 of MSC/Circ.566.	Yes
1.3 For the purpose of performing duties related to navigation, traffic surveillance and manoeuvring, **the field of vision from a workstation** shall be such as to enable observation of all objects which may affect the safe conning of the ship. The field of vision from a workstation shall be in accordance with the guidelines on navigation bridge visibility, as specified in IMO Resolution A708 as it applies to new ships. For other functions, other workstations may be arranged singularly or in combination, provided the field of vision complies with the foregoing.	**SOLAS V/Reg.22 Navigation bridge visibility** **Res.A.708(17)** Refer to 3 Field of vision **MSC/Circ.982** Refer to 5.1.1.1 Field of Vision **IACS Rec.95** B 5 Workstation arrangements and required fields of vision The bridge should be designed and arranged with the aim of: .... The workstations for primary bridge functions should be arranged to serve their functions under all operating conditions and different manning of the bridge and provide the fields of vision required for visual observations and easy cooperation between bridge personnel, promoting effective and safe bridge resource management. **ISO 8468** : Refer to 4.2 Field of vision	N/A	Yes

1.4 The bridge layout design and workstations are to enable the ship to be navigated and manoeuvred safely **by two navigators** in cooperation.	**MSC/Circ.982** 5.1.3.3 Passageway Dimensions The distance from the bridge front bulkhead, or from any consoles or installations placed against the front bulkhead, to any consoles or installations placed away from the bridge front should be sufficient for two persons to pass each other. The distance of a passageway between the front bulkhead and any consoles should preferably be at least 1 000 mm, and not less than 800 mm. 5.3.1.1 Workstation Area The workstations for navigating and manoeuvring, monitoring and for the bridge wings should be planned, designed and placed within an area spacious enough for not less than two operators, but close enough for the workstations to be operated by one person. **IACS Rec.95** B 5.1 Workstations for navigating and manoeuvring and for monitoring should be arranged within an area spacious enough for two persons to carry out the tasks in close cooperation, but sufficiently close together to enable the watch officer to control and safely carry out all the tasks from one working area under normal operating conditions. **ISO 8468** : Refer to 5.2.3 The main workstations should be planned, designed and placed within an area spacious enough for not less than two operators, but close enough to allow the stations to be operated by one person.	N/A	Yes
1.5 **External sound signals** from ships and **fog signals** that are audible on the open deck, shall also be audible inside the wheelhouse; a transmitting device shall be provided to reproduce such signals inside the wheelhouse (recommended frequency range: 70 to 700 Hz).	**SOLAS V/Reg.19.2.1.8** All ships irrespective of size shall have; when the ship's bridge is totally enclosed and unless the Administration determines otherwise, a sound reception system, or other means, to enable the officer in charge of the navigational watch to hear sound signals and determine their direction **Res.MSC.86(70) - PERFORMANCE STANDARDS FOR SOUND RECEPTION SYSTEMS** 2 FUNCTIONAL REQUIREMENTS 2.1 Sound reception systems should be capable of: .1 receiving sound signals from all directions in the audio band 70 Hz - 820 Hz; .2 reproducing incoming sound signals acoustically inside the bridge; .3 indicating the approximate direction of incoming sound signals to determine at least whether the sound signal being detected is forward or abaft of the beam and from which side of the ship it is being detected; and .4 suppressing unwanted background noise and allowing reception of meaningful sounds. **ISO 8468** 4.4 Sound reception system 4.4.1 Sounds of interest to navigation that are audible on open deck area shall also be audible inside the wheelhouse. 4.4.2 The ship may be fitted with a technical device receiving sounds outside the wheelhouse and reproducing such sounds inside the wheelhouse after amplification.	For SOLAS ships, the sound reception system is required only for ships having totally enclosed bridge. Otherwise, it is deemded as optional equipment.	Yes
1.6 The requirements and guidelines of **ISO Standard 8468** should be regarded as a basic reference for the design of the bridge layout.	N/A	General requirement	N/A
2. Bridge Instrumentation and Controls			
2.1 Functions to be ensured The instrumentation and controls at the workstation for navigation and traffic surveillance/manoeuvring shall be arranged to enable the officer of the watch to:	N/A	General requirement	Yes
2.1.1 determine and plot the ship's position, course, track and speed; 2.1.2 analyse the traffic situation; 2.1.3 decide on collision avoidance manoeuvres; 2.1.4 alter course; 2.1.5 change speed; 2.1.6 effect internal and external communications related to navigation and manoeuvring, radio communication on the VHF; 2.1.7 give sound signals; 2.1.8 hear sound signals;	SOLAS II-1/Reg.29 "Steering gear" SOLAS III/Reg.6.4 "On-board communications and alarm systems" LSA Code 7.2.2 "Public address system" SOLAS IV/Reg.4 "Functional requirements" SOLAS V/Reg.19 "Carriage requirements for shipborne navigational system and equipment" MSC/Circ.982 : Refer to "Appendix 2 Proposed equipment for workstation"	IACS Rec.95 and ISO 8468 provide very similar requirements.	Yes

2.1.9 monitor course, speed, track, propeller revolutions (pitch), rudder angle and depth of water;	IACS Rec.95 : Refer to "B 1 Functions, tasks and means" ISO 8468 : Refer to "5.3 Tasks to be performed"		
2.1.10 record navigational data (may be manually recorded from data available at the workstation).			
2.2 Equipment to be fitted			
2.2.1 Irrespective of their size, gross tonnage and date of construction, **all OMBO ships** are in any case to be equipped with the instrumentation and controls described under 2.3 to 2.5 hereafter.	N/A	Dedicated requirement for OMBO ships	No
2.3 Safety of navigation: Collision-Grounding			
2.3.1 The ship is to be equipped with an **ARPA system** including, or associated with, a collision avoidance system, meeting the requirements of IMO Resolution A422(XI). The ARPA function may be independent or built into the radar equipment. The system is to be based on the assumption that all floating objects may come onto a collision course with own ship if the object's course is changed up to 45° with its speed maintained. A warning shall be given to the navigator at a time which shall be adjustable in the range of 6 to 30 minutes, having regard to the time to danger (TCPA). The whole equipment is to feature the following capability: – true motion and relative motion modes, – daylight-visible display, – automatic acquisition and tracking of 20 radar targets, – guard zone system, featuring adjustable parameters, notably warning and alarm set for CPA and TCPA, – simulator function showing the likely effects of a course or speed change in relation to tracked targets, – incorporated self-checking properties.	**SOLAS V/Reg.19.2.8.1** 2.8 All ships of 10,000 gross tonnage and upwards shall, in addition to meeting the requirements of paragraph 2.7 with the exception of paragraph 2.7.2, have: .1 an automatic radar plotting aid, or other means, to plot automatically the range and bearing of at least 20 other targets, connected to a device to indicate speed and distance through the water, to determine collision risks and simulate a trial manoeuvre; and **Res.A.422(11)** "PERFORMANCE STANDARDS FOR AUTOMATIC RADAR PLOTTING AIDS (ARPA)" **Res.A.823(19)** "PERFORMANCE STANDARDS FOR AUTOMATIC RADAR PLOTTING AIDS (ARPAs)" **Res.MSC.192(79), as amended** "ADOPTION OF THE REVISED PERFORMANCE STANDARDS FOR RADAR EQUIPMENT" **IACS Rec.95** : Refer to "Table C 2.3" **ISO 8468** : Refer to "6.2 Distribution of equipment in workstations" **MSC/Circ.563** : Refer to "E 3.2 and 3.3" for symbol of guard zone system	Res.A.422(11) has been amended by Res.A.823(19). ARPAs installed on or after 1 January 1997 conform to performance standards Res.A.823(19). ARPAs installed before 1 January 1997 conform Res.A.422(11). A guard zone is deemed as "Acquisition/activation zone" specified in Res.MSC.192(79)	Yes
2.3.2 An **automatic pilot** is to be provided and monitored by an off-course alarm addressed to the navigator, in case of malfunction. This alarm shall be derived from a system independent from the automatic steering system. An overriding control device shall be provided at the navigating and manoeuvring workstation. Alternatively, track piloting equipment may be considered.	**SOLAS V/Reg.19.2.8.2** 2.8 All ships of 10,000 gross tonnage and upwards shall, in addition to meeting the requirements of paragraph 2.7 with the exception of paragraph 2.7.2, have: .2 a heading or track control system, or other means, to automatically control and keep to a heading and/or straight track. **Res.MSC.74(69)** : Refer to "annex 2 for track control systems (TCS)" **Res.MSC.64(67)** : Refer to "annex 3 for heading control systems (HCS)" **IACS Rec.95** : Refer to "Annex A 1 Table of tasks and related means for safe operations"	N/A	Yes
2.3.3 The navigator is to be given **an alarm** in case of deviation from the planned route. This alarm is to be adjustable having regard to the time to danger of grounding.	**Res.MSC.74(69)** : Refer to "annex 2 for track control systems (TCS)" **Res.A.817(19)**, as amended : Refer to "10.5.3" **IACS Rec.95** : Refer to "C 3 Bridge alarm management"	N/A	Yes
2.3.4 **Pre-warning** is to be given at the approach of a way-point.	**Res.MSC.74(69)** : annex 2 for track control systems (TCS)		
2.3.5 An alarm is to be initiated when the **water depth** beneath the ship is less than a predetermined value.	**SOLAS V/Reg.19.2.3.1** 2.3 All ships of 300 gross tonnage and upwards and passenger ships irrespective of size shall, in addition to meeting the requirements of paragraph 2.2, be fitted with: .1 an echo sounding device, or other electronic means, to measure and display the available depth of water; **Res.A.817(19)**, as amended : Refer to "10.5.3" **Res.MSC.74(69)** : Refer to "5.3.1 Depth alarm" **MSC/Circ.982** : Refer to "Appendix 2" **IACS Rec.95** : Refer to "Annex A 1 Table of tasks and related means for safe operations"	N/A	Yes
2.4 Position fixing			

2.4.1 Ships are to be provided with **position fixing systems** appropriate to the intended service areas.	**SOLAS V/Reg.19.2.1.6** 2.1 All ships irrespective of size shall have: .6 a receiver for a global navigation satellite system or a terrestrial radionavigation system, or other means, suitable for use at all times throughout the intended voyage to establish and update the ship's position by automatic means; **Res.MSC.112(73)** on ADOPTION OF THE REVISED PERFORMANCE STANDARDS FOR SHIPBORNE GLOBAL POSITIONING SYSTEM **(GPS)** RECEIVER EQUIPMENT **Res.MSC.113(73)** on ADOPTION OF THE REVISED PERFORMANCE STANDARDS FOR SHIPBORNE **GLONASS** RECEIVER EQUIPMENT **Res.MSC.114(73)** on ADOPTION OF THE REVISED PERFORMANCE STANDARDS FOR SHIPBORNE **DGPS AND DGLONASS** MARITIME RADIO BEACON RECEIVER EQUIPMENT **Res.MSC.115(73)** on ADOPTION OF THE REVISED PERFORMANCE STANDARDS FOR SHIPBORNE **COMBINED GPS/GLONASS** RECEIVER EQUIPMENT **Res.MSC.233(82)** on ADOPTION OF THE PERFORMANCE STANDARDS FOR SHIPBORNE **GALILEO** RECEIVER EQUIPMENT **Res.MSC.379(93)** on PERFORMANCE STANDARDS FOR SHIPBORNE **BEIDOU** SATELLITE NAVIGATION SYSTEM (BDS) RECEIVER EQUIPMENT **Res.MSC.449(99)** on PERFORMANCE STANDARDS FOR SHIPBORNE INDIAN REGIONAL NAVIGATION SATELLITE SYSTEM **(IRNSS)** RECEIVER EQUIPMENT	N/A	Yes
2.4.2 At least 2 independent **radars** shall be provided. One of them shall operate within the X-band.	**SOLAS V/Reg.19.2.3.2** (X-band Radar for ships of 300 GT above) **SOLAS V/Reg.19.2.7.1** (S-band Radar for ships of 3,000 GT above) **Res.MSC.192(79)**, as amended "ADOPTION OF THE REVISED PERFORMANCE STANDARDS FOR RADAR EQUIPMENT" **IACS Rec.95** : Refer to "Annex A 1 Table of tasks and related means for safe operations" **MSC/Circ.982** : Refer to "Appendix 2" **ISO 8468** : Refer to "6.2 Distribution of equipment in workstations"	N/A	Yes
2.4.3 A **gyro compass** system is to be provided.	**SOLAS V/Reg.19.2.5.1** 2.5 All ships of 500 gross tonnage and upwards shall, in addition to meeting the requirements of paragraph 2.3 with the exception of paragraphs 2.3.3 and 2.3.5, and the requirements of paragraph 2.4, have: .1 a gyro compass, or other means, to determine and display their heading by shipborne non-magnetic means, being clearly readable by the helmsman at the main steering position. These means shall also transmit heading information for input to the equipment referred in paragraphs 2.3.2, 2.4 and 2.5.5; **IACS Rec.95** : Refer to "Annex A 1 Table of tasks and related means for safe operations" **MSC/Circ.982** : Refer to "Appendix 2" **Res.A.424(11)** on PERFORMANCE STANDARDS FOR GYRO-COMPASSES **ISO 8728, Ships and marine technology** — Marine gyro-compasses	N/A	Yes

2.4.4 A **speed log** system is to be provided.	**SOLAS V/Reg.19.2.3.4** 2.3 All ships of 300 gross tonnage and upwards and passenger ships irrespective of size shall, in addition to meeting the requirements of paragraph 2.2, be fitted with: .4 speed and distance measuring device, or other means, to indicate speed and distance through the water; **SOLAS V/Reg.19.2.9.2** 2.9 All ships of 50,000 gross tonnage and upwards shall, in addition to meeting the requirements of paragraph 2.8, have: .2 a speed and distance measuring device, or other means, to indicate speed and distance over the ground in the forward and athwartships direction. **Resolution A.824(19)**, as amended on PERFORMANCE STANDARDS FOR DEVICES TO INDICATE SPEED AND DISTANCE **MSC/Circ.982** : Refer to "Appendix 2" **IACS Rec.95** : Refer to "Annex A 1 Table of tasks and related means for safe operations" **IEC 61023, Maritime navigation and radiocommunication equipment and systems — Marine speed and distance measuring equipment (SDME)** — Performance requirements — Methods of testing and required test results	N/A	Yes
2.4.5 An **echo sounding** system is to be provided.	**SOLAS V/Reg.19.2.3.1** 2.3 All ships of 300 gross tonnage and upwards and passenger ships irrespective of size shall, in addition to meeting the requirements of paragraph 2.2, be fitted with: .1 an echo sounding device, or other electronic means, to measure and display the available depth of water; **Res.MSC.74(69)** : Refer to "Annex 4" **MSC/Circ.982** : Refer to "Appendix 2" **IACS Rec.95** : Refer to "Annex A 1 Table of tasks and related means for safe operations" **ISO 9875, Ships and marine technology** — Marine echo-sounding equipment	N/A	Yes
2.5 Controls – Communication			
2.5.1 A **propulsion plant remote control system** is to be provided on the bridge.	**MSC/Circ.982** : Refer to "Appendix 2" **IACS Rec.95** : Refer to "Annex A 1 Table of tasks and related means for safe operations"	N/A	Yes
	SOLAS III/Reg.6.4.2		

2.5.2 A **whistle control** device is to be provided.	4.2 A general emergency alarm system complying with the requirements of paragraph 7.2.1 of the Code shall be provided and shall be used for summoning passengers and crew to muster stations and to initiate the actions included in the muster list. The system shall be supplemented by either a public address system complying with the requirements of paragraph 7.2.2 of the Code or other suitable means of communication. Entertainment sound systems shall automatically be turned off when the general emergency alarm system is activated. **LSA Code 7.2.1 General emergency alarm system** 7.2.1.1 The general emergency alarm system shall be capable of sounding the general emergency alarm signal consisting of seven or more short blasts followed by one long blast on the ship's whistle or siren and additionally on an electrically operated bell or klaxon or other equivalent warning system, which shall be powered from the ship's main supply and the emergency source of electrical power required by regulation II-1/42 or II-1/43, as appropriate. The system shall be capable of operation from the navigation bridge and, except for the ship's whistle, also from other strategic points. The alarm shall continue to function after it has been triggered until it is manually turned off or is temporarily interrupted by a message on the public address system. **MSC/Circ.982** : Refer to "Appendix 2" **IACS Rec.95** : Refer to "Annex A 1 Table of tasks and related means for safe operations" **ISO 8468** : Refer to "5.3 Tasks to be performed a) 7)"	N/A	Yes
2.5.3 A **window wipe and wash** control device is to be provided.	**MSC/Circ.982** : Refer to "Appendix 2" **IACS Rec.95** : Refer to "Annex A 1 Table of tasks and related means for safe operations" **ISO 8468** : Refer to "5.3 Tasks to be performed a) 14)"	N/A	Yes
2.5.4 A main workstation console **lighting control** device is to be provided.	**MSC/Circ.982** : Refer to "Appendix 2" **IACS Rec.95** : Refer to "B 3.5" **ISO 8468** : Refer to "6.4 Illumination and individual lighting of equipment" and "7.4 Lighting"	N/A	Yes
2.5.5 **Steering pump selector/control switches** are to be provided.	**MSC/Circ.982** : Refer to "Appendix 2" **IACS Rec.95** : Refer to "Annex A 1 Table of tasks and related means for safe operations" **ISO 8468** : Refer to "6.2 Distribution of equipment in workstations"	N/A	Yes
2.5.6 An **internal communication** system is to be provided.	**SOLAS III/Reg.6.4.2** 4.2 A general emergency alarm system complying with the requirements of paragraph 7.2.1 of the Code shall be provided and shall be used for summoning passengers and crew to muster stations and to initiate the actions included in the muster list. The system shall be supplemented by either a public address system complying with the requirements of paragraph 7.2.2 of the Code or other suitable means of communication. Entertainment sound systems shall automatically be turned off when the general emergency alarm system is activated. **LSA Code 7.2.2 Public address system** 7.2.2.1 The public address system shall be a loudspeaker installation enabling the broadcast of messages into all spaces where crew members or passengers, or both, are normally present, and to muster stations. It shall allow for the broadcast of messages from the navigation bridge and such other places on board the ship as the Administration deems necessary. It shall be installed with regard to acoustically marginal conditions and not require any action from the addressee. It shall be protected against unauthorized use. **MSC/Circ.982** : Refer to "Appendix 2" **IACS Rec.95** : Refer to "Annex A 1 Table of tasks and related means for safe operations" **ISO 8468** : Refer to "6.2 Distribution of equipment in workstations"	N/A	Yes

2.5.7 A **V.H.F. radiotelephone** installation is to be provided.	**SOLAS IV/Reg.6.3** 3 Control of the VHF radiotelephone channels, required for navigational safety, shall be immediately available on the navigating bridge convenient to the conning position and, where necessary, facilities should be available to permit radiocommunications from the wings of the navigating bridge. Portable VHF equipment may be used to meet the latter provision. **SOLAS IV/Reg.7.1.1** 1 Every ship shall be provided with : .1 a VHF radio installation capable of transmitting and receiving ; **Res.A.803(19)** as amended, on PERFORMANCE STANDARDS FOR SHIPBORNE VHF RADIO INSTALLATIONS CAPABLE OF VOICE COMMUNICATION AND DIGITAL SELECTIVE CALLING **MSC/Circ.982** : Refer to "Appendix 2" **IACS Rec.95** : Refer to "Annex A 1 Table of tasks and related means for safe operations" **ISO 8468** : Refer to "6.2 Distribution of equipment in workstations"	N/A	Yes
2.5.8 The systems or controls under 2.5.1 to 2.5.7 are to be fitted within **the reach of the officer** of the watch when seated or standing at the main navigating and manoeuvring workstation.	**MSC/Circ.982** 5.3.1.2 Single Operator Console Width for Seated Operations The console should be dimensioned and configured so that all relevant controls can be reached from a sitting position. **IACS Rec.95** : Refer to "B 7 Workstation layout, consoles and chair arrangement" **ISO 8468** A.3.2.2 All the equipment to be operated at the workstation for navigation and manoeuvring shall be located within reach for a seated person with safety belt fastened. Equipment and indicators to be monitored shall be easily readable from this position.	N/A	Yes
2.5.9 A wheelhouse **heating/cooling control** device is to be provided.	**MSC/Circ.982** : Refer to "5.2.2 Ventilation and Air-conditioning" and "Appendix 2" **IACS Rec.95** : Refer to "B 3.1" **ISO 8468** : Refer to "7.5 Heating, ventilation and air conditioning"	N/A	Yes
2.5.10 A NAVTEX automatic receiver and recorder is to be provided.	**SOLAS IV/Reg.7.1.4** 1 Every ship shall be provided with : .4 a receiver capable of receiving International NAVTEX service broad-casts if the ship is engaged on voyages in any area in which an International NAVTEX service is provided; **Res.MSC.148(77)** on THE REVISED PERFORMANCE STANDARDS FOR NARROW-BAND DIRECT-PRINTING TELEGRAPH EQUIPMENT FOR THE RECEPTION OF NAVIGATIONAL AND METEOROLOGICAL WARNINGS AND URGENT INFORMATION TO SHIPS (NAVTEX) **MSC/Circ.982** : Refer to "Appendix 2" **IACS Rec.95** : Refer to "Annex A 1 Table of tasks and related means for safe operations"	N/A	Yes
3. Prevention of Accidents caused by Operator's Unfitness			
3.1 Bridge safety system			

3.1.1 A **vigilance system** is to be provided to indicate that an alert officer of the navigational watch is present on the bridge.	**SOLAS V/Reg.19.2.2.3** 2.2 All ships of 150 gross tonnage and upwards and passenger ships irrespective of size shall, in addition to the requirements of paragraph 2.1, be fitted with: .3 a bridge navigational watch alarm system **(BNWAS)**, as follows: **Res.MSC.128(75)** on PERFORMANCE STANDARDS FOR A BRIDGE NAVIGATIONAL WATCH ALARM SYSTEM **(BNWAS)** **IACS Rec.95** : Refer to "D 2 Prevention of operational errors" **ISO 8468** : Refer to "5.6.2 Bridge navigational watch alarm system **(BNWAS**)"	BNWAS is appropriate for this purpose	Yes
3.1.2 Any system used for verification of the officer of the navigational watch's alertness shall not cause undue interference with the performance of bridge functions.	**IACS Rec.95** : Refer to "D 2 Prevention of operational errors" **ISO 8468** : Refer to "5.6.2 Bridge navigational watch alarm system (BNWAS)"	General requirement	Yes
3.1.3 The system shall be so **designed and arranged** that it could not be operated in an unauthorized manner, as far as practicable.	**IACS Rec.95** : Refer to "D 2 Prevention of operational errors" **ISO 8468** : Refer to "5.6.2 Bridge navigational watch alarm system (BNWAS)"	N/A	Yes
3.1.4 Any system used for **periodic verification** of the officer of the navigational watch's alertness shall be adjustable up to 12 minute intervals and constructed, fitted and arranged so that only the ship's master has access to the component for setting the appropriate intervals.	**Res.MSC.128(75)** on PERFORMANCE STANDARDS FOR A BRIDGE NAVIGATIONAL WATCH ALARM SYSTEM (BNWAS) 4.1.2 Operational sequence of indications and alarms 4.1.2.1 Once operational, the alarm system should remain dormant for a period of between 3 and 12 min (Td).	N/A	Yes
3.1.5 The system shall provide for the **acknowledgement** by the officer of the navigational watch at the navigating and traffic surveillance/manoeuvring workstation and other appropriate locations in the bridge from where a proper lookout may be kept.	**ISO 8468** : Refer to "5.6.2 Bridge navigational watch alarm system (BNWAS)" Where a system requires manual acknowledgement by the operator, this shall be possible at the workstation for navigation and manoeuvring, and also at other appropriate locations from where a proper lookout may be kept.	N/A	Yes
3.1.6 Such a system shall be connected to the **alarm transfer system** described in 3.2.	**ISO 8468** : Refer to "5.6.3 Alarm transfer system"	N/A	Yes
3.1.7 An alarm is to operate on the bridge in the **event of a failure** of the bridge safety systems.	**ISO 8468** : Refer to "5.6.2 Bridge navigational watch alarm system (BNWAS)" An alarm is to operate on the bridge in the event of a failure of the watch alarm system.	N/A	Yes
3.1.8 The requirements of 3.1.1 to 3.1.7 do not prevent the Classification Societies from accepting any technical systems that adequately verify or help maintain the alertness of the officer of the watch at intervals up to 12 minutes.	N/A	General requirement	N/A
3.2 Alarm/warning transfer system – communications			
3.2.1 Any alarm/warning that requires bridge operator response shall be **automatically transferred** to the master and, if he deems it necessary, to the selected back-up navigator and to the public rooms, if not acknowledged on the bridge within 30 seconds. Such transfer is to be carried out through the systems required by 3.2.3 and 3.2.7 where applicable.	**Res.MSC.128(75)** on PERFORMANCE STANDARDS FOR A BRIDGE NAVIGATIONAL WATCH ALARM SYSTEM (BNWAS) 4.1.2 Operational sequence of indications and alarms 4.1.2.1 Once operational, the alarm system should remain dormant for a period of between 3 and 12 min (Td). 4.1.2.2 At the end of this dormant period, the alarm system should initiate a visual indication on the bridge. 4.1.2.3 If not reset, the BNWAS should additionally sound a first stage audible alarm on the bridge 15 s after the visual indication is initiated. 4.1.2.4 If not reset, the BNWAS should additionally sound a second stage remote audible alarm in the back-up officer's and/or Master's location 15 s after the first stage audible alarm is initiated. 4.1.2.5 If not reset, the BNWAS should additionally sound a third stage remote audible alarm at the locations of further crew members capable of taking corrective actions 90 s after the second stage remote audible alarm is initiated. **ISO 8468** : Refer to "5.6.3 Alarm transfer system" Means may be provided on the bridge to immediately activate a second, and subsequently third, stage remote audible alarms by means of an Emergency Call push button or similar.	N/A	Yes

3.2.2 **Acknowledgment of alarms/warnings** shall only be possible from the bridge.	**Res.MSC.128(75)** on PERFORMANCE STANDARDS FOR A BRIDGE NAVIGATIONAL WATCH ALARM SYSTEM (BNWAS) 4.1.3 Reset function 4.1.3.1 It should not be possible to initiate the reset function or cancel any audible alarm from any device, equipment or system not physically located in areas of the bridge providing proper look out. **ISO 8468** : Refer to "5.6.3 Alarm transfer system" Acknowledgement and cancellation of alarms shall only be possible from fixed locations on the bridge.	N/A	Yes
3.2.3 The alarm/warning transfer shall be operated through a **fixed installation.**	**Res.MSC.128(75)** on PERFORMANCE STANDARDS FOR A BRIDGE NAVIGATIONAL WATCH ALARM SYSTEM (BNWAS) 4.1.4 Emergency call facility Means may be provided on the bridge to immediately activate the second, and subsequently third, stage remote audible alarms by means of an "Emergency Call" push button or similar.	N/A	Yes
3.2.4 Provision is to be made on the bridge for the operation of a navigation **officer call-alarm** to be clearly audible in the spaces of 3.2.1.		N/A	Yes
3.2.5 The alarm transfer system shall be continuously powered and shall have an automatic changeover to a standby power supply in case of loss of normal power supply.	**Res.MSC.128(75)** on PERFORMANCE STANDARDS FOR A BRIDGE NAVIGATIONAL WATCH ALARM SYSTEM (BNWAS) 6.3 Power supply The BNWAS should be powered from the ship's main power supply. The malfunction indication, and all elements of the Emergency Call facility, if incorporated, should be powered from a battery maintained supply.	N/A	Yes
3.2.6 At all times, including during blackout, the officer of the watch shall have access to facilities enabling **two way speech communication** with another qualified officer. The bridge is to have priority over the communication system. Note: The **automatic telephone network** is acceptable for this purpose, provided that it is automatically supplied during black-out situation and that it is available in the locations specified in 3.2.1.	**SOLAS II-1/Reg.42.2.3.1 & 43.2.4.1** 2.4 For a period of 18 h : .1 all internal communication equipment as required in an emergency ; **IACS UI SC 4** Emergency source of electrical power (Chapter II-1, Regulation 42.2.3.1 & 43.2.4.1) Internal communication equipment required in an emergency is generally: 1. The means of communication which is provided between the navigating bridge and the steering gear compartment 2. The means of communication which is provided between the navigating bridge and the position in the machinery space or control room from which the engines are normally controlled 3. The means of communication which is provided between the bridge and the radio telegraph or radio telephone stations. **MSC/Circ.982** : Refer to "Appendix 2" **IACS Rec.95** : Refer to "B 1 Functions, tasks and means"	It is not clear whether the common telephone network(intercom) in back-up officer's and/or Master's location or public rooms should be connected to emergency source of power.	No
3.2.7 If, depending on the shipboard work organization, the back-up navigator may attend locations not connected to the fixed installation(s) described in 3.2.1, he shall be provided with a wireless portable device enabling both the **alarm/warning transfer** and two way speech communication with the officer of the watch.	**SOLAS III/Reg.6.2** Radio life-saving appliances 2.1 Two-way VHF radiotelephone apparatus 2.1.1 At least three two-way VHF radiotelephone apparatus shall be provided on every passenger ship and on every cargo ship of 500 gross tonnage and upwards. At least two two-way VHF radiotelephone apparatus shall be provided on every cargo ship of 300 gross tonnage and upwards but less than 500 gross tonnage. Such apparatus shall conform to performance standards not inferior to those adopted by the Organization. If a fixed twoway VHF radiotelephone apparatus is fitted in a survival craft it shall conform to performance standards not inferior to those adopted by Organization.	Alternatively, two-way VHF or walkie-talkie(transceiver) may be considered such a wireless portable device. However, these devices are generally not capable of transferring alarm/warning.	No
4. Equipment Design and Reliability			
4.1 Environmental conditions			

4.1.1 Shipborne navigational equipment specified in **IMO Publication 978-88-04E** 'PERFORMANCE STANDARDS FOR NAVIGATIONAL EQUIPMENT' shall be capable of continuous operation under the conditions of various sea states, vibration, humidity, temperature and electromagnetic interference likely to be experienced in the ship in which it is installed.	**SOLAS V/Reg.17 Electromagnetic compatibility** 1 Administrations shall ensure that all electrical and electronic equipment on the bridge or in the vicinity of the bridge, on ships constructed on or after 1 July 2002, is tested for electromagnetic compatibility taking into account the recommendations developed by the Organization. 2 Electrical and electronic equipment shall be so installed that electromagnetic interference does not affect the proper function of navigational systems and equipment. 3 Portable electrical and electronic equipment shall not be operated on the bridge if it may affect the proper function of navigational systems and equipment. **Res.A.813(19)** on GENERAL REQUIREMENTS FOR ELECTROMAGNETIC COMPATIBILITY (EMC) FOR ALL ELECTRICAL AND ELECTRONIC SHIP'S EQUIPMENT **MSC/Circ.982** : Refer to "5.2 Work Environment" **IACS Rec.95** : Refer to "B 3 Working environment" **IACS UI SC 194** Installation of electrical and electronic appliances on the bridge and vicinity of the bridge **ISO 8468** : Refer to "7 Bridge working environment"	N/A	Yes
4.1.2 Equipment which has been additionally specified in these Rules is to comply with the environmental conditions specified in **IACS UR E10.**	**IACS UR E10** Test Specification for Type Approval	N/A	Yes
4.1.3 **Documentary evidence** in the form of Certification and/or test results are to be submitted to the satisfaction of the Classification Society. Where acceptable evidence is not available, the requirements of IACS UR E10 should be complied with.	**SOLAS V/Reg.18** Approval, surveys and performance standards of navigational systems and equipment and voyage data recorder **IACS UR E10** Test Specification for Type Approval **IACS UI SC 194** Installation of electrical and electronic appliances on the bridge and vicinity of the bridge 4. Evidence to be provided All electrical and electronic appliances installed on the bridge and vicinity of the bridge other than mandatory navigation and communication equipment having been type tested according to IEC 60945, as well as loose equipment placed on board by the builders or owners shall be listed and be provided with at least the following information. The list and the evidence of equipment are to be kept onboard. - equipment description - manufacturer - type / model - evidence of EMC compatibility which may be: • type approval certificate covering EMC requirements for bridge installations; • test certificate or report / conformity statement; or • exemption statement.	N/A	Yes
4.2 Design – reliability			

4.2.1 **Power supply** Local distribution panels shall be arranged for all items of electrically operated navigational equipment. These panels are to be supplied by two exclusive circuits, one fed from the main source of electrical power and one fed from an emergency source of electrical power. Each item of navigational equipment is to be individually connected to its distribution panel. The power supplies to the distribution panels shall be arranged with automatic changeover facilities between the two sources. Failure of the main power supply to the distribution panels shall initiate an audible and visual alarm.	**SOLAS II-1/Reg.42.2.3.2** Emergency source of electrical power in passenger ships 2.3 For a period of 36 h : .2 the shipborne navigational equipment as required by regulation V/12 *;where such provision is unreasonable or impracticable the Administration may waive this requirement for ships of less than 5,000 tons gross tonnage ; **SOLAS II-1/Reg.43.2.4.2** Emergency source of electrical power in cargo ships 2.4 For a period of 18 h : .2 the shipborne navigational equipment as required by regulation V/12* ;where such provision is unreasonable or impracticable the Administration may waive this requirement for ships of less than 5,000 tons gross tonnage ; **MSC/Circ.982** : Refer to "5.4.1.3 Failure or Reduction of Power Supply" and "5.4.1.10 Power supply" Required alarm systems should be continuously powered and should have an automatic change-over to a stand-by power supply in case of loss of normal power supply. **IACS Rec.95** : Refer to "Table C 2.3" **SN.1/Circ.288** : Refer to "14 Power supply" **ISO 8468** : Refer to "6.6 Power supply requirements" Equipment required to undertake a primary bridge function should be connected, as appropriate, to a self-contained emergency source of electrical power as provided in the SOLAS convention.	N/A	Yes
4.2.2 **Loss of power** Following a loss of power which has lasted for 30 seconds or less, all primary functions are to be readily reinstated. Following a loss of power which has lasted for more than 30 seconds, as many as practical primary functions shall be readily reinstated.	**SOLAS II-1/Reg.42.3.1.2** Emergency source of electrical power in passenger ships 3.1 Where the emergency source of electrical power is a generator, it shall be : .2 started automatically upon failure of the electrical supply from the main source of electrical power and shall be automatically connected to the emergency switchboard; those services referred to in paragraph 4 shall then be transferred automatically to the emergency generating set. The automatic starting system and the characteristic of the prime mover shall be such as to permit the emergency generator to carry its full rated load as quickly as is safe and practicable, subject to a maximum of 45 s ;unless a second independent means of starting the emergency generating set is provided, the single source of stored energy shall be protected to preclude its complete depletion by the automatic starting system ;and **SOLAS II-1/Reg.43.3.1.3** Emergency source of electrical power in cargo ships 3.1 Where the emergency source of electrical power is a generator, is shall be : .3 provided with a transitional source of emergency electrical power as specified in paragraph 4 unless an emergency generator is provided capable both of supplying the services mentioned in that paragraph and of being automatically started and supplying the required load as quickly as is safe and practicable subject to a maximum of 45 s. **MSC.1/Circ.1464/Rev.1** : Refer to "5.4 SOLAS REGULATION II-1/41.5" **IACS UI SC 157** Main Source of Electrical Power 2.2 Where the electrical power is normally supplied by one generator provision shall be made, upon loss of power, for automatic starting and connecting to the main switchboard of stand-by generator(s) of sufficient capacity with automatic restarting of the essential auxiliaries, in sequential operation if required. Starting and connection to the main switchboard of the stand-by generator is to be preferably within 30 seconds, but in any case not more than 45 seconds, after loss of power. Where prime movers with longer starting time are used, this starting and connection time may be exceeded upon approval from the society.	There is no definition of "primary function" and the term "primary functions" is not clear to determine which equipment or system is to be applied. Also, it should be identified whether the term "~readily reinstated" means the equipment is reinstated or restarted automatically without manual operation such as power-on or not. For reference, ECDIS is automatically re-initialized when changing from one source of power supply to another, or any interruption of the supply for a period of up to 45 s. (Refer to Res.A.817(19) 15.2)	No
4.2.3 Where **computerized equipment** are interconnected through a computer network, failure of the network should not prevent individual equipment from performing their individual functions.	ISO 8468	General requirement	Yes
4.3 Ergonomical recommendations			

4.3.1 **Lighting** The lighting required on the bridge should be designed so as not to impair the night vision of the officer on watch. Lighting used in areas and at items of equipment requiring illumination whilst the ship is navigating is to be such that night vision adaptation is not impaired, e.g. red lighting. Such lighting is to be arranged so that it cannot be mistaken for a navigation light by another ship. It is to be noted that red lighting is not to be fitted over chart tables so that possible confusion in colour discrimination is avoided.	**MSC/Circ.982** : Refer to "5.2.5 Illumination and Lighting" A satisfactory level of lighting should be available to enable the bridge personnel to complete such tasks as maintenance, chart and office work satisfactorily, both at sea and in port, daytime and night time. **IACS Rec.95** : Refer to "B 3 Working environment" **ISO 8468** : Refer to "6.4 Illumination and individual lighting of equipment" and "7.4 Lighting"	N/A	Yes
4.3.2 **Noise levels** The noise level on the bridge should not interfere with verbal communication, mask audible alarms or be uncomfortable to bridge personnel.	**MSC/Circ.982** : Refer to "5.2.3 Noise and Acoustics" Workplace noise should be maintained at levels that do not: (1) interfere with necessary voice, telephone and radio communications, (2) cause fatigue or injury and (3) degrade overall system effectiveness. **IACS Rec.95** : Refer to "B 3 Working environment" **ISO 8468** : Refer to "7.3 Noise"	N/A	Yes
4.3.3 **Vibration level** The vibration level on the bridge should not be uncomfortable to the bridge personnel.	**MSC/Circ.982** : Refer to "5.2.4 Vibration" Uncomfortable levels of vibration should be avoided on the bridge. Vibrations on the bridge should be reduced to such extent that the bridge personnel are neither hindered in their functions nor put at a health risk. **IACS Rec.95** : Refer to "B 3 Working environment" **ISO 8468** : Refer to "7.2 Vibration" Uncomfortable levels of vibration shall be avoided on the bridge.	N/A	Yes
4.3.4 **Wheelhouse space heating/cooling** Unless justified, wheelhouse spaces are to be provided with heating and air cooling systems. System controls are to be readily available to the officer of the watch.	**MSC/Circ.982** : Refer to "5.2.2 Ventilation and Air-conditioning" 5.2.2.1 Air-conditioning The wheelhouse should be equipped with an adequate air-conditioning or mechanical ventilation system to regulate temperature and humidity. The temperature and the humidity should be adjustable within the limits of the foregoing requirements 5.2.1, by closed wheelhouse doors and windows. 5.2.2.2 Hot Air Discharge Heating systems should be designed so that hot air discharge is not directed at personnel. 5.2.2.3 Cold Air Discharge Air conditioning systems should be designed such that cold air discharge is not directed at personnel. 5.2.2.4 Air Velocities Ventilating systems should not produce air velocities exceeding 0,5 m/s. If possible, the preferred air velocity of 0,3 m/s should be used to preclude manual pages from being turned or papers from being blown off work surfaces. **IACS Rec.95** : Refer to "B 3 Working environment" **ISO 8468** : Refer to "7.5 Heating, ventilation and air conditioning"	N/A	Yes

4.3.5 **Navigator's safety** There are to be no sharp edges or protuberances on the surfaces of the instruments and equipment installed on the bridge which could cause injury to the navigator. Sufficient **hand-rails** or equivalent thereto are to be fitted inside the wheelhouse or around instruments and equipment in the wheelhouse for safety in bad weather. Adequate means are to be made for **anti-slip** of the floor, whether it be dry or wet. **Doors** to the bridge wings are to be easy to open and close. Means are to be provided to hold the doors open at any position. Where provision for **seating** is made in the wheelhouse, means for securing are to be provided, having regard to storm conditions.	**MSC/Circ.982** : Refer to "5.2.6 Occupational Safety" 5.2.6.1 Non-slip Surfaces Wheelhouse, bridge wings and upper bridge decks should have non-slip surfaces. 5.2.6.2 General Wheelhouse Safety There should be no sharp edges or protuberances which could cause injury to personnel. 5.2.6.3 Hand and Grab Rails Sufficient hand- or grab-rails should be fitted to enable personnel to move or stand safely in bad weather. Protection of stairway openings should be given special consideration. 5.2.6.4 Safety Equipment Marking All safety equipment carried on the bridge should be clearly marked, be easily accessible and have its stowage position clearly indicated. **IACS Rec.95** : Refer to "B 3 Working environment" **ISO 8468** : Refer to "7.8 Safety of personnel" 7.8.1 The bridge area shall be free of physical hazards to bridge personnel. 7.8.2 Guidelines: There should be no sharp edges or protuberances which could cause injury to personnel. The bridge deck should be free of trip hazards such as curled up carpet edges, loose gratings, duckboards or equipment. Means should be provided for properly securing portable equipment. 7.8.3 Sufficient hand- or grab-rails shall be fitted to enable personnel to move or stand safely in bad weather. Protection of stairway openings shall be given special consideration. 7.8.4 All safety equipment carried on the bridge shall be clearly marked, be easily accessible and have its stowage position clearly indicated.	N/A	Yes
5. Tests and Surveys			
5.1 Testing of the equipment after installation onboard			
5.1.1 After fitting onboard, the installations are to be submitted to the tests deemed necessary to demonstrate correct operation. Some **tests** may be carried out at the quayside, while others are to be effected at sea trials.	**Res.A.1140(31)** on SURVEY GUIDELINES UNDER THE HARMONIZED SYSTEM OF SURVEY AND CERTIFICATION (HSSC), 2019 **IACS Rec.95** : Refer to "Annex B" These elements also need to be considered by surveyors on the basis of documentation at the stage of plan approval, while the functioning of systems after installation needs to be verified by tests and trials before the ship is put in service. **IACS UR E10** Test Specification for Type Approval	N/A	Yes
5.1.2 **On-board tests and sea trials** are to be carried out in accordance with the test procedures submitted in advance to the Society for approval. Tests and trials are to be performed under the **supervision of the Surveyors**.	**Res.A.1140(31)** on SURVEY GUIDELINES UNDER THE HARMONIZED SYSTEM OF SURVEY AND CERTIFICATION (HSSC), 2019 **IACS Rec.95** : Refer to "A 6.7 Program for on board tests of equipment and systems" a) A program for the on board testing of the bridge equipment and systems required to be carried, as well as additional navigation equipment installed, should be submitted for approval at the earliest possible stage before sea trials. **IACS UR E10** Test Specification for Type Approval	N/A	Yes
5.2 Surveys			
5.2.1 **Periodical surveys** are to be carried out to the Surveyor's satisfaction, in order to verify that the equipment and arrangements required for the **class notation** are being maintained in good working order.	**SOLAS I/Reg.7 "Surveys of passenger ships"** **SOLAS I/Reg.8 "Surveys of life-saving appliances and other equipment of cargo ships"** **SOLAS I/Reg.9 "Surveys of radio installations of cargo ships"** **SOLAS V/Reg.16 "Maintenance of equipment"** **Res.A.1140(31)** on SURVEY GUIDELINES UNDER THE HARMONIZED SYSTEM OF SURVEY AND CERTIFICATION (HSSC), 2019	Most of the requirements in UR N 1 are subject to a periodical survey items which should be confirmed by surveyors under the SOLAS requirements.	Yes

Appendix 2

Other relevant instruments developed since approval of UR N 1 (November 1992) relating to bridge operations

1. Amendment status of SOLAS Chapter V

1994 amend (Res.MSC.31(63)) : Reg.22 - Navigation bridge visibility

1995 amend (Res.MSC.46(65)) : Reg.8 - Routeing

1995 amend (SOLAS/CONF.3/46) : Reg.10-1 - Master's discretion for safe navigation

1995 amend (SOLAS/CONF.3/46) : Reg.23 - Operational limitations

1997 amend (Res.MSC.65(68)) : Reg.8-2 - Vessel traffic services

2000 amend (Res.MSC.99(73)) : SOLAS chapter V has been completely revised.

- *Heading or Track control system*
- *Means of correcting heading and bearings*
- *Properly adjusted transmitting heading device (THD)*
- *Back up arrangements for electronic nautical publications (not mandatory)*
- *Receiver for a global navigation satellite system /terrestrial radio navigation system*
- *Automatic tracking aid*
- *Second automatic tracking aid*
- *Electronic plotting aid*
- *ECDIS (not mandatory)*
- *Automatic identification system (AIS)*
- *Voyage data recorder (VDR)*
- *Speed and distance measuring device (over the ground in the forward and athwartship direction)*
- *Rate of turn indicator*
- *Sound reception system*

2002 amend (Res.MSC.123(75)) : Reg.21 - International Code of Signals

2002 amend (SOLAS/CONF.5/32) : Reg.19 - Carriage requirements for shipborne navigational systems and equipment

2003 amend (Res.MSC.142(77)) : Reg.22 - Navigation bridge visibility

2004 amend (Res.MSC.170(79)) : Reg.19 - Carriage requirements for shipborne navigational systems and equipment and Reg.20 - Voyage data recorders

2006 amend (Res.MSC.201(81)) : Reg.22 - Navigation bridge visibility

2009 amend (Res.MSC.282(86)) : Reg.19 - Carriage requirements for shipborne navigational systems and equipment

- *ECDIS (mandatory)*

- *Back up arrangements for ECDIS*

- *BNWAS*

2013 amend (Res.MSC.350(92)) : Reg.19 - Carriage requirements for shipborne navigational systems and equipment

2. IMO Resolutions or Circulars

Res.A.813(19) : GENERAL REQUIREMENTS FOR ELECTROMAGNETIC COMPATIBILITY (EMC) FOR ALL ELECTRICAL AND ELECTRONIC SHIP'S EQUIPMENT

Res.A.916(22) : GUIDELINES FOR THE RECORDING OF EVENTS RELATED TO NAVIGATION

Res.A.1046(27) : WORLDWIDE RADIONAVIGATION SYSTEM

Res.MSC.86(70) : ADOPTION OF NEW AND AMENDED PERFORMANCE STANDARDS FOR NAVIGATIONAL EQUIPMENT

Res.MSC.191(79) : Performance standards for the presentation of navigation-related information on shipborne navigational displays

Res.MSC.252(83) : Revised performance standards for Integrated Navigation Systems (INS)

Res.MSC.467(101) : GUIDANCE ON THE DEFINITION AND HARMONIZATION OF THE FORMAT AND TRUCTURE OF MARITIME SERVICES IN THE CONTEXT OF E-NAVIGATION"

MSC/Circ.982 : GUIDELINES ON ERGONOMIC CRITERIA FOR BRIDGE EQUIPMENT AND LAYOUT

MSC/Circ.1061 : GUIDANCE FOR THE OPERATIONAL USE OF INTEGRATED BRIDGE SYSTEMS (IBS)

MSC.1/Circ.1474 : GUIDANCE ON THE BRIDGE NAVIGATIONAL WATCH ALARM SYSTEM (BNWAS) AUTO FUNCTION

MSC.1/Circ.1512 : GUIDELINE ON SOFTWARE QUALITY ASSURANCE AND HUMAN-CENTRED DESIGN FOR E-NAVIGATION

MSC.1/Circ.1593 : INTERIM GUIDELINES FOR THE HARMONIZED DISPLAY OF NAVIGATION INFORMATION RECEIVED VIA COMMUNICATION EQUIPMENT

MSC.1/Circ.1609 : GUIDELINES FOR THE STANDARDIZATION OF USER INTERFACE DESIGN FOR NAVIGATION EQUIPMENT

MSC.1/Circ.1612 : GUIDANCE FOR NAVIGATION AND COMMUNICATION EQUIPMENT INTENDED FOR USE ON SHIPS OPERATING IN POLAR WATERS

SN.1-Circ.288 : Guidelines For Bridge Equipment And Systems, Their Arrangement And Integration

3. IACS Resolutions

SC 95 Communication between Navigating Bridge and Machinery Space

SC 194 Installation of electrical and electronic appliances on the bridge and vicinity of the bridge

SC 203 Carriage requirements for shipborne navigational systems and equipment

SC 235 Navigation bridge visibility to ship's side

UR E 10 Test Specification for Type Approval

UR E 22 On Board Use and Application of Computer based systems

Rec.52 Power Supply to Radio Equipment required by SOLAS Chapter IV, and Electrical/ Electronic Navigation Equipment required by SOLAS Chapter V, reg. 19

Rec.95 Recommendation for the Application of SOLAS Regulation V/15; Bridge Design, Equipment Arrangement and Procedures (BDEAP)

4. International standards (not for specific navigation equipment)

ISO 14612, Ships and marine technology -- Ship's bridge layout and associated equipment -- Additional requirements and guidelines for centralized and integrated bridge functions

IEC 60945, Maritime navigation and radiocommunication equipment and systems — General requirements

IEC 61209, Maritime navigation and radiocommunication equipment and systems — Integrated bridge systems (IBS)- Operational and performance requirements, methods of testing and required test results

IEC 61924, Maritime navigation and radiocommunication equipment and systems — Integrated navigation systems — Operational and performance requirements, methods of testing and required test results

IEC 60533, Electrical and electronic installations in ships. Electromagnetic compatibility (EMC). Ships with a metallic hull

P.1.2.7 Design pressure

The design pressure *P* to be considered in formula (2) of P1.2.2 is the maximum working pressure and it is not to be less than the highest set pressure of any safety valve relief valve.

For special cases, the design pressure will be specially considered. For pipes containing ~~heated~~ fuel oil heated above 60 ^{o}C the design pressure is to be taken not less than 14 bar."

Technical Background Document
Review of UR P1.2.7 Design Pressure

Objective and scope

At the 20th Meeting of AHG/PPV ABS informed Members that this requirement was relocated from UR F35 (Rev. 2, 1992) however, further it was preceded by first para addressing fuel oils heated above 60 ^{0}C. ABS noted that existing formulation of UR is too strict for fuel oil transfer systems and proposed to review it.

Source of reviewed requirement

IACS UR F F35 and P 1.2.7

Points of discussion

Members unanimously agreed amendment of P1.2.7.

Technical Background Documents

1. Review of UR P1 – P3

- Objective and Scope

Review of UR P1.2, P2.1, P2.2, P2.3, P2.5, and P3 has been carried out in line with annual Task 1A. The main goal of this review was elimination of ABS' reservation. As has been noted by ABS: "P1 & P2 have not been implemented since the ABS Rules are formatted around US standards such as ANSI, ASME, USC Regulations, etc. P 1 & P2 are not conductive (sic) to incorporate in the Rules". With regard to P3, it needed to be changed editorially.

Additional ABS comments relative to the UR P:

P 1.2.7:
- Do not regard 14 bar as design pressure, otherwise, strainers, filters, heaters will have to be designed for 14 bar which may not be practicable. Also the testing pressure for these components will need to 1.5 the design pressure which may be a contentious issue. Accordingly ABS proposed that the 14 bar pressure should be considered as a special safeguard for the joints (see MSC Circ 647 & 851).
- Working Group needed to discuss and determine whether the 14 bar pressure was applicable to valves also. Further, ABS has been informed by their office in the Pacific that pressure rating of JIS f 7399-1989 "Marine Fuel oil Tank Emergency Shut-off valves", commonly used in that region, states that "Maximum working pressure shall be 0.098 MPa [1kg/cm2], although hydraulic inspection for body will be 0.686 MPa. Accordingly, it would not be possible to apply the 14 bar pressure to the suction side of the pump.

IACS Permanent Secretariat Note: After a considerable length of discussion on the design pressure for the associated fittings in P1.2.7, GPG finally agreed to the Table 8. New P1.4 was developed for valves and fittings in the piping systems. (GPG s/n 0077a)

P 2.2 Table (1):

- There was a need to define what constitutes "special safeguard". ABS observation of member societies Rules indicated that there were no provisions made for application of this in the design, construction or operational matters.
- ABS requested the WG to develop a list of provisions which may be considered "special safeguards" for various systems conveying flammable, toxic or corrosive media.
- The reference to toxic and corrosive fluids may be out of place, as such systems were invariably cargo systems, which were outside the scope of P2. Accordingly considerations should be given to deleting this.

- Source of Proposed Requirements

ABS proposals on correction the UR P1, P2 and P3 circulated by e- mail dated 13 September 2000 has

Unanimous agreement has been achieved.

2. Review of UR P 2.7 Types of Connections

- Objective and Scope

Review of UR P2.7 has been carried out in view that some types of widely used for essential service pipe joints have not been covered by existing URs.

- Source of Proposed Requirements

SOLAS - 74 as amended
IMO Res. A753 (18) "Guidelines for the application of plastic pipes on ships".
ISO/NP - 15837 Standard specification for performance of gasketed mechanical couplings for use in piping systems.
DNV Type approval of pipe couplings (Part of Certification Notes No 2.9)
GL Regulations for the Performance of Type Tests, section 9 " Pipe couplings", section 10 "Pipe unions".
ASTM F 1476 Standard specification for performance of gasket mechanical couplings for use in piping application.
ASTM F1387 Standard Specification for Performance of Mechanically Attached Fittings
JIS B 0151 Iron and steel pipe fittings - Vocabulary
JIS B 2351 25mpa (25 kg/cm^2) bite type tube fittings for hydraulic use

- Points of discussion

Unanimous agreement has been achieved.

3. Review of UR P2.10

- Objective and Scope

Shipyards are continuously asking to omit the hydraulic test prescribed for distant pieces by alternative method such as NDT based on their successful records and current practice.

- Source of Proposed Requirements

The existing UR P 2.10 and current practice of the Members.

Point of discussion

It was noted that existing requirements to pipe strength calculation as well as to selection of pipe wall thickness can not be applied for distance pieces because their wall thickness are appointed depend upon the thickness of ship's shell. Some Societies are considering it as the part of ship structure but not the part of piping system. In this regard it was unanimously agreed to exclude "distance pieces" from P 2.10.

UR P2.2, Table 1

- Objective and Scope

Review has been carried for harmonization of piping classification with new amendments to SOLAS Reg. II/15 "Arrangements for oil fuel, lubricating oil and other flammable oils".

- Source of Proposed Requirements

SOLAS - 74 with Amendments,
Rules of IACS Members.

- An unanimous agreement has been achieved.

Date of submission: 13 May 1999
By AHG/PPV Chairman

Technical Background Documents

1. Review of UR P1 – P3

- Objective and Scope

Review of UR P1.2, P2.1, P2.2, P2.3, P2.5, and P3 has been carried out in line with annual Task 1A. The main goal of this review was elimination of ABS' reservation. As has been noted by ABS: "P1 & P2 have not been implemented since the ABS Rules are formatted around US standards such as ANSI, ASME, USC Regulations, etc. P 1 & P2 are not conductive (sic) to incorporate in the Rules". With regard to P3, it needed to be changed editorially.

Additional ABS comments relative to the UR P:

P 1.2.7:

- Do not regard 14 bar as design pressure, otherwise, strainers, filters, heaters will have to be designed for 14 bar which may not be practicable. Also the testing pressure for these components will need to 1.5 the design pressure which may be a contentious issue. Accordingly ABS proposed that the 14 bar pressure should be considered as a special safeguard for the joints (see MSC Circ 647 & 851).
- Working Group needed to discuss and determine whether the 14 bar pressure was applicable to valves also. Further, ABS has been informed by their office in the Pacific that pressure rating of JIS f 7399-1989 "Marine Fuel oil Tank Emergency Shut-off valves", commonly used in that region, states that "Maximum working pressure shall be 0.098 MPa [1kg/cm2], although hydraulic inspection for body will be 0.686 MPa. Accordingly, it would not be possible to apply the 14 bar pressure to the suction side of the pump.

IACS Permanent Secretariat Note: After a considerable length of discussion on the design pressure for the associated fittings in P1.2.7, GPG finally agreed to the Table 8. New P1.4 was developed for valves and fittings in the piping systems. (GPG s/n 0077a)

P 2.2 Table (1):

JIS B 2351 25mpa (25 kg/cm^2) bite type tube fittings for hydraulic use

- Points of discussion

Unanimous agreement has been achieved.

3. Review of UR P2.10

- Objective and Scope

Shipyards are continuously asking to omit the hydraulic test prescribed for distant pieces by alternative method such as NDT based on their successful records and current practice.

- Source of Proposed Requirements

The existing UR P 2.10 and current practice of the Members.

Point of discussion

It was noted that existing requirements to pipe strength calculation as well as to selection of pipe wall thickness can not be applied for distance pieces because their wall thickness are appointed depend upon the thickness of ship's shell. Some Societies are considering it as the part of ship structure but not the part of piping system. In this regard it was unanimously agreed to exclude "distance pieces" from P 2.10.

Summary of comments of IACS AHG/PPV on External review of UR P2.7.4 & P2.11.

March 2001

Items of UR	**Comments and ðroposals of external bodies on UR P 2.7.4 & P2.11 drafts**	**Decisions and proposed answers to external bodies developed by AHG/PPV**
CHIBRO COMO FAX No 235/SP/00gc dated 03.07.2000		
UR P2.7.4		
Table 7	Include drawing of Pressfitting Type connection under heading Compression Couplings	Agree. Draft will be modified. Term Press Type will be used instead of term Pressfitting Type. Pressfitting is proprietary name and should not be included. Press Type is to be used as generic description. The use of such connections is to be restricted to Class III piping systems and is not to be accepted in steam systems. As the connections include a rubber seal ring they are to be restricted to service as for slip-on joints
Table 8	Ditto	Agree.
Table 9	Ditto	Agree.
UR P 2.11		
Table 10	Include “may be performed simultaneously with vibration test”	Disagree. Actual situation on board is that vibration and pressure pulsation are presented simultaneously
	Include column “pressfitting joints and similar”	Disagree. Press Type is covered by headline Compression couplings Note 2 will be modified as following: “except .press type
	Replace P2.11.5.3.8 with P2.11.5.5.8	Agree.
P2.11.2	First line. Add “pressfitting”	Disagree. Comment as comment above to Table 10.
P2.11.3	First line. Add phrase “or by delegate Company”	Disagree. This proposal contradicts with the existing procedures and common practice of the Classification Societies.

	Add phrase "linear thermal expansion related to the fluid temperature"	Disagree. Relates to specific items only. Specific items should be considered on case by case basis.
P2.11.4	Change the second phrase as following: "The manufacturer has to submit the evidence…that…all the components are adequately resistant to working the media at declared design pressure and temperature	Agree. Phrase will be changed as following: "…all the components are adequately resistant to working the media at design pressure and temperature specified."
P2.11.5.2	Include "(maximum, minimum and intermediate sizes)".	Disagree. This inclusion would implicitly require a test on the minimum size and on the maximum size precisely, which is not necessary. For example, range is ND20 to ND500. Size ND40, ND250 and 450 could be representative of the range. ND20 and ND500 are not necessary to be tested.
P2.11.5.3	Add as following: "Were not specified, the length of pipes/tubing to be connected by means of the joint to be tested will be long at least five time of their diameter. Before assembling the joint it shall be verified the conformity of components to the design requirements. In all cases the assembly of the joint shall be carried out only according to the manufacturer' s instructions. No adjustment operations on the joint assembly, other than that specified by the manufacturer, are permitted during the test.	Agree. Phrase will be changed as following: "Where not specified, the length of pipes to be connected by means of the joint to be tested is to be at least five times of pipe diameter. Before assembling the joint, conformity of components to the design requirements, is to be verified. In all cases the assembly of the joint shall be carried out only according to the manufacturer' s instructions. No adjustment operations on the joint assembly, other than that specified by the manufacturer, are permitted during the test."
P2.11.5.5.1a)	Change the forth para as following: "No visual indication leakage or slip out is permitted. In the event where there is a drop in pressure and there is visual indication of leakage or slip off, the test may be repeated."	Disagree. To leave the initial sentence disregarding the proposal. Reason: since tests refer only to the tightness of joints.
P2.11.5.5.2a)	The first line. Add "pressfitting joints" after "pipe unions"	Disagree. Comment as in P2.11.2 above.

	The third para : add “1.5 of” before the word “design”	Disagree. Not necessary because these are tightness tests and in line with appropriated practice, tightness tests are to be carried out at design pressure.
	Change “5%” to “+5%”	Disagree. Proposal is in contradiction with the text.
P2.11.5.5.3	The first line. Add “pressfitting joints” after “pipe unions”	Disagree. Comment as in P2.11.2 above
P2.11.5.5.4	The third para, add sentence by phrases; “at the maximum pressure. Then the pressure will be increased till the breaking-off. This pressure value will be annotated.	Agree partially. Text will be added by phrase: “ ..at the maximum pressure. This pressure value will be annotated.”
	Add “with an increasing rate of 10% per minute” after words “test pressure”.	Agree. Text will be added by phrase: “with an increasing rate of 10% of test pressure per minute”.
	The second para. Delete “and the manufacturer instructions” after reference to P2.11.5.3.	Agree.
P2.11.5.5.6	The second para, first line change “30” to “60”. Add “±10%” after “800^{0}C”	To leave the initial wording as it is. Reference is made to IACS Unified Requirements UR F42 that is accepted as fire proof test.
P2.11.5.5.7	The second para. Add “(3 min)’ after words “is stabilized”. Change 5 to 15 in the end of sentence.	Disagree. No use in applying such changes.
P2.11.5.5.7	2nd §: Include “test specimen” after “mechanical joint assembly”	Agree.
	Add “+5%” after “170 mbar”	Disagree. To leave the initial sentence as it is. No use in applying such changes.
Tailor Kerr Engineering Ltd, FAX No? Dated 23.07.00 and 24.07.00		
1	It is proposed to use definition of ASTM 1476 for	Disagreed.

	identification of different kind of pipe connections	Definition of ASTM 1476 can not be used due to contradictions both accepted classification of joints and terminology.
2	Use symbol from DIN 86128 for identification the Gripe type MJ	Disagreed. Each Society has the right to accept any National or International standard, which has not contradictions with URs.
3	Adopt fireproof test as prescribed by DIN 86230BS ISO EN 1155140:1999 accept the existing test.	Disagreed. Comment as above.
P2.11.5.5.3	Change recommended pressure pulsation test to simple on/of pump test as less expensive.	Disagree. Actual situation on board is that vibration and pressure pulsation are presented simultaneously.
P2.11.5.5.6	It is proposed to point out position of the measuring thermocouple and place it on 50 mm directly below the specimen. Noted that specimen should be completely engulfed in the flame envelope.	Disagree. The sentence is clear enough. This temperature is temperature on the surface of joint. The 2nd sentence – agree. Text will be changed.
Ihara Science corp., FAX No 00033 dated 16.07.00		
P2.11.5.5.2	(1) Usage of oil as test fluid is proposed.	Agree. Oil, as testing fluid will be specified.
	(2) This proposal is not clear understood.	The specimen shown is not intended to depict any specific type of joint. The diagram will be changed to avoid misunderstanding.
	(3) Distance identified as 30 mm has to be differ depending upon the OD of tested specimen	Disagree. Figure 1 is to be corrected. Distance of 30 mm will be indicated as distance till nearest edge of the joint.
P2.11.5.5.3	(1) Trapezoidal waveform diagram with maximum pressure of 1.33 rated pressure in line with ISO 6803 is recommended for pressure pulsation test	Disagree. Connections are intended to marine service is to meet to stricter standard.
	(2) Reason for adoption of test pressure equal 1.5 of rated pressure is requested	Systems are required by the rules to withstand pressure 1.5 $\times$ design pressure i.e. relief valves setting. Accordingly all components within a system should be designed for the same parameters.
	(3) Usage of oil as test fluid is proposed.	Agree. Oil as testing fluid will be specified

	(4) Separation of pressure pulsation and vibration test is requested	Disagree. Actual situation on board is that vibration and pressure pulsation present simultaneously.
P2.11.5.5.4	Usage of oil as test fluid is proposed	Agree. Oil as testing fluid will be specified
P2.11.5.5.5	Usage of inert gas as alternative selective option for sealed pressurized fluid is proposed	To leave the text as it is. Detection of gas leakage requires specialist equipment and the stored energy in large connections may introduce hazard.
P2.11.5.5.6	Point out acceptable level of temperature tolerance	Disagree. Reference is made to IACS Unified Requirements UR F42 that is accepted as fire proof test.
P2.11.5.5.8	Reduce number of assembling - disassembling to 8 times.	Disagree. Connections are intended to marine service are to meet stricter standard.
Straube Werke, FAX dated 24.07.00		
UR P2.7.4		
P2.7.4.2	First line. Add the phrase “or the pipe can get crushed” after “...wall thickness”	Disagree. “Crushed” implies pipe destruction, which is not the intent of the requirement.
P2.4.7	Cancel. This problem exists with every pipe joining method.	Disagree. This is contained in every Classification Society Rules.
P2.4.7.9	Cancel. If P2.7.4 is followed, there is no supplementary danger on oil systems.	Disagree Ditto.
P2.7.4.11	Change as following ”Slip-on joints can be used in pipe lines in cargo holds, tanks, and other spaces which are not easy accessible, limitation of use can be made by the Classification Society.	Disagree. Ditto.

Table 8	Change footnote 2 as following: “Has to be approved by Classification Society for use inside machinery spaces of category A. Is accepted in other Machinery spaces providing the joints are located in easily visible and accessible positions.	Disagree. Ditto
P2.11.5.5.6	Fire endurance test installation and accomplishment has to be identical to ISO 19921 respectively DIN 86232	Disagree. Ditto
RASMUSSEN GMBH FAX No WB / uu dated 12.07.2000		
UR P2.7.4.		
P2.7.1	1) Knob out test is recommended	Disagree. P2.7.1.2 is not connected with P2.7.4.
P2.7.4.9	2) Rasmussen’ s couplings are suitable for this type of application	Noted.
P2.7.4.10	3) Rasmussen’ s couplings able to compensate some defects cause by incorrect mounting	Noted.
P2.7.4.11	4) Rasmussen’ s couplings can be used in this condition provided there are fixed points and supports for each pipe lengths.	Noted.
Table 7	5) Include the drawing of Flex type connection	Agree. Table 7 will be added by the drawing under heading “Slip Type”.
Table 8	6) Make some changes in application of Slip-on joints	Disagree. To leave it as it is. Proposed changes of application of Slip-on joints are in contrary with requirements of each Society Rules.
Table 9	7) The wall thickness should be added for Class I, II and III as well as for materials steel, stainless steel and CuNi10Fe	Disagree. To leave it as it is. Comment as a.m.
P2.11		
P2.11.5	The axial forces should be defined by manufacturer.	Disagree. Contradicts with the common practice of IACS Members.

VICTAULIC FAX dated 02.10.2000, e-mail of 29.09.2000		
UR P2.7.4 & P2.7.11	To make clear distinction between Grooved Type and Grip/Slip Type joints couplings and include Grooved Type Joints in the figures contained in the drafts	Agree. Text of UR P2.7.4 and P2.11 will be corrected taking into account Victaulic' s proposals.
P2.11.5.5.6	Victaulic grooved couplings should be accepted for all areas requiring fire resistant pipe connections without additional testing	Disagree. Contradicts with the common practice of IACS Members.
Parker Hanfin Corporation, e-mail of 13.10.2000		
1)	Parker Hannifin Corporation is submitting suggestions, questions and clarification **only** for mechanical joints falling into: Compression Coupling category. A) Bite-Type B) Flared Type No comments are targeted at the Welded/Brazed, Grip or Slip type categories.	Noted
2)	The document uses the terms "pipe" and "piping." Recommend: A) replace "pipe" with "tube/pipe" B) replace "piping" with "tubing/piping" Most bite-type and flared type Compression Couplings are designed for use with tube. Separation of pressure pulsation and vibration test is requested	Disagree .IACS Requirements as well as Classification Society Rules do not differentiate between tubing and piping. Terminology pipe uses through out a.m. documents. Usage of another terminology in one specific documents may cause confusion

3)	It is our understanding that O-Ring Face Seal (ISO-8434-3) tube fittings and tube connection methods (Silver Braze and Mechanical Flange) would be categorized in the Compression Coupling Flared Type. O-Ring Face Seal Fittings are used extensively in hydraulic systems and are currently meet the demanding performance testing mandated by ABS and DNV classed vessels. The "Examples of Mechanical Joints" – Table 7 within P.2.7.4 is not clear as to the inclusion of aforementioned fittings.	The opinion of IACS expert group is that where joints imply flanges whether the sealing is by means of joints or O – rings, these will be considered as a non standard flange connections, which are covered by UR P2.7.2.
4)	Most manufacturers of compression and flare fittings currently rely on ISO-8434 as the governing body for dimensional, performance and testing requirements. ISO 8434-5 currently mandates performance testing of these types of mechanical connections. Many of the IACS proposed unified testing requirements are already addressed in ISO-8434-5. It is our recommendation that IACS adopt these industry standard testing requirements where appropriate. A copy has been attached for IACS technical body/expert review.	Disagree. Each Society has the right to accept any National or International standard, which has stricter testing requirements.
UR P2.11		
P2.11.1	1^{st} sentence: change "intending" to "intended"	Agree.
Table 10	Why is flare type excluded from the repeated assembly test?	Agree. Note 2 of Table 10 will be corrected.
Fig. 1 and Fig. 3	Is 150% PD considered an instantaneous spike pressure? If yes, is it a targeted spike or just a permissible aberration?	This is an instantaneous spike pressure. It is a targeted spike. Corresponding changes will be made in Fig.3.

P2.11.5.5.2 a)	S —. . on 0.25 of the yield stress: change "stress" to "strength"	Disagree. "Stress" is common appropriate term when are speaking about the allowable yield sress.
P2.11.5.5.3	1st sentence, 3rd line: change "assembles" to "assemblies"	Agree.
P2.11.5.5.4	3rd paragraph: change "5 minutes" to "0.5 minute"	Disagree. Time period of 0.5 min is considered as too short time for visual inspection.
P2.11.5.5.5	What is the rationale behind the equation L ?	Agree. It will be replaced with phi/4.
P2.11.5.5.7	1st sentence, 2nd line: change "to encounter" to "to be encountered"	Agree.
DEUTSCH METAL COMPONENTS, FAX of 10.06.2000		
P2.11	Question: What specification … 10^7 cycles based on ?	This value is specified by ISO 8434-5.
THERMO SEALED CASTINGS/LOKRING TECH., 23.11.2000		
Table 7 and 8	Include "Mechanically Attached Fittings"	Agree. Tables 7 & 8 will be modified and added by Machine grooved Type connections.
	"MAF" considered to be equivalent to welding.	Disagree. In accordance with IACS UR P2.7 welded connections are considered as separate type with other scope of application.
Table 9	Include separate line for "MAF"	Agree. Table 9 will be modified.
P2.11.5. 5.2	Use of doc. "QUALIFICATION OF NON-STANDARD PIPING .„.B31 APPLICATIONS" as an alternative for vibration tests.	Disagree. Each Society has the right to accept any National or International standard, which has stricter testing requirements.
P2.11.5. 5.6	API 607 considered as alternative.	Disagree. Comments as above.
TYCO FIRE PRODUCTS, FAX of 04.10.2000		
P 2.7.4, Table 7	Add picture of grooved coupling connection	Agree. Tables 7 and 8 will be modified and added by Machine grooved Type connection.

P 2.7.4, Table 8	Add grooved couplings only for use with the items listed in seawater category.	Disagree. Scope of application of Machine grooved ~~Cut/Roll Grooved~~ Type connections are considering in long term are not to be restricted so far.
P2.11	ISO 6182-12 standard should be referenced for testing and qualification of the couplings.	Disagree. Each Society has the right to accept any National or International standard, which has stricter testing requirements.

UR P2.1 Application

Summary

In Rev.3 of this UR, the applicability of UR P2 has been clarified, in relation with IMO instruments such as IBC Code, IGC Code and IGF Code.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev.3 (Oct 2023)	9 October 2023	1 January 2025
Rev.2 (Nov 2001)	-	-
Rev.1 (1987)	-	-
Original version (1981)	-	-

- **Rev.3 (Oct 2023)**

1 Origin of Change:

☑ Suggestion by IACS member

2 Main Reason for Change:

To clarify the applicability of piping systems in relation to IMO instruments concerned.

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None.

4 History of Decisions Made:

1) In the course of work to avoid overlapping between UR P1 and IMO instruments concerned, it was observed that the last paragraph of UR P2.1 should also be amended in a similar manner to UR P1.1.
2) It was decided that the revision of UR P1 and P2 will be carried out under task PM20906f, taking into account the scope of work in the approved Form A for PM20906
3) After rounds of discussion, this Panel has fixed the amendment on applicability and for the purpose of clarity rephrased the title of P2.1 as "Applicability" and set out new paragraphs for IMO instrument concerned.

5 Other Resolutions Changes:

UR P1 (Rev.6). UR P2.2 (Rev.5)

6 Any hinderance to MASS, including any other new technologies:

None.

7 Dates:

Original Proposal	: 07 September 2020	(Ref: PM20304eIMf)
Panel Approval	: 07 September 2023	(Ref: PM16301fIMzg)
GPG Approval	: 09 October 2023	(Ref: 23164_IGc)

- **Rev.2 (Nov 2001)**

No HF is available.

- **Rev.1 (1987)**

No HF or TB is available.

- **New (1981)**

No HF or TB is available.

****

Part B. Technical Background

List of Technical Background (TB) documents for UR P2.1:

Annex 1. **TB for Rev.3 (Oct 2023)**

See separate TB document in Annex 1.

Note:

No Technical Background (TB) documents are available for original version and Rev.1.

Technical Background (TB) for Rev.2 (Nov 2001) can be found the consolidated "Technical Background for URs".

Technical Background (TB) document for UR P2.1 (Rev.3 Oct. 2023)

1. Scope and objectives

To clarify the applicability of piping systems in relation to IMO instruments concerned.

2. Engineering background for technical basis and rationale

Although it is acknowledged that certain types of piping systems addressed in the related IMO instruments such as IGC Code, IGF Code are not covered by UR P1 and P2, the applicability of the URs has not been updated since 2001.

2a. Specification of the data utilised in the development/revision of the proposed IACS Resolution, if any

None.

3. Source/derivation of the proposed IACS Resolution

None.

4. Summary of Changes intended for the revised Resolution:

1) Title of P2.1 has been rephrased as "Application" to better reflect the intent of the Section.
2) The piping systems not falling under the UR P2 are clearly defined in a new paragraph P2.1.2, with separate sub-paragraphs dedicated to IBC Code, IGC Code/IGF Code and SOLAS regulation II-1/2.29.

5. Points of discussions or possible discussions

A member opined that the term "process piping" should not be specified for ships subject to the IBC Code and after rounds of discussion it was decided to retain the term "process piping" as shipboard hydrocarbon/chemical process piping system in UR P2.1.2.1.

6. Attachments if any

None

UR P2.2 Classes of pipes

Summary

In Rev.5 of this UR, the Table 1 has been revisited.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev.5 (Oct 2023)	9 October 2023	1 January 2025
Rev.4 (Nov 2001)	-	-
Rev.3 (May 2000)	-	-
Rev.2 (1987)	-	-
Rev.1 (1975)	-	-
Original version (1974)	-	-

- **Rev.5 (Oct 2023)**

1 Origin of Change:

☐ Suggestion by IACS member

2 Main Reason for Change:

To refine the Table 1 of UR P2.2, also investigation the request from Industry (CIMAC) on the classification of piping intended for the use of "urea".

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None.

4 History of Decisions Made:

1) While considering the revision of UR P2.1, it was found that the term "Liquefied Gas" in Table 1 of UR P2.2 may need to be revisited.
2) It was decided that the revision of UR P1 and P2 will be carried out under task PM20906f, taking into account the scope of work in the approved Form A for PM20906.
3) Since the Panel could not find technical rationale to regard the piping downstream from the storage tank closing valve to the SCR catalyst belonging to Class III for application of UR P2.2, MP Chair requested CIMAC to provide the technical reasons.

5 Other Resolutions Changes:

UR P2.1 (Rev.3)

6 Any hinderance to MASS, including any other new technologies:

None.

7 Dates:

Original Proposal	: 07 October 2020	(Ref: PM20304eIMg)
Panel Approval	: 07 September 2023	(Ref: PM16301fIMzg)
GPG Approval	: 09 October 2023	(Ref: 23164_IGc)

- **Rev.4 (Nov 2001)**

No HF is available.

- **Rev.3 (May 2000)**

No HF or TB is available.

- **Rev.2 (1987)**

No HF or TB is available.

- **Rev.1 (1975)**

No HF or TB is available.

- **New (1974)**

No HF or TB is available.

****

Part B. Technical Background

List of Technical Background (TB) documents for UR P2.2:

Annex 1. **TB for Rev.5 (Oct 2023)**

See separate TB document in Annex 1.

***Note**:*

No Technical Background (TB) documents are available for Original version, Rev.1, Rev.2 and Rev.3.

Technical Background (TB) for Rev.4 (Nov 2001) can be found the consolidated "Technical Background for URs".

Technical Background (TB) document for UR P2.2 (Rev.5 Oct. 2023)

1. Scope and objectives

To refine the Table 1 of UR P2.2, also investigation the request from Industry (CIMAC) on the classification of piping intended for the use of "urea".

2. Engineering background for technical basis and rationale

In parallel with the clarification that certain types of piping systems addressed in the related IMO instruments such as IGC Code, IGF Code are not covered by UR P1 and P2, the Table 1 of UR P2.2 was also revisited, in particular the applicability of the term "Liquified Gas".

2a. Specification of the data utilised in the development/revision of the proposed IACS Resolution, if any

None.

3. Source/derivation of the proposed IACS Resolution

None.

4. Summary of Changes intended for the revised Resolution:

1) The term "Liquefied Gas" has been removed from the Table 1, taking into account revision of UR P1 and P2.
2) Table 1 is modified to address the Industry (CIMAC) request concerning the piping downstream from the storage tank closing valve to the SCR catalyst (UR M77)

5. Points of discussions or possible discussions

Industry (CIMAC) raised an issue related to the piping downstream from the storage tank closing valve to the SCR catalyst belonging to Class III for application of UR P2.2.

Due to lack of qualified majority support and no clear technical rationale, MP Chair requested CIMAC to provide the technical reasons.

The CIMAC rationale based on ISO 18611-3:2014 was reviewed by the Panel and reflected in Table 1 and Notes thereto which are applicable to the piping downstream from the storage tank closing valve to the SCR catalyst (UR M77).

6. Attachments if any

UR P2.7.3 Slip-on threaded joints

Summary

In Rev.3 of this UR, the use of threaded joints for small bore instrumentation equipment into piping systems conveying flammable media has been investigated and clarified.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev.3 (Oct 2023)	9 Oct 2023	1 January 2025
Rev.2 (Nov 2001)	-	-
Rev.1 (1987)	-	-
Original version (1974)	-	-

- **Rev.3 (Oct 2023)**

1 Origin of Change:

☑ Suggestion by IACS member

2 Main Reason for Change:

To clarify the usage of threaded joints for small bore instrumentation equipment into piping systems conveying flammable media.

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None.

4 History of Decisions Made:

1) The Panel investigated the industry practice in several yards to utilize threaded joints for connecting small bore instrumentation equipment (pressure/temp. sensors) to fuel oil lines, which is now against UR P2.7.3.
2) After rounds of discussion, this Panel has fixed the requirement for slip-on threaded joints to the end, with limitation on maximum outside diameter of such piping and example of recognized standards.

5 Other Resolutions Changes:

None.

6 Any hinderance to MASS, including any other new technologies:

None.

7 Dates:

Original Proposal	: 10 May 2022	(Ref: PM22301_IMa)
Panel Approval	: 07 September 2023	(Ref: PM16301fIMzg)
GPG Approval	: 09 October 2023	(Ref: 23163_IGc)

- **Rev.2 (Nov 2001)**

No HF is available.

- **Rev.1 (1987)**

No HF or TB is available.

- **New (1974)**

No HF or TB is available.

****

Part B. Technical Background

List of Technical Background (TB) documents for UR P2.7.3:

Annex 1. **TB for Rev.3 (Oct 2023)**

See separate TB document in Annex 1.

***Note**:*

No Technical Background (TB) documents are available for Original version and Rev.1.

Technical Background (TB) for Rev.2 (Nov 2001) can be found the consolidated "Technical Background for URs".

Technical Background (TB) document for UR P2.7.3 (Rev.3 Oct. 2023)

1. Scope and objectives

To clarify the usage of threaded joints for small bore instrumentation equipment into piping systems conveying flammable media.

2. Engineering background for technical basis and rationale

The Panel investigated the industry practice in several yards to utilize threaded joints for connecting small bore instrumentation equipment (pressure/temp. sensors) to fuel oil lines, which is now against UR P2.7.3 but found to be permitted in international standards for slip-on threaded joints such as ASME B31.1 and ASME 31.3.

2a. Specification of the data utilised in the development/revision of the proposed IACS Resolution, if any

None.

3. Source/derivation of the proposed IACS Resolution

None.

4. Summary of Changes intended for the revised Resolution:

1) this Panel has fixed the requirement for slip-on threaded joints to the end, with limitation on maximum outside diameter of such piping and example of recognized standards.

5. Points of discussions or possible discussions

A member proposed to remove the size limitation of O.D 25mm, which was shared by several members but not supported by the majority.

6. Attachments if any

None.

UR P2.7.4 “Mechanical joints”

Summary

In Rev.11 of this UR, the requirements for mechanical joints were reviewed with respect to definition, applicability and size limitation.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev.11 (Oct 2023)	09 October 2023	1 January 2025
Rev.10 (Jan 2021)	25 January 2021	1 July 2022
Rev.9 (Oct 2018)	13 October 2018	1 January 2020
Rev.8 (Mar 2016)	2 March 2016	1 January 2017
Rev.7 (Sept 2007)	21 September 2007	-
Rev.6 (May 2006)	12 May 2006	-
Rev.5 (Nov 2003)	20 November 2003	1 January 2007
Rev.4	-	-
Rev.3	-	-
Rev.2	-	-
Rev.1	-	-
Original version	-	-

- **Rev.11 (Oct 2023)**

1 Origin of Change:

☑ Suggestion by IACS member

2 Main Reason for Change:

There was a suggestion for Press type joint to extend the applicability to Class I and II piping systems, while giving a clear definition of Swage and Press type joint and possible change of the terms for the two joints. The Panel had rounds of discussion over the suggestion, together with other revision proposals such as pressure pulsation test and deletion of size limitation for certain type of joints.

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None

4 History of Decisions Made:

The Panel prepared a draft version of the UR and decided to have an Industry Hearing, in order to listen to Industry Opinion and improve the UR in due consideration of Industry Advice and relevant International Standards etc. in practice. After thorough review of the Industry Hearing and following deliberations at the Panel, this revision of UR has been finalized.

5 Other Resolutions Changes:

P2.11 (Rev.6) is also revised under the same task number.

6 Any hinderance to MASS, including any other new technologies:

None

7 Dates:

Original Proposal:	16 April 2019	(by a Member)
Panel Approval:	07 September 2023	(Ref: PM16301fIMzg)
GPG Approval:	09 October 2023	(Ref: 23164_IGc)

- **Rev.10 (Jan 2021)**

1 Origin of Change:

☑ Suggestion by IACS member

2 Main Reason for Change:

To amend UR P2.7.4 to provide a new Table 7 with a classification according to service condition for each piping system (dry, wet, dry/wet) and develop appropriate fire test requirements in P2.11.5.5.6.

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None

4 History of Decisions Made:

The Machinery Panel commented on revisions by correspondence and at regularly scheduled meetings.

5 Other Resolutions Changes:

None

6 Any hinderance to MASS, including any other new technologies:

None

7 Dates:

Original Proposal: 13 June 2016 (Made by a Member)
Panel Approval: 12 November 2020 (Ref: PM16301_IMzf)
GPG Approval: 25 January 2021 (Ref: 14079aIGe)

- **Rev.9 (Oct 2018)**

.1 Origin of Change:

☑ Suggestion by IACS member

.2 Main Reason for Change:

To amend UR P2.7.4 to provide a picture for typical compression type mechanical joints and clarify applicability of limitation in use of slip on joints.

.3 List of non-IACS Member Classification Societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

The Machinery Panel commented on revisions by correspondence and at regularly scheduled meetings.

.5 Other Resolutions Changes:

None

.6 Dates:

Original Proposal: 28 February 2017 made by a Member
Panel Approval: 20 September 2018 (Ref: 28th Panel meeting)
GPG Approval: 13 October 2018 (Ref: 18028_IGn)

- **Rev.8 (Mar 2016)**

.1 Origin of Change:

☑ Suggestion by IACS member

.2 Main Reason for Change:

To review the application and details of fire resistant type tests for mechanical joints.

.3 List of non-IACS Member Classification Societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

The Machinery Panel commented on revisions by correspondence and at regularly scheduled meetings.

.5 Other Resolutions Changes:

P2.11 (Rev.4) and P2.12 (Rev.2) are also revised under the same task number.

.6 Dates:

Original Proposal: 30 January 2012 Made by a Member
Panel Approval: 28 December 2015 (Ref: PM11921)
GPG Approval: 2 March 2016 (Ref: 14079_IGe)

- **Rev.7 (Sept 2007)**

No history file or TB document available.

- **Rev.6 (May 2006)**

No history file or TB document available.

- **Rev.5 (Nov 2003)**

No history file or TB document available.

- **Rev.4**

Annex 6. **TB for Rev.10 (Jan 2021)**

See separate TB document in Annex 6.

Annex 7. **TB for Rev.11 (Oct 2023)**

See separate TB document in Annex 7.

Note: *There are no Technical Background (TB) documents available for Original Version, Rev.1, Rev.2, Rev.3 and Rev.4.*

Technical Background

UR M44 Rev.6 and P2 Rev.5

The UK MAIB report on its investigation of the causes of an engine fire in the high-speed ferry 'Stena Explorer' concluded that it was due to the incorrect reassembly of a compression fitting in a high pressure fuel line.

IACS did not concur in the MAIB recommendation to discontinue the use of such fittings, and so advised the MAIB in a letter from the GPG Chairman on 15 September 2003 (3051_IGb).

However WP/MCH proposed amendments to UR M44 and P2 to enhance relevant requirements for approval and maintenance.

They are:

UR M44:

i) Add suffix 7 to Item 33,

ii) Add FOOTNOTE 7.
7. operation and service manuals are to contain maintenance requirements (servicing and repair) including details of any special tools and gauges that are to be used with their fitting/settings together with any test requirements on completion of maintenance.

iii) Add NOTE 5.
5. Where the operation and service manuals identify special tools and gauges for maintenance purposes (see footnote 7.) refer to UR P2.7.4.14.

UR P2:

i) add P2.7.4.14: The installation of mechanical joints is to be in accordance with the manufacturer's assembly instructions. Where special tools and gauges are required for installation of the joints, these are to be supplied by the manufacturer.

ii) Add sentence above P2.7.4.1 :
The application and pressure ratings of different mechanical joints are to be approved by the Classification Society. The approval is to be based on Type Approval procedure in P2.11.

The amendments were approved by GPG on 30 September 2003 (3051aIGb)

Technical Background

UR P2.7.4 (**Rev.6**, May 2006) and UR P2.11(**Rev.**1, May 2006)

1. Background:

ABS reported to Council on 13 Feb 06 as follows:

> In reviewing the latest UR Implementation Matrix distributed by Perm Sec's 5059_IAf, it is noted that besides ABS, three other Societies (KR, LR and IRS) had not indicated that they have implemented UR P2.7.4 (Rev. 5/Nov 2003).
>
> It is further noted that these Societies also did not indicate an expected date of implementation on their Form 2.
>
> Further UR P2.11 (Rev.2/Nov 2001) was adopted for type appproval of mechanical (pipe) joints in 2001, but was made mandatory for all mechanical (pipe) joints by the amendment to P2.7.4.1 in 2003. Again, looking at the UR Implementation Matrix distributed by 5059_IAf, we note that seven other Societies (BV, CCS, DNV, GL, KR, LR and IRS) had not indicated that they have implemented UR P2.11 (Rev.2/Nov 2001) and that none of these Societies, except IRS, indicated an expected date of implementation on its Form 2.
>
> Therefore, this message is to declare an ABS reservation against UR P2.7.4 (Rev.5/Nov 2003) and P2.11 (Rev.2/Nov 2001) until such time as Members agree to a uniform implementation date for these requirements.

Council tasked GPG to establish a uniform application date for these requirements and ascertain the implementation status.

2. Discussion

2.1 Implementation status
All GPG members provided information relative to their status of implementation for IR P2.

2.2 P2.7.4.1

GPG Chairman assessed: In reading P2.7.4.1, it does not appear to me that the requirement is intended to mandatorily require Type Approval of the subject fittings; it appears to require compliance with the same type testing requirements

as would be required for type approval of the fitting, i.e., pipe unions, compression couplings and slip-on joints are not required to be type approved, but must be approved based on the Type Approval procedure in P2.11.
Renewal of approval is only associated with type approval.

2.3 P2.11.1
DNV pointed out that the General Part of P2.11.1 has a vague expression (Individual Societies may specify more severe testing conditions…and also accept alternative testing…).

2.4 A uniform implementation statement was developed and approved.

Approved on 12 May 2006 (5059bICa)

Submitted by Permsec
28 April 2006

Technical Background

UR P2.7.4 (Rev. 7, Sept 2007) (PM6304)

Scope and objectives

The aim of this task was to resolve the reservation by NK in respect of slip-on joints for steam pipes on deck (item 33 in Table 7) and to ensure a uniform application of this requirement.

Points of discussion

There was agreement amongst Panel members that slip type joints should be allowed on restrained pipes in steam piping systems on deck. GL and NK pointed out that the gasket material must be suitable for the temperature and pressure range in question.

A footnote 7) is added to table 7 and a corresponding entry made in item 33 'Steam' in the column for "Slip-on joints".

Decision by voting (if any)

The UR was adopted unanimously.

Machinery Panel Chairman
Hamburg, 13 July 2007

Permanent Secretariat note (October 2007):

Approved by GPG 21 September 2007, ref. 7630_IGb.

Technical Background (TB) document for UR P2.7.4 (Rev.8 Mar 2016)
& UR P2.11 (Rev.4 Mar 2016) & UR P2.12 (Rev.2 Mar 2016)

1. Scope and objectives

.1 To review the requirements regarding the application and details of pipe coupling joints and flexible hoses partly based upon IMO Resolution A.753(18) and update UR P2 accordingly.

.2 To review the categorization of pipe coupling joints in Table 6 of P2.7.4 and update UR P2 accordingly.

2. Engineering background for technical basis and rationale

.1 UR P2 required coupling joints and flexible hoses intended for installation in piping systems for flammable media and sea water systems be of a fire resistant type regardless of installation location. On the other hand, SOLAS regulations, such as II-2/Reg.4.2.4, etc., do not necessarily require that they be of a fire resistant type when a means of ignition is not present in the installation location.

In recent years, a member has received questions from various shipyards and manufacturers asking whether fire endurance tests for coupling joints or flexible hoses arranged in locations with low fire risk, e.g., open decks, are necessary.

Moreover, some members have experienced problems when conducting fire endurance tests due to test specimen size. ISO19921/22, which specifies fire endurance test procedures, requires that the specimen be completely engulfed in the flame envelope and this can be difficult to achieve in the case of very large test specimens.

.2 A member received the following comment from a pipe coupling manufacturer which expressed their concern about a possible misinterpretation of the performance capabilities for mechanical pipe joints:

- The illustration labelled “Machine Grooved Type” in Table 6 of P2.7.4 is not accurate.

3. Source / derivation of the proposed IACS Resolution

None.

4. Summary of Changes intended for the revised Resolution:

See attached table.

5. Points of discussions or possible discussions

See attached table.

6. Attachments if any

None.

Paragraph	Proposals and summarised comments from IACS Members	Conclusion
P2.7.4 Table 6	Proposal: • Since the illustration labelled “Machine Grooved Type” in Table 6 is not accurate, it should be replaced by the illustration provided by the *Victaulic Company*.	• Agreed.
P2.7.4 Table 7, Footnote 3. P2.12.3.5	Proposal: • In consideration with SOLAS II-2/Reg. 4.2.3.1 and 4.2.4, slip-on joints and flexible hoses which are used for L.O. lines and other flammable oils, and are installed on open decks do not need to be of a fire-resistant type. • In consideration with SOLAS II-2/Reg. 4.2.2.5.1, slip-on joints and flexible hoses used for F.O. lines should be of a fire-resistant type even when installed on open decks. • “open decks” means areas defined in SOLAS II-2/Reg. 9.2.3.3.2.2(10) and 9.2.4.2.2.2(10). This means that cargo areas of tankers, ships carrying liquefied gases in bulk and ships carrying dangerous chemicals in bulk are not included for “open decks”. Comments: • Consideration should be given to specific applications and media, e.g. non fire resistance types for sea water on open deck and fire resistant types for cargo oil, fuel and fire extinguishing systems. Moreover, the table should distinguish between wet and dry applications, e.g. fire extinguishing systems, bilge systems, sounding and vent pipes. • Fire fighting systems on open deck with non-fire resistant connection may be broken by fire and putting to workless condition. Destruction of piping lines with flammable media cause deterioration of fire conditions. • In considering the SOLAS requirements for fuel oil and other flammable liquids, there will need to be a strong technical argument as to why it only applies to fuel lines and not lubricating oil or other flammable liquid lines e.g. hydraulic actuating systems.	• Some members were still in question as to why it only applies to fuel lines and not to other flammable liquid lines e.g. hydraulic actuating systems. Background of the regulations was not confirmed during discussion. • However, following the decision by the qualified majority, proposals were agreed.
P2.7.4 Table 7	Proposal: • Revised Table 7 was proposed in an effort to present the information clearer as is currently the case and to accommodate feedback from coupling manufacturers. In particular: • The footnotes are moved to the systems, thus making them applicable to all connection types. Complaints have received from manufacturers that the restrictions currently only apply to slip-on joints.	• Agreed.
P2.7.4.3	Proposal: • Delete P2.7.4.3 because it is obvious and testing will only highlight discrepancies from this requirement.	• Agreed.
P2.7.4.7	Proposal: • Replace “sea openings” with terminology such as “ship’s side below the waterline”.	• Agreed.

	Comment: • Suggest to modify as follows: "ship's side below the ~~waterline~~ <u>bulkhead deck of passenger ships and freeboard deck of cargo ships</u>". This is the wording used in SOLAS, Reg. II-1 / 15 (title).	
P2.7.4.8	Proposal: • Delete P2.7.4.8 as this is obvious.	• Agreed.
P2.7.4.11	Proposal: • Unrestrained slip-on joints are not defined and slip-on joints should not be used for compensation of lateral pipe deformation. The P2 test requirements for slip-on joints assume there is no lateral deformation. Comment: • Chair explained that the intention of P2.7.4.11 is to minimise the use of slip-on joints where it is inevitable to compensate for lateral movements of piping. In practice, slip-on joints are frequently used for that purpose, hence to prohibit the use of slip-on joints for compensation of lateral deformation may be too rigorous. In this respect, modification is proposed by Chair.	• Modification was agreed based on the Chair's proposal. • The first figure of "Slip type slip-on joints" in Table 6 in UR P2.7.4 was also replaced.
P2.11.5.3	Proposal: • The requirement "at least five times" should be re-considered. Classification societies do not need to specify minimum pipe length. This should be left up to manufacturers.	• Did not achieve a majority. • Keep as is.
P2.11.5.5.1 (a)	Proposal: • Sixth paragraph. Delete "Other" and replace with "An".	• Agreed.
P2.11.5.5.1 (b) and (c)	Proposal: • Delete (b) and (c). These sections are covered in the sixth paragraph of (a)	• Panel concurred that it is an additional requirement for compression coupling. • Keep as is.
P2.11.5.5.2	Proposal: • Delete the second paragraph as this is obvious.	• Panel unanimously agreed to delete the second part of the text.
P2.11.5.5.2 (a)	Proposal: • Delete the fifth paragraph as this is obvious. Comment: • Visual examination of the joint assembly is to be carried out.	• Panel unanimously agreed to delete the second part of the text.
P2.11.5.5.3	Proposal: • For large diameters, tests according to Fig. 3 are difficult to perform and very expensive. As an alternative it is suggested also to refer to BS 4368: Part 4. Comment: • Direct reference to BS, a regional standard, is not appropriate.	• Direct reference to BS, a regional standard, was not supported. • Keep as is.
P2.11.5.5.4	Proposal: • (Burst pressure test) Third paragraph. Delete the last sentence or modify it to provide more clarity.	• Agreed to delete.
P2.12.3.5	Proposal: • (P2.12.3.5) Only water is permitted as a test medium. With a view to ensuring	• Agreed by the qualified majority.

	maximum safety for both the operating personnel and the test bed in the event of damage to the hose during the test, the use of combustible test media is excluded. This poses an issue. All marine coupling on the market at the moment are tested to ISO 15540/41 therefore can never be used on a dry system.	
P2.11.5.5.6.3	Proposal: • (Fire endurance test) The standard specifies a sensible method of testing pipe couplings where the flame shall envelop the test specimen. This will result in problems with very large test specimens. In such cases, alternative test methods and/or test procedures should be accepted. Comments: • Provides practical cases in which alternative test methods has been accepted. • A UR may allow an alternative method to be used only if a minimum set of criteria is provided to ensure the equivalency between the required method and the alternative one. Otherwise, the acceptance of the tested specimen may differ among Classification Societies.	• None of members have experienced such cases in which alternative test methods have been accepted. • Regardless of practical cases, proposal was agreed by the qualified majority.
P2.11.5.5.6.4	Proposal: • (Fire endurance test) Define requirements for the thermal insulation materials used for the fire sleeves of couplings. • A flammability test according to IEC 60695-11-5 is to be carried out.	• Agreed with following modifications: *Thermal insulation materials applied on~~used for fire sleeves of~~ couplings are to be non-~~flammable~~combustible in dry condition and when subjected to oil spray. A ~~flammability~~non-combustibility test according to ~~IEC 60695-11-5~~ISO 1182 is to be carried out.*
P2.11.5.5.7	Proposal: • (Vacuum test) Delete the third paragraph since the tests cannot be correctly carried out without monitoring the pressure.	• Agreed.

Technical Background (TB) document for UR P2.7.4 (Rev.9 Oct 2018)

1. Scope and objectives

To amend UR P2.7.4 to provide a picture for typical compression type mechanical joints and clarify applicability of limitation in use of slip on joints

2. Engineering background for technical basis and rationale

- The industry asked to update and reconsider the Table 6 due to difficulty of classification for one kind of compression type mechanical joint (called as 'Swagelok').

- Note 2 in table 7 was referring to all type of coupling whereas the intention was to only apply to slip-on joints.

3. Source / derivation of the proposed IACS Resolution

- The industry asked to update and reconsider the Table 6 due to difficulty of classification for one kind of compression type mechanical joint (called as 'Swagelok').

- The mistake in note 2 was noted by IACS Members

4. Summary of Changes intended for the revised Resolution:

- Added a type of compression coupling in Table 6 and Table 8

- Text of note 2 modified to refer only to slip-on joints

5. Points of discussions or possible discussions

UR P2.7.4 (Rev.9)

Regarding 'Typical Compression Type' in Table 6, members agreed to update Table 6 together with Table 8. Members considered that the 'Swagelok' type is not defined as specifically 'compression' type and it is nearer to normal compression type or bite type than 'swage' type fittings. This consideration was also reflected in Table 8.

6. Attachments if any

None

Technical Background (TB) document for UR P2.7.4 (Rev.10 Jan 2021)

1. Scope and objectives

To amend UR P2.7.4 to provide a new Table 7 with a classification according to service condition for each piping system (dry, wet, dry/wet)

2. Engineering background for technical basis and rationale

- The industry asked to update and reconsider the test requirements as given by Table 7 in order to extend the range of application for slip-on-joints.
- IACS members noted inconsistent fire test requirements with respect to service conditions (dry, wet, wet/dry).

3. Source / derivation of the proposed IACS Resolution

See paragraph 2.

4. Summary of Changes intended for the revised Resolution:

- Paragraph P2.7.4.9: introducing reference to MSC/Circ.734
- Added footnotes to Table 6 providing a definition for swage type and press type mechanical joints
- Amend introduction text of Table 7 with respect to considering relevant statutory requirements
- Amend Table 7 by detailed specification of fire endurance test condition wet, dry/wet, dry. Test requirements for dry/wet test specified (times are 8 min (dry)/22 min(wet)) and test exposure time greater than 30 minutes.
- Amend system specification in row 14 to "Permanent water filled …".
- Merging old row 15 *Non water filled fire extinguishing systems, e.g. foam, drencher systems and 16 fire main (not permanently filled)* to new row 15 *Non-permanent water filled fire extinguishing systems, e.g. foam, drencher systems and fire main (not permanently filled)*.

5. Points of discussions or possible discussions

- Insertion of reference to MSC/Circ.734. One member society did not support the reference to MSC/Circ.734 in P2.7.4.9 as the expression "easily accessible" appears to relate to "other spaces" while the interpretation of same expression in the Circular relates to valves. However, the qualified majority agreed with the reference to the Circular.
- Test requirements in Table 7 may be in conflict with statutory requirements. Panel agrees to note in the introduction that statutory requirements need to be taken into consideration.

- Dry/wet test in general discussed with respect to weakening existing requirements. Panel agreed that dry/wet test is only applicable for systems flooded after fire alarm. Thus, for these systems dry/wet test is more stringent than wet test.

- Times for dry/wet test of 8/22 minutes are specified considering BS LPS1219 requiring 7.5 minutes dry and had been discussed with relevant industry.

- Difference between 925°C requirements in IMO instruments and 800°C fire resistant test applied by IACS (ISO 19921) discussed. Panel noted that these requirements relate to different objectives, IMO test focuses on properties of all materials used (melting temperature ≥ 925°C) whereas the IACS test (flame temperature ≥ 800°C) focuses on integrity of the component. Conflict in test temperature could not be resolved.

Technical Background (TB) document for UR P2.7.4 (Rev.11 Oct 2023)

1. Scope and objectives

To introduce definitions for swage type joints and press type joints in IACS UR P2, while understanding the rationale behind the requirement allowing use of press type joints only for Class III piping.

And to evaluate if there are sufficient reasons to maintain the present requirement or amend the UR to allow press type joints to be used for other classes of piping, based on investigation/tests and industry hearing.

2. Engineering background for technical basis and rationale

A request of Type Approval resulted in a different interpretation on the type of mechanical joint subject to type approval between a Manufacturer and a Class Society, e.g. their "*Press Type*" joint was interpreted as "*Radial Swage Type*" by the Manufacturer and, as consequence, understood acceptable for Class I and II pipes like "*Swage Type*", and as "*Press Type*" by the Class Society and therefore acceptable only for Class III piping.

Therefore, in order to have a uniform application of "Press Type" and "Swage Type" mechanical joints depending upon the class of piping, a proposal was put forward to introduce definitions in IACS UR P2 allowing to clearly distinguish swage type from press type joints.

In addition, the technical rationale (or specific feature) that caused press type joints to be considered suitable only for Class III piping, while swage type joints suitable for Class I and II piping, has been considered unclear and the opportunity to amend UR P2 to allow the use of press type joint for Class I and II piping, subject to investigation/tests on the technical factors (such as minimum thickness and shrinkage), should be evaluated.

To take this opportunity, review of existing requirements for mechanical joints should be conducted. For instance, the size limitation issue can be revisited. According to a member's understanding which was supported by the qualified majority, mechanical joints of compression couplings could be used in various piping systems and need not lower the safety of such systems. Namely, if the test requirements are sufficient to demonstrate that the mechanical joints are "fit-for-purpose" and, if the specimens cover relevant dimensions, any diameter limitation seems not to be meaningful.

The draft revision of UR P2 prepared by the Panel is presented to Industry to listen to Industry Opinion and to improve the UR with due consideration of Industry advice and relevant Standards in practice.

3. Source/derivation of the proposed IACS Resolution

Varying interpretation on the "*Press Type*" mechanical joints joint as described in item 2.
Size limitation issue was originated from PM16301.

4. Summary of Changes intended for the revised Resolution:

Among the initially intended changes, following is finally adopted for this revision of the UR as a result of Industry Hearing and Panel deliberation:

- Deletion of size limitation on Class I and II piping systems for Compression Couplings (bite type, typical compression type and flared type);
- Applicability of pressure pulsation test to make mandatory for Class I and II.

5. Points of discussions or possible discussions

It has been observed that present terms for the two mechanical joints i.e. Press type and Swage type are widely used and supported by the Industry, and the change of terms i.e. Radially Swaged type and Axially Swaged type and the extension of applicability for Press type (Radially Swaged type) to Class I & II are not well shared by the Industry and further necessitate substantive modification e.g. additional high pressure/temperature performance verification such as ASTM F1387 and EC PED Directive requirements.

In the light of above, the Panel decided not to proceed the revision of terms and extension of applicability until relevant requirement for performance verification is in ready and if such is agreed by the Panel and shared by the Industry.

Also it was considered prudent not to give a specific footnotes of definition for the two mechanical joints (Press type, Swaged type) in this revision, but to put more relevant definition in the next revision which is aligned with the terms (Radially Swaged type, Axially Swaged type) based on Mechanically Attached Fittings that were agreed by the Panel and utilized for the Industry Hearing.

For future revision work, it was proposed by a Member that qualification and testing requirements of the mechanically attached fittings as per ASTM F1387 ought to be considered as the basis for type testing and qualification of mechanically attached fittings as well as acceptance of ASTM F3226/F3226M for the press type fittings that are limited to class III piping systems as defined by IACS UR P2.

By the same Member, it was argued at the last moment and recorded here for further revision work that "the deletion of the restricted sizing of these fittings will be considered acceptable subject to successful qualification testing of the largest size fitting and availability of the installation tools for onboard installation of such fittings by ships crew. With regards to the final proposal that the classification societies will develop their own testing facilities for the future developments of these mechanical fitting and testing of the larger size fittings. We express reservations that the provision of such testing facilities is outside the scope of the class societies".

6. Attachments if any

The outcome of Industry Hearing is summarized below
Industry Hearing for task PM16301f: Proposal of amendment to UR P2 – Application of swage type and press type mechanical joints

IACS Inquiry 1	IACS, in the process of revising UR P2.7.4, would like to hear your esteemed opinions on the further application of "press type" (which is renamed as "radially swaged type") couplings into class I and II piping system, as well as the deletion of size limitation on typical compression type, bite type and flared type. The main purpose of the hearing is to get sufficient information and agreement from industry in revising Table 6 (including the footnotes) and Table 8 of UR P2.7.4. Please find the attached copy of the draft UR.	
Reply from **Company A**	the term "swaged type" and "press type" coupling are renamed as "axially swaged type" and "radially swaged type" (see Table 6 and Footnotes thereto) the name radially swaged type is a good solution. It represents correctly the kind of fitting. the changes proposed in Table 8 for "radially swaged type" coupling (i.e. accepting used for Class I and Class II piping) will be cancelled, unless sufficient information that "radially swaged type" couplings may be allowed on piping systems classes I and II is provided during this industry hearing. We have an important experience about production and selling of press-fitting systems destined to naval applications. We are first class supplier for the most important producers of ships and yachts in the word. Our opinion is that the fittings "radially swaged type" must be used only for Class III applications. The applications (media pressures and temperatures) dedicated to Class I and II are too burdensome (attached the table that we use like reference). Using press-fitting in Class I and II could be create not safe conditions. concerning OD limitations proposed in Table 8 for "typical compression type", "bite type" and "flared type" intended to high pressure systems, the view of industry is sought) we are producers of "radially swaged type" fittings, so we prefer not write our opinion.	
Reply from **Company B**	Introduction: Press Type fittings as identified on IACS UR P2.7.4 Table 7 Press Type, comprise an international defined technology that has been incorporated into multiple standards, industry articles, symposia and definitions. The change to Radially Swaged Type is inconsistent in creating a better definition as it already exists and refers to a different product/technology. ---------omission---------- ---------omission---------- Conclusion: The term "PRESS" is established internationally in multiple standards and is a common term for the technology. Radially Swaged Type fittings	

	differ to Press Type fittings by the fact that the sealing is obtained from a resilient and elastomeric sealing element instead of a metal to metal seal for the radially swaged type fittings. The PRESS TYPE designation included in IACS UR P2.7.4 Table 7 is consistent with the definitions for Press technology included in available international standards, shipbuilding symposia and industry references. We believe changing the Press Type designation to Radially Swaged Type does not clarify the reference to the technology consistent with existing international land and shipbuilding standards and therefore object to the change.	
Reply from **Company C**	We would like to demonstrate that "radially swaged type" fittings (press fittings) are also suitable for media belonging to IACS pipe classes I, II and are also reliable for pipe diameter larger than d 60.3 mm: Model XXX press fittings (now stated as radially swaged type) are suitable for media belonging to piping classes I, II and III. This is proven by the German TUEV type approval "TÜV.A.271-16" (see enclosure) as well as other national and international approvals and expert assessments regarding industrial applications. • The TUEV approval refers to the European **Pressure Equipment Directive** (2014/68/EU) and allows the use of Model XXX press fitting systems for fluids of groups 1 and 2. • This means that dangerous, poisonous and flammable media can also be conveyed with Model XXX press fitting systems (radially swaged types). • With reference to the TUEV approval Model XXX press fitting systems (radially swaged types) are approved up to a nominal size of **DN 100**. • Model XXX press fitting systems are also approved up to **DN 100** by ABS, BV, LRS, CCS, DNV(GL), RINA, Class NK, RMRS and therefore they are tested according to the **IACS rules**. Based on the explanations above, we consider the use of press fitting systems (radially swaged types) also for classes I and II and for diameter **> 60.3 mm** too to be suitable and applicable.	
Reply from **Company D**	A1. The fact that the press type has been renamed to the radial swage type and can be used for class I and II piping systems will make it possible to use types that have been disabled for many years, expanding product development options. However, high temperature, the product performance verification test by which will be available to the high-pressure considered as important. A2. About the difference between compression coupling and slip-on joint. Since each product has its own strengths and weaknesses, it is important for the piping designer to make appropriate judgments (product performance, workability, safety, cost) before making a selection. A3. We think that there is no problem with removing the size restrictions of the bite type and flared type as long as safety can be ensured.	
IACS view	IACS deems that IACS unified requirements for mechanical joints in P2.7.4 and P2.11 are in line with ASTM F3226/F3226M (Press-Connect) rather than ASTM F1387 (Mechanically Attached Fittings) when it comes to detail testing criteria, applicability and classification etc. and as	

highlighted out by some manufacturers in order to apply press type to Class I and II piping systems, high pressure/temperature performance verification such as those in ASTM F1387 or PED will be further considered and specifically set out in the UR, while the size limitation may be relieved without additional provisions.

In this respect, it would be prudent to not proceed with revision of terms (swage, press) and applicability (Class I and II) until the relevant requirement for performance verification procedure is in ready and if such is agreed by this Panel.

Ref.) classification and testing requirement (ASTM F3226 vs ASTM F1387)
ASTM F3226/F3226M (Press-Connect)

Class 1—100 psi (0.69 MPa) maximum.
Class 2—200 psi (1.38 MPa) maximum.
Class 3—300 psi (2.07 MPa) maximum.

Hydrostatic Proof Testing:
Hydrostatic Burst Test:
Pull-Out Test:
Vacuum Test:
Vibration Test:
Fire Test:
Impulse Pressure Test:
Ammonia Vapor Test, for Copper Alloys Containing 15 % Zinc or Greater

ASTM F1387 (Mechanically Attached Fittings)
Class 1—1.38 MPa (200 psi) maximum.
Class 2—2.76 MPa (400 psi) maximum.
Class 3—4.83 MPa (700 psi) maximum.
Class 4—6.90 MPa (1000 psi) maximum.
Class 5—10.34 MPa (1500 psi) maximum.
Class 6—13.79 MPa (2000 psi) maximum.
Class 7—20.69 MPa (3000 psi) maximum.
Class 8—25.86 MPa (3750 psi) maximum.
Class 9—34.48 MPa (5000 psi) maximum.
Class 10—41.37 MPa (6000 psi) maximum.

Description of Test	Number of Specimens		Applicability of Test	
	Permanent	Separable	Permanent	Separable
Examination of specimen	22	28	yes	yes

Mercurous nitrate test	2	2	. . .[E]	. . .[E]

IACS Inquiry 2

Also, IACS plans to modify the applicability of pressure pulsation test to mechanical joints in pipe Class I and II (i.e. changing from the optional requirement to the mandatory requirement).

Reply from **Company A**	Nil	
Reply from **Company B**	Nil	
Reply from **Company C**	Nil	
Reply from **Company D**	About changing the impact pressure test from optional requirements to mandatory requirements. I think it is good to make it an indispensable requirement from the situation that occurs in the piping of a ship. However, companies with ample funds can introduce new test equipment and follow suit, including the adoption of the dry test of fire resistance test revised in January 2021. However, even if they have technical capabilities, the introduction of test equipment is expensive, so companies that cannot try will be forced to withdraw from the industry. Since the industry itself is expected to decline, each ship class association should own test equipment and create an environment where each manufacturer can easily take on the challenge of developing new products. I think that will lead to the creation of a mechanical joint that provides sufficient safety, is reliable, and is easy to install.	
IACS view	IACS deems that we may proceed as proposed.	

UR P2.9 "Pressure tests of piping after assembly on board"

Summary

This UR provides requirements for pressure tests of piping after assembly on board. This revision provides alternative pressure test as pneumatic leak testing for water sensitive system.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev.3 Oct 2023	9 October 2023	01 January 2025
Rev.2 1987	-	-
Rev.1 1975	-	-
Original version 1974	-	-

- **Revision 3 (Oct 2023)**

1 Origin of Change:

■ Suggestion by IACS member

2 Main Reason for Change:

For hydrostatic testing of piping systems after assembly on board, this revision accepts pneumatic leak testing for water sensitive system.

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None

4 History of Decisions Made:

One member initiated an issue about a relaxation of the pressure test for piping after assembly on board. After a conversation with other WG, this revision is developed.

5 Other Resolutions Changes:

None

6 Any hinderance to MASS, including any other new technologies:

None

7 Dates:

Original Proposal	: 01 January 2021	(Made by: PM16301f)
Panel Approval	: 07 September 2023	(Ref: PM16301fIMzg)

Part B. Technical Background

List of Technical Background (TB) documents for UR P2.9:

Annex 1. **TB for Rev.3 (Oct 2023)**

See separate TB document in Annex 1.

***Note**: No Technical Background (TB) documents are available for Original version and Rev.1, Rev.2.*

Technical Background (TB) document for UR P2.9 (Rev.3 Oct 2023)

1. Scope and objectives

According to UR P2.9, piping systems after assembly on board are conducted pressure tests under not less than 1.5P regardless of performing pressure test before installation on board based on UR P2.8.

This revision confirms the necessity of a pressure test after assembly via TB. In addition, provides alternative pressure test as pneumatic leak testing for water sensitive system.

2. Engineering background for technical basis and rationale

Based on opinions from another Working group who have the specialty of inspection, the Working group keeps requirements on hydrostatic testing. While maintaining the text, provides additionally a paragraph for water sensitive systems.

Besides, taking into account the scope of UR P2, the text about the pressure of test is updated by deleting the expression for gas pipes.

2a. Specification of the data utilised in the development/revision of the proposed IACS Resolution, if any

None

3. Source/derivation of the proposed IACS Resolution

None

4. Summary of Changes intended for the revised Resolution:

- Deleting the expression indicating gas pipes depending on the scope of UR P2 that gas fuel pipe is out of scope.

- Adding the paragraph on pneumatic leak testing for water sensitive systems instead of hydrostatic testing.

5. Points of discussions or possible discussions

One member raised an issue of the necessity of pressure tests for pipes after assembly on board and their test pressure. Even though hydrostatic tests are conducted in 1.5P according to UR P2.8, UR P2.9 Rev.2 have required hydrostatic testing in order to check for leakage. Furthermore, IGC 5.13.2.2 and IGF code 16.7.3.2 accept waivers of pressure test for pipes completely manufactured and equipped with all fittings.

However, another working group that consists of experts in the survey has reviewed as follows :

> *The working group has discussed the issue, 'whether the pressure test as per UR P2.9 can be waived if the piping system has successfully passed the hydrostatic test required by UR P2.8' and unanimously agreed to the view that the pressure test is not to be waived as per UR P2.9 because fuel systems and heating coils*

are typically manufactured in sections in a work shop and assembled onboard the vessel, and the piping shall be pressure tested after installation.

Depending on the above opinion, the working decided to keep the current text excluding the expression ‘gas fuel lines’ which is out of scope of UR P2.

In addition, the texts for pneumatic leak testing as an alternative to pressure tests are established additionally for water sensitive systems and IACS Rec.140 Part F is referred to enhance the safety during the alternative test.

6. Attachments if any

None.

UR P2.11 "Type Approval of Mechanical Joints"

Summary

In Rev.6 of this UR, the requirements for mechanical joints were reviewed to align with revision work conducted for UR P2.7.4.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev.6 (Oct 2023)	9 October 2023	1 January 2025
Rev.5 (Jan 2021)	25 January 2021	1 July 2022
Rev.4 (Mar 2016)	2 March 2016	1 January 2017
Rev.3 (Aug 2012)	9 August 2012	1 January 2014
Corr.1 (Apr 2007)	11 April 2007	-
Rev.2 (Nov 2006)	28 November 2006	-
Rev.1 (May 2006)	12 May 2006	-
Original version (Nov 2001)	17 November 2001	1 January 2007

- **Rev.6 (Oct 2023)**

1 Origin of Change:

☑ Suggestion by IACS member

2 Main Reason for Change:

There was a suggestion for Press type joint to extend the applicability to Class I and II piping systems, while giving a clear definition of Swage and Press type joint and possible change of the terms for the two joints. The Panel had rounds of discussion over the suggestion, together with other revision proposals such as pressure pulsation test and deletion of size limitation for certain type of joints.

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None

4 History of Decisions Made:

The Panel prepared a draft version of the UR and decided to have an Industry Hearing, in order to listen to Industry Opinion and improve the UR in due consideration of Industry Advice and relevant International Standards etc. in practice. After thorough review of the Industry Hearing and following deliberations at the Panel, this revision of UR has been finalized.

5 Other Resolutions Changes:

P2.7.4 (Rev.11) is also revised under the same task number.

6 Any hinderance to MASS, including any other new technologies:

None

7 Dates:

Original Proposal:	16 April 2019	(Ref: PM16301fIMa)
Panel Approval:	07 September 2023	(Ref: PM16301fIMzg)
GPG Approval:	09 October 2023	(Ref: 23164_IGc)

- **Rev.5 (Jan 2021)**

1 Origin of Change:

☑ Suggestion by IACS member

2 Main Reason for Change:

To review the application and details of fire-resistant type tests for mechanical joints

in course of revision UR P2.7.4 (Rev.10).

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None

4 History of Decisions Made:

The Machinery Panel commented on revisions by correspondence and at regularly scheduled meetings.

5 Other Resolutions Changes:

UR P2.7.4 (Rev.10) are also revised under the same task number.

6 Any hinderance to MASS, including any other new technologies:

None

7 Dates:

Original Proposal: 13 June 2016 (Made by a Member)
Panel Approval: 12 November 2020 (Ref: PM16301_IMzf)

Technical Background

UR P2.7.4 (**Rev.6**, May 2006) and UR P2.11(**Rev.**1, May 2006)

1. Background:

ABS reported to Council on 13 Feb 06 as follows:

> In reviewing the latest UR Implementation Matrix distributed by Perm Sec's 5059_IAf, it is noted that besides ABS, three other Societies (KR, LR and IRS) had not indicated that they have implemented UR P2.7.4 (Rev. 5/Nov 2003).
>
> It is further noted that these Societies also did not indicate an expected date of implementation on their Form 2.
>
> Further UR P2.11 (Rev.2/Nov 2001) was adopted for type appproval of mechanical (pipe) joints in 2001, but was made mandatory for all mechanical (pipe) joints by the amendment to P2.7.4.1 in 2003. Again, looking at the UR Implementation Matrix distributed by 5059_IAf, we note that seven other Societies (BV, CCS, DNV, GL, KR, LR and IRS) had not indicated that they have implemented UR P2.11 (Rev.2/Nov 2001) and that none of these Societies, except IRS, indicated an expected date of implementation on its Form 2.
>
> Therefore, this message is to declare an ABS reservation against UR P2.7.4 (Rev.5/Nov 2003) and P2.11 (Rev.2/Nov 2001) until such time as Members agree to a uniform implementation date for these requirements.

Council tasked GPG to establish a uniform application date for these requirements and ascertain the implementation status.

2. Discussion

2.1 Implementation status
All GPG members provided information relative to their status of implementation for IR P2.

2.2 P2.7.4.1

GPG Chairman assessed: In reading P2.7.4.1, it does not appear to me that the requirement is intended to mandatorily require Type Approval of the subject fittings; it appears to require compliance with the same type testing requirements

as would be required for type approval of the fitting, i.e., pipe unions, compression couplings and slip-on joints are not required to be type approved, but must be approved based on the Type Approval procedure in P2.11.
Renewal of approval is only associated with type approval.

2.3 P2.11.1
DNV pointed out that the General Part of P2.11.1 has a vague expression (Individual Societies may specify more severe testing conditions…and also accept alternative testing…).

2.4 A uniform implementation statement was developed and approved.

Approved on 12 May 2006 (5059bICa)

Submitted by Permsec
28 April 2006

Technical Background for Revision of UR P2.11.5.5.6 and UR P2.11.5.5.1
(UR P2.11, rev. 2, November 2006)

UR P2.11.5.5.6

For mechanical joints, the fire endurance test is to be conducted according to the procedures specified in UR P2.11.5.5.6.

<u>The current UR P2.11.5.5.6. states that</u> "*Mechanical joint assembly test specimen is to be subjected to fire for 30 min at a temperature of 800 degrees centigrade, while water at the design pressure of the joints is circulated inside. Specimen is to be completely engulfed in the flame envelope*."

However, it has come to member societies' attention that there have been cases where tests were conducted using a furnace without apparent "flame" under the consent of several member societies. Whereas other societies were insisting on the "flame engulfing the test specimen", which often resulted in the use of increased number of flame burners, these additional burners in turn required additional fire-retardant packing due to higher heat input. This inconsistent implementation of the fire test requirements among member societies has prompted the review of the current UR P2.

Member societies agreed to remove the wording "*Specimen is to be completely engulfed in the flame envelope*" as this requirement is contained in the referenced standard ISO 19921:2005 (E), paragraph 7.1 and 7.8, and does not need to be duplicated.

Meanwhile, it was pointed out that:

- the subject UR would need to specify detailed test procedures as well as test acceptance criteria, and ISO 19922 (2005) was found to be the appropriate international standard for this purpose.
- ISO 19921 (2005) specifies nearly identical test conditions and acceptance criteria compared with the current UR, and therefore it would be best to adopt established international standard in its entirety. This reference to ISO 19921 in the UR can eliminate the current wording, i.e., "*Mechanical joint assembly test specimen is to be subjected to fire for 30 min at a temperature of 800 degrees centigrade, while water at the design pressure of the joints is circulated inside. Specimen is to be completely engulfed in the flame envelope*."

The panel agreed with the above points, and concluded that the final draft should reflect the same.

UR P2.11.5.5.1

Changes to UR P2.11.5.5.1 (a) were made to bring it in line with the ISO standards referenced in UR P2.11.5.5.6.

Hamburg, 14 November 2006
IACS Machinery Panel Chairman

Permanent Secretariat note:

Subject no. 5059a, agreed by GPG and Council 28/11/2006 (IGf)

Technical Background for Revision of UR P2.11.5.5.6 and UR P2.11.5.5.1
(UR P2.11, Rev. 2, November 2006 and Corr.1, April 2007)

Rev.2, November 2006

UR P2.11.5.5.6
For mechanical joints, the fire endurance test is to be conducted according to the procedures specified in UR P2.11.5.5.6.

The current UR P2.11.5.5.6. states that "*Mechanical joint assembly test specimen is to be subjected to fire for 30 min at a temperature of 800 degrees centigrade, while water at the design pressure of the joints is circulated inside. Specimen is to be completely engulfed in the flame envelope*."
However, it has come to member societies' attention that there have been cases where tests were conducted using a furnace without apparent "flame" under the consent of several member societies. Whereas other societies were insisting on the "flame engulfing the test specimen", which often resulted in the use of increased number of flame burners, these additional burners in turn required additional fire-retardant packing due to higher heat input. This inconsistent implementation of the fire test requirements among member societies has prompted the review of the current UR P2.

Member societies agreed to remove the wording "*Specimen is to be completely engulfed in the flame envelope*" as this requirement is contained in the referenced standard ISO 19921:2005 (E), paragraph 7.1 and 7.8, and does not need to be duplicated.

Meanwhile, it was pointed out that:

- the subject UR would need to specify detailed test procedures as well as test acceptance criteria, and ISO 19922 (2005) was found to be the appropriate international standard for this purpose.
- ISO 19921 (2005) specifies nearly identical test conditions and acceptance criteria compared with the current UR, and therefore it would be best to adopt established international standard in its entirety. This reference to ISO 19921 in the UR can eliminate the current wording, i.e., "*Mechanical joint assembly test specimen is to be subjected to fire for 30 min at a temperature of 800 degrees centigrade, while water at the design pressure of the joints is circulated inside. Specimen is to be completely engulfed in the flame envelope*."

The panel agreed with the above points, and concluded that the final draft should reflect the same.

UR P2.11.5.5.1

Changes to UR P2.11.5.5.1 (a) were made to bring it in line with the ISO standards referenced in UR P2.11.5.5.6.

Hamburg, 14 November 2006
IACS Machinery Panel Chairman

Permanent Secretariat note:

Subject no. 5059a, agreed by GPG and Council 28/11/2006 (IGf)

Correction 1, April 2007

After publication of the revised UR the RS Panel member pointed out that the addition of the requirement in UR P2.11.5.5.1 “For services other than flammable fluids, leakage rate is not to be more than 0.2 l/min“ is not appropriate as this requirement relates to the fire endurance test only. At the 5th Machinery Panel (March 2007) meeting this was considered by Panel members and it was agreed that this sentence should be deleted from UR P2.11.5.5.1.

Hamburg, 29 March 2007
IACS Machinery Panel Chairman

Permanent Secretariat note:

During GPG discussion, ABS (5059aABc & ABd) asked Machinery Panel to confirm whether the sentence being deleted from P2.11.5.5.1 would be added to P2.11.5.5.6. Machinery Panel (5059aPMd) confirmed that they felt it was not necessary since P2.11.5.5.6 refers to ISO standard ‘ISO 19921: 2005(E)’, which includes a Note in Section 8 - Assessment - "For services other than flammable fluids, a leakage rate of not more than 0.2 l/min is considered acceptable".

Technical Background for UR P2.11 Rev.3, Aug 2012

1. Scope and objectives

Update of pull-out test in 2.11.5.5.5.

The panel is in the opinion that this test as specified, where merely the internal pressure is causing the axial force, is not sufficient for proving the coupling's ability to withstand axial forces encountered in actual service.

There is no safety factor included for situations where thermal expansion, vibrations etc. will require the coupling to have increased ability to withstand axial forces.

2. Engineering background for technical basis and rationale

The test requirement is altered such that the test pressure and external axial force are to be applied simultaneously in order to achieve a more realistic situation.
According to experience this amended test procedure is what the manufacturers in the market are already enforcing on their products.

3. Source / derivation of the proposed IACS Resolution

None

4. Summary of Changes intended for the revised Resolution:

Update of pull-out test in 2.11.5.5.5.

5. Points of discussions or possible discussions

None

6. Attachments if any

None

Technical Background (TB) document for UR P2.11 (Rev.4 Mar 2016)
& UR P2.7.4 (Rev.8 Mar 2016) & UR P2.12 (Rev.2 Mar 2016)

1. Scope and objectives

.1 To review the requirements regarding the application and details of pipe coupling joints and flexible hoses partly based upon IMO Resolution A.753(18) and update UR P2 accordingly.
.2 To review the categorization of pipe coupling joints in Table 6 of P2.7.4 and update UR P2 accordingly.

2. Engineering background for technical basis and rationale

.1 UR P2 required coupling joints and flexible hoses intended for installation in piping systems for flammable media and sea water systems be of a fire resistant type regardless of installation location. On the other hand, SOLAS regulations, such as II-2/Reg.4.2.4, etc., do not necessarily require that they be of a fire resistant type when a means of ignition is not present in the installation location.

In recent years, a member has received questions from various shipyards and manufacturers asking whether fire endurance tests for coupling joints or flexible hoses arranged in locations with low fire risk, e.g., open decks, are necessary.

Moreover, some members have experienced problems when conducting fire endurance tests due to test specimen size. ISO19921/22, which specifies fire endurance test procedures, requires that the specimen be completely engulfed in the flame envelope and this can be difficult to achieve in the case of very large test specimens.

.2 A member received the following comment from a pipe coupling manufacturer which expressed their concern about a possible misinterpretation of the performance capabilities for mechanical pipe joints:

- The illustration labelled “Machine Grooved Type” in Table 6 of P2.7.4 is not accurate.

3. Source / derivation of the proposed IACS Resolution

None.

4. Summary of Changes intended for the revised Resolution:

See attached table.

5. Points of discussions or possible discussions

See attached table.

6. Attachments if any

None.

<table>
<tr><th>Paragraph</th><th>Proposals and summarised comments from IACS Members</th><th>Conclusion</th></tr>
<tr><td>P2.7.4
Table 6</td><td>Proposal:
• Since the illustration labelled “Machine Grooved Type” in Table 6 is not accurate, it should be replaced by the illustration provided by the Victaulic Company.</td><td>• Agreed.</td></tr>
<tr><td>P2.7.4
Table 7,
Footnote 3.

P2.12.3.5</td><td>Proposal:
• In consideration with SOLAS II-2/Reg. 4.2.3.1 and 4.2.4, slip-on joints and flexible hoses which are used for L.O. lines and other flammable oils, and are installed on open decks do not need to be of a fire-resistant type.
• In consideration with SOLAS II-2/Reg. 4.2.2.5.1, slip-on joints and flexible hoses used for F.O. lines should be of a fire-resistant type even when installed on open decks.
• “open decks” means areas defined in SOLAS II-2/Reg. 9.2.3.3.2.2(10) and 9.2.4.2.2.2(10). This means that cargo areas of tankers, ships carrying liquefied gases in bulk and ships carrying dangerous chemicals in bulk are not included for “open decks”.
Comments:
• Consideration should be given to specific applications and media, e.g. non fire resistance types for sea water on open deck and fire resistant types for cargo oil, fuel and fire extinguishing systems. Moreover, the table should distinguish between wet and dry applications, e.g. fire extinguishing systems, bilge systems, sounding and vent pipes.
• Fire fighting systems on open deck with non-fire resistant connection may be broken by fire and putting to workless condition. Destruction of piping lines with flammable media cause deterioration of fire conditions.
• In considering the SOLAS requirements for fuel oil and other flammable liquids, there will need to be a strong technical argument as to why it only applies to fuel lines and not lubricating oil or other flammable liquid lines e.g. hydraulic actuating systems.</td><td>• Some members were still in question as to why it only applies to fuel lines and not to other flammable liquid lines e.g. hydraulic actuating systems. Background of the regulations was not confirmed during discussion.
• However, following the decision by the qualified majority, proposals were agreed.</td></tr>
<tr><td>P2.7.4
Table 7</td><td>Proposal:
• Revised Table 7 was proposed in an effort to present the information clearer as is currently the case and to accommodate feedback from coupling manufacturers. In particular:
  • The footnotes are moved to the systems, thus making them applicable to all connection types. Complaints have received from manufacturers that the restrictions currently only apply to slip-on joints.</td><td>• Agreed.</td></tr>
<tr><td>P2.7.4.3</td><td>Proposal:
• Delete P2.7.4.3 because it is obvious and testing will only highlight discrepancies from this requirement.</td><td>• Agreed.</td></tr>
<tr><td>P2.7.4.7</td><td>Proposal:
• Replace “sea openings” with terminology such as “ship’s side below the waterline”.</td><td>• Agreed.</td></tr>
</table>

	Comment: • Suggest to modify as follows: "ship's side below the ~~waterline~~ bulkhead deck of passenger ships and freeboard deck of cargo ships". This is the wording used in SOLAS, Reg. II-1 / 15 (title).	
P2.7.4.8	Proposal: • Delete P2.7.4.8 as this is obvious.	• Agreed.
P2.7.4.11	Proposal: • Unrestrained slip-on joints are not defined and slip-on joints should not be used for compensation of lateral pipe deformation. The P2 test requirements for slip-on joints assume there is no lateral deformation. Comment: • Chair explained that the intention of P2.7.4.11 is to minimise the use of slip-on joints where it is inevitable to compensate for lateral movements of piping. In practice, slip-on joints are frequently used for that purpose, hence to prohibit the use of slip-on joints for compensation of lateral deformation may be too rigorous. In this respect, modification is proposed by Chair.	• Modification was agreed based on the Chair's proposal. • The first figure of "Slip type slip-on joints" in Table 6 in UR P2.7.4 was also replaced.
P2.11.5.3	Proposal: • The requirement "at least five times" should be re-considered. Classification societies do not need to specify minimum pipe length. This should be left up to manufacturers.	• Did not achieve a majority. • Keep as is.
P2.11.5.5.1 (a)	Proposal: • Sixth paragraph. Delete "Other" and replace with "An".	• Agreed.
P2.11.5.5.1 (b) and (c)	Proposal: • Delete (b) and (c). These sections are covered in the sixth paragraph of (a)	• Panel concurred that it is an additional requirement for compression coupling. • Keep as is.
P2.11.5.5.2	Proposal: • Delete the second paragraph as this is obvious.	• Panel unanimously agreed to delete the second part of the text.
P2.11.5.5.2 (a)	Proposal: • Delete the fifth paragraph as this is obvious. Comment: • Visual examination of the joint assembly is to be carried out.	• Panel unanimously agreed to delete the second part of the text.
P2.11.5.5.3	Proposal: • For large diameters, tests according to Fig. 3 are difficult to perform and very expensive. As an alternative it is suggested also to refer to BS 4368: Part 4. Comment: • Direct reference to BS, a regional standard, is not appropriate.	• Direct reference to BS, a regional standard, was not supported. • Keep as is.
P2.11.5.5.4	Proposal: • (Burst pressure test) Third paragraph. Delete the last sentence or modify it to provide more clarity.	• Agreed to delete.
P2.12.3.5	Proposal: • (P2.12.3.5) Only water is permitted as a test medium. With a view to ensuring	• Agreed by the qualified majority.

	maximum safety for both the operating personnel and the test bed in the event of damage to the hose during the test, the use of combustible test media is excluded. This poses an issue. All marine coupling on the market at the moment are tested to ISO 15540/41 therefore can never be used on a dry system.	
P2.11.5.5.6.3	Proposal: • (Fire endurance test) The standard specifies a sensible method of testing pipe couplings where the flame shall envelop the test specimen. This will result in problems with very large test specimens. In such cases, alternative test methods and/or test procedures should be accepted. Comments: • Provides practical cases in which alternative test methods has been accepted. • A UR may allow an alternative method to be used only if a minimum set of criteria is provided to ensure the equivalency between the required method and the alternative one. Otherwise, the acceptance of the tested specimen may differ among Classification Societies.	• None of members have experienced such cases in which alternative test methods have been accepted. • Regardless of practical cases, proposal was agreed by the qualified majority.
P2.11.5.5.6.4	Proposal: • (Fire endurance test) Define requirements for the thermal insulation materials used for the fire sleeves of couplings. • A flammability test according to IEC 60695-11-5 is to be carried out.	• Agreed with following modifications: *Thermal insulation materials applied on~~used for fire sleeves of~~ couplings are to be non-~~flammable~~combustible in dry condition and when subjected to oil spray. A ~~flammability~~non-combustibility test according to ~~IEC 60695-11-5~~ISO 1182 is to be carried out.*
P2.11.5.5.7	Proposal: • (Vacuum test) Delete the third paragraph since the tests cannot be correctly carried out without monitoring the pressure.	• Agreed.

Technical Background (TB) document for UR P2.11 (Rev.5 Jan 2021)

1. Scope and objectives

To review the application and details of fire-resistant type tests for mechanical joints considering dry/wet test

2. Engineering background for technical basis and rationale

- The industry asked to update and reconsider the test requirements as given by Table 7 of UR P2.7.4 in order to extend the range of application for slip-on-joints.
- IACS members noted inconsistent fire test requirements with respect to service conditions (dry, wet, wet/dry).
- Accordingly, test requirements for fire testing of UR P2.11.5.5.6 are amended.

3. Source / derivation of the proposed IACS Resolution

None

4. Summary of Changes intended for the revised Resolution:

- New paragraph .6.2 (fire endurance test) for dry/wet test as well as for 30 minutes dry test.
- Inserting a note (after .6.2) providing details on the test boundary condition.
- Reviewing test requirements for insulation (ref. paragraph .6.5)
- Amend section 6 notes by explanation how to handle test requiring exposure times greater than 30 minutes
- Amending the publication year of referenced standards in the text

5. Points of discussions or possible discussions

- Times for dry-wet test of 8/22 minutes are specified considering BS LPS1219 requiring 7.5 minutes dry and had been discussed with relevant industry.
- One Member Society proposed to modify, as follows, the proposed text for paragraph P2.11.5.5.6.5.1 as in their understanding no IACS Member Societies require fire testing according to ISO 1182 on thermal insulation materials which are declared "non-combustible" by the FTP Code:

> *"Thermal insulation materials applied on couplings are to be non-combustible according to ISO 1182 ~~referred to in~~ as required by the Fire Test Procedures Code defined in SOLAS regulation II-2/3."*

The above modification was supported by the qualified majority.

6. Attachments if any

Main comments received in the industry hearing

Main comments received in the industry hearing

Industry comments	Comments by Panel
A company appreciates the division to dry and wet fire mains. We believe that our pipe couplings are not a sufficient connector for dry fire mains and should not be installed inside this applications.	Noted
It is not clear to us why "Bilge" lines are defined as dry/wet lines. The Bilge collects all kind of media flushing out of connections (mostly flanges) caused by the permanent movement of the body of the ship. The more flange connections are used, the more "wet" is the Bilge line. Since non-leaking connectors such as our FGR pipe couplings are installed inside ships, the Bilge is becoming a more and more dry line.	
We would like to propose the conditions for the wet/dry test as 2 min dry / 28 min wet and in addition to that to delete the dry test and all applications for gasketed mechanical joints defined as "dry".	8/22 minutes to be further considered. Noted. It is up to the manufacturer to decide on range of application. Safety Panel, in general, considers that without clear background provided for either the Machinery Panel proposal (8 min dry test) or for industry proposal (2 min dry test) the informed advice cannot be suggested by the Safety Panel; Safety Panel cannot agree with a dispensation from 30 min dry test, and currently is not in position to provide alternative figures for supporting this new testing approach.
Regarding the duration of the dry/wet test we identified several regulations and specifications for fire detection and alarming systems for land based fire-extinguishing systems that can be easily transferred to maritime vessels. DIN EN 12854 and 12259 handle fire detection and responding sprinkler systems. The VdS regulation 2100 defines the responding time of dry central fire alarm systems. Whereas for wet systems the responding time is Zero (water flushes out as soon as the sprinkler opens), there are strict time limitations for dry sprinkler systems. The detecting time of dry fire extinguishing systems must be less then 30sec and max. 5 sec until the valves will open and flushing the water with 5m/sec into the distribution lines. Referring to the experience of operating test with dry detection and alarming systems that have to be done frequently the max. responding time is less than 30 sec till the water reaches the fire area.	
When the water flushes with 5 m /s through the lines, it means that after 120 sec (2 min), it went 600 m, after 240 sec (4 min) 1,200 m and after 480 sec (8 min), it went 2,400 m. Considering the length of e.g. the "Harmony of the Seas" by 362 m, after 8 min the water passes the fire area minimum 6 times.	
In regard of the responding time of 30 sec and a 4-times safety factor we came to the conclusion to propose a change of the dry/wet test to more realistic conditions such as 2min dry/28 min wet, still considering the heat impact during the heating-up.	
Firefighting systems not filled with water should have be filled with water in a few seconds or maybe 1 minute in case of fire. The sensor (smoke or heat) or sprinkler should tiger by 70°C for land application maybe on board a little bit higher or…. Therefore we do not achieve such high temperature (800°C) before the system is 100% filled with water. We do not see any improvement of safety. If we are wrong than old type of pipe connection like flange are a danger as well. Because the pipeline will move in all directions because of the thermal expansion. In that case the only possible pipe connection is welding……	
Regarding Fire suppression systems, what is the basis of requiring an 8 minute dry fire test + 22 minute wet fire test? Most fire protection systems are designed to deliver water in under 2 minutes when a sprinkler head has been activated. If a fire suppression system is not delivering water to the activated sprinkler head in under 2 minutes, a revision to the requirements of fire suppression system water delivery requirements would be a more justifiable revision than to create an additional test method that mandate that only mechanical joints endure an 8 minute dry burn test which is not a true representation of a timeline the fitting would be exposed to in their installed environment and then a 22 minute wet test. Fire Sprinkler installation requirements should effectively reduce the allowed time for the water to arrive at the activated sprinkler head.	

Industry comments	Comments by Panel
Taking firstly the UR P2.7.4 Rev 10 Draft I can confirm that we have successfully completed IACS witnessed testing both of the 8 minutes dry / 22 minutes wet and the 30 minutes dry proposed testing schedules. We are therefore able to comply with the proposed revisions to Table 7, should they be adopted, with modified versions of our fire resistant coupling	Noted
We do not know if flanged connections are more safe than other mechanical joints in case of fire and temperatures of 800°C.. (please consider the thermal expansion of the pipe and the heat that cause loss material strength more than 50% for steel)	Noted, not a new requirement.
There is no reason why SLIP ON JOINT have to be easily accessible. Maybe all pipe connections have to be easily accessible to be sure… If they have to be please specify what is easily accessible…	Reference to MSC/Circ.734 added in P2.7.4.9 and Table 7, Footnote 2
Just to our knowledge, what is the difference between point 9 Table 7 “Fuel oil 32” and point 10/11/12 Table 7 “Lubrication oil line 23 “. Why are the numbers reversed?	Editorial, has been aligned
Please specify dry/wet, just to avoid any endless discussions. We think for bilge lines even if they are dry, there is no higher risk or danger. Bilge lines are located on the ground never in the top floor. (Fire and heat always goes up)	Even if the scenario is unlikely the integrity of bilge lines needs to be ensured
Just be aware that ISO 19921 and 19922 is made for wet testing with a medium temperature of 80°C inside of pipe. Bilge and firefighting medium is normally +/- 20° C. That means you have to specify that more detailed. Also the test procedure is not so easy to use for a dry test. Many criteria are not easy to apply for dry tests.	Noted, reference to standards will be kept
Is not necessary for all mechanical (with parts of rubber) pipe connection. No one is able from our side of few. Even flanges not. For that system only 100% welded pipeline should be allowed. By the way at the moment no test lab in the world is able to test pipe connections under dry conditions. But for us it is important the you write in the URP THE FIRE TEST HAVE TO BE DONE WITH AN ACREDITED EXTERNAL TEST LAB.	Noted. It is up to the manufacturer to decide on range of application. Requirement for accredited test lab is considered too strict. Test bench and test procedure is to be verified and tests are to witnessed by a society surveyor.
Here it started with the objection that no flange connections are considered here. Which I regard as very important because the flange connection does not always comply with the flame protection requirements or tightness requirements due to the choice of gasket and flange design (loose flange, welding flange, etc.). (Various own inhouse tests have shown that flanges do not meet the requirements.)	Open item Flange connections may also fail dry fire tests, extension of Table 7 for flange connections to be considered in a next step. No change at present, to be considered in next revision.
Test standard problem 1) Since there are no international standards in the dry test, the test method is not clear. 2) The test content is only for the time classification. Therefore, the possibility of passing the test is unknown at present because it has little experience. 3) Each Classification society and company may have different interpretation of the test. 4) 30 minutes Dry test definition is missing. 5) Each Classification society and company may have different interpretation of the test.	Test method is considered to be sufficiently clearly described in ISO 19921:2005 and P2.11.5.5.6

Industry comments	Comments by Panel
I would like the members to ask the question, are there any documented failures of mechanical joints due to installation in dry pipe applications or dry fire main systems due to exposure to fire that have been presented as the justification for proposing these additional test requirements? If not, what is now driving the proposed revisions? Have any Non Mechanically Attached Fitting pipe joining methods been tested to this requirement successfully and if so what joining methods have been found to be compliant or are we to assume that brazed and welded pipe joining methods with pass this test without having been proven?	Change not triggered by failures but to reflect realistic conditions w.r.t. dry and wet exposure of piping systems, such as not permanently water filled fire extinguishing systems. Brazed connections are not permissible where fire resistance is required (melting point below 925 deg. C). Welded pipe joints are considered to be fire resistant.
Regarding UR P2.11 Rev 5 Draft please note that P2.11.5.5.6.2 lines 9-10 should read "then maintained to at least 5 bar" for clarity.	Wording changed from 'above' to 'at least'
For clarity, we would strongly recommend that the P2.11.5.5.6.5.1 clearly and unambiguously states that the thermal insulation materials "used" (rather than "applied", which can be misleading) are to be non-combustible to SOLAS regulation II-2/3, defined by the FTP Code Annex 1, Part 1 Fire Test Procedures "The non-combustibility shall be verified in accordance with the test procedure in the appendix to this part (ISO 1182)". The previous wording "A non-combustibility test according to ISO 1182 is to be carried out" was admirably clear and unambiguous to owners, surveyors, manufacturers and shipbuilders alike and should not be excluded from the revised paragraph.	Reference to ISO 1182 added in P2.11.5.5.6.5.1
At P2.11.5.5.6.5.3 It should not be assumed that the thermal insulation is to be fitted during the installation. In the case of our product, for example, the thermal insulation is pre-installed. Therefore, it should be clearly stated, for example "…….where fire resistance is required, unless the mechanical joint is delivered already fitted with thermal insulation before installation."	Text added to P2.11.5.5.6.5.3
In paragraph 7 the time to change the term "slip-on" is long overdue. The term is used pejoratively in industry to imply that what can be "slipped- on" can also be "slipped-off" and a change would, I am sure, be welcomed. The term "joints with resilient sealing arrangements" is much better, although a little cumbersome. A more accurate and easily adopted term would be "Gasketed Mechanical Couplings" which is to be found in ASTM F1476 and is commonly abbreviated to "GMCs" by industry. GMCs are further defined as: Type 1 – grooved mechanical couplings Type 2 – plain end mechanical couplings And classified as: Class 1 - rigid and restrained Class 2 - flexible and restrained Class 3 – flexible and unrestrained	Open item To be considered in a future revision
Finally, the drawings in the current UR P2 Table 6 "Examples of mechanical joints" are also out of date and unrepresentative of the market. New, generic representations would be highly preferable. I have attached, by way of example only, two cross sections of a Type 2 Class 2 and a Type 2 Class 3 GMC.	Open item To be considered in a future revision

Industry comments	Comments by Panel
Adoption of these proposed revisions will in many cases exclude most of the popular pipe joining methods that are used in many dry pipe applications including fire suppression systems as any Mechanically Attached Fitting that utilized a sealing elements are not likely to endure an 8 minute dry fire test without leakage. The result will be an very significant increase in the cost of ship building for dry pipe applications and fire suppression systems that drastically reduce the ability for ship builders to utilize the safest flame free pipe joining installation methods.	Noted. It is up to the manufacturer to decide on range of application. Reference to 'safest flame free' is not understood.

Technical Background (TB) document for UR P2.11 (Rev.6 Oct 2023)

1. Scope and objectives

To update the requirements for mechanical joint type approval, aligning with the revision introduced into UR P2.7.4, also considering other aspects peculiar to UR P2.11.

2. Engineering background for technical basis and rationale

Refer to item 2 of TB for UR P2.7.4 (Rev.11).

3. Source/derivation of the proposed IACS Resolution

Refer to item 3 of TB for UR P2.7.4 (Rev.11).

4. Summary of Changes intended for the revised Resolution:

Among the initially intended changes, following update for Table 9 is finally adopted for this revision of the UR because of Industry Hearing and Panel deliberation:

- To reflect the revision on pressure pulsation test (mandatory for Class I and II);
- To review the applicability and adequacy of exemption note 3 to vacuum test, and to rectify it to fire endurance test.
- Note 3 added and considered apply to row 6 that fire endurance test for compression couplings and pipe unions when tightening surfaces made with metal-to-metal joint since metal-to-metal join will remain tight in case of fire as there is no sensitive material to heat used in such joint.
- To rephrase Footnote 2 to Table 9 "except permanent joint type (e.g., press type and swage type)", considering that repeated assembly test is for "a specimen 10 cycle repetition" of dismantle, re-assemble and tightness test and thereby not required for permanent joint type such as press type and swage type.

5. Points of discussions or possible discussions

Refer to item 5 of TB for UR P2.7.4 (Rev.11).

In addition, it was pointed out by a member that the footnotes no.3 to Table 9 is not relevant to vacuum test but to fire endurance test. Members could not find the background of exception for the vacuum test and decided to keep the footnote No.3 on vacuum test. Furthermore, members have also understood that fire endurance test is basically performed for metallic pipe components with resilient and elastomeric seals in accordance with the scope of ISO 19921 & 19922 and can be applied the footnote No.3 as well.
Slip on joints shall contain elastomeric seals and thereby not relevant to metal-to-metal tightening surfaces.

Note 3 of table 9 in respect of exclusion of compression couplings and pipe unions from the fire endurance testing requirements is based on the understanding that these types of fittings do not include any component which may readily deteriorate in the event of fire.

6. Attachments if any

Refer to item 6 of TB for UR P2.7.4 (Rev.11).

UR P2.12 “Flexible Hoses”

Summary

In Rev.3 of this Resolution, the term “short length” for flexible hoses and the criteria for the selection of “different nominal diameters of hose type” for prototype tests were clarified, and the way to refer to instruments other than those specified by IACS was unified.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev.3 (Feb 2021)	16 February 2021	1 July 2022
Rev.2 (Mar 2016)	2 March 2016	1 January 2017
Corr.1 (Jan 2013)	10 January 2013	-
Rev.1 (Aug 2007)	24 August 2007	1 July 2008
New (Jan 2005)	2 January 2005	Unknown

- **Rev.3 (Feb 2021)**

1 Origin of Change:

☑ Suggestion by a Member

2 Main Reason for Change:

To clarify the expressions “short length” in UR P2.12.1.1 and the criteria for the selection of “different nominal diameters of hose type” for prototype tests in UR P2.12.5.2.

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None

4 History of Decisions Made:

Issue raised on 18 March 2019

Qualified majority on 24 June 2019 in favor of developing:

- a definition of the "short length" in UR P2.12.1.1
- criteria for the selection of “different nominal diameters of hose type” in UR P2.12.5.2.

The Machinery Panel commented on drafts by correspondence during the second half of 2019.

In the latest rounds of discussion, an additional modification was made to comply with the following format when industry standards are referred to:

[Standard Designation], [version/revision, if applicable], [year of publication] (examples: API Spec 2F, 6th Edition, 1997; ISO 4624, 2002), where [version/revision, if applicable] and/or [year of publication] are decided by IACS and are not necessarily to be the current/latest version.

To take this opportunity, references to IMO instruments have been specified in the following format (in case where the number of amendments is large) based upon confirmation of amendments up to the latest one:

regulation/paragraph x.x.x of SOLAS Chapter X/MARPOL Annex X/the XXX Code, as amended by IMO resolutions up to MSC.xx(xx)/MEPC.xx(xx)

5 Other Resolutions Changes:

None

6 Any hinderance to MASS, including any other new technologies:

None

7 Dates:

Original Proposal:	18 March 2019 (Message following 29th MP Meeting Made by: Machinery Panel Member)
Panel Approval:	16 December 2020 (Ref: PM16301g_IMj)
GPG Approval:	16 February 2021 (Ref: 19200_IGd)

- **Rev.2 (Mar 2016)**

1 Origin for Change:

☑ Suggestion by IACS member

2 Main Reason for Change:

To review the application and details of fire resistant type tests for flexible hoses.

3 List of non-IACS Member Classification Societies contributing through the TC Forum and/or participating in IACS Working Group:

None

4 History of Decisions Made:

The Machinery Panel commented on revisions by correspondence and at regularly scheduled meetings.

5 Other Resolutions Changes

P2.7.4 (Rev.8) and P2.11 (Rev.4) are also revised under the same task number.

6 Dates:

Original Proposal: 30 January 2012 Made by a Member
Panel Approval: 28 December 2015 (Ref: PM11921)
GPG Approval: 2 March 2016 (Ref: 14079_IGe)

- **Corr.1 (Jan 2013)**

1 Origin of Change:

☑ Suggestion by an IACS member

2 Main Reason for Change:

To correct the namings of ISO 6802 and ISO 6803.

3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

4 History of Decisions Made:

Machinery Panel Chairman informed GPG of this correction, which was raised by a Machinery Panel member. Noting that this is a straightforward correction, GPG Chairman requested Permanent Secretariat to issue a correction to the UR. A simple history file was made to record this correction.

5 Other Resolutions Changes

None

6 Dates:

Original Proposal: 09 January 2013 Made by Machinery Panel Chairman
GPG Approval: 10 January 2013 (Ref: 13008_IGa)

- **Rev.1 (Aug 2007)**

Note: *There is no separate Technical Background (TB) document available for the Corr.1 (Jan 2013)*

Technical Background document for draft UR P2.8 on Flexible hoses (WP/MCH task 12)

1. Scope and objective

The Flexile Hoses both metallic and non-metallic materials widely used in machinery spaces of ships for connection between fixed piping system and items of machinery or equipment that is subject to movement. Taking into account that use of non-standard hoses or their improper installation connect with risk of fire or flooding at the 19th Meeting of AHG/PPV it was decided to unify the requirements and test procedures for flexile hoses.

2. Points of discussion

Permissible of use the Flexile Hoses for thermal oil systems, requirements to end connections as well as requirements to fire resistant and pressure impulse testing have been discussed. The draft UR was accepted by the WP without reservations.

3. Source of proposed requirements

1. Reg. II-2/2.2.5.1, II-2/2.3.1, II-2/2.4
2. Rules in force of IACS Members
3. ISO 6802 - Rubber and plastic hoses and hose assemblies - Hydraulic pressure impulse test without flexing
4. ISO 6308 - Rubber and plastic hoses and hose assemblies - Hydraulic pressure impulse test with flexing
5. ISO 15540 - Ships and marine technology - Fire resistance of hose assemblies – Test method
6. ISO 15540 - Ships and marine technology - Fire resistance of hose assemblies - Requirements for test bench
7. ISO 7840- Small craft - Fire resistant of fuel hoses 8. ISO 10380 Pipework- Corrugated metal hoses and hose assemblies

4. Notes by the Permanent Secretariat

GPG added the following changes to the draft UR P2.12:
1) P2.12.2.2: The following new sentence was added:
"Flexible hoses in high pressure fuel oil injection systems are not to be accepted"
2) P2.12.5.3: With regard to the "5 minutes" testing period, the following reference to the international standards was added:
"The international standards, e.g. EN or SAE for burst testing of non-metallic hoses, require the pressure to be increased until burst without any holding period at 4 x MWP"

TB submitted by the WP/MCH Chairman.

Technical Background
UR P2.12 (Rev.1) – August 2007
Revision of UR P2.12.3.1

In the current UR P2.12.3.1, it is prescribed that "Flexible hoses constructed of rubber or plastics materials and intended for use in bilge, ballast, compressed air, oil fuel, lubricating, hydraulic and thermal oil systems are to incorporate a single, double or more, closely woven integral wire braid or other suitable material reinforcement".
However, according to flexible hose manufacturers, flexible hoses made of plastic materials such as Teflon and Nylon are not able to be incorporated by closely woven integral wire braid or other suitable material reinforcement.
Because, fluorine rein has property of bad wet ability and bad adhesion to other substances, therefore, the incorporated woven wire braid easily peels off from fluorine rein.

UR P2.12 was established in order for the use of non-standard hoses or improper installation not to cause the fire or flooding. Member societies agreed that it was sufficient as flexible hose that plastic hoses such as Teflon and Nylon hoses were satisfied with National or International standard, e.g. ISO mentioned in UR P2.12, even if closely woven integral wire braid or other suitable material reinforcement was not incorporated.

The changes to UR P2.12.3.1 were adopted unanimously by Panel members.

Hamburg, 3 July 2007
IACS Machinery Panel Chairman

Permanent Secretariat note (September 2007):
The changes to UR P2.12.3.1 were approved by GPG on 24 August 2007 (ref. 6216_IGe) with an implementation date of 1 July 2008.

Technical Background (TB) document for UR P2.12 (Rev.2 Mar 2016)

& UR P2.7.4 (Rev.8 Mar 2016) & UR P2.11 (Rev.4 Mar 2016)

1. Scope and objectives

.1 To review the requirements regarding the application and details of pipe coupling joints and flexible hoses partly based upon IMO Resolution A.753(18) and update UR P2 accordingly.

.2 To review the categorization of pipe coupling joints in Table 6 of P2.7.4 and update UR P2 accordingly.

2. Engineering background for technical basis and rationale

.1 UR P2 required coupling joints and flexible hoses intended for installation in piping systems for flammable media and sea water systems be of a fire resistant type regardless of installation location. On the other hand, SOLAS regulations, such as II-2/Reg.4.2.4, etc., do not necessarily require that they be of a fire resistant type when a means of ignition is not present in the installation location.

In recent years, a member has received questions from various shipyards and manufacturers asking whether fire endurance tests for coupling joints or flexible hoses arranged in locations with low fire risk, e.g., open decks, are necessary.

Moreover, some members have experienced problems when conducting fire endurance tests due to test specimen size. ISO19921/22, which specifies fire endurance test procedures, requires that the specimen be completely engulfed in the flame envelope and this can be difficult to achieve in the case of very large test specimens.

.2 A member received the following comment from a pipe coupling manufacturer which expressed their concern about a possible misinterpretation of the performance capabilities for mechanical pipe joints:

- The illustration labelled “Machine Grooved Type” in Table 6 of P2.7.4 is not accurate.

3. Source / derivation of the proposed IACS Resolution

None.

4. Summary of Changes intended for the revised Resolution:

See attached table.

5. Points of discussions or possible discussions

See attached table.

6. Attachments if any

None.

Paragraph	Proposals and summarised comments from IACS Members	Conclusion
P2.7.4 Table 6	Proposal: • Since the illustration labelled “Machine Grooved Type” in Table 6 is not accurate, it should be replaced by the illustration provided by the *Victaulic Company*.	• Agreed.
P2.7.4 Table 7, Footnote 3. P2.12.3.5	Proposal: • In consideration with SOLAS II-2/Reg. 4.2.3.1 and 4.2.4, slip-on joints and flexible hoses which are used for L.O. lines and other flammable oils, and are installed on open decks do not need to be of a fire-resistant type. • In consideration with SOLAS II-2/Reg. 4.2.2.5.1, slip-on joints and flexible hoses used for F.O. lines should be of a fire-resistant type even when installed on open decks. • “open decks” means areas defined in SOLAS II-2/Reg. 9.2.3.3.2.2(10) and 9.2.4.2.2.2(10). This means that cargo areas of tankers, ships carrying liquefied gases in bulk and ships carrying dangerous chemicals in bulk are not included for “open decks”. Comments: • Consideration should be given to specific applications and media, e.g. non fire resistance types for sea water on open deck and fire resistant types for cargo oil, fuel and fire extinguishing systems. Moreover, the table should distinguish between wet and dry applications, e.g. fire extinguishing systems, bilge systems, sounding and vent pipes. • Fire fighting systems on open deck with non-fire resistant connection may be broken by fire and putting to workless condition. Destruction of piping lines with flammable media cause deterioration of fire conditions. • In considering the SOLAS requirements for fuel oil and other flammable liquids, there will need to be a strong technical argument as to why it only applies to fuel lines and not lubricating oil or other flammable liquid lines e.g. hydraulic actuating systems.	• Some members were still in question as to why it only applies to fuel lines and not to other flammable liquid lines e.g. hydraulic actuating systems. Background of the regulations was not confirmed during discussion. • However, following the decision by the qualified majority, proposals were agreed.
P2.7.4 Table 7	Proposal: • Revised Table 7 was proposed in an effort to present the information clearer as is currently the case and to accommodate feedback from coupling manufacturers. In particular: • The footnotes are moved to the systems, thus making them applicable to all connection types. Complaints have received from manufacturers that the restrictions currently only apply to slip-on joints.	• Agreed.
P2.7.4.3	Proposal: • Delete P2.7.4.3 because it is obvious and testing will only highlight discrepancies from this requirement.	• Agreed.
P2.7.4.7	Proposal: • Replace “sea openings” with terminology such as “ship’s side below the waterline”.	• Agreed.

	Comment: • Suggest to modify as follows: "ship's side below the ~~waterline~~ bulkhead deck of passenger ships and freeboard deck of cargo ships". This is the wording used in SOLAS, Reg. II-1 / 15 (title).	
P2.7.4.8	Proposal: • Delete P2.7.4.8 as this is obvious.	• Agreed.
P2.7.4.11	Proposal: • Unrestrained slip-on joints are not defined and slip-on joints should not be used for compensation of lateral pipe deformation. The P2 test requirements for slip-on joints assume there is no lateral deformation. Comment: • Chair explained that the intention of P2.7.4.11 is to minimise the use of slip-on joints where it is inevitable to compensate for lateral movements of piping. In practice, slip-on joints are frequently used for that purpose, hence to prohibit the use of slip-on joints for compensation of lateral deformation may be too rigorous. In this respect, modification is proposed by Chair.	• Modification was agreed based on the Chair's proposal. • The first figure of "Slip type slip-on joints" in Table 6 in UR P2.7.4 was also replaced.
P2.11.5.3	Proposal: • The requirement "at least five times" should be re-considered. Classification societies do not need to specify minimum pipe length. This should be left up to manufacturers.	• Did not achieve a majority. • Keep as is.
P2.11.5.5.1 (a)	Proposal: • Sixth paragraph. Delete "Other" and replace with "An".	• Agreed.
P2.11.5.5.1 (b) and (c)	Proposal: • Delete (b) and (c). These sections are covered in the sixth paragraph of (a)	• Panel concurred that it is an additional requirement for compression coupling. • Keep as is.
P2.11.5.5.2	Proposal: • Delete the second paragraph as this is obvious.	• Panel unanimously agreed to delete the second part of the text.
P2.11.5.5.2 (a)	Proposal: • Delete the fifth paragraph as this is obvious. Comment: • Visual examination of the joint assembly is to be carried out.	• Panel unanimously agreed to delete the second part of the text.
P2.11.5.5.3	Proposal: • For large diameters, tests according to Fig. 3 are difficult to perform and very expensive. As an alternative it is suggested also to refer to BS 4368: Part 4. Comment: • Direct reference to BS, a regional standard, is not appropriate.	• Direct reference to BS, a regional standard, was not supported. • Keep as is.
P2.11.5.5.4	Proposal: • (Burst pressure test) Third paragraph. Delete the last sentence or modify it to provide more clarity.	• Agreed to delete.
P2.12.3.5	Proposal: • (P2.12.3.5) Only water is permitted as a test medium. With a view to ensuring	• Agreed by the qualified majority.

	maximum safety for both the operating personnel and the test bed in the event of damage to the hose during the test, the use of combustible test media is excluded. This poses an issue. All marine coupling on the market at the moment are tested to ISO 15540/41 therefore can never be used on a dry system.	
P2.11.5.5.6.3	Proposal: • (Fire endurance test) The standard specifies a sensible method of testing pipe couplings where the flame shall envelop the test specimen. This will result in problems with very large test specimens. In such cases, alternative test methods and/or test procedures should be accepted. Comments: • Provides practical cases in which alternative test methods has been accepted. • A UR may allow an alternative method to be used only if a minimum set of criteria is provided to ensure the equivalency between the required method and the alternative one. Otherwise, the acceptance of the tested specimen may differ among Classification Societies.	• None of members have experienced such cases in which alternative test methods have been accepted. • Regardless of practical cases, proposal was agreed by the qualified majority.
P2.11.5.5.6.4	Proposal: • (Fire endurance test) Define requirements for the thermal insulation materials used for the fire sleeves of couplings. • A flammability test according to IEC 60695-11-5 is to be carried out.	• Agreed with following modifications: *Thermal insulation materials <u>applied on</u>~~used for fire sleeves of~~ couplings are to be non-~~flammable~~<u>combustible</u> in dry condition and when subjected to oil spray. A ~~flammability~~<u>non-combustibility</u> test according to ~~IEC 60695-11-5~~<u>ISO 1182</u> is to be carried out.*
P2.11.5.5.7	Proposal: • (Vacuum test) Delete the third paragraph since the tests cannot be correctly carried out without monitoring the pressure.	• Agreed.

Technical Background (TB) document for UR P2.12 (Rev.3 Feb 2021)

1. Scope and objectives

As set out in GPG 87 FUA 2, UR P2.12, Rev.3 of this UR is to cite the year of publication of the standards referenced in the text of the UR.

2. Engineering background for technical basis and rationale

Clarification on the term "short length" for flexible hoses and the criteria for the selection of "different nominal diameters of hose type" for prototype tests

.1 UR P2.12.1.1 defines a flexible hose assembly as a "short length of metallic or non-metallic hose normally with prefabricated end fittings ready for installation". In addition, according to IMO Circular MSC.1/Circ.1321, for flammable oil systems, "Flexible pipes, hoses and hose assemblies – which are flexible hoses with end fittings attached – should be in as short lengths as practicable, but should not, in general, exceed 1.5 m in length, and only be used where necessary to accommodate relative movement between fixed piping and machinery parts".
It was agreed to introduce this maximum length criteria in the UR P2.12.1.1.

.2 UR P2.12.5.2 requires the tests, "as applicable, to be carried out on different nominal diameters of hose type complete with end fittings for pressure, burst, impulse resistance and fire resistance in accordance with the requirements of the relevant standard"'. It was agreed to follow the approach of ISO 15540 - Ships and marine technology - Fire resistance of hose assemblies – Test methods, paragraph 6, which requires the tests to be carried out on a minimum of three hose diameters and the smallest, the middle and the largest nominal diameters to be tested for each series. It was also considered that a test on a hose with a diameter D qualifies a hose for the range 0.5D – 2D.

Format for references to Industry standards

[Standard Designation], [version/revision, if applicable], [year of publication] (examples: API Spec 2F, 6th Edition, 1997; ISO 4624, 2002), where [version/revision, if applicable] and/or [year of publication] are decided by IACS and are not necessarily to be the current/latest version.

3. Source/derivation of the proposed IACS Resolution

See paragraph .2 above.

4. Summary of Changes intended for the revised Resolution:

See paragraph .2 above. For Industry standards, UR P2.12 has been updated to specify the revision/version of the ISO standards as follows:

ISO standards	Replaced by
ISO 6802	ISO 6802:2018
ISO 6803	ISO 6803:2017
ISO 10380	ISO 10380:2012
ISO 15540	ISO 15540:2016
ISO 15541	ISO 15541:2016

5. Points of discussions or possible discussions

Clarification on the term "short length" for flexible hoses

The initial draft for Revision of UR P2.12.1.1 was worded as follows:

Note: Flexible hose assemblies for flammable oil systems should not, in general, exceed 1.5 m in length. See IMO Circular MSC.1/Circ.1321, paragraph 2.1.
One member opined that the reference to the IMO Circular was not necessary.
Some members proposed to introduce the criteria for the length of flexible hoses to be < 1.5 m as a mandatory requirement and not as a recommendation.
One member also proposed to include flammable and toxic media in the scope of the Note, in addition to essential services.
All proposals were supported by a majority of the members and reflected in the final version of the revision.

Criteria for the selection of “different nominal diameters of hose type” for prototype tests
The initial draft for Revision of UR)2.12.5.2 was worded as follows:
Note:
Prototype tests are to be carried out for each size of hose assembly. However, for ranges with more than 3 different diameters, the prototype tests may be carried out only for:

- *the smallest diameter,*
- *the largest diameter,*
- *Intermediate diameters selected based on the principle that prototype tests carried out for a hose assembly with a diameter D are considered valid only for the diameters ranging between 0.5 D and 2 D.*

One member proposed the following modification:
"However, for ranges with more than 3 different diameters, <u>at least the following samples are to be tested</u> ~~the prototype tests may to be carried out only for~~".

One member opined that, in order to avoid conflict with the requirements of ISO 15540:2016 in the case of fire resistance tests, the following text should be added at the end of the Note.

"For fire resistance tests the specimens shall be selected in accordance with ISO 15540:2016."

Both modifications were agreed by a majority of the members and reflected in the final version of the revision.

Other proposals
At the final stage of discussion, the following modification was proposed by a Member, but the qualified majority agreement has not been achieved:

Note * The international standards, e.g. EN or SAE for burst testing of non-metallic hoses, require the pressure to be increased until burst without any holding period at <u>minimum of</u> 4 x M<u>A</u>WP<u>/Design pressure</u>.
<u>MAWP =Maximum Allowable Pressure or Design Pressure.</u>

UR P2.13 “Installation”

Summary

In the Revision 1 of UR P2.13, the examples in the round brackets in paragraph P2.13.1.1 have been deleted as they are considered not appropriate/useful for the purpose of this requirement (in fact a chain locker is designed to be open to seawater and fish holds may also contain seawater) and the cargo holds to which this UR is to be applied have been clarified.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev.1 (Jan 2021)	21 January 2021	1 July 2022
New (Oct 2018)	13 October 2018	1 January 2020

- **Rev.1 (Jan 2021)**

1 Origin for Change:

☑ Suggestion by IACS member

2 Main Reason for Change:

To revise the UR P2.13 (New, Oct. 2018) in order to delete the requirement of protection of seawater pipes in other spaces where pipes may be subject to impacts as it is considered vague, and the examples in the round brackets in paragraph P2.13.1.1 as they are considered not appropriate/useful for the purpose of this requirement (in fact a chain locker is designed to be open to seawater and fish holds may also contain seawater).

3 List of non-IACS Member Classification Societies contributing or participating in IACS Working Group:

None

4 History of Decisions Made:

Machinery Panel by correspondence

5 Other Resolutions Changes

None

6 Any hinderance to MASS, including any other new technologies:

None

7 Dates:

Original Proposal: 21 February 2019 (Ref: PM16301dIMa)
Panel Approval: 24 December 2020 (Ref: PM20305_IMi)
GPG Approval: 21 January 2021 (Ref: 19141_IGi)

- **New (Oct 2018)**

1 Origin for Change:

☑ Suggestion by IACS member

2 Main Reason for Change:

Triggered by an NTSB recommendation towards IACS, members agreed to add a new section 13 to UR P2.

3 List of non-IACS Member Classification Societies contributing through the TC Forum and/or participating in IACS Working Group:

None

4 History of Decisions Made:

See separate TB document in Annex 1.

Annex 2. **TB for Rev.1 (Jan 2021)**

See separate TB document in Annex 2.

◄▼►

Technical Background (TB) document for UR P2.13 (New Oct 2018)

1. Scope and objectives

- To develop new installation requirements for seawater supply pipes located in cargo holds

2. Engineering background for technical basis and rationale

UR P2.13 (New)

UR P2.13.1 has been developed to protect seawater supply piping located in cargo holds from mechanical damage. IACS found it appropriate to apply this provision to new vessels with contracts on or after 1 January 2020.

It is noted that for plastic piping, a similar yet generalized provision is included in UR P4.6.3.3.

3. Source / derivation of the proposed IACS Resolution

- P2.13.1 was developed based on a US NTSB recommendation following the sinking of the vessel 'El Faro'. The NTSB report opined that "It is likely that the seawater piping below the waterline to the vessel's emergency fire pump in cargo hold 3 was inadequately protected from impact and was struck by one or more cars that had broken free of their lashings" (NTSB Report). The recommendation made to IACS was that "your members to require that on new and existing vessels, seawater supply piping below the waterline in all cargo holds be protected from impact" (Rec M-17-56).

4. Summary of Changes intended for the revised Resolution:

- Add new section P2.13.1 in respect of protection of piping in cargo holds

5. Points of discussions or possible discussions

UR P2.13 (New)

It should also be noted that although the NTSB recommendation to IACS (see the HF-TB) suggests this be implemented for new and existing ships, it is proposed to not retroactively apply this new provision in UR P2 to existing ships. This is because, although the new proposal to UR P2 specifically points out this topic to improve awareness, it is generally noted that existing designer's practice and some Rules may generally include this subject already and has been applied on existing vessels

6. Attachments if any

None

Technical Background (TB) document for UR P2.13 (Rev.1, Jan 2021)

1. Scope and objectives

To revise the UR P2.13 (New, Oct. 2018) in order to delete the requirement of protection of seawater pipes in other spaces where pipes may be subject to impacts as it is considered vague, and the examples in the round brackets in paragraph P2.13.1.1 as they are considered not appropriate/useful for the purpose of this requirement.

2. Engineering background for technical basis and rationale

The examples in the round brackets in paragraph P2.13.1.1 were considered not appropriate/useful for the purpose of this requirement for the reason that a chain locker is designed to be open to seawater and fish holds may also contain seawater.

3. Source / derivation of the proposed IACS Resolution

P2.13.1 was developed based on a US NTSB recommendation following the sinking of the vessel 'El Faro'. The NTSB report opined that "It is likely that the seawater piping below the waterline to the vessel's emergency fire pump in cargo hold 3 was inadequately protected from impact and was struck by one or more cars that had broken free of their lashings" (NTSB Report). The recommendation made to IACS was that "your members to require that on new and existing vessels, seawater supply piping below the waterline in all cargo holds be protected from impact" (Rec M-17-56).

4. Summary of Changes intended for the revised Resolution:

The wording "and in other spaces where pipes may be subject to impacts (e.g. fish holds, chain lockers)" has been deleted.

The whole P2.13.1.1. has been reworded to read: "P2.13.1.1 Seawater pipes in cargo holds for dry cargoes, including cargo spaces of container ships, ro-ro ships, are to be protected from impact of cargo where they are liable to be damaged."

5. Points of discussions or possible discussions

After a first consideration by the Panel the qualified majority agreed to delete the examples in the round brackets but regarding the text of the requirement the following four (4) Options were proposed to the Panel attention:

Option 1

"P2.13.1.1 Seawater pipes located in cargo holds are to be protected from impact where they are liable to be damaged by cargo."

Option 2

"P2.13.1.1 Seawater pipes located in cargo holds and in other spaces where pipes may be subject to impacts are to be protected from mechanical damage."

Option 3

"P2.13.1.1 Seawater pipes located in cargo and service spaces below the waterline where pipe failure could cause flooding are to be protected from mechanical damage."

Option 4

"P2.13.1.1 Seawater pipes below freeboard deck located in cargo holds and in other compartments where pipes may be subject to impacts are to be protected from mechanical damage."

The qualified majority of Panel Members agreed to **Option 1 and 2,** with preference for Option 2.

Following discussion at GPG, the OPTION 2 was not accepted by the qualified majority and the UR was reverted back to the Panel, which developed and approved the new text, without reference to "other places where pipes may be subject to impacts" nor relevant examples, and with limitation to pipes below the freeboard deck.

- In the latest rounds, a discussion was also carried out as to whether "cargo holds" should include hold spaces as normally provided on gas carriers/oil and/or chemical tankers or cargo tanks, and it was confirmed that the intention of this UR is to cover spaces for the carriage of cargo where mechanical damage by cargo can occur, and does not include spaces like hold spaces of gas carriers/oil and/or chemical tankers or cargo tanks.

  In this regard an IACS Member proposed to modify the UR to read as follow: "...are to be protected from impact <u>only</u> where they are liable to be damaged by cargo..."; the proposal was however not supported by the qualified majority.

- An IACS Member proposed to extend the field of application of UR P2.13.1.1 in order to consider not only seawater pipes but also other pipes, like those containing dangerous substances (e.g. ammonia), that can be damaged by an impact; the proposal was however not supported by the qualified majority.

- An IACS Member proposed to modify the requirement in UR P2.13.1.1, as follows, for the reason that in their understanding the pipes can be also damaged during the loading or unloading operations of cargoes:

  "*Seawater pipes located in cargo holds are to be protected from impact where they are liable to be damaged <u>during cargo handling or</u> by cargo.*"

  The proposal was however not supported by the qualified majority.

- Based upon GPG instruction, Machinery Panel received Safety Panel provided the modified text as follows:

  "Seawater pipes in cargo holds are to be protected from impact where they are liable to be damaged by cargo"

- During a further review by Machinery Panel, draft amendments to SOLAS Chapter II-1 were also taken into account. The text to be specified in UR P2.13.1.1 has been updated as follows:

  "Seawater pipes in cargo holds <u>for dry cargoes, including cargo spaces of container ships and car carriers, etc.</u> are to be protected from impact where they are liable to be damaged by cargo".

- Among the following proposals raised at GPG, Machinery Panel agreement has not been achieved on the last proposal:

  - deletion of the word "*etc.*"

- replacement of the term "*car carriers*" with "*ro-ro ships*"

- a change of the phrase "*protected from impact <u>of cargo</u> where they are liable to be damaged ~~by cargo~~*" which may result that seawater pipes in cargo holds need to be protected in all cases, when other damages (e.g. damages of such pipes occurred in the event of hull damages) shall be taken into account; and

- a change of the term "*cargo holds for dry cargoes*" to "*cargo holds of dry cargo ships*" which may result that cargo holds of combination carriers are excluded from the scope of application of Rev.1 of UR P2.13.

UR P3 “Air Pipe Closing Devices”

Summary

In Rev.5 of this UR, changes have been made to address numerical analysis using CFD (computational fluid dynamics) as an alternative means to undertake reverse flow test.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev.5 (Apr 2021)	13 April 2021	1 July 2022
Rev.4 (Jan 2016)	22 January 2016	1 January 2017
Rev.3 (Nov2012)	2 November 2012	1 January 2014
Rev.2 (March2004)	4 March 2004	-
Corr.1 (April2002)	30 April 2002	-
Rev.1 (May2001)	17 May 2001	-
Corr1 (May1998)	20 May 1998	-
New (1991)	-	-

- **Rev.5 (Apr 2021)**

1 Origin of Change:

☑ Suggestion by IACS member

2 Main Reason for Change:

As per IACS UR P3 Rev 4 2016, para 3.4.1.c, Reverse flow test shall be performed in order to Type approve Air pipe automatic closing devices/ the air vent valves. This test may require very high flow velocity depending on the geometry of the valve and hence would require manufacturers to use vacuum pumps of very high capacity to conduct the test. This poses practical difficulty for the manufacturer to conduct the test in case of large diameter vents. To overcome this difficulty, Rev. 5 is proposed to include CFD simulation as an alternative means for determining permissible reverse flow.

To take this opportunity, references to IMO instruments have been specified in the following format based upon confirmation of amendments up to the latest one:

> *regulation/paragraph x.x.x of SOLAS Chapter X/MARPOL Annex X/the XXX Code, as amended by IMO resolutions up to MSC.xx(xx)/MEPC.xx(xx)*

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None

4 History of Decisions Made:

Form A was approved on 06/02/2019 by Machinery Panel.

A Member proposed an initial draft to Panel on 27/02/2019:

The discussion on the initial draft led to the following conclusions:

- Consideration of CFD for air pipe heads up to twice the size of the validated CFD model is unanimously agreed to be deleted.
- Intended CFD simulations are applicable for pipe heads of 400 mm nominal diameter and above

As per the concerns and comments received from the panel additional points are discussed and following outcome from the same are obtained

- The information about using of CFD modelling is not needed to be stated in the certificate.
- Paragraph 3.2.5 regarding the clear area through an air pipe closing device in the open position to be retained.

Based on the discussions following is summarized

- Mesh convergence studies are to be carried out and documented.
- Exclusive mention of carrying out CFD simulations as an alternative means of reverse flow test 'in case of inability of physical tests' is considered not necessary in UR text.
- Para 3.2.5 is qualified to be retained as a general requirement

5 Other Resolutions Changes:

None

6 Any hinderance to MASS, including any other new technologies:

None

7 Dates:

Original Proposal:	13 August 2018 (Made by Machinery Panel)
Panel Approval:	29 March 2021 (Ref: 19039_PMb)
GPG Approval:	13 April 2021 (Ref: 19039_IGb)

- **Rev.4 (Jan 2016)**

.1 Origin of Change:

☑ Suggestion by an IACS member

.2 Main Reason for Change:

This revision of UR P3 is done to clarify the definition of the term "chambers" in UR P3.2.9 for its uniform application as per the agreed IACS common understanding, more specifically whether the side covers of air pipe head is also part of chamber to be of minimum thickness of 6 mm.

3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

Agreed Form A was submitted to GPG by 15132_PMa dated 31 July 2015.

.5 Other Resolutions Changes

None

.6 Dates:

Original Proposal: 8 April 2015 Made by a Member
Panel Approval: 22nd Panel Meeting
GPG Approval: 22 January 2016 (Ref: 15132_IGe)

- **Rev.3 (Nov 2012)**

.1 Origin of Change:

☑ Suggestion by an IACS member

.2 Main Reason for Change:

To clarify the type-test method of P3 for tightness test and to evaluate tests to prove the ability to handle vacuum and criteria for the relationship area requirement and flow characteristics.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

Form A was agreed in May 2011.

.5 Other Resolutions Changes

None

.6 Dates:

Original Proposal: *10 March 2011 Made by a Member*
Panel Approval: *24 September 2012*
GPG Approval: *02 November 2012 (Ref: 11068_IGd)*

- **Rev.2 (March 2004)**

The review by AHG/FDG of BEA/mer technical report on air vent arrangements recommended amending the UR P3.

All recommendations arising from AHG/FDF review were accepted by the WP and introduced into the draft revision.

Original Proposal was made on 12 February 2004 and GPG Approval was given on 04 March 2004 (GPG subject No: 3003cIGb).

See separate TB document in Part B Annex 2.

- **Corr.1 (April 2002)**

A member suggested editorial refinements to the UR P3 on 29 April 2002 and done on 30 April 2002.

No TB document available.

- **Rev.1 (May 2001)**

AHG/PPV submitted proposed revision replacing the existing P3 to GPG 50 (0077a, 18/1/2001).

Review of UR P1.2, P2.1, P2.2, P2.3, P2.5, and P3 has been carried out in line with annual Task 1A. The main goal of this review was elimination of IACS member reservation. As has been noted that: "P1 & P2 have not been implemented since the Rules are formatted around US standards such as ANSI, ASME, USC Regulations, etc. P 1 & P2 are not conductive (sic) to incorporate in the Rules". With regard to P3, it needed to be changed editorially.

Members unanimously agreed to the revision.

See separate TB document in Part B Annex 1.

- **Corr.1 (May 1998)**

P.3.2.1 contained editorial error i.e. inclination of ±40 deg. C, which should read ±40 degrees. The error was corrected

No TB document available.

- **New (1991)**

No HF file or TB document available.

****

Part B. Technical Background

List of Technical Background (TB) documents for UR P3:

Annex 1. **TB for Rev.1 (May 2001)**

See separate TB document in Annex 1.

Annex 2. **TB for Rev.2 (Mar 2004)**

See separate TB document in Annex 2.

Annex 3. **TB for Rev.3 (Nov 2012)**

See separate TB document in Annex 3.

Annex 4. **TB for Rev.4 (Jan 2016)**

TB submitted on 6 Feb 2001 by AHG/PPV Chairman

P 3 (Rev.1)
Technical Background Documents

1. Review of UR P1 – *P3*

• <u>Objective and Scope</u>

Review of UR P1.2, P2.1, P2.2, P2.3, P2.5, and P3 has been carried out in line with annual Task 1A. The main goal of this review was elimination of a Member's reservation. As has been noted by the Member: "P1 & P2 have not been implemented since the Rules are formatted around US standards such as ANSI, ASME, USC Regulations, etc. P 1 & P2 are not conductive (sic) to incorporate in the Rules". With regard **to P3,** it needed to be changed editorially.

Member's additional comments relative to the UR P:

P 1.2.7:
• Do not regard 14 bar as design pressure, otherwise, strainers, filters, heaters will have to be designed for 14 bar which may not be practicable. Also the testing pressure for these components will need to 1.5 the design pressure which may be a contentious issue. Accordingly the Member proposed that the 14 bar pressure should be considered as a special safeguard for the joints (see MSC Circ 647 & 851).
• Working Group needed to discuss and determine whether the 14 bar pressure was applicable to valves also. Further, the Member has been informed by their office in the Pacific that pressure rating of JIS f 7399-1989 "Marine Fuel oil Tank Emergency Shut-off valves", commonly used in that region, states that "Maximum working pressure shall be 0.098 MPa [1kg/cm2], although hydraulic inspection for body will be 0.686 MPa. Accordingly, it would not be possible to apply the 14 bar pressure to the suction side of the pump.

P 2.2 Table (1):
• There was a need to define what constitutes "special safeguard". A Member's observation of other Member societies Rules indicated that there were no provisions made for application of this in the design, construction or operational matters.
• Member requested the WG to develop a list of provisions which may be considered "special safeguards" for various systems conveying flammable, toxic or corrosive media.
• The reference to toxic and corrosive fluids may be out of place, as such systems were invariably cargo systems, which were outside the scope of P2. Accordingly considerations should be given to deleting this.

<u>• Source of Proposed Requirements</u>

A Member's proposals on correction the UR P1, P2 and **P3** circulated by e- mail dated 13 September 2000 has been used as a basis document for revision.

<u>• Points of discussion</u>

Unanimous agreement has been achieved.

Technical Background document for the revision of UR P3

1. Scope and Objective

The review by AHG/FDF of BEA/mer technical report on air vent arrangements recommended to amend the UR P3.

2. Points of discussion

All recommendations arising from AHG/FDF review were accepted by the WP and introduced into the draft revision.

3. Source/derivation of proposed amendments

AHG/FDF Report to GPG as attached.

4. Decision

The draft was agreed by consensus. No Member requested any issue to be reflected in the TB.

KP 12/02/04

5. GPG

Approved by GPG 4 March 2004, 3003cIGb, as submitted.

IACS AHG/FDF
Report dated 27th May 2002 to IACS on:

Task 03: Review of the BEA/mer technical report on air vent arrangements

1. **IACS Directive**

Following discussion on the FRAMO system installed on the IEVOLI SUN, GPG decided to task AHG/FDF to review the recommendations contained in the BEA/mer technical report on air vent arrangements and advise GPG. (0233_Igc, 29 August 2001). No Form A.

2. **The BEA/mer Recommendations**

A free translation of the recommendations contained within the BEA/mer report "Technical note on vent arrangements in ballast tanks and other spaces", dated 7 may 2001 is as follows.

- IACS and classification societies should circulate a technical note about the problems identified on automatic vent arrangements, installation precautions, frequency of inspections, maintenance and replacement of elements subject to deterioration.
- Include the inspection of vent arrangements in the technical specification of the shipowner for repair works during ship stops.
- Frequency of inspections.
  Follow instructions assigned by manufacturers (it is recommended to make an inspection every two years and a complete replacement of the vent arrangement between 8 to 10 years).
- For new ships, take into account a better protection of the vent arrangements against green seas at the time of their installation on board.
- Improve the means of protection against corrosion (treatment, coating) and ensure proper preparation of sampling.
- Improve the seal between the vent arrangement and seat (appropriate floating ball / joint coupling) and smooth the seating arrangements of the ball.
- Improve the design to facilitate inspection and maintenance of the parts mostly exposed to corrosion (the connecting pipe inside of the casing and the air vent pipe, which should be as short as possible).

It seems that some manufacturers have already taken into account some modifications.

3. **Review of the BEA/mer recommendations**

The seven recommendations listed above have been considered by AHG/FDF and are commented as below:

i) The first recommendation calls for IACS to circulate a technical note describing problems identified with automatic air pipe heads, installation, inspection and maintenance. Members of AHG/FDF reported that many types of problems had been found on survey, but that the most prevalent were those due to corrosion and/or lack of maintenance. Air pipe heads constructed from galvanised steel were considered to be more prone to problems caused by corrosion. It was therefore concluded that the most effective approach to combat these problems was through a defined survey regime. A draft UR Z[ ] for automatic air pipe heads is in development.

ii) Include the inspection of vent arrangements in the technical specification of the ship owner for repair works during ship stops.
This is interpreted to refer to the owners/managers repair specification for docking/dry docking. Deficiencies should be identified and reported, ISM paragraph 5.1.5 refers.

iii) Frequency of inspections.
AHG/FDF agreed that annual external inspections should continue as at present. In addition the draft UR Z[ ] is proposing requirements for the dismantling and survey of air pipe heads at each Special (Renewal) Survey. This is to provide for the internal inspection of air pipe heads, which for some types requires its removal from the air pipe.

iv) Better protection against green seas.
Members considered those proposals for strength requirements under Task 01 if extended to the remainder of the ship length could address this item.

v) Improve the means of protection against corrosion.
The meaning of 'ensure proper preparation for sampling' is not clear, but is interpreted as a reference to the quality control for the corrosion protection (e.g. galvanising).

As for the mechanism that may have caused the particular type of corrosion found in the air pipe head from the Ievoli Sun, AHG/FDF postulated the following.

During the ballasting of tanks, it is common practice to press the tanks up by filling until water is flowing through the air pipe heads onto the deck. This means that quite a high velocity of water is impacting on the lower part of the inner chamber for some types of head. As ballast is usually taken on in fairly shallow water it is quite likely to contain some sediment. The action of water containing particles of sand, earth, etc will then tend to erode the zinc coating particularly over the area where the flow up the pipe is diverted around the outer chamber. This is the area where heavy corrosion was found on the recovered air pipe head from the Ievoli Sun. Once the thin coating has worn through, the steel is locally exposed and corrosion commences.

AHG/FDF also found from results of surveys that corrosion can occur beneath the ball where this is normally resting on a galvanised steel surface. This may also be attributed to erosion. It is therefore recommended that a resting bar or bars or other device be introduced such as to prevent the ball from touching the inner chamber in its normal position.

AHG/FDF considered that zinc coating should be deposited on the air pipe head by the hot method, and should have a thickness of 70 – 100 microns.

For heads constructed from cast iron, a suitable epoxy or equivalent coating should be applied. For both types it was considered that a harder coating should be used in areas which could be susceptible to erosion when ballast water is pumped through.

AHG/FDF further considered that a minimum thickness of 6 mm should be specified for the inner and outer chambers of an automatic air pipe head.

vi) Improve the seal between the vent arrangement and seat.
Members considered UR P3.2.3 and P3.2.7 covered this.

vii) Improve the design to facilitate inspection and maintenance.
Members considered UR P3.2.2 covered this.

4. Recommendations for consideration into UR P3

AHG/FDF suggest that consideration be given to the following items for possible inclusion into UR P3:

i) provision of bars or cage or other device for preventing the ball or float from contacting the inner chamber in its normal state,

ii) for galvanised steel air pipe heads, the zinc coating to be applied by the hot method, and the thickness to be 70 to 100 microns.

iii) for areas of the head susceptible to erosion (e.g. those parts directly subjected to ballast water impact when the tank is being pressed up, for example the inner chamber area above the air pipe, plus an overlap of 10^{o} or more either side) an additional harder coating should be applied. This may be an aluminium bearing epoxy, or other equivalent, coating, applied over the zinc, and

iv) a minimum thickness of 6 mm for the inner and outer chambers of an automatic air pipe head.

Technical Background for UR P3 Rev.3, Nov 2012

1. Scope and objectives

To clarify the type-test method of P3 for tightness test and to evaluate tests to prove the ability to handle vacuum and criteria for the relationship area requirement and flow characteristics.

2. Engineering background for technical basis and rationale

2.1 With respect to the type tests of air pipe closing devices, the tightness tests for such devices, in principle, should be performed under strict conditions such as having the opening facing upward, etc. based upon design requirements.
Since the UR does not clarify any test method regarding the above, certain classification societies only require type test examinations to be carried out at an inclination of 40 degrees in a single fixed direction. However, performing the required testing for the device under such less restrictive conditions might influence the test outcome in a negative way.

Therefore, in order to carry out unified type tests for such devices under strict conditions, new specific type test conditions based upon the direction in which the opening of the device faces are needed as shown in Figure 1 to 4.

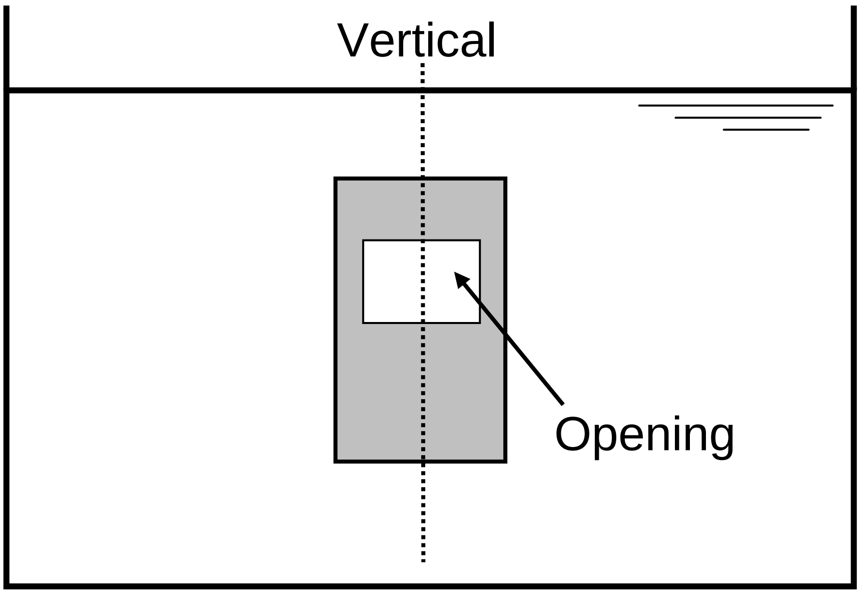

Fig 1: Normal position

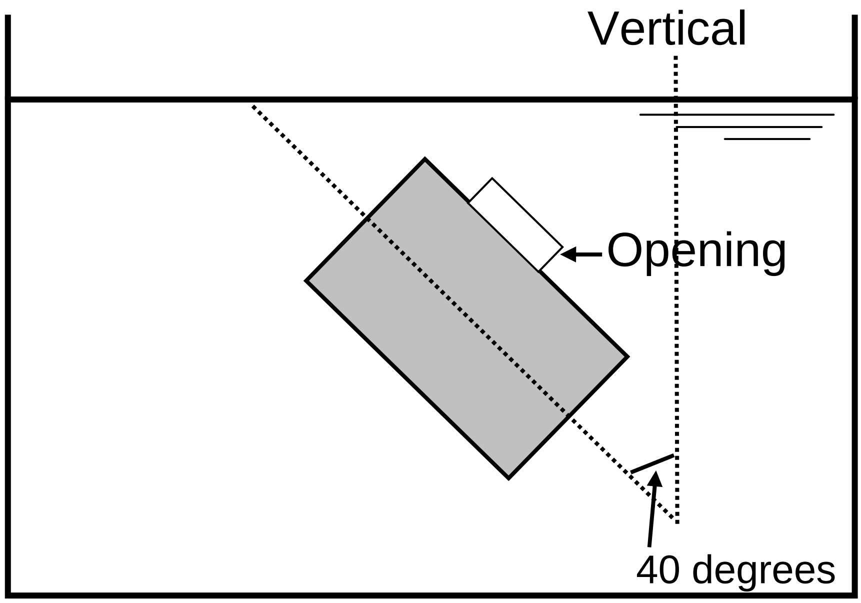

Fig 2: Inclination 40 degrees opening facing upward

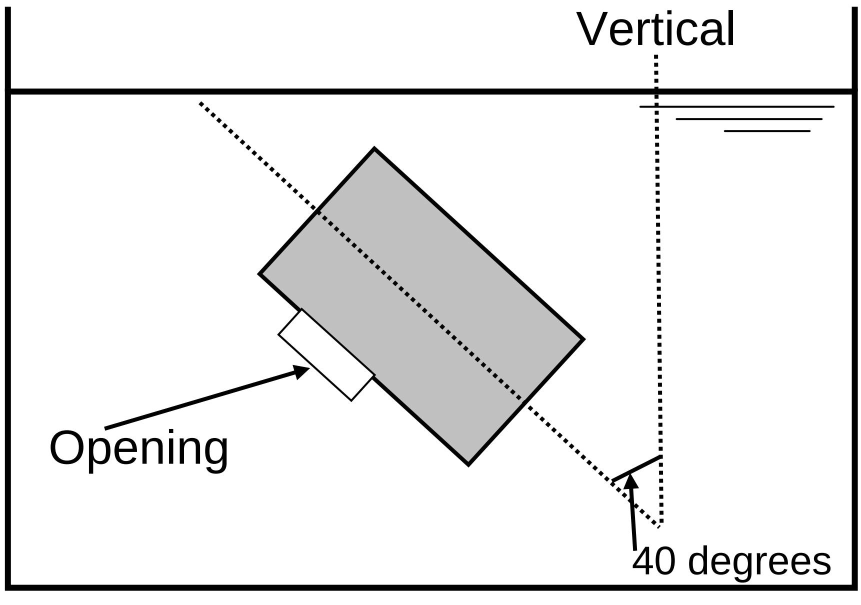

Fig 3: Inclination 40 degrees opening facing downward

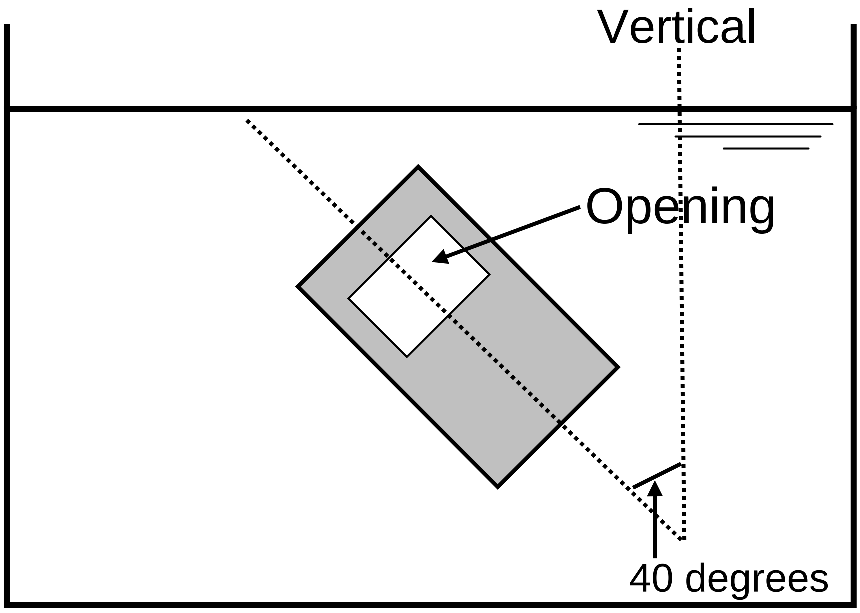

Fig 4: Inclination 40 degrees opening facing sideways

2.2 A problem exists in which the float of an air pipe closing device is sucked into the opening by the negative pressure in the tank. As a result, the float is blocking the flow of air resulting from the typical emptying of tanks and may become damaged under these conditions.

Therefore, a new test item related to reverse flow is needed.

These are reflected in the revision of P3.

3. Source/derivation of the proposed IACS Resolution

None

4. Summary of Changes intended for the revised Resolution:

The original requirement in UR P3 is to be amended by revising the original paragraph P3.4.1 b) iii) and adding a new paragraph P3.4.1 c) as follows:

Discharge / Reverse flow test is added
The air pipe shall allow the passage of air to prevent excessive vacuum developing in to the tank. A reverse flow test shall be performed. A vacuum pump or another suitable device shall be connected to the opening of the air pipe leading to the tank. The flow velocity shall be applied gradually at a constant rate until the float gets sucked into the inlet of the air pipe and blocks the flow. The velocity at the point of blocking shall be recorded. 80% of the value recorded will be stated in the certificate.

5. Points of discussions or possible discussions

All of the proposals were agreed to unanimously except for deleting P3.2.5, where several members argued that this general criterion which has been working well should be kept in order not to carry out the flow characteristic evaluation on each air pipe.

One member argued that as P3.2.5 does not take into consideration the effect of grids and the inner geometry of the vent head it was proposed to delete P3.2.5 and include the following under P3.5. Product documentation:
“Every vent head shall be delivered with the flow characteristic curve recorded during Type Testing (ref P3.4.1.a)”.
However, this was not supported by the majority of the members.

Technical Background (TB) document for UR P3 (Rev.4 Jan 2016)

1. Scope and objectives

This revision of UR P3 is done to clarify the definition of the term "chambers" in UR P3.2.9 for its uniform application as per the agreed IACS common understanding, more specifically whether the side covers of air pipe head is also part of chamber to be of minimum thickness of 6 mm.

2. Engineering background for technical basis and rationale

Keeping in mind that the understanding of "chambers" proposed by an IACS Member has received strong support from the Statutory Panel Member, it was decided to develop an IACS common understanding to clarify UR P3.2.9 based on Member's practical experience on application of UR P3.

The requirement in UR P3.2.9 "The inner and the outer chambers of an automatic air pipe head is to be of a minimum thickness of 6 mm" is provided to take into account any erosion caused by high velocity ballast water containing sediment flowing through the inner and outer chambers of automatic air pipe heads.
As per LL Convention Reg. 20(1), the point where water may have access below shall be at least 760 mm on the freeboard deck and 450 mm on the superstructure deck. The part of air pipe below this point shall be of substantial construction.
Therefore, as far as the mentioned covers are below the point where water may have access below and their function is integral to providing functions of the closing device, they shall be of substantial construction.

For this reason, there is a fear of such erosion occurring to side covers.

Furthermore, if the side cover is dented by a mechanical damage or wave, it may have a bad effect on the performance of an air pipe due to the reduction of total flow area; accordingly, it seems necessary that the side cover should be as strong as the housing and the minimum wall thickness of 6 mm should apply.

Therefore, in order to improve overall robustness of the air pipe head, if its function is integral to providing functions of the closing device, the side cover is considered as a part of chambers where the minimum wall thickness shall be not less than 6 mm.

This is reflected in the revision of P3.2.9.

3. Source/derivation of the proposed IACS Resolution

None.

4. Summary of Changes intended for the revised Resolution:

The original requirement in UR P3 is to be amended by revising the original paragraph P3.2.9 as follows:

P3.2.9 The inner and the outer chambers of an automatic air pipe head is to be of a minimum thickness of 6 mm. Where side covers are provided and their function is integral to providing functions of the closing device as outlined in P3.2.6, they shall have a minimum wall thickness of 6 mm.

5. Points of discussions or possible discussions

None.

6. Attachments if any

None.

Technical Background (TB) document for UR P3 (Rev.5 Apr 2021)

1. Scope and objectives

This revision of UR P3 is done to include CFD as an alternative method to carry out reverse flow test for very high flow velocity depending on the geometry of the valve as per the agreed IACS member society.

2. Engineering background for technical basis and rationale

As a feedback from industry in some cases reverse flow test at high speed are very difficult to conduct due the requirement of high capacity pumps. In accordance to this an alternative means utilizing CFD simulation to carry out reverse flow test is proposed.

In general, it is noted that in case of inability to carry reverse flow test for bigger size valves, the highest velocity observed during the actual test is noted for certification. Thus, a reasonably bigger size of 400mm and above is decided for the purpose of CFD simulation.

Following is to be adopted for such CFD simulations –

1. Any CFD solver of user choice is acceptable.

2. The flow velocity at which the float of the valve rises up and blocks the outflow is to be noted as the threshold velocity.

3. Mesh convergence is an essential step to be undertaken.

4. The mesh convergence studies with at least two mesh sizes are suggested to be carried out. The convergence to be checked for parameters like the pressure (or force) on float of the valve. The initial base mesh size can be equal to (nominal diameter of pipe/100) as a maximum. Further, this mesh can be refined keeping the mesh refinement ratio of ≥ 1.3. The results can be accepted if the difference in the converged values of the considered mesh sizes are less than or equal to ~5% (as a generalized CFD practice).

5. The result found (threshold velocity) can be compared with available experimental results of same size and type of valve for validation.

6. Post validation of the model developed for the simulation this methodology can be applied for higher size & type of valves and the obtained results can be accepted.

3. Source/derivation of the proposed IACS Resolution

Request from a member society

4. Summary of Changes intended for the revised Resolution:

1. The first paragraph of P3.4.1.c is divided into P3.4.1.c.i and P3.4.1.c. ii. Text of Rev 4 is retained in P3.4.1. c.i. New text is proposed in P3.4.1.c. ii to include the

proposal for CFD inclusion for reverse flow test. It defines the applicability of the numerical test as well as the validation technique to be undertaken for the test. The need for mesh convergence study for the accuracy of the simulation are also defined in the modification.

2. The second paragraph of P3.4.1.c is shifted to the end of P3.4.1.b

5. Points of discussions or possible discussions

The UR was reviewed and discussed within IACS Machinery Panel via email correspondence. Having not been able to find the technically valid rationale to delete Requirement 3.2.5, it was agreed that this Requirement should be retained in this revision and that Machinery Panel should continue the review of this Requirement in 2021.

At the stage of finalizing Rev.5, Machinery Panel confirmed that the intention of the existing requirement related to the limitation of the max. flow to 80% of the tested flow (to be recorded in the certificate) was to provide a safety margin and therefore decided that this should be applied in the case of numerical simulation testing based on computational fluid dynamics (CFD).

UR P4 "Production and Application of Plastic Piping Systems on Ships"

Summary

In Rev.8 of this Resolution, two points have been added to paragraph 4.6.7 of UR P4 as a result of the changes made in UI SC299.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev.8 (Sep 2024)	30 Sep. 2024	1 January 2026
Rev.7 (June 2022)	June 2022	1 July 2022
Rev.6 (Feb 2021)	15 February 2021	1 July 2022
Rev.5 (Dec 2018)	17 Dec. 2018	1 January 2020
Rev.4 (Dec 2008)	Dec. 2008	1 January 2010
Rev.3 (Feb 2005)	Feb. 2005	1 January 2007
Rev.2 (July 1999)	July 1999	Unknown
Rev.1 (May 1998)	May 1998	Unknown
Corr.1 (1997)	1997	Unknown
New (1996)	1996	Unknown

- **Rev.8 (Sep 2024)**

1 Origin of Change:

☑ Based on IMO Regulation (SDC 8/10/7, SDC 9/10/1) changes to UI SC299.

2 Main Reason for Change:

Safety Panel has been discussing the need for a (water)tightness test after a fire test of heat-sensitive bulkhead penetrations of passenger ships.

This resulted in submission of papers SDC 8/10/7 (ref.to S/N 20084c) and SDC 9/10/1 (ref. to IGb) to the IMO, the content of which was included in MSC.1/Circ.1362/Rev.2 (the unified interpretations of SOLAS II-1/13.2.3), subsequently approved by MSC 107. The result of which are the changes made in UI SC299.

The interpretation in UI SC299 does not refer specifically to plastic piping, but refers to "heat-sensitive piping", and requires hydrostatic testing to ensure watertight integrity after a fire test.

Considering plastic piping as heat-sensitive piping, it is suggested to add .4 in paragraph 4.6.7 of UR P4 and to align UR P4 with IMO Res. MSC.429(98)/Rev.2 and it's interpretation to SOLAS Chapter II-1, regulation 13.2.3. This change implies heat-sensitive piping materials to be successfully tested for watertightness after having undergone fire test.

3 Surveyability review of UR and Auditability review of PR

The draft revision 8 of the UR P4 has been reviewed by Survey Panel without comments.

- **Rev.7 (June 2022)**

1 Origin of Change:

☐ **Suggestion by IACS member**

2 Main Reason for Change:

To provide for clear specification of the specimen size and number to be used in fire endurance testing on flange connections in plastic piping systems relating to IMO Res. A.753.

To take this opportunity, references to IMO instruments have been slightly modified, taking into account the latest Format according to IACS Procedures Volume 1 (Rev.16).

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None

4 History of Decisions Made:

None

5 Other Resolutions Changes:

Panel Approval: 9 November 2020 (Ref: PM20906_IMf)
GPG Approval: 15 February 2021 (Ref: 20206bIGb)

- **Rev.6 (Feb 2021)**

1 Origin of Change:

☑ Other (Update to comply with the required format when industry standards are referred to)

2 Main Reason for Change:

There was a need to update this UR to comply with the following format when industry standards are referred to:

[Standard Designation], [version/revision, if applicable], [year of publication] (examples: API Spec 2F, 6th Edition, 1997; ISO 4624, 2002), where [version/revision, if applicable] and/or [year of publication] are decided by IACS and are not necessarily to be the current/latest version.

To take this opportunity, references to IMO instruments have been specified in the following format based upon confirmation of amendments up to the latest one:

In case where the number of amendments is large:

regulation/paragraph x.x.x of SOLAS Chapter X/MARPOL Annex X/the XXX Code, as amended by IMO resolutions up to MSC.xx(xx)/MEPC.xx(xx)

In case where the number of amendments is small:

regulation/paragraph x.x.x of SOLAS/MARPOL/the XXX Code, as amended by resolutions MSC/MEPC.xx(xx), (...) and MSC/MEPC.xx(xx)

Technical Background (TB) document for UR P4 (Rev.2 July 1999)

P4.3.3 Impact Resistance

Objective and Scope

- Review of UR P4.3.3 has been carried out in view of the test method stipulated by ASTM D2444 - 93 is not applicable in Classification Society practice.

Source of Proposed Requirements

- IMO Res. A 753 (18) "Guidelines for the application of plastic pipes on ships".

- ASTM D2444 - 93 "Standard test method for determination of the impact resistance of thermoplastic pipe and fittings by means of a tup (falling weight)".

- ASTM F 1173 - 95 "Standard specification for thermosetting resin fibreglass pipe and fittings to be used for marine application".

A unanimous agreement has been achieved.

Date of submission: 13 May 1999
By AHG/PPV Chairman

Technical Background (TB) document for UR P4 (Rev.3 Feb 2005)

1. Technical background for revision of P4.1. 4.2 and 4.5

In conjunction with the approval of polyethylene (PE), polypropylene (PP) and polybutylene(PB) plastic pipes it was realized that there appears to be a discrepancy between the requirements in UR P4.3.4 and common industrial practice.

These types plastic pipes are well established and have been widely used for many years, for service temperatures up to 80°C, in potable, sanitary and water heating systems in shore and marine applications. Many of the Member Societies have issued type approvals for these pipe types and services.

However, by the nature of PE, PP and PB materials these pipe types cannot comply with the requirements of UR P4.3.4. Actually, the heat distortion temperatures (HDT) of such pipe materials, as determined by ISO 75 A or equivalent, and specified in UR P4.3.4, would be much less than 80°C. Plastic pipe manufacturers commonly claim that the raw materials' heat distortion temperatures according to these standards are usually not even determined since they are not considered relevant in order to justify plastic pipes' long-term hydrostatic strength under relevant service temperatures. These HDT values would, at best, be indicative of plastic materials' short-term behaviour related to stiffness and relevant plastic pipe standards, as DIN 8077/ 8078, do not even refer to HDT.

Rather, the methods commonly used in this regard are specified in industry established, dedicated standards, as predominately ISO 9080 (Determination of long-term hydrostatic strength of thermoplastic materials in pipe form by extrapolation) or ISO 15874 (Plastic piping systems for hot and cold water installations, PP). Results of long term endurance tests, usually carried out in accordance with these standards, show that PE, PP or PB type plastic pipes could last for more than twenty years under specified pressure and temperature loads, while under the current UR P4.3.4 they would not even be acceptable.

2. Technical background for new UR P4.7 (Test Specification For Plastic Pipes)

1. Scope and objective

Development of Unified Requirements / Recommendation and Type Test Procedure for Plastic Pipes has been initiated by LR and supported by IXX AHG/PPV Meeting and GPG. The main goal of development was to unified test requirements and testing procedures of plastic pipes.

2. Points of discussion or possible discussion

Relevant provisions of IMO Res. A753(18), national and international standards have been discussed.

3. Source/derivation of proposed requirements

.1 IMO Res. A 753(18) Guidelines for the application of plastic pipes on ships.
.2 ISO 15493:2003 Plastic piping systems for industrial applications.

.3 ISO 75: 2004 Plastics. Determination of temperature of deflection under load.

.4 ISO 2507: 1995 Thermoplastic pipes and fittings. Vicat softening temperature.

.12 ASTM D 2412-02 Standard test method for determination of external loading characteristics of plastic pipe by parallel plate loading

.13 ASTM D 2444-99 Standard test method for determination of impact resistance of thermosetting pipe and fittings by means of a tup (falling weight)

.14 ASTM D 2992-01 Standard practice hydrostatic or pressure design basis for fiberglass (glass fiber reinforced thermosetting resin) pipe and fittings

.15 ASTM F 1173-95 Thermosetting resin fiberglass pipe and fittings to be used for marine application

Note: Refer to REC 86.

Notes by the Permanent Secretariat

Implementation Date

1.1 P4.2.3

Members agreed: The changes in P4.2.3 are being made to correct a problem, so Members will want to effect changes to their rules/procedures in line with P4.2.3 as quickly as possible. Therefore, a uniform application date is not needed.

1.2 P4.7

ABS proposed: P4.7 is new and should have a uniform application date agreed by Members so as to obviate problems were Members to try to start implementing P4.7 at different times and run into resistance. Therefore, we propose that the requirements of UR P4.7 be uniformly implemented by IACS Societies from 1 Jan 2007.

However, One Member disagreed and advised that:

It should not be compulsory for exiting type approved plastic pipes to be re-evaluated in accordance with P4 (Rev.3) not later than 1 Jan 2007. Member has already issued the type approval certificates for existing plastic pipes with 5 year validity (4069nNKb, 18/02/2005).

Finally, Members agreed to the following statement:

"The requirements of UR P4.7 are to be uniformly implemented by all IACS Societies to any new plastic pipe submitted for approval from 1 January 2007 and to any existing plastic pipe from the date of the first renewal of approval after 1 January 2007.

Technical Background (TB) document for UR P4 (Rev.4 Dec 2008)

Machinery Panel Task PM7302 - Revision of UR P4.5.4

1. Clause P4.3 of the UR P4 Rev.3 (February 2005), stipulates as follows:
"The specification of piping is to be in accordance with a recognised national or international standard acceptable to Classification Society. In addition, the following requirements apply:"

P4.3 then lists "additional requirements". These additional requirements are related to the application of pipes, rather than the manufacturing process of pipes itself. Therefore these additional requirements may not contradict that of selected national or international standards to which the pipes are manufactured.

2. Whereas P4.5.4 stipulates as follows:

"P4.5 Material approval and Quality Control During Manufacture

.4 Each pipe and fitting is to be tested by the manufacturer at a hydrostatic pressure not less than 1.5 times the normal pressure."

Contrary to the requirements of the P4.3, in many cases, the requirement of P4.5.4 (i.e., 100% hydrostatic pressure test at 1.5 times the rated pressure as a routine test) is not consistent with the selected national or international standard to which pipes are manufactured. The hydrostatic pressure test requirement of P4.5.4 is thought to be over and above the industry standards. However, the rationale for such an additional requirement is not apparent.

The following table shows the requirements of hydrostatic pressure test during manufacturing stipulated in five industry standards that the present study cited.

Standard	Manufacturing process	Test Requirements
ASTM D 1785 Standard specification for Poly(Vinyl Chloride) (PVC) Plastic Pipe, Schedule 40, 80 and 120	Continuously-extruded pipe	1. Prototype test: Sustained pressure test at 2.1 times the pipe pressure rating for 1000 hours, and Burst pressure test: 3.2 times the pipe pressure rating. 2. No routine hydrostatic pressure test requirement during production.
ASTM F 441/F 441M Standard specification for Chlorinated Poly(Vinyl Chloride) (CPVC) Plastic Pipe, Schedule 40 and 80	Continuously - extruded pipe	1. Prototype test: Sustained pressure test at 2.1 times the pipe pressure rating for 1000 hours, and Burst pressure test: 3.2 times the pipe pressure rating. 2. No routine hydrostatic pressure test requirement during production.

Standard	Manufacturing process	Test Requirements
ASTM F 1412 Standard specification for Polyolefin Pipe and Fittings for Corrosive Waste Drainage Systems	Continuously-extruded pipe	1. As prototype test, randomly selected fused joints are to be tested to 50 psi for 5 minutes. No pressure test requirements for pipe itself. 2. No routine hydrostatic pressure test requirement during production.
ASTM F 1173 Standard specification for thermosetting Resin Fiberglass Pipe Systems to Be Used for Marine Applications	Filament wound and centrifugally cast	1. Burst test, one sample per 150 joints during production. 2. 5% of pipe joints to be tested to 1.5 times the rated pressure during production.
API 15LR Specification for Low Pressure Fiberglass Line Pipe and Fittings	Filament wound and centrifugally cast	1. As prototype test, long-term cyclic hydrostatic pressure test. 2. One sample per lot (5,000 feet) to be tested to 1.5 times the rated pressure during production.

While routine pressure testing is imposed on produced FRP pipes on a sampling basis, no routine pressure test is required for PVC or CPVC pipes.

3. The level of quality assurance and quality control in production is as follows. Typically, pipes and fittings are made automatically by computerized processes, including optical measurements on line and automatic rejection of products out of tolerance. Furthermore scheduled spot checks and additional mechanical tests are made manually several times per shift to control the process itself. Typically these pipes and fittings are designed for at least a short term hydrostatic failure pressure at 4 times the MAWP, and a long term hydrostatic failure pressure at 2.5 times the MAWP.

It should be noted that the production processes based on continuous extrusion (as in PVC and CPVC pipes) and those based on centrifugal casting with wound filament (as in FRP pipe) are very different. It is thought that the difference in the testing requirements for these two manufacturing processes is simply reflecting the fact that the chance of quality failure of continuously extruded PVC or CPVC pipes is remote, and also the fact that the 100% hydrostatic test on every produced pipe, even FRP pipes, may not be warranted.

From the historically satisfactory testing results that are reported, it seems that 100% hydrostatic pressure testing at the factory on every pipe produced is not necessary.

4. Note that IMO Resolution A.753(18) “Guidelines for the application of plastic pipes on Ships” has a similar requirement to that currently in IACS UR P4. Clause 3.5 of this resolution however reads as follows:

“Each length of pipe should be tested at the manufacturer’s production facility to a hydrostatic pressure not less than 1.5 times the rated pressure of the pipe. Other test criteria may be accepted by the Administration.”

It seems that the last sentence “Other test criteria may be accepted by the Administration” is echoing the view expressed in 2 and 3 above.

5. In conclusion, IACS Members have agreed that when plastic pipes are designed and manufactured to recognized industry standards acceptable to the Society, the requirement of 100% hydrostatic test for every produced pipe as per the UR P4.5.4 may not be necessary, accordingly the following wording has been added at the end of the clause P4.5.4:
“Alternatively, for pipes and fittings not employing hand lay up techniques, the hydrostatic pressure test may be carried out in accordance with the hydrostatic testing requirements stipulated in the recognized national or international standard to which the pipe or fittings are manufactured, provided that there is an effective quality system in place.”41

Submitted by Machinery Panel Chairman
1 December 2008

Permanent Secretariat note (January 2009):
Rev.4 of UR P4 was approved by GPG on 22 December 2008 with an implementation date of 1 January 2010 (ref. 7761_IGc).

Technical Background (TB) document for UR P4 (Rev.5 Dec 2018)

1. Scope and objectives

Task PM15907a was initiated in continuation to PM15907 (pertaining to a query from a plastic pipe manufacturer on collapse pressure of P4.3.1.4, Rev.4) considering the IMO amendments to Res. A.753(18) together with member suggestions for clarifications of ambiguously worded text and addition of exhaust emission abatement piping systems in the fire endurance matrix.

2. Engineering background for technical basis and rationale

a. The previous editions of the UR were based on sections of the IMO Guidelines for the application of plastic pipes on ships (Res. A.753(18)). IMO amended Res.A.753(18) by Res. MSC.313(88) to introduce two (2) additional fire endurance test levels (L1W and L2W), and by Res. MSC.399(95) to take into account technological developments and the 2010 FTP Code requirements. Therefore a revision of the UR was needed so that the UR does not lag behind the IMO publications.

b. The Panel received a query by a plastic pipe manufacturer about the extent of application of the requirements in UR P4.3.1.4, Rev.4 (Machinery Panel Task no. PM15907). It appears that the aforementioned paragraph of the UR can be read as a standalone requirement, while IMO Res.A.753(18), as amended, considers collapse test pressure only under “External pressure” (2.1.3 of the Annex to the Resolution), specifying in 2.1.3.1 that external pressure should be taken into account in the design of piping for any installation “which may be subject to vacuum conditions inside the pipe or a head of liquid acting on the outside of the pipe”. In addition, clause 2.1.3.2 of the Resolution (“Piping should be designed for a nominal external pressure"…) could be interpreted as “applicable to all piping systems" (according to the title of Article 2.1) and not only to those piping systems actually subjected to an external pressure.

c. Some parts of the UR appeared to be ambiguously worded, as for example P4.2.3 for plastic pipes of thermoplastic materials such as PE, PP, PB, and intended for non-essential services.

d. Technological developments in exhaust emission abatement systems allow the use of plastic pipes, accordingly the fire endurance matrix should also consider urea supply or exhaust gas cleaning effluent pipelines in connection with their location/routing.

3. Source/derivation of the proposed IACS Resolution

The text of the UR is derived from the background given in 2 above.

4. Summary of Changes intended for the revised Resolution:

UR P4 Rev.5	**Revisions**
Title	"Plastic Pipes" has been replaced by "Plastic Piping Systems".
P4.1.1	Paragraph has been revised per item 2 of the Annex to IMO Res. MSC.313(88).
P4.1.3	Definition of "joint" has been further clarified.
P4.2.1 & P4.2.2	Paragraphs have been revised per item 1 of the Annex to IMO Res. MSC.313(88).
P4.2.3	The applicable sections for pipes intended for non-essential systems have been clarified. The reference to thermoplastic materials PE, PP and PB has been removed.
Footnote (asterisk)	Reference to IMO Res. MSC.313(88) and MSC.399(95) has been added.
P4.3.1.3	Clarification for external pressure has been added. Previous paragraphs 4 and 5 have been incorporated in the section for external pressure.
P4.3.1.4 (new numbering)	New paragraph on wall thickness has been added.
P4.3.1.5 (new numbering)	Previous paragraph number P4.3.1.6 has been renumbered.
P4.3.4.1 & P4.3.4.2	"Distortion" reads now "Distortion/deflection"; ASTM D648 has been added as equivalent to ISO 75 method A.
P4.4.1.1, P4.4.1.2(i), P4.4.1.2(ii)	Reference to IMO Res. MSC.313(88) and MSC.399(95) has been added.
P4.4.1.2(i)	Paragraph has been revised per item 3 of the Annex to IMO Res. MSC.313(88).
P4.4.1.2(ii)	Paragraph has been revised per item 4 of the Annex to IMO Res. MSC.313(88).
P4.4.1.4	New paragraph on safe return to port has been added.
Table 1 Fire Endurance Requirements Matrix	- L1 has been replaced by L1W in rows 14, 15 and 23 per item 8 of the Annex to IMO Res. MSC.313(88); - L2 has been replaced by L2W in rows 16, 17 and 31 per item 8 of the Annex to IMO Res. MSC.313(88); - Row no. 32 has been added per item 24 of the Annex to IMO Res. MSC.399(95); - New rows no. 33 and 34 have been added to address exhaust gas cleaning system effluent line and urea supply system; - Abbreviations and Footnotes 1-10 have been revised for alignment with the Annex to IMO Res. MSC.313(88) and MARPOL Regulation numbering; - New Footnotes 11, 12 and 13 have been added; - Location definitions have been revised as regards SOLAS regulation numbering.

P4.4.2.1 & P4.4.2.2	The paragraphs have been revised per items 8, 9, 11 and 12 of the Annex to IMO Res. MSC.399(95)
P4.4.2.3	A criterion for ASTM D635 has been added together with a reference to national standards.
P4.5.1	A clarification for exception as required in P4.2.3 has been added.
P4.6.1.1	The paragraph has been revised per item 5 of the Annex to IMO Res. MSC.313(88).
P4.6.3.2	The reference to Classification society has been removed.
P4.6.7.1	The paragraph has been revised to refer to the 2010 FTP Code.
P4.6.7.2	Clarification for a metallic shut-off valve has been added.
P4.7.1	The paragraph has been revised per item 1 of the Annex to IMO Res. MSC.313(88).
P4.7.2.III	New row 7 has been added; Title has been revised by the addition of "as applicable".
P4.7.3	Footnote has been revised to refer to amendments to Res. A.753(18).

5. Points of discussions or possible discussions

- A query was sent to IACS by a plastic pipe manufacturer stating that paragraph P4.3.1.4 (Rev.4) "in no case is the collapse pressure to be less than 3 bar" is interpreted differently by class societies in connection with IMO Res. A.753(18). In particular, same maker asked IACS opinion whether plastic pipes of a scrubber system need to meet P4.3.1.4. Due to split views between member societies, IACS advised the maker that the matter is under study and will advise on its conclusions. Furthermore, the reply stated that "Unified Requirements (UR) are minimum technical requirements adopted by IACS which, subject to ratification by the governing body of each IACS Member, are to be incorporated in their Rules and practices. URs set forth minimum requirements; each IACS Member remains free to set more stringent requirements or express a reservation if it cannot agree to a UR or parts thereof. UR P4 (Rev.4) is applied by IACS Societies ever since its implementation from 1 January 2010".

- During the discussion within the Panel (PM15907) on whether the collapse pressure applies to all pipes or only to those under external pressure, it was agreed to remove the paragraph numbering in P4.3.1.4 so that that the requirement in the UR falls under the section "external pressure"; however in order to cover piping systems other than those that are normally subject to external pressure, the requirement has been extended to all pipe installations which are to remain operational in case of flooding damage or pipes that would allow progressive flooding to other compartments through damaged piping or through open ended pipes in the compartment (P4.3.1.3ii).

- Apparently a standard specifying a minimum wall thickness of plastic pipes is not available contrasting with steel pipes which have a minimum wall thickness. It would appear in this regard that pipes that are not subject to vacuum or external pressure may have a wall thickness and fibre reinforcement suitable for internal pressure only. In this regard a new paragraph has been added clarifying that in the absence of standards for pipes not subject to external pressure, the requirements of P4.3.1.3ii apply.

- A member society suggested that applications in temperatures below -25deg.C should be also addressed. The suggestion was not followed based on the understanding that low temperature applications may be considered on a case-by-case basis.

- According to a member society N/A in the fire endurance matrix needs further clarification; it was clarified in this regard that N/A is not to be interpreted as "0" or "X".

- A suggestion to add a reference to the "operating temperature" to P4.1.6 was not finally followed based on the understanding that "under operating conditions" covers the specific suggestion.

- The 60mm/min maximum flame spread criteria in P4.4.2.3 when using the procedure of ASTM D635 has been agreed based on the already agreed EU RO Mutual Recognition Technical Requirements.

- The urea piping requirement and associated footnote 12 was introduced based on discussions within the panel on UR M77.2.8 and Panel decision (PM16912). Furthermore, at a member's suggestion, a new row for Exhaust Gas Cleaning System effluent line has been inserted in the Fire Endurance Matrix with associated footnotes.

- With regard to P4.2.3 (Rev.4), there seem no reason for limiting the paragraph to thermoplastic materials, therefore the reference to materials such as polyethylene(PE), polypropylene(PP), polybutylene(PB) has been deleted.

- The previous wording of P4.2.3 in conjunction with P4.5.1 raised questions on the applicability of sections for plastic pipes for non-essential services. In this regard the specific sections that apply for such pipes have been clarified in the revised P4.2.3.

- A new suggested paragraph addressing safe return to port purposes under P4.6.7 was agreed to be transferred under the Fire Endurance Matrix as Footnote 13.

- It has been agreed that the application statement follows the scheme discussed during the revision of UR E10, i.e. differentiating between application for type approval by a maker and installation on new ships (based on the contract for construction date).

- During the discussion, a member society suggested that "In case of specifying the requirement that clarifies requirements to be applied to non-essential plastic pipes (e.g.: pipes for drinking water, domestic water and sanitary water, etc.), which requirements are not clear whether to be applied to such pipes in UR P4 Rev.4 (especially, test for flame spread specified in P4.4.2), it may become difficult to use standardized products (e.g.: plastic pipe meets ISO standard) that have been used so far.". However, as a result of discussion, Machinery Panel member concluded that at least P4.3.1.3 (ii), P4.4.2, P4.5.2 to P4.5.7 and P4.6 are necessary for safety of non-essential plastic pipes and it should be clearly specified in P4.2.3.

- One Member Society asked Members agreement to their understanding that a valve which can be closed remotely, but cannot be opened remotely is acceptable as “remotely controlled valves” according to UR P4, Table1, Footnote 1; Panel Members advised of their agreement in general this understanding. A proposal for modification of UR P4, Table1, Footnote 1 according to this understanding was offered to Panel Members but after discussion the qualified majority agreed to keep the existing text “Where non-metallic piping is used, remotely controlled valves to be provided at ship’s side (valve is to be controlled from outside space)” in order to be aligned with the text used in Footnote 1 of Appendix 4 of Res. A.753(18) as amended.

6. Attachments if any

None

Technical Background (TB) document for UR P4 (Rev.6 Feb 2021)

1. Scope and objectives

UR P4 (Rev.5) does not reflect the agreed format for referencing the ISO and ASTM standards. Rev.6 has been developed to comply with the agreed format.

2. Engineering background for technical basis and rationale

A) Format for references to Industry standards

Format:
[Standard Designation], [version/revision, if applicable], [year of publication] (examples: API Spec 2F, 6th Edition, 1997; ISO 4624, 2002), where [version/revision, if applicable] and/or [year of publication] are decided by IACS and are not necessarily to be the current/latest version.

B1) Format for references to IMO instruments (where the number of amendments is large)

Format:
regulation/paragraph x.x.x of SOLAS Chapter X/MARPOL Annex X/the XXX Code, as amended by IMO resolutions up to MSC.xx(xx)/MEPC.xx(xx)

B2) Format for references to IMO instruments (where the number of amendments is small)

Format:
regulation/paragraph x.x.x of SOLAS/MARPOL/the XXX Code, as amended by resolutions MSC/MEPC.xx(xx), (...) and MSC/MEPC.xx(xx)

3. Source/derivation of the proposed IACS Resolution

None

4. Summary of Changes intended for the revised Resolution:

UR P4 has been updated to specify the revision/version of the ISO and ASTM standards as follows:

ISO and ASTM standards	Replaced by
ISO 75	ISO 75-2:2013
ASTM D648	ASTM D648-18
ASTM D635	ASTM D635-18

5. Points of discussions or possible discussions

None

6. Attachments if any

None

Technical Background (TB) document for UR P4 (Rev.7 June 2022)

1. Scope and objectives

Task PM20303a was initiated by member suggestions for clarifications of ambiguously worded text regarding fire endurance test on flange connections with respect to considering joints as well as number, type and dimensions of specimen. In context of this review minor corrections were made.

2. Engineering background for technical basis and rationale

a. The section 4.4. "Requirements for Pipes/Piping Systems Depending on Service and/or Locations" of the UR appeared to be ambiguously worded compared to IMO Res. A.753(18), as amended by IMO Res. MSC.313(88) and IMO Res. MSC.399(95).

b. Existing fire endurance can be read that only pipes and their associated fittings needs to be tested. According to Appendix 1 of Res. A.753(18) test specimen "should be prepared with the joints and fittings intended for use". In order to better align UR P4 and Res. A.753(18) Paragraph 4.4.1.1 has been amended by introducing the term "joints", i.e. test consider pipe, fittings and joints.

c. Section 4.4. does not contain any specification regarding number and type of specimen to be tested. Likewise, the specifications in Res. A.753(18) are vague. In order to assure safety of plastic pipe system tests need to consider representative specimens, i.e. having lowest fire resistance. For pipes test conditions are most demanding for minimum wall thickness, respectively for minimum diameter for given t/D ratio. (Minimum diameter provides most unfavourable ratio between surface and internal volume, i.e. smallest cooling effect.)
For fittings most demanding test conditions 0 are for the specimens tee and/or reducer both with minimal wall thickness.

d. Section 4.4: for selection of pipe specimen two categories specified, i.e. pipes below 200 mm outer diameter and pipes with a diameter equal to or greater than 200 mm. The threshold of 200 mm was specified on typical t/D ratios that show relative constant values for pipes ≥ 200 mm (see Attachment 1). In order to avoid discussion on small variation in t/D ratio a tolerance band of ±10% was set.

e. Fittings were not considered because wall thickness of fittings is not lower than for pipes respectively joints.

f. The significance of fire endurance test shall not be impaired by unintentional cooling during the tests. Accordingly, test condition specification is amended to prohibit any replacement of fluid loss by fresh water or nitrogen.

g. It was clarified in Para. 4.6.10.1 that for pressure test after installation open ended pipes in essential services may be treated as pipes of non-essential services.

3. Source/derivation of the proposed IACS Resolution

The text of the UR is derived from the background given in 2 above.

4. Summary of Changes

UR P4 Rev.6	Revisions
4.1.8	UR amended by definition for “essential for the safety of ship”
4.1.8	Footnote specifying some piping systems essential for the safety of ship
4.1.9	UR amended by a definition for “essential services” referring to UI SC134 as used in Table 1.
4.2.2	Paragraph revised excluding mechanical joints approved for metallic systems, i.e. joints need to be tested for usage with plastic pipe
4.4.1.1	Paragraph amended by the term “joints”
4.4.1.2	New paragraph for specification of test specimens considering pipes, joints and fittings. Additional explanatory footnotes. Two categories for selection of pipe specimen.
4.4.1.2	Due to a comment made by a member on the fire endurance testing sizes of 46CFR141-3, the expression "Unless instructed otherwise by the Flag Administration" has been inserted
4.4.1.3	New paragraph for specification of test conditions regarding constant test pressure. Further, reference to Res. A.753(18) including amendments by IMO Resolutions MSC.313(88) and MSC.399(95)
	Previous Para. 4.4.1.2 to 4.4.1.4 renumbered accordingly
4.6.10.1	Amended so that open ended pipes in essential services need not to be pressure tested after installation

5. Points of discussions or possible discussions

- A member of the panel asked for the interpretation of UR P4.4 and subsequently the panel identified the need for revising this part in view of improve clarity.

- Specification of test specimen (type, dimensions respectively dimension ratio) including dimensions of specimen. Specimen dimensions leading to highest demands in testing.

Technical Background (TB) document for UR P4 (Rev.8 Sep 2024)

1. Scope and objectives

Task PM23931 was initiated by member suggestion for clarifications of (water)tightness test after a fire test of heat-sensitive bulkhead penetrations of passenger ships. The result of which are the changes made in UI SC299. In context of this review, minor corrections were made in UR P4.

2. Engineering background for technical basis and rationale

a. Safety Panel has been discussing the need for a (water)tightness test after a fire test of heat-sensitive bulkhead penetrations of passenger ships. This resulted in submission of papers SDC 8/10/7 (ref.to S/N 20084c) and SDC 9/10/1 (ref. to IGb) to the IMO, the content of which was included in MSC.1/Circ.1362/Rev.2 (the unified interpretations of SOLAS II-1/13.2.3), subsequently approved by MSC 107. The result of which are the changes made in UI SC299.

b. The interpretation in UI SC299 does not refer specifically to plastic piping, but refers to "heat-sensitive piping", and requires hydrostatic testing to ensure watertight integrity after a fire test.

c. Considering plastic piping as heat-sensitive piping, it is suggested to add .4 in paragraph 4.6.7 of UR P4 and to align UR P4 with IMO Res. MSC.429(98)/Rev.2 and its interpretation to SOLAS Chapter II-1, regulation 13.2.3. This change implies heat-sensitive piping materials to be successfully prototype tested for watertightness after having undergone fire test.

3. Source/derivation of the proposed IACS Resolution

The text of the UR is derived from the background given in 2 above.

4. Summary of Changes

UR P4 Rev.8	Revisions
4.6.7.4	A new paragraph .4 has been added to 4.6.7

5. Points of discussions or possible discussions

- A member of the panel asked for the interpretation of UR P4 due to the changes made to UI SC299 and subsequently the panel identified the need for revising this part in view of improve clarity.
- Considering plastic piping as heat-sensitive piping and requires hydrostatic testing to ensure watertight integrity after a fire test.
- After considering Member's comments, the word "prototype approved" has been changes to "prototype tested".
- One of the members comment about cable penetrations was made clear as the text in UI SC299 waives the requirement.

- The draft revision 8 of UR P4 document has been reviewed by Survey Panel without comments.

6. Attachments if any

None

TECHNICAL BACKGROUND DOCUMENT

UR P5 Ballast water systems. Requirements on ballast water exchange at sea.

1. Scope and objectives

Draft of UR on ballast water systems suitable for providing for the exchange of ballast water at sea has been developed in accordance with Task 62 and 69 of WP/MCH Work Programme.

Presented UR contains measures ensuring safe operation of ballast systems that used for BWE at sea. UR includes requirements to main components of ballast system such as piping, pumps, ballast tanks, sea chests and openings, as well as to control features.

2. Points of discussion

Focus of discussion was concentrate on evaluation of acceptable requirements to the sizes of air pipes and ballast water escapes from ballast tanks as well as on evaluation of capacity of pumping equipment. The draft was approved by Members unanimously and submitted to GPG.

GPG have returned the draft to WP to address concerns expressed by ABS and BV GPG Members. The WP carried out a review of the draft and accommodated these concerns. To assure ourselves of the completeness of the work, the draft was given to ABS and BV Members to liaise with their GPG Members for their comments. ABS accepted the draft with minor amendments. BV have not responded. With this status of agreements the WP approved the draft for submission to GPG.

In GPG discussion, BV proposed and GPG agreed an addition to para 3.1 *"……and /or emptying purposes."* A further proposed amendment *"The number of valves and the arrangement shall be suitable for the BWE method which will be applied."* was not agreed, being considered unsuitable for a UR.

Approved by GPG 16 April 2004, 8067_IGs (TB corr 13/05/04).

3. Source of proposed requirements

Reference is made to the following relevant documents:

Rules of the Classification Societies – IACS Members
IACS Hazard Identification (HAZID) of Ballast Water Exchange at Sea – Bulk Carrier.
IACS Requirements Concerning Mobile Offshore Units.
MEPC 42/11/1 Technical Analysis of the Dilution Method by the Experts on Ship Design, Safety and Environmental Aspects
MEPC 45/2/10 Evaluation of Safety Aspects in Relation to Ballast Water Exchange
MEPC 46/3/2 Draft Consolidated Text of International Convention for Control and Management of Ships, Ballast Water and Sediments.
MSC 74/WP.14 Design Suggestion for Ballast Water and Sediment Management Options.
IMO Res. A.868(20) Guidelines for the Control and Management of Ship's Ballast Water to Minimize the Transfer of Harmful Aquatic Organisms and Pathogens.
MEPC 49/INF.6 Harmful Aquatic Organisms in Ballast Water. Draft International Convention for the Control and Management of Ships Ballast Water and Sediments
MEPS/Circ.389 MSC/CIRC.1021 Design suggestion or ballast water and sediments management options in new ships
MEPS49/2/8 Guidelines for Ballast Water Exchange. Submitted by UK

TB for UR P5 Del (April 2011)

Machinery panel report to GPG70 states that:

PM5301 (4069f)

a) The 12th Machinery Panel Meeting agreed to close this task and establish a new task with the aim of developing a UI related to unclear items related to ballast water exchange at sea in the MO Resolution MEPC.124(53) Guidelines for Ballast Water Exchange (G6).

b) On IACS home page under Unified Requirement is stated:
"P5 (May 2004) Ballast water systems. Requirements on ballast water exchange at sea.
Withdrawn (Dec 2004), pending revision to take further account of operational matters."

Actions from GPG:

1. The Panel request that P5 is removed from the list of Unified Requirement
2. The Panel requests that task 4069f is closed.

GPG70 accepted the report from Machinery Panel during GPG70 and hence, approved UR P5 Del (April 2011)

UR P6 "SHELL TYPE EXHAUST GAS HEATED ECONOMIZERS THAT MAY BE ISOLATED FROM THE STEAM PLANT SYSTEM"

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev. 1 (June 2015)	09 June 2015	1 July 2016
New (May 2005)	May 2005	1 January 2007

• Rev.1 (June 2015)

1 Origin of Change:

☑ Suggestion by IACS member

2 Main Reason for Change:

- UR P6 was developed in response to a serious accident at a steam boiler which was mainly the result of several human mistakes; P6.3.2 to P6.3.4 seem to be trying to ensure that the valve operates even in case of poor maintenance.

  However, no sufficient experience is available on construction and installation of special design safety valves or bursting discs, and experience shows that the satisfactory operation of systems can be achieved only on the condition that proper maintenance is done and the equipment is operated by competent personnel.

- To reduce the reservations on IACS URs

3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

4 History of Decisions Made:

The issue was raised within the Machinery Panel. After hearing on the member's experience and requirements it was agreed to amend the IACS UI and associated HF and TB.

5 Other Resolutions Changes:

None

6 Dates:

Original Proposal: 19 March 2014 made by Machinery Panel (Form A submitted to GPG under 14159_PMa dated 13 Oct. 2014)
Panel Approval: 18 May 2015
GPG Approval: 09 June 2015 (Ref: 14159_IGb)

• New (May 2005)

See TB document in Part B.

Part B. Technical Background

List of Technical Background (TB) documents:

Annex 1. **TB for NEW (May 2005)**

See separate TB document in Annex 1.

Annex 2. **TB for Rev.1 (June 2015)**

See separate TB document in Annex 2.

Annex 1 Technical Background to UR P6 (New, May 2005)

SHELL TYPE EXHAUST GAS HEATED ECONOMIZERS THAT MAY BE ISOLATED FROM THE STEAM PLANT SYSTEM
WP/MCH Task 66

1. Background:
Following an incident involving a severe explosion on an exhaust gas heated economiser on the Island Princess, the UK MAIB issued a Report with recommendations to IACS, LRS, MCA and IMO.
1. Develop guidelines for the examination of crack defects in shell-to-flat-endplate and furnace-to-flat endplate welded joints in shell-type boilers, similar to the guidelines published by the Safety Assessment Federation Ltd. The guidelines should be submitted to ship owners associations and IMO.
2. Extend the scope of periodical surveys to cover examination for cracking in the region of circumferential weld joints between shell and flat-end plates.
3. Require classification surveyors and ship owners to report:

(i) Cases where shell boiler or economiser repairs are necessary because of cracking;
(ii) Cases where boiler or economiser safety valves are found to have seized.

The above should be submitted to IACS for the purpose of trend analysis and the identification of problem types.

4. Review procedures and frequency of testing of safety valves of fully flooded economisers.
5. Review the requirements for remote monitoring of economiser's pressure.
6. Encourage ship owners to develop a boiler installation portfolio.

2. Issues addressed by WP/MCH:
All classification societies were requested to review their records of similar installations
The following points were addressed in the development of requirements.
• The design and construction details with particular reference to the welding, heat treatment and inspection arrangements at the tube plate connection to shell.
• Design of safety relief devices for shell type exhaust gas heated economisers that can be isolated from the steam plant system and that be subject to the accumulation of solid matter in-way of the relief valves.
• Requirements for pressure indication.
• Requirements for removable lagging to enable ultrasonic examination of the tube plate to shell connection.
• Requirements for feed water arrangements to address pre-heating and deaeration.
• Requirements operating instructions covering feed water treatment and sampling periodic checks on the system.
• Classification survey requirements.
The draft unified requirements incorporate all these points.
(Ref:: The Survey Panel Task no.7 "Amend Z18 to consider surveys of Exhaust Gas Heated Economizers". Target date 4Q-2005. UK MAIB REC nos 1, 2 and 4(Island Princess) will be addressed)

(Submitted by WP/MCH, 2004)

Annex to TB.

GPG comments:

1. General

DNV, on 31 January 2005, invited GPG to further consider the draft UR P6, stating that operational aspects and/or consequences thereof seemed not to have been included in the original draft. DNV provided GPG with a modified draft. Following a considerable length of discussion, ABS provided a summary of GPG comments on 11 March 2005 as follows (4069jABi). Most of the ABS proposals was agreed.

4069jABi is copied hereunder:

"Quote"

1. P6.1 – CCe (25 Feb) and NKd (3 Mar) recommended that the practicability of applying UR P6 to shell economizers fitted on existing ships should be evaluated before its implementation. ABS agrees with this recommendation and requests other members' opinions. This statement has been placed in square brackets.

2. P6.1 – With the delays in finalizing this UR, ABS will now not be able to implement this UR from 1 January 2006. We suggest a new implementation date of 1 January 2007 (which will also allow for the practicability of application to existing ships, raised above, to be dealt with.)

3. P6.3.1 – There appears to be agreement with NVh (1 Mar) that one safety valve must be provided if the total heating surface is less than 50 m2 and two safety valves must be provided if the total heating surface is 50m2 or more. This should satisfy item 4 of CCe (25 Feb). ABS supports this proposal.

4. P6.3.2 – NKe (3 Mar) and LRj (7 Mar) added a requirement for the guide bush of safety valves, which was not supported by RIe (7 Mar). ABS agrees with RIe that such a requirement cannot be uniformly enforced and should be deleted. This statement is included in square brackets.

(GPG: deleted. However, an additional item was added to P6.7 "Procedures for maintenance and overhaul of safety valves)

5. a) P6.3.1 – CCe (25 Feb) further suggested that the two safety valves should not be installed in one chest. This was not supported by NKe (3 Mar) since the bursting disk would provide an additional level of protection. However, resolution of this item is dependent upon item (b) below. This statement is included in square brackets.

   b) P6.3.3 – CCe (25 Feb) contends that a bursting disk or alternative means is redundant if the economizer is fitted with two safety valves. ABS suggests a revision to apply P6.3.3 only for cases where a single safety valves is provided (i.e., total heating surface below 50 m2). This revision is shown in square brackets.

   c) If members agree that a bursting disk is only required when a single safety valve is fitted, then a case may be made for the suggestion in CCe that the safety valves should not be installed in one chest since there would be no bursting disk. If, however, members decide to require a bursting disk even when two safety valves are fitted, then the comments raised in NKe would be valid and the bursting disk would provide suitable protection, permitting the two safety valves to be fitted on the same chest.

d) ABS supports the idea that a bursting disk is not required if there are two safety valves. Accordingly, we recommend that the text in square brackets in P6.3.1 shown in attached file, should be deleted and that the text in square brackets at the beginning of P6.3.3 should be retained.

6. P6.3.3.2 – BVe (23 Feb) has advised that they do not consider a high pressure warning device to be an acceptable alternative to a bursting disk or additional safety valve. Further, RIe does not support the automatic reduction of engine load. The entire P6.3.3.2 is included in square brackets. ABS recommends that the entire P6.3.3.2 be deleted.

7. P6.3.8 - CCe (25 Feb) proposed new text concerning acceptance of exceptions, alterations or equivalence. ABS does not believe that this additional text can be uniformly applied. It has not been included in the draft UR.

ABS suggests that the Chairman invite members' positions on each of the points raised above with a view to finding for which items at least 2/3 majority support exists.

Regards,
S. R. McIntyre
ABS IACS GPG Member

“Unquote”

2. Council decided that:

- P6.1: Delete both options and task MCH Panel to evaluate the applicability of this UR to existing economizers(MCH Panel was so tasked);
- P6.3.3: Where no safety valves incorporating the features described in P6.3.2 are fitted, a bursting disc according to P6.3.3 is to be provided.

End

Technical Background to UR P6 (Rev.1, June 2015)

1. Scope and objectives

To revise the UR P6 by removing P6.3.2 and P6.3.3, due to:

- lack of availability or experience in using special design safety valves
- lack of experience in using bursting discs on steam boilers
- objection from members concerning the use of bursting discs

The application of the UR P6 (Rev. 0) is seen as problematic and reservations have arisen.

2. Engineering background for technical basis and rationale

No sufficient experience is available with the construction and installation of special design safety valves (bellows or shear pin) or bursting discs.

The UR seems to be trying to ensure that the valve operates even in case of poor maintenance, but experience shows that satisfactory operation of systems can be achieved only on the condition that proper maintenance is done and the equipment is operated by competent personnel.

3. Source/derivation of the proposed IACS Resolution

N/A

4. Summary of Changes intended for the revised Resolution:

- Deletion of P6.3.2 (requirement for special design safety valves)
- Deletion of P6.3.3 (requirement of bursting disc in way of special design safety valves)
- Replacement of “solid matter deposits” in P6.3.4 with “condensate”
  : It is considered that the primary function of the drain is to prevent a preload on the safety valve exerted by the static head of water in the steam exhaust pipe. The requirement for the drain itself is therefore to prevent the accumulation of condensate as opposed to preventing the build-up of solid matter deposits, which could be one cause of an accumulation of condensate. A separate requirement would be needed to prevent the accumulation of solid matter deposits through appropriate sizing of the drain.

IACS Unified Requirement S 1 (Rev.5 June 2001)

Requirements for Loading Conditions, Loading Manuals and Loading Instruments

Technical Backgrounds:

a) Objective/Scope

The objective was to eliminate Members' reservations:

b) Source of Proposed Requirements

WP/S was not able to find a way to accommodate Members' reservations in S 1 and invited GPG to consider the matter which was seen to be a policy issue.

c) Points of Discussion

- NK's reservation against S1.2.1 (NK did not consider that a loading instrument should be required for existing Chemical and Gas Carriers.

- ABS and others' reservation (ABS did not require a loading instrument for Category I ships less than 122 meters in length built before the last revision of UR S 1 was issued (Rev.4 1997).

In particular, S 1 (Rev.2, 1983) required loading instruments for certain categories of ships subject to ILLC 1966 regardless of length for which class request was received on or after 1 July 1984. However, Members' implementation of S 1 (Rev.2, 1983) was not in uniform.

- GPG decided that
  - to remove NK's reservation, the application length required for Category I ships shall be changed to "100 m in length" in S1.2.1.
  - to resolve Members' inconsistent implementation of the prior edition of S 1 (Rev.3, 1983), the following wording shall be added to the Note: "For ships constructed before 1 July 1988, the relevant revisions of this UR as well as Members reservations to those revisions of this UR apply.

Date: 15 May 2001,
Prepared by the Permanent Secretariat

Technical Background to changes proposed in respect of UR's S1A, Annex 2 to S1A, S12, S17, S18, S19, S20 and S22

The objective of the proposal is to reflect the IMO interpretation of 'single side skin construction' in the above mentioned Unified Requirements for bulk carriers. The Working Party on Strength discussions were unable to yield unanimous agreement and the following matters remain unresolved:

- The titles for UR's S17, S18, S19, S20 and S22 include the wording 'single side skin'. It was generally considered that this wording should now be deleted as the text clearly defines the scope of application and refers additionally to arrangements with double side skin construction. The GL Member does not support this view on the basis that the expression 'single side skin' appears in the text of SOLAS Chapter XII. In view of this difference, the wording 'single side skin' has been enclosed in square brackets pending further consideration by GPG.

- In order to clarify how the breadth of the side shell should be measured, the phrase 'between topside tank and hopper tank' has been used in S17.1(ii) and (iii), S18.1(ii) and (iii), S19.1(ii), S20.1(ii) and (iii), and S22(ii). This was not supported by the ABS member who considers that the IMO definition of single side skin construction does not necessarily refer only to the location between topside and hopper tanks. Also this was not supported by the CRS Member who considers that MSC 89(71), which identifies that measurements are to be made perpendicular to the side shell, provides sufficient guidance**.** For these reasons, the text has been enclosed in square brackets pending further consideration by GPG.

In addition to the above, two other issues have been raised as follows:

- The ABS Member has requested that the following be considered in respect of the deletion of reference to damage stability requirements from paragraph S17.1 of URS17. It is noted that the reference was originally included in order to cover a six months difference in implementation timetables between SOLAS and IACS. Although both implementation dates have now passed and the need for this provision is limited, there could still be cases where it is relevant due to a change of Class from a non-IACS Society to an IACS Society. It is, therefore, proposed that the present clause in URS17 be replaced by an alternative clause within a unified requirement more specifically related to stability requirements. Support for this proposal has been indicated by PRS, DNV, KR, RINA, CRS and LR.

- The GL Member has requested that consideration be given to amending URS20 and URS22 such that these requirements are only applicable when corrugated bulkheads are fitted. This matter has not received support from the other WP/S Members and is considered to be outside the scope of the present Task.

Submitted by WP/S Chair on 31 May 2000
(Note: For GPG action, refer to GPG Chair's message 0064dIGa, 31/7/00)

Technical Background to changes proposed with respect to UR S1A & S11

The objective of the attached proposals is to prohibit the practice of using partially filled ballast tanks, in design conditions, to control longitudinal strength. To accomplish this, it is proposed that appropriate changes be incorporated into the portion of UR S11.2.1.2 that describes items related to the load conditions that are considered in longitudinal strength calculations. This change also necessitates deletion of a conflicting reference in S1A.3c), which deals with partial filling of peak tanks.

The change was agreed unanimously and no unresolved issues remain.

Submitted by WP/S Chairman on 28 August 2001.

UR S2 "Definition of ship's length *L* and of block coefficient C_b"

Summary

The length definition has been aligned on the CSR BC & OT definition for avoiding discrepancies between IACS resolutions and CSR.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev.2 (June 2019)	27 June 2019	01 July 2020
Rev.1 (May 2010)	24 May 2010	-
NEW (1973)	*No record*	-

- ### Rev.2 (June 2019)

1 Origin for Change:

❒ Based on IACS Requirement *(Common Structural Rules for Bulk Carriers and Double Hull Oil Tankers)*

2 Main Reason for Change:

Alignment of the definition of the length L between IACS Common Structural Rules for Bulk Carriers and Double Hull Oil Tankers and the UR S resolutions.

3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

4 History of Decisions Made:

The review of UR S highlighted the need for harmonizing the length definition between the UR S requirement and the length definition in the CSR BC & OT.
The Hull Panel agreed unanimously to update this UR S2 during the HP29 meeting.

5 Other Resolutions Changes

None

6 Any hindrance to MASS, including any other new technologies:

None

7 Dates:

Original proposal: Sept 2018, made by Hull Panel
Panel approval: 11 June 2019 (Ref: 19093_PHb)
GPG Approval: 27 June 2019 (Ref: 19093_IGd)

- ## Rev.1 (May 2010)

.1 Origin for Change:

- ❒ Based on IACS Requirement *(Common Structural Rules for Bulk Carriers and Double Hull Oil Tankers)*

.2 Main Reason for Change:

Following the introduction of the IACS Common Structural Rules for Bulk Carriers and Double Hull Oil Tankers, Hull Panel were tasked to review all the UR S files to consider whether or not they are applicable to ships covered by the CSR.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None.

.4 History of Decisions Made:

- ❒ Based on IACS Requirement *(Common Structural Rules for Bulk Carriers and Double Hull Oil Tankers)*

.5 Main Reason for Change:

Following the introduction of the IACS Common Structural Rules for Bulk Carriers and Double Hull Oil Tankers, Hull Panel were tasked to review all the UR S files to consider whether or not they are applicable to ships covered by the CSR.

.6 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None.

.7 History of Decisions Made:

After review it was decided that for CSR ships the requirements of UR S2 are superseded by those of the Common Structural Rules and therefore do not apply.

.8 Other Resolutions Changes

All UR S files, except UR S8, S9, S15, S16, S19, S22, S23, S30 and S31.

.9 Dates:

Original proposal: *2007, made by Hull Panel Task 50*
Panel submission to GPG: *19 April 2010*
GPG Approval: *24 May 2010 (Ref. 10051_IGd)*

- **NEW (1973)**

No TB document available.

Part B. Technical Background

List of Technical Background (TB) documents for UR S2:

Annex 1. **TB for Rev.2 (June 2019)**

See separate TB document in Annex 1.

◄▼►

Note: *There are no separate Technical Background (TB) documents for the original resolution (1973) and Rev.1 (May 2010)*

Technical Background document for UR S2 (Rev.2 June 2019)

1. Scope and objectives

This revision intends to provide a definition of the Rule length and the block coefficient harmonised between the UR S resolutions and the CSR.

2. Engineering background for technical basis and rationale

The CSR definition of the Rule length is based on the scantling draught of the ship instead of the summer load waterline draught corresponding to the freeboard assigned to the ship.
The design draught is a scantling parameter well known at design stage while the summer load waterline draught could be selected at a later stage of the ship design. This summer load waterline draught could not be higher than the design draught, the draught corresponding to the geometric freeboard and the maximum draught complying with the stability requirements. This summer load waterline draught could result from an owner decision based on port fees to pay, could vary during the ship's life or could be different between sisterships.
The selection of length based on the scantling draught avoids those variations and consequently is more stable.
The Cb definition follows the Rule length definition as regard to the draught. The displacement, the moulded breath B and the draught correspond to the scantling draught Ts.

3. Source / derivation of the proposed IACS Resolution

Comparison of lengths resulting to the current and proposed definitions has been performed on ships of different sizes and types: Gas carrier, Chemical tanker, Passenger ship.

The figure 1 gives the length variation considering the scantling draught (Ts) of the summer freeboard draught (Tswl). The figure 2 shows the comparison between the following ratios:

$$L\ Ratio = \frac{L\ at\ Ts}{L\ at\ Tswl} \qquad Cb\ Ratio = \frac{Cb\ at\ Ts}{Cb\ at\ Tswl}$$

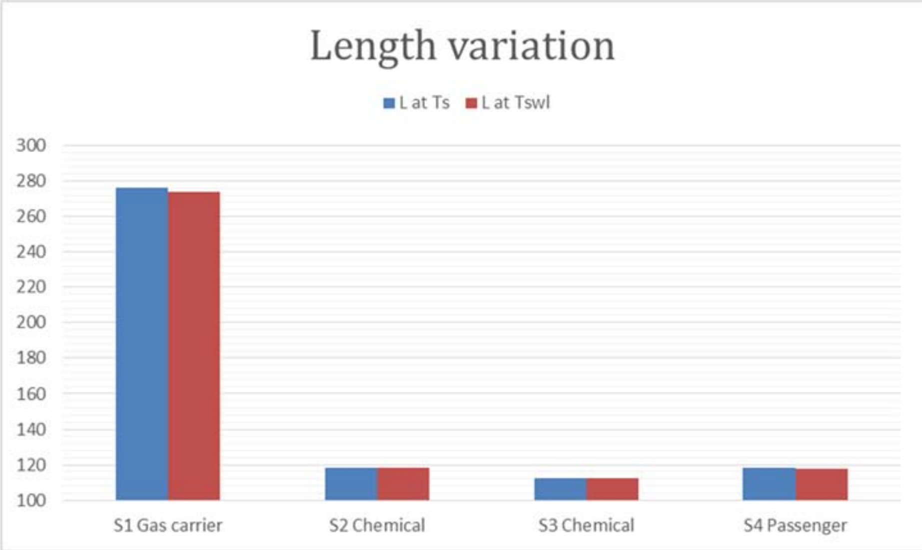

Figure 1

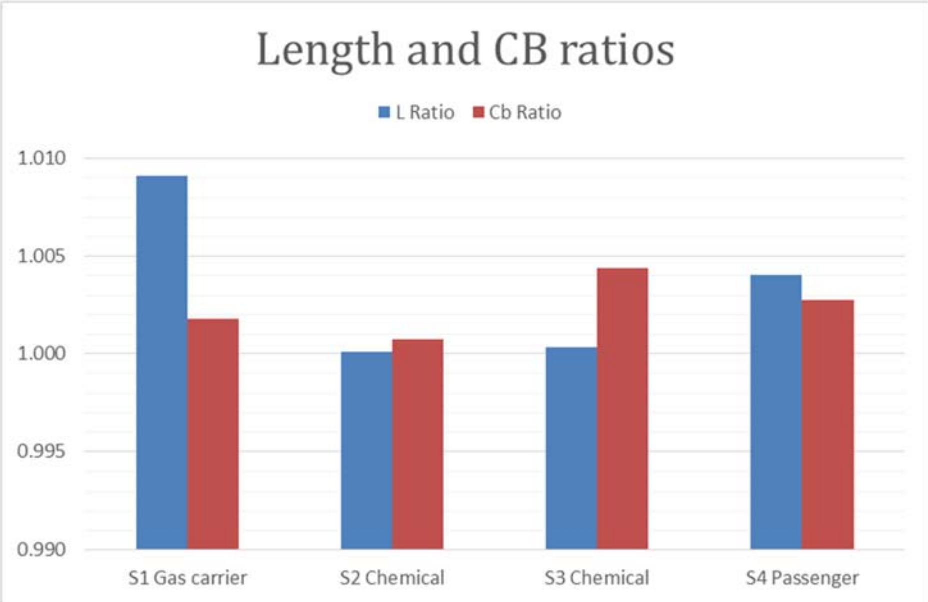

Figure 2

4. Summary of Changes intended for the revised Resolution:

Replacement of the draught at summer load waterline by scantling draught.
Addition of a method to evaluate the length for ships without rudderstock (e.g. ships fitted with azimuth thrusters).

5. Points of discussions or possible discussions

The Hull Panel agreed unanimously to update this UR S2 during the HP29 meeting and the data presented in this TB during the HP30 meeting.

6. Attachments if any

N/A

UR S3 "Strength of end bulkheads of superstructures and deckhouses"

Summary

The Revision 2 of UR S3 has been developed to consider the minimum thickness of plating for ships with L_1<65m stipulated in S3.4.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev.2 (June 2023)	26 June 2023	01 July 2024
Rev.1 (May 2010)	24 May 2010	-
NEW (1973)	*No record*	-

- **Rev.2 (June 2023)**

1 Origin for Change:

☑ Suggestion by IACS Members

2 Main Reason for Change:

IACS Hull Panel members had a discussion for application of IACS resolutions to small vessels. A small group of 3 members was formed within Hull Panel and they identified that the minimum thickness in S3.4 is too onerous to apply to small vessel. They developed the requirement for small ships.

3 List of non-IACS Member Classification Societies contributing or participating in IACS Working Group:

None

4 History of Decisions Made:

A small group within Hull Panel proposed to amend the requirements in S3.4 for ships with L_1<65m. HP members provided comments to elaborate the phrase of the requirement for more clarification and agreed the updated proposal.

5 Other Resolutions Changes

None

6 Any hinderance to MASS, including any other new technologies:

None

7 Dates:

Original proposal	: 25 April 2022	(Ref: PH18020_IHag)
Panel Approval	: 08 June 2023	(Ref: PH18020_IHaq)
GPG Approval	: 26 Jne 2023	(Ref: 22183cIGb)

- **Rev.1 (May 2010)**

.1 Origin for Change:

☑ Based on IACS Requirement *(Common Structural Rules for Bulk Carriers and Double Hull Oil Tankers)*

.2 Main Reason for Change:

Following the introduction of the IACS Common Structural Rules for Bulk Carriers and Double Hull Oil Tankers, Hull Panel were tasked to review all the UR S files to consider whether or not they are applicable to ships covered by the CSR.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None.

.4 History of Decisions Made:

After review it was decided that for CSR bulk carriers the requirements of UR S3 are superseded by those of the Common Structural Rules and therefore do not apply. However for CSR oil tankers the requirements of UR S3 are still valid.

Additionally the opportunity was taken to correct a couple of typos in the equations in S3.2.

.5 Other Resolutions Changes

All UR S files, except UR S8, S9, S15, S16, S19, S22, S23, S30 and S31.

.6 Dates:

Original proposal: *2007, made by Hull Panel Task 50*
Panel submission to GPG: *19 April 2010*
GPG Approval: *24 May 2010 (Ref. 10051_IGd)*

- **NEW (1973)**

No TB document available.

Part B. Technical Background

List of Technical Background (TB) documents for UR S3:

Note: *There are no separate Technical Background (TB) documents for the original resolution (1973), Rev.1 (May 2010) and Rev.2 (June 2023).*

UR S4 "Criteria for the use of high tensile steel with minimum yield stress of 315 N/mm^2, 355 N/mm^2 and 390 N/mm^2"

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev 4 (Apr 2017)	21 April 2017	-
Rev.3 (May 2010)	24 May 2010	-
Rev.2 (Apr 2007)	2 April 2007	-
Rev.1 (1974)	No record	-
New (1973)	No record	-

- **Rev.4 (Apr 2017)**

.1 Origin for Change:

☑ Based on GPG request 10158jIGo dated 20/12/2016 (GPG81 FUA13)

.2 Main Reason for Change:

IACS GPG requests to modify the UR S4 in view to remove the reservations made by 7 Members.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None.

.4 History of Decisions Made:

Based on a proposal made by a GPG Member, Hull Panel reviewed the text. Some modifications were made:

- I_{min} : The condition on I_{min} parameter is already covered by UR S11 (Rev 8, S11.3.1.2)
- L : This parameter was used in the I_{min} definition. This definition is no more needed.
- W_{min} : This parameter (defined in UR S7) was used in the I_{min} definition. This definition is no more needed.
- Replacement of Y: For consistency with other UR S, the Y parameter was replaced by R_{eH}.

.5 Other Resolutions Changes

None.

.6 Dates:

Original proposal: 2017 made by Hull Panel
Panel submission to GPG: 27 March 2017 (Ref: PH9008)
GPG Approval: 21 April 2017 (Ref: 10158jIGq)

- **Rev.3 (May 2010)**

.1 Origin for Change:

☑ Based on IACS Requirement *(Common Structural Rules for Bulk Carriers and Double Hull Oil Tankers)*

.2 Main Reason for Change:

Following the introduction of the IACS Common Structural Rules for Bulk Carriers and Double Hull Oil Tankers, Hull Panel were tasked to review all the UR S files to consider whether or not they are applicable to ships covered by the CSR.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None.

.4 History of Decisions Made:

After review it was decided that for CSR ships the requirements of UR S4 are superseded by those of the Common Structural Rules and therefore do not apply.

.5 Other Resolutions Changes

All UR S files, except UR S8, S9, S15, S16, S19, S22, S23, S30 and S31.

.6 Dates:

Original proposal: 2007, made by Hull Panel Task 50
Panel submission to GPG: 19 April 2010
GPG Approval: 24 May 2010 (Ref. 10051_IGd)

- **Rev.2 (Apr 2007)**

Addition of criteria for HTS with min yield Stress of 390N/mm^2 – see TB document in Part B.

See separate TB document in Annex 2.

◄▲►

Note: *There are no separate Technical Background (TB) documents for the original resolution (1973), Rev.1 (1974) and Rev.3 (May 2010).*

TECHNICAL BACKGROUND OF UR S4 (REV.2)

1. Scope and objective

To revise UR S4 to give criteria for high tensile steel with specified minimum yield stress of 390 N/mm^2

2. Background

Raised by NK in PH6018bNKa of 6 October 2006. Different values of the material factor "*k*" for high tensile steel with specified minimum yield stress of 390 N/mm^2 are used among IACS member societies, although one unified value has been implemented into the Common Structural Rules for Bulk Carriers and Double Hull Oil Tankers. To obtain a unified criterion for the use of such high tensile steel, it was agreed to revise UR S4 during the 5th Hull Panel meeting without any objection.

In addition, LR pointed out the inconsistency of terminology regarding 'Yield stress':

- URS4 uses the term ***Minimum Upper Yield Point*** ;
- CSR Oil Tankers uses the term ***Specified Minimum Yield Stress*** ; and
- CSR Bulk Carriers uses the term ***Minimum Yield Stress***.

3. Points of discussions

1. It is recognized that IACS member societies have used different values varied between 0,66 to 0,70 as a material factor "*k*" for high tensile steel with specified minimum yield stress of 390 N/mm^2 in the application of the hull girder bending strength standard specified in UR S11.3, which would be based on technical and experimental backgrounds of each societies.
2. On the other hand, it is unanimously agreed by all IACS member societies that the unified material factor of 0,68 should be used for such high tensile steel as specified in Ch.3 Sec.1 2.2.1 of the Common Structural Rules for Bulk Carriers and Sec.6/1.1.4 of the Common Structural Rules for Double Hull Tankers.
3. It is considered therefore that UR S4 should be revised for the uniform application of the hull girder bending strength standard and also being in line with the Common Structural Rules for Bulk Carriers and Double Hull Oil Tankers.
4. Regarding the consideration for the usage of such high tensile steel in other IACS URs, it is also agreed that the material factor of 0,68 is applied to the following URs which have already used the material factor "*k*". (Any amendment is not necessary.)
   - S7 : Minimum longitudinal strength standards
   - S8 : Bow doors and inner doors
   - S9 : Side shell doors and stern doors
   - S10 : Rudders, sole pieces and rudder horns (except for non-welded part as specified in S10.1.3.1 which uses material factor "K" (capitol letter))
   - S11 : Longitudinal strength standard
   - S12 : Side Structures in Single Side Skin Bulk Carriers (only for web height to thickness ratio and flange width to thickness ratio)
   - S31 : Renewal Criteria for Side Shell Frames and Brackets in Single Side Skin Bulk Carriers and Single Side Skin OBO Carriers not Built in accordance with UR S12 Rev.1 or subsequent revisions (only for web height to thickness ratio)

5. It is recognized that for other URs such as S18, S20, S21, etc., material characteristics for high-tensile steels are considered by using the yield stress of the material directly, and for future developed UR such consideration will be discussed separately from the agreed material factor.
6. The consideration for the local strength requirements in the usage of such high tensile steel, other than those specified in the above, still remains at each society's discretion.
7. For the terminology regarding "Yield stress", it is agreed that those in S4 are changed to "minimum yield stress" which is used in the most of URs concerning Strength of Ships (S) and Materials and Welding (W), including UR S11, temporally, those used in all URs of "S" Series should be reviewed and corrected if necessary, after the harmonization of CSR.

4. Amendment.

The Hull Panel agreed to revise UR S4 so as to implement new material factor *k* of 0,68 for high tensile steel with minimum yield stress of 390 N/mm^2.

5. Source/Derivation of proposed interpretation

N.A.

6. Decision by voting

N.A.

Submitted by Hull Panel Chairman
13 March 2007

<u>Permanent Secretariat Note (3 April 2007):</u>

During GPG discussion KR reminded GPG of a previous proposal to delete 'with respect to longitudinal strength' from the title of UR S4 and this was agreed.
UR S4 (Rev.2) was adopted on 2 April 2007 (6221_IGd).

Technical Background (TB) document for UR S4 (Rev.4 Apr 2017)

1. Scope and objectives

To revise UR S4 to remove reservation made by 7 IACS Members.

2. Engineering background for technical basis and rationale

GPG requests Hull Panel to review the UR S4 based on a GPG member proposal.

3. Source/derivation of the proposed IACS Resolution

None.

4. Summary of Changes intended for the revised Resolution

The Hull Panel agreed to revise UR S4 according to the text proposed for the Rev 4.

5. Points of discussions or possible discussions

The draft text was discussed during the HP26 meeting.

During the discussions, it was pointed that the conditions linking the application of k = 0.68 with the moment of Inertia at the midship section was not relevant. The sentence "provided that the moment of inertia of the midship section is not less than:" and the subsequent parameter definitions (I_{min}, L, W_{min}) were removed. The minimum inertia and the minimum section modulus conditions are respectively covered by UR S11 (Rev 8) and UR S7 (Rev 4) respectively.

For applying a consistency for the minimum yield strength, it was decided to replace Y with ReH which is used in other UR S.

Finally, LR confirmed they are satisfied with the wording relative to the fatigue assessment request for using a k value equal to 0.66, as this assessment is made according to the requirements of the Society.

6. Attachments if any

None.

UR S5 “Calculation of midship section moduli for conventional ship for ship's scantlings”

Summary

Editorial correction of a unit.

Rev.1 (1980)	No record	-
New (1978)	No record	-

- **Corr.2 (Nov 2021)**

.1 Origin of Change:

☑ Suggestion by HP-Chair

.2 Main Reason for Change:

A misspelling of 'sheer strake' in Table 4 has been corrected. Also, the footnote in Table 4 has been corrected so as to reflect the use of the correct grade for various strakes/plates ('stringer plate', 'sheer strake' and 'bilge strake') . The locations of 'stringer plate', 'sheer strake' and 'bilge strake' have been indicated in Figure 1.

.3 List of non-IACS Member Classification Societies contributing or participating in IACS Working Group:

None

.4 History of Decisions Made:

Correction was prepared by HP Chair and distributed to Hull Panel for Approval.

.5 Other Resolutions Changes

None

.6 Any hinderance to MASS, including any other new technologies:

None

.7 Dates:

Original proposal	: 04 October 2021 by Hull Panel
Panel Approval	: 20 October 2021 (Ref: PH21020_IHd)
GPG Approval	: 05 November 2021 (Ref: 21025_IGd)

- **Corr.1 (Mar 2021)**

.1 Origin of Change:

☑ Suggestion by HP-Chair

.2 Main Reason for Change:

The reference in description of Table 5 to SOLAS XII/6.5.3 needs to be updated based on changes in SOLAS via resolution MSC.216(82). In MSC.216/82) SOLAS XII/6.3 is deleted and the subsequent paragraphs renumbered so that the correct reference will become SOLAS XII/6.4.3.

.3 List of non-IACS Member Classification Societies contributing or participating in IACS Working Group:

None

.4 History of Decisions Made:

Correction was prepared by HP Chair and distributed to Hull Panel for Approval. To be more general, the reference is shortened to SOLAS XII/6.4

.5 Other Resolutions Changes

None

.6 Any hinderance to MASS, including any other new technologies:

None

.7 Dates:

Original proposal	: January 2021
Panel Approval	: 22 February 2021 (Ref: PH21003_IHb)
GPG Approval	: 10 March 2021 (Ref: 21025_IGb)

- **Rev.9 (July 2018)**

.1 Origin of Change:

☑ Suggestion by IACS Members

.2 Main Reason for Change:

This revision of UR S6 addresses two topics handled by the hull panel upon request from members.

UR S6.1 and 6.2 Limiting temperature:

The material requirements in CSR and UR S6.1 apply for design temperature down to -10ºC and low temperature requirements in S6.2 apply for design temperature below -20ºC. This leaves a gap with no clear requirements to material for ships having a design ambient temperature between -10ºC and -20ºC degrees. It was agreed to develop unified requirements to close to this gap. (Hull Panel ref PH16010)

UR S6.4 Cold Cargo for ships other than liquefied gas carriers:

CSR OT and CSR BC&OT includes an assumption about cargo temperature between 0ºC and 80ºC, ref. CSR Pt 1 Ch 1 Sec 1 [1.3.2]. In general bulk carriers and tankers are occasionally loading cargos with temperature below 0ºC, and it has been questioned if additional requirements should apply. The Hull Panel therefore agreed to develop unified requirements for cold cargoes for introduction in UR S6 (Hull Panel ref. PH14005) for ships other than liquefied gas carriers.

.3 List of non-IACS Member Classification Societies contributing through the TC Forum and/or participating in IACS Working Group:

None.

.4 History of Decisions Made:

This update address the identified gap in the requirements covering the temperature range between -10ºC and -20ºC.

In addition, material requirements are introduced for cargo tank boundaries on tanks designed for carriage of cold cargo.

The technical background for these changes is included in Annex 6.

.5 Other Resolutions Changes

None.

.6 Dates:

Original proposal: September 2017
Panel Approval: 13 June 2018 (Ref: PH14005)
GPG Approval: 06 July 2018 (18083_IGd)

- **Rev.8 (Dec 2015)**

.1 Origin for Change:

☑ Suggestion by IACS Member

.2 Main Reason for Change:

The Polar Code defines the Polar Service Temperature using lowest mean daily low temperature whereas the design temperature defined in UR S6 is based on the lowest mean daily average temperature. Hence the relationship between the design temperature in UR S6 and the Polar Service Temperature needs to be established.

In addition, a question was raised in the Hull Panel regarding the need to clarify which structures are exposed to low air temperatures when applying the material classes and grades given in Table 8.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None.

.4 History of Decisions Made:

PT61 carried out an investigation to determine the statistical difference between the lowest mean daily average temperature and the lowest mean daily low temperature. This was then related to the Polar Service Temperature which is to be taken as 10 degrees below the lowest mean daily low temperature. Hence, the design temperature is to be taken as being no greater than 13 degrees Celsius higher than the Polar Service Temperature.

Regarding internal structure exposed to low air temperatures, after discussion within the Hull Panel, it was decided that it is only necessary to consider the outermost stake of plating of internal structure connected with the hull envelope as being exposed to low air temperatures.

.5 Other Resolutions Changes

None

.6 Dates:

Original proposal: 21 August 2015, made by PT61 & Hull Panel Chairman
Panel submission to GPG: 23 November 2015 (Ref: PH15005)
GPG Approval: 11 December 2015 (Ref: 13180a)

- **Rev.7 (Apr 2013)**

.1 Origin for Change:

☑ Suggestion by IACS Member

.2 Main Reason for Change:

A question was raised in the Hull Panel regarding the applicability of Table 2 of UR S6 to Liquefied Natural Gas (LNG) Carriers.

See TB document in Part B.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None.

.4 History of Decisions Made:

After discussion within the Hull Panel, it was decided that Table 2 of UR S6 could lead to inconsistencies when applied to LNG Carriers. Therefore, a new Table was added to provide the minimum material grades for LNG Carriers and an addition was made to Table 1, item C5.1. In addition, Table 1, items B3 and C8 were clarified and editorial changes were made to the text in UR S6.1.

.5 Other Resolutions Changes

None

.6 Dates:

Original proposal: *23 October 2012, made by Hull Panel Chairman*
Panel submission to GPG: *25 January 2013*
GPG Approval: *18 April 2013 (Ref. 13039_IGe)*

- **Rev.6 (May 2010)**

.1 Origin for Change:

☑ Based on IACS Requirement *(Common Structural Rules for Bulk Carriers and Double Hull Oil Tankers)*

.2 Main Reason for Change:

Following the introduction of the IACS Common Structural Rules for Bulk Carriers and Double Hull Oil Tankers, Hull Panel were tasked to review all the UR S files to consider whether or not they are applicable to ships covered by the CSR.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None.

.4 History of Decisions Made:

After review it was decided that for CSR ships the requirements of UR S6 are superseded by those of the Common Structural Rules and therefore do not apply.

.5 Other Resolutions Changes

All UR S files, except UR S8, S9, S15, S16, S19, S22, S23, S30 and S31.

(UR S6, Rev.3, May 2002)
Technical Background to changes proposed with respect to Table 1 of UR S6

The objective of the attached proposal is to clarify the application of the Notes of Table 1 in UR S6, in order to avoid different interpretations on their application, in particular for what concerns the plating at corners of large hatch openings.

It is now clarified that "large hatch openings" are to be intended as the "cargo hatch openings" in the strength deck and the relevant requirements are now specified. A distinction is made between ships such as container carriers and bulk/ore carriers. For these latter, less stringent requirements may be applied in the region outside 0,6L amidships based on the fact that lower hull girder stresses occur in this area.

The application to continuous hatch coamings has been clarified by introducing a length criterium (0,15L, above which coamings are considered as being subjected to hull girder stresses). Requirements for the steel grades of end brackets and deck house transition of longitudinal cargo hatch coamings have been introduced, based on damage statistics results.

The change was agreed unanimously and no unresolved issues remain..

Submitted by WP/S Chairman
Date: 14 March 2002

Technical Background
S6.1 in Rev. 4 of UR S6

The objective of the attached proposal is to clarify that the minimum width requirement of single strakes (800 + 5*L mm, need not be greater than 1800 mm) applies to those strakes located at the four corners of the ship's cross section, plus deck strakes on top of longitudinal bulkheads.

In addition, the fact that ship's geometry may impose limitations to the width of the above strakes (e.g. in some containerships), is taken into account.

TECHNICAL BACKGROUND

UR S6, REV.5 (SEPT 2007)

IACS HULL PANEL TASK 17 - 'Review of UR S6 for side shell plating exposed to low temperatures'

1. Scope and objective

Consider requirements on selection of steel grades, with a view to preventing brittle fracture in the side shell plating of ships operating in areas with low air temperatures.

2. Background

Transportation Safety Board of Canada reports and correspondence with IACS concerning hull fractures in the 'Lake Carling' and its sister ship 'Ziemia Gornoslaska'. The TSB expressed concern over the current requirements of UR S6 for side shell plating which it did not consider adequate for ships operating near or below 0ºC.

3. Points of discussions/Analysis

3.1 General

The brittle fracture damage of MV 'Lake Carling' and analyses done in connection to this incident have been pointing at the following main issues:

- Application of material for side shell
- Material grade requirements for materials subjected to lower temperatures
- Stress level
- Consequence of brittle failure

3.2 Analysis

The issue of steel toughness requirements, or to be more accurate lack of measured steel toughness requirements for normal strength ship steel grade A ship steel, has been raised as a major issue within both IACS and IMO by the Transport Safety Board of Canada. They based there assumptions on the brittle fracture that occurred in 19 mm grade A plate of the side shell of MV 'Lake Carling' which initiated at a temperature of approximately 0°C (fracture initiated below the water line and is therefore assumed to be near 0°C, air temperature was minus 6°C).

Earlier, IACS WP/MW was asked to review the IACS testing requirements for normal strength ship steel grade A, which presently has no requirement for Charpy V-notch impact testing the steel mill. The working party reported back and quite rightly confirmed that there is no need to change the current test arrangements. It is more correct to consider changes to the requirements selecting the grade of material to be used, in this case IACS UR S6.

Lloyd's Register has recently taken the opportunity, with the kind permission of the Transport Safety Board of Canada, to carry out further tests on steel plate taken from the 'Lake Carling' and its sister ship the 'Ziemia Gornoslaska'; these have not been too encouraging, see the table shown below.

Steel Source	**Lake Carling**	**Z Gornoslaska**[1]
Charpy V-notch 27J transition temperature	L= +10°C T= +10°C	L= +20°C
Fracture appearance transition temperature FATT (50% Crystalline)	L= +10°C T= +15°C	L= +15°C
FATT (70% Crystalline)	L= -5°C	L= +5°C
Minimum CTOD (BS 7448) @ -19°C	0.01 mm	
Minimum CTOD (BS 7448) @ 0°C	0.25 mm	
Note 1, Z Gornoslaska is a sister ship to the Lake Carling.		

IACS UR S6.1 was developed based on world wide service using a lowest mean daily average temperature of -10°C. Areas of navigation to this temperature are given in statistical tables and charts such as the "Pilot" series of publications published by Hydrographer of the Navy or other authoritative reference, see Figure 1 as an example. This temperature for example, allows for navigation in the Northern Baltic and the St. Lawrence.

Therefore IACS UR S6, will allow the use of grade A steel as follows;

Class I, grade A up to 30 mm at temperatures down to -10°C
Class II, grade A up to 20 mm at temperatures down to -10°C and grade B up to 25 mm at temperatures down to -10°C
Class III, grade A up to 15 mm at temperatures down to -10°C and grade B up to 20 mm at temperatures down to -10°C.

This indicates that the current rule IACS UR S6 allows the use of non-impact tested steel in **greater** thicknesses and to a **lower** temperature than that involved in the Lake Carling incident. Thickness increase and lower temperature each increase the risk of brittle fracture.

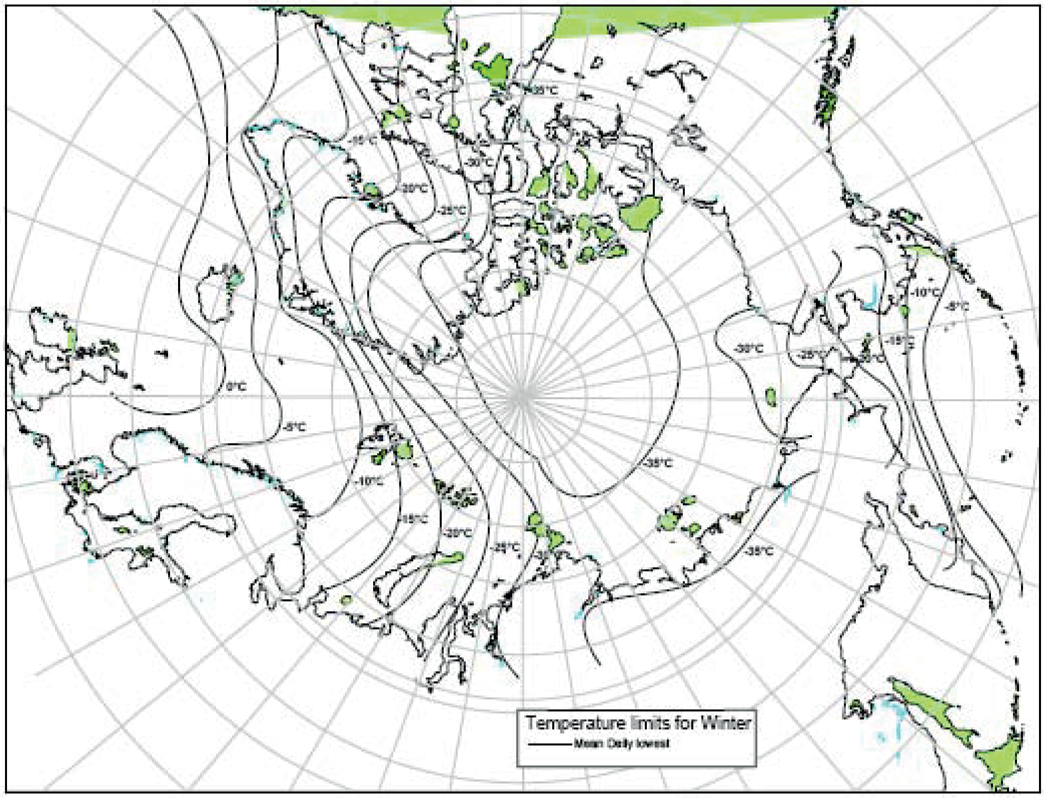

Chart based on temperature data points from Admiralty Pilot Books, published by HMSO

Figure 1 – Example of Navigation Chart based on Temperature

4. Proposed upgrading

In the proposed revision Table 1 is revised into Tables 1 to 5 for easier interpretation.

The following areas are upgraded to minimum grade B/AH regardless of Class:

a) For ships with length exceeding 150 m and with single strength deck and without inner continuous longitudinal bulkhead(s) between bottom and the strength deck, single side strakes in way of cargo hold:

- High shear stresses
- Serious consequences (flooding/reduced hull girder capacity) of brittle failure

b) Shell strakes in way of ice strengthening:

- High ice pressures and impacts from collision with ice resulting in high stresses, high strain rates and possible plastic deformation at temperatures close to (below or equal) 0º C.

c) For vessels with length exceeding 150 m and with single strength deck, within 0.4L amidships, for longitudinal strength members of strength deck plating and continuous longitudinal members above strength deck, excluding hatch coamings, as these members may be:

- Subjected to high hull girder tensile stresses
- Subjected to temperatures down to -10º C
- critical / brittle fracture may have serious consequences for the hull girder integrity

In addition is the new requirement for single side shell strakes and lower bracket in way of single side (D/DH) as given in CSR for bulk carriers also included.

"S6.1 Ships in normal world wide service

Materials in the various strength members are not to be of lower grade than those corresponding to the material classes and grades specified in Table 1 through Table 6. General requirements are given in Table 1, while additional minimum requirements for ships with length exceeding 150m and 250m, bulk carriers subject to the requirements of SOLAS regulation XII/6.5.3, and ships with ice strengthening are given in Table 2 through Table 5. The material grade requirements for hull members of each class depending on the thickness are defined in Table 6.

Table 1 – Material Classes and Grades for ships in general

Structural member category	***Material class/grade***
SECONDARY: *A1. Longitudinal bulkhead strakes, other than that belonging to the Primary category* *A2. Deck plating exposed to weather, other than that belonging to the Primary or Special category* *A3. Side plating*	*- Class I within 0.4L amidships* *- Grade A/AH outside 0.4L amidships*
PRIMARY: *B1. Bottom plating, including keel plate* *B2. Strength deck plating, excluding that belonging to the Special category* *B3. Continuous longitudinal members above strength deck, excluding hatch coamings* *B4. Uppermost strake in longitudinal bulkhead* *B5. Vertical strake (hatch side girder) and uppermost sloped strake in top wing tank*	*- Class II within 0.4L amidships* *- Grade A/AH outside 0.4L amidships*
SPECIAL: *C1. Sheer strake at strength deck (*)* *C2. Stringer plate in strength deck (*)* *C3. Deck strake at longitudinal bulkhead, excluding deck plating in way of inner-skin bulkhead of double-hull ships (*)*	*- Class III within 0.4L amidships* *- Class II outside 0.4L amidships* *- Class I outside 0.6L amidships*
C4. Strength deck plating at outboard corners of cargo hatch openings in container carriers and other ships with similar hatch opening configurations	*- Class III within 0.4L amidships* *- Class II outside 0.4L amidships* *- Class I outside 0.6L amidships* *- Min. Class III within cargo region*
C5. Strength deck plating at corners of cargo hatch openings in bulk carriers, ore carriers, combination carriers and other ships with similar hatch opening configurations	*- Class III within 0.6L amidships* *- Class II within rest of cargo region*

C6. Bilge strake in ships with double bottom over the full breadth and length less than 150m (*)	*- Class II within 0.6L amidships* *- Class I outside 0.6L amidships*
C7. Bilge strake in other ships (*)	*- Class III within 0.4L amidships* *- Class II outside 0.4L amidships* *- Class I outside 0.6L amidships*
C8. Longitudinal hatch coamings of length greater than 0.15L *C9. End brackets and deck house transition of longitudinal cargo hatch coamings*	*- Class III within 0.4L amidships* *- Class II outside 0.4L amidships* *- Class I outside 0.6L amidships* *- Not to be less than Grade D/DH*

(*) Single strakes required to be of class III within 0.4L amidships are to have breadths not less than 800+5L (mm), need not be greater than 1800 (mm), unless limited by the geometry of the ship's design.

Table 2 – Minimum Material Grades for ships with length exceeding 150m and single strength deck

Structural member category	***Material grade***
Longitudinal strength members of strength deck plating	*Grade B/AH within 0.4L amidships*
Continuous longitudinal strength members above strength deck	*Grade B/AH within 0.4L amidships*
Single side strakes for ships without inner continuous longitudinal bulkhead(s) between bottom and the strength deck	*Grade B/AH within cargo region*

Table 3 – Minimum Material Grades for ships with length exceeding 250m

Structural member category	***Material grade***
Shear strake at strength deck (*)	*Grade E/EH within 0.4L amidships*
Stringer plate in strength deck (*)	*Grade E/EH within 0.4L amidships*
Bilge strake (*)	*Grade D/DH within 0.4L amidships*

(*) Single strakes required to be of grade E/EH and within 0.4L amidships are to have breadths not less than 800+5L (mm), need not be greater than 1800 (mm), unless limited by the geometry of the ship's design.

Table 4 – Minimum Material Grades for single-side skin bulk carriers subjected to SOLAS regulation XII/6.5.3

Structural member category	***Material grade***
Lower bracket of ordinary side frame (*),(**)	*Grade D/DH*
Side shell strakes included totally or partially	*Grade D/DH*

between the two points located to 0.125ℓ above and below the intersection of side shell and bilge hopper sloping plate or inner bottom plate (**)	

(*) The term of "lower bracket" means webs of lower brackets and webs of the lower part of side frames up to the point of 0.125ℓ above the intersection of side shell and bilge hopper sloping plate or inner bottom plate.

(**) The span of the side frame, ℓ, is defined as the distance between the supporting structures.

5. Source/Derivation of proposed interpretation

N.A.

6. Decision by voting

N.A.

Submitted by Hull Panel Chairman
20 July 2007

Permanent Secretariat note (September 2007):

Adopted by GPG 18 September 2007, ref. 7632_IGb, with an effective date of 1 July 2008.

Technical Background Document for UR S6 (Rev. 7 Apr 2013)

1. Objective/Scope

The objective of this revision is to clarify the scope of application with regard to LNG Carriers, and to identify the minimum steel grades for selected structures on LNG Carriers. Table 2 is clarified and a new Table 3 is added for LNG Carriers.

2. Source of Proposed Requirements

The proposed requirements are based on the technical justifications for the current requirements, current practice within industry, and discussion within the Hull Panel (via correspondence and at Hull Panel Meetings).

3. Technical Basis and Rationale

In general, the proposed revisions reflect the industry practice.

Regarding Table 2, the current practice is to not apply Table 2 to the longitudinal strength members located above the strength deck of LNG carriers. Four (4) LNG carriers with lengths greater than 150 meters were examined and a table of the material grades for plating of the strength deck and above is shown in as follows. These LNG carriers have higher grade steel in the strength deck, inner deck and deck girders that can be attributed to the need for higher grade steel along the tank boundary. However, most of the vessels have low grade steel in the trunk deck that is lower than the minimum material grade in Table 2. This indicates that Table 2 is not being applied in way of the "double deck" area.

Vessel		A	B	C	D
Length (m)		332	278	266	205
Material Grade	Strength Deck Plating	E	E	E	E
	Trunk Deck Plating	A, B	A,D	A	D
	Inner Deck Plating	DH, E	E	E[2]	E
	Deck Girders	E	E, E[1]	E, E[2]	E

Notes:
1. Steel Quality Z25
2. Grade E Steel having improved weld toughness.

Therefore, the proposal is based on the following:
1) Although LNG carriers have a single strength deck, the trunk deck and inner deck can be considered a "double deck" and therefore Table 2 does not apply.
2) The inner deck will have a high material grade due to its nature as a cargo tank boundary. Similar to the inner deck, the deck girders are generally of a higher grade steel. However, in case of an unusual design, a minimum material grade should be set for the inner deck and deck girders.
3) A minimum material grade is required for the portions of the strength deck contributing to the longitudinal strength to provide a level of toughness to reduce the likelihood of crack initiation, as indicated in the Technical Background to Rev. 5.
4) As the material class indicated in Item B3 of Table 1 is acceptable and common practice, an additional minimum material grade is not required for the trunk deck.

5) The higher grade of the strength deck and deck girders may provide some crack arresting for the trunk deck.

An additional review of twenty-eight LNG carriers with delivery dates from 2005 to 2013 showed that the material of the trunk deck and inner deck plating at corners of liquid dome openings is E or EH grade in all vessels due to these corners being high stress areas. Therefore, a new item was added to Table 1 to account for this.

4. Summary of Changes

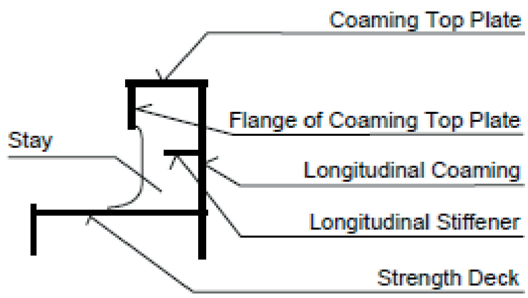
4.1 Clarification of the scope of application for Table 2

A note is added for Table 2, indicating that it does not apply LNG carriers which are covered by a new Table 3 (mainly membrane-type LNG carriers).

4.2 Clarification of the Structural member category

Structural member categories were modified in Tables 1 (item B3) and 2 to clarify that the steel grade applies to the plating only. The detail requirements in all Tables of UR S6 are only applicable to plating and not to the attached stiffeners. Note, the material grade requirements for stiffeners fall under the statement in UR S6 "For strength members not mentioned in Tables 1 to 6, Grade A/AH may generally be used." The only exceptions where stiffeners are explicitly covered in UR S6 are follows:

(a) Table 1, C8, the hatch coaming consist of the vertical coaming plating and the horizontal coaming top plate and the top plate flange. See the following figure.



Transverse Section of Longitudinal
Coaming for Container Vessels

(b) Table 5 (of Rev 7), for "Lower bracket of ordinary side frame", clearly applies to vertical "stiffeners" that make up the side frame of bulk carriers.

4.3 Insertion of new table and figure

As a result of the clarification to the scope of application of Table 2 as indicated in 4.1 and 4.2 above, a new table was added to identify the minimum steel grades of LNG carriers (mainly membrane-type LNG carriers). This table has been inserted as a new Table 3. In addition, a figure was added to identify the three decks used in Table 3 to define the structural member categories. This figure has been inserted as a new Figure 1.

4.4 Addition to Table 1, item C5.1

A new item was added as item C5.1 to indicate that the highly stressed corners of the trunk deck and inner deck plating of the liquid dome openings of LNG carriers requires a higher class/grade of steel, similar to how higher grade steel is need at the corners of cargo hatch openings on bulk carriers.

4.5 Removal of footnote mark (*) from Table 1, item C6

The reference in Table 1, item C6 to the footnote was removed since the footnote is not applicable to this item.

4.6 Clarification of Table 1, item C8

Text was added to Table 1, item C8 to clarify that that the minimum material grade or class is also applicable to the coaming top plate and flange of longitudinal hatch coamings.

4.7 Reorganization of text for UR S6.1

Two paragraphs of UR S6.1, which were previously located after the Tables 1-7, were moved ahead of the tables to make them more visible. The first paragraph was reorganized into a list to clearly identify each table and text was added to identify the new Table 3. For clarify, the second sentence in the third paragraph of S6.1 was amended.

4.8 Correction of table and figure numbering and references

The table and figure numbering and references through the UR S6 were corrected as necessary.

5. Points of Discussion

Prior to the proposed revision, points of discussion were:

(a) The applicability (or non-applicability) of Table 2 to LNG carriers
(b) Technical justification of Table 2 (for ships with L>150m)
(c) Technical justification of Table 3 (for ships with L>250m)

Following the proposed revision, points of discussion were:

(a) Structural member category
    The original wording is not clear and could be confusing. It is intended that the material grade requirements in UR S6 are applicable to the plating and not the longitudinal stiffeners. The reason for requiring the enhanced material grade of plating in certain locations is to act as crack arresters within the hull girder of the vessel.
(b) Application of Table 3
    Table 3 is applicable to membrane type gas carriers only. Gas Carriers with other containment designs, such as the MOSS spherical tank design, would apply Table 2.
(c) Scope of new Item C5.1 in table 1
(d) Minimum material grade for Stiffeners on longitudinal hatch coamings of length greater than 0.15L

Technical Background (TB) document for UR S6 (Rev.8 Dec 2015)

1. Scope and objectives

The objective of this revision is to establish the relationship between the Polar Service Temperature and the IACS design temperature defined in UR S6.

In addition, a question was raised in the Hull Panel regarding the need to clarify which structures are exposed to low air temperatures when applying the material classes and grades given in Table 8.

2. Engineering background for technical basis and rationale

See attachment for basis of revisions to design temperature.

It was decided that while internal structure is not directly exposed to low air temperatures, it is affected by low air temperatures where it is connected to the hull envelope. Hence, the strake of plating which is attached to the hull envelope is to be considered as being exposed to low air temperatures. However, in order to prevent a very narrow strake being used, it was considered prudent to include a minimum requirement for the width of the strake under consideration. 600 mm was chosen as this minimum requirement as UR I2 uses 600 mm when determining whether a contiguous inboard framing member in the vicinity of inboard framing members exposed to the environment should be required to be material class I.

3. Source/derivation of the proposed IACS Resolution

The proposed requirements are based on an investigation carried out by PT61 based on temperature data which was submitted to the IMO during the development of the Polar Code.

The issue of internal structures being exposed to low air temperatures was discussed within the Hull Panel.

4. Summary of Changes intended for the revised Resolution:

S6.2 Clarification of the scope of application for Table 8

A note has been added to Table 8 indicating that only the outermost strake of internal plating is to be considered as being exposed to low air temperatures.

S6.3 Re-definition of design temperature

For the purpose of assigning a Polar Class certificate in accordance with the Polar Code, the design temperature has been re-defined such that it relates to the Polar Service Temperature.

In addition, the statistical mean observation period used to derive the temperature has been aligned with the Polar Code.

Figure 2 has been updated.

5. Points of discussions or possible discussions

The amendments relating to temperature were discussed within PT61 and reviewed by the Hull Panel.

The amendments relating to internal structure exposed to low air temperature were discussed within the Hull Panel with the main discussion point as follows:

a) Under what circumstances internal structure would be exposed to low air temperatures. In Rev. 7, the internal bulkheads above the ballast waterline were considered to be exposed but this was considered to be unrealistic and unnecessarily onerous. Following consultation with the Chair of EG/M&W who was of the opinion that there would be some thermal transfer between the hull envelope plating and the internal structure, it was decided that the strake of plating attached to the hull envelope should be considered as being exposed to low air temperatures but that the requirements could be relaxed for the rest of the internal structure.

List of Tables

Recommended Changes of IACS Standards to incorporate the Polar Service Temperature defined in Polar Code

1. Overview

The International Code for Ships Operating in Polar Waters (Polar Code) has been developed to supplement existing IMO instruments. The goal of the Polar Code is to provide for safe ship operation and the protection of the polar environment by addressing risks present in polar waters and not adequately mitigated by other IMO instruments. The Polar Code is to be implemented by adopting changes to the existing requirements of the International Convention for the Safety of Life at Sea (SOLAS), the International Convention for the Prevention of Pollution from Ships (MARPOL) and other relevant binding IMO instruments.

The key principles for developing the Polar Code have been to use a risk-based approach in determining scope and to adopt a holistic approach in reducing identified risks. The Polar Code considers hazards which may lead to elevated levels of risk. The risk level within polar waters may differ depending on the geographical location, time of the year with respect to daylight, ice-coverage, etc. Thus, the mitigating measures required to address the above specific hazards may vary within polar waters.

Low air temperature is identified as a hazard as it affects the working environment and human performance, maintenance and emergency preparedness tasks, material properties and equipment efficiency, survival time and performance of safety equipment and systems.

The Polar Code defines Polar Service Temperature (PST) as a temperature specified at least 10^{o}C below the lowest mean daily low temperature (MDLT) for the intended area and season of operation in polar waters. Ships will be required to list the PST on the Polar Ship Certificate if intending to operate in polar water areas and seasons where the MDLT is less than 10 ^{o}C and materials of hull structures and machinery are to be certified according to the PST. Furthermore ship systems and equipment are required by the code to be fully functional at the polar service temperature. IACS, as a recognized organization approved by the Administration, needs to incorporate the PST into its standards such that as its member societies can provide consistent classification and certification for Polar Code compliant ships.

This document is prepared to establish the relationship between the MDLT and IACS design temperature, t_D, defined in UR S6, and to make recommendations how the PST can be introduced to the existing IACS requirements for ships operating in Polar waters.

2. Objective

The main objective of this study is to prepare the recommendation for changes to IACS UR S6.3 to incorporate the Polar Service Temperature (PST) that can be used in selecting the required steel grade for ships operating in low air temperature environments.

The Polar Code also requires ship system and equipment to be fully functional at the PST. A complete list of clauses of Polar Code is compiled that make reference to Polar Service Temperature (PST). This list is to be reviewed by relevant IACS Panel or working group to develop the implementation plans, if necessary.

3. Temperature Referenced in Polar Code IACS UR S6

A. Definition of Temperatures in Polar Code

The following terminologies are defined in the Polar Code.

1.2.9 *Mean Daily Low Temperature (MDLT)* means the mean value of the daily low temperature for each day of the year over a minimum 10 year period. A data set acceptable to the Administration may be used if 10 years of data is not available.

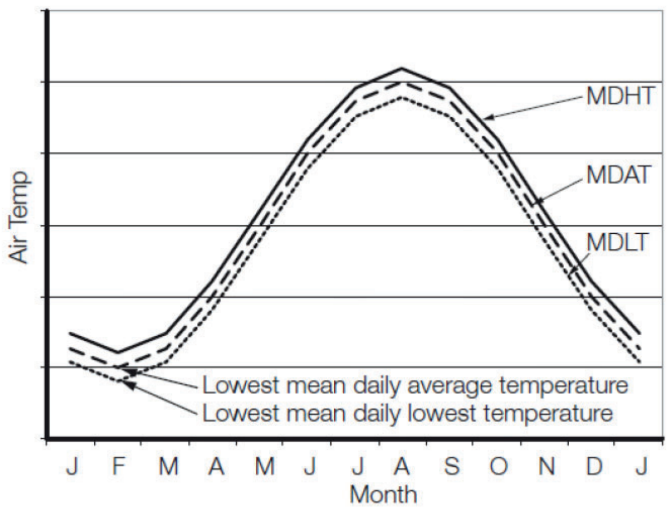
1.2.11 *Polar Service Temperature (PST) means* a temperature specified for a ship which is intended to operate in low air temperature, which shall be set at least 10°C below the lowest MDLT for the intended area and season of operation in polar waters.

1.2.12 *Ship intended to operate in low air temperature* means a ship which is intended to undertake voyages to or through areas where the lowest Mean Daily Low Temperature (MDLT) is below -10°C.

B. Additional Guidance to the Definition of Temperatures in Polar Code

PART I-B ADDITIONAL GUIDANCE REGARDING THE PROVISIONS OF THE INTRODUCTION AND PART I-A

1 ADDITIONAL GUIDANCE TO SECTION 2 (DEFINITIONS) OF THE INTRODUCTION



Definitions used in the figure above

MDHT – Mean Daily High Temperature
MDAT – Mean Daily Average Temperature
MDLT – Mean Daily Low Temperature

Guidance instructions for determining MDLT:

1 Determine the daily low temperature for each day for a 10 year period.
2 Determine the average of the values over the 10 year period for each day.
3 Plot the daily averages over the year.
4 Take the lowest of the averages for the season of operation.

C. Polar Code Clauses which Refer to the Polar Service Temperature (PST)

The following list provides the relevant section heading and clauses that make reference to the polar service temperature (PST).

PART I-A, SAFETY MEASURES,
CHAPTER 1 – GENERAL

1.4 Performance standards

1.4.1 Unless expressly provided otherwise, ship systems and equipment addressed in this Code shall satisfy at least the same performance standards referred to in SOLAS.

1.4 2 For ships operating in low air temperature, a polar service temperature (PST) shall be specified and shall be at least 10°C below the lowest MDLT for the intended area and season of operation in polar waters. Systems and equipment required by this Code shall be fully functional at the polar service temperature.

1.4.3 For ships operating in low air temperature, survival systems and equipment shall be fully operational at the polar service temperature during the maximum expected rescue time.

CHAPTER 3 – SHIP STRUCTURE

3.2 Functional requirements

In order to achieve the goal set out in paragraph 3.1 above, the following functional requirements are embodied in the regulations of this chapter:

.1 for ships intended to operate in low air temperature, materials used shall be suitable for operation at the ships polar service temperature; and

.2 in ice strengthened ships, the structure of the ship shall be designed to resist both global and local structural loads anticipated under the foreseen ice conditions.

3.3 Regulations

3.3.1 In order to comply with the functional requirements of paragraph 3.2.1 above, materials of exposed structures in ships shall be approved by the Administration, or a recognized organization accepted by it, taking into account standards acceptable to the Organization[6] or other standards offering an equivalent level of safety based on the polar service temperature.

Foot Note 6 Refer to IACS UR S6 Use of Steel Grades for Various Hull Members – Ships of 90 m in Length and Above (latest version) or IACS URI Requirements concerning Polar Class (latest version), as applicable.

CHAPTER 6 – MACHINERY INSTALLATIONS

6.2 Functional requirements

6.2.1.2 In addition, for ships intended to operate in low air temperatures:

.2 materials used shall be suitable for operation at the ships polar service temperature.

6.3.2 In addition, for ships intended to operate in low air temperatures, the following apply:

.1 in order to comply with the functional requirement of paragraph 6.2.1.2 above, exposed machinery and electrical installation and appliances shall function at the polar service temperature;

.3 in order to comply with the functional requirements of paragraph 6.2.1.2.2 above, materials of exposed machinery and foundations shall be approved by the Administration, or a recognized organization accepted by it, taking into account standards acceptable to the Organization[10, 11] or other standards offering an equivalent level of safety based on the polar service temperature.

Foot Note 10 Refer to Polar Class 1-5 of IACS URI Requirements concerning Polar Class (2011)

Foot Note 11 Refer to Polar Class 6-7 of IACS URI Requirements concerning Polar Class (2011)

[Author's note: These footnotes in the latest Polar Code (MSC 94/21/Add.1, Annex 6) are incorrect. It should have referred to IACS UR S6 since this clause addresses material of exposed machinery and foundations.]

CHAPTER 7 – FIRE SAFETY/PROTECTION

7.2 Functional requirements

7.2.2 In addition, for ships intended to operate in low air temperature, the following apply:

.1 all components of fire safety systems and appliances shall be designed to ensure availability and effectiveness under the polar service temperature; and

.2 materials used in exposed fire safety systems shall be suitable for operation at the polar service temperature.

7.3 Regulations

7.3.1 In order to comply with the requirement of paragraph 7.2.1.1, the following apply:

.1 isolating and pressure/vacuum valves in exposed locations are to be protected from ice accretion and remain accessible at all time; and

.2 all two-way portable radio communication equipment shall be operable at the polar service temperature.

7.3.3 In addition, for ships intended to operate in low air temperature, the following apply:

.1 In order to comply with the requirement of paragraph 7.2.2.1, portable and semi-portable extinguishers shall be located in positions protected from freezing temperatures, as far as practical. Locations subject to freezing are to be provided with extinguishers capable of operation under the polar service temperature.

.2 In order to comply with the functional requirements of paragraph 7.2.2.2 above, materials of exposed fire safety systems shall be approved by the Administration, or a recognized organization accepted by it, taking into account standards acceptable to the Organization[12] or other standards offering an equivalent level of safety based on the polar service temperature.

Foot Note 12 Refer to IACS UR S6 Use of Steel Grades for Various Hull Members – Ships of 90 m in Length and Above (2013) or IACS URI Requirements concerning Polar Class (2011).

APPENDIX 1 Form of Certificate for Ships operating in Polar Waters

POLAR SHIP CERTIFICATE

2.3.1 Polar Service Temperature: ……..°C/Not Applicable

APPENDIX 2 Model Table of Contents for the Polar Water Operational Manual (PWOM)

SAFETY MEASURES

Division 3 – Risk management

Chapter 1 Risk mitigation in limiting environmental condition

1.2 Measures to be considered in adverse temperature conditions

Guidance: The PWOM should contain guidance on operational restrictions in the event that temperatures below the ships polar service temperature are encountered or forecast. These may include delaying the ship, postponing the conduct of certain types of operation, using temporary heating, and other risk mitigation measures.

D. Current IACS UR S6 Use of steel grades for various hull members - ships of 90 m in length and above

The current IACS UR S6.3 (Rev. 7, April 2013) defines the design temperature that shall be used in selecting material grade for various strength members including those for vessels operating in low temperature environments. The design temperature is defined as follows:

S6.3 Design temperature t_D

The design temperature t_D is to be taken as the lowest mean daily average air temperature in the area of operation.

Mean: Statistical mean over observation period (at least 20 years)

Average: Average during one day and night

Lowest: Lowest during year

For seasonally restricted service the lowest value within the period of operation applies.

Fig. 1 illustrates the temperature definition.

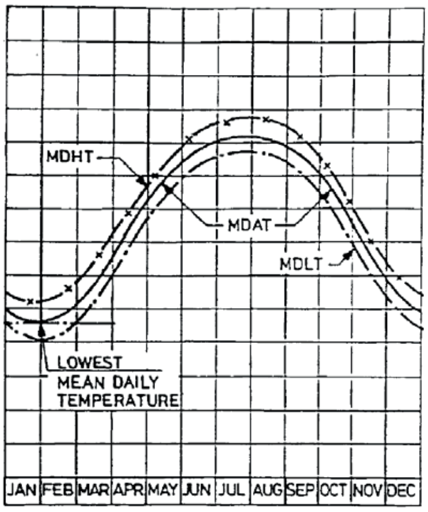


Fig. 1 Commonly used definitions of temperatures

MDHT = Mean Daily High (or maximum) Temperature

MDAT = Mean Daily Average Temperature

MDLT = Mean Daily Low (or minimum) Temperature

4. Relationship between MDAT and MDLT

It is noted that the Polar Service Temperature (PST) is defined at least 10°C below the lowest Mean Daily Low Temperature (MDLT).

IACS UR S6.3 references both the lowest Mean Daily Low Temperature (MDLT) and the lowest Mean Daily Average Temperature (MDAT) while the latter is defined as the design temperature, t_D. The design temperature, t_D, is to be used in selecting the material grade in various operational conditions.

The following analysis is carried out to establish the relationship between the lowest Mean Daily Low Temperature (MDLT) and the lowest Mean Daily Average Temperature (MDAT) in various Polar regions.

The temperature data submitted to IMO Ship Design Committee meeting by Canada and Argentina are reanalyzed for this study. In addition, the temperature data in the Arctic regions published by ABS is also used for this study.

A. Temperature data of Polar and Sub-polar Regions Submitted by Canada

The government of Canada submitted "Statistical data on temperature in polar and sub-polar regions" at the IMO Ship Design Committee meeting in November 2013, SDC 1/INF.12. This submission provides information on statistical temperature data for polar and sub-polar regions.

This data set includes temperature data from 13 weather monitoring stations: ten Arctic and Sub-Arctic stations and three Antarctic stations. The reporting stations are Barrow, Churchill, Dutch Harbour, Helsinki, Iqualuit, Montreal, Murmansk, Base Esperanza, Nogliki (Sakhalin East), Resolute, Dudinka, Dumont Durville, and Byrd station. The location of the weather reporting stations are shown in **Figure *1***

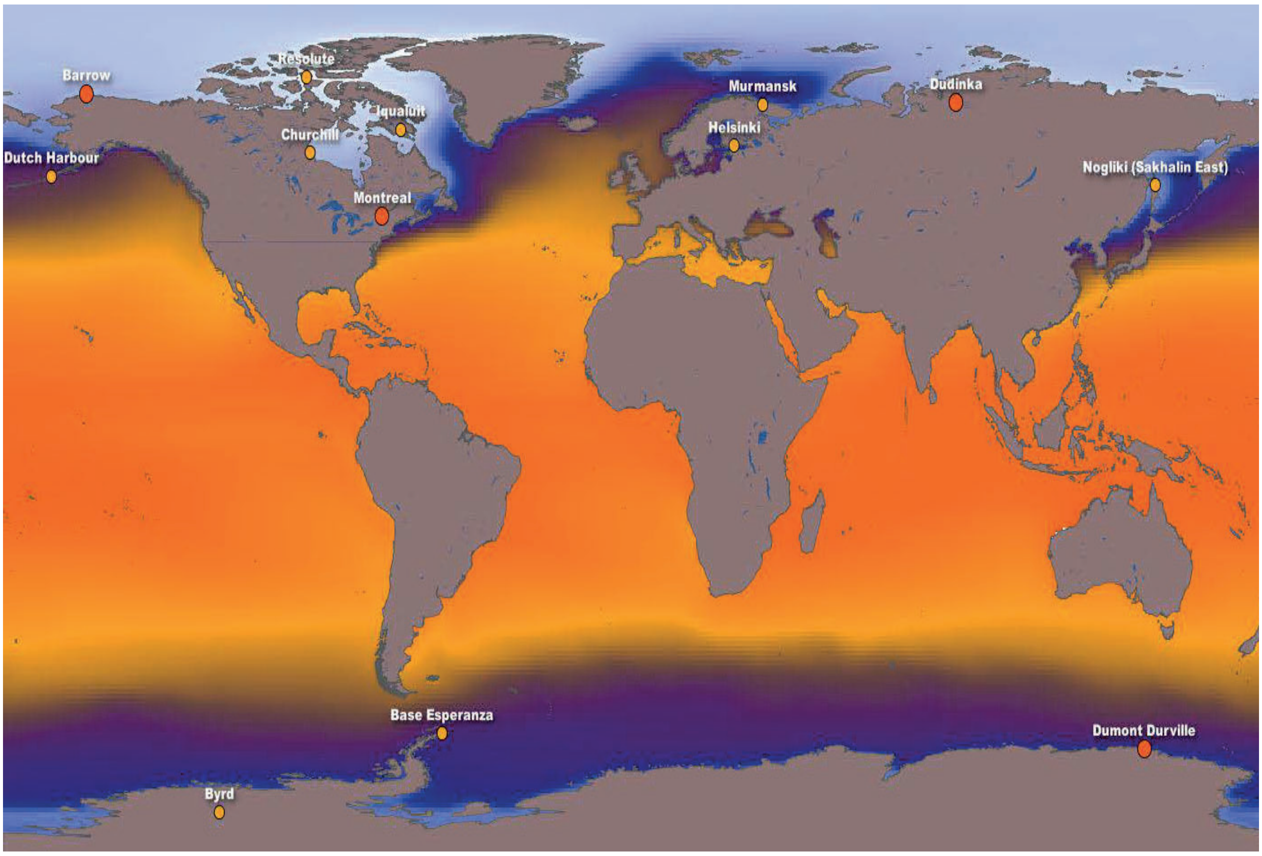

Figure 1 Location of weather monitoring stations

The temperature data was included a table of monthly MDAT and MDLT for 13 stations and various statistics to establish the reference temperature in the Polar regions. The submittal, however, did not include the relationship between the MDLT and MDAT. The data set submitted by Canada was reanalyzed in this report to establish the relationship between the MDLT and MDAT. It was found that the data from Byrd station had errors, and was therefore excluded from this study

The original data set from the Canada submittal SDC 1/INF.12 is provided in

Table 1.

Table 1 Temperature Data submitted by Canada, from SDC 1/INF.12

B. Temperature data of Antarctic Station Submitted by Argentina

The government of Argentina submitted "Result of a statistical analysis of temperature variations" at the IMO Ship Design Committee meeting in November 2013, SDC 1/13/14. This document presents the results of a statistical analysis of temperature variations obtained from Carlini Base in the Antarctic with a view to determining design temperatures.

The submitted document included the monthly average MDAT and monthly average MDLT for the period 2001-2010 at Carlini Base, located at 62° 14' S; 58° 40' W. The location of Carlini Base is shown in Figure 5

Figure 5 Location of Carlini Base in the Antarctic

Table 3 shows the monthly average MDAT, MDLT and the difference at Carlini Base. Figure 6 shows the difference of monthly average MDAT and MDLT for each month.

Table 3 Monthly Average MDAT, MDLT and the difference at Carlini Base (2001-2010)

C. Temperature data from ABS Guide for Vessels Operating in Low Temperature Environments (2015)

The operation of merchant vessels in low temperature environments presents many challenges for designers, builders, Owners, and Operators. These challenges include both hardware issues related directly to the construction, outfitting, and operation of vessels, as well as those issues pertaining to the ability of the crew to function in a difficult environment. To assist the marine industry, ABS issued the Guide for Vessels Operating in Low Temperature Environments (ABS LTE Guide) and the latest update is published in 2015.

The ABS LTE Guide includes year-round temperature data obtained for selected coastal sites throughout the Arctic. Temperatures at sea are on average slightly higher than those on the adjacent land. Therefore, land based temperature data will normally represent more severe conditions (i.e. colder temperature statistics). The selected eleven Arctic stations are: Aasiaat, Greenland; Alazeja River, Russia; Barrow, USA; Clyde, Canada; Golomjannyj, Russia; Malye Karmakuly, Russia; Ostrov Kotelnyj, Russia; Pelly Island, Canada; Resolute, Canada; Reykjavik, Iceland; Tromso, Norway. The location of the selected Arctic stations are provided in Figure 7. The MDAT and MDLT for the location are given for the 1st and the 15th day of the month.

Figure 7 Location of the selected Arctic stations

Table 4 is the difference of MDAT and MDLT on the 1st and 15th day of each month at the selected locations.

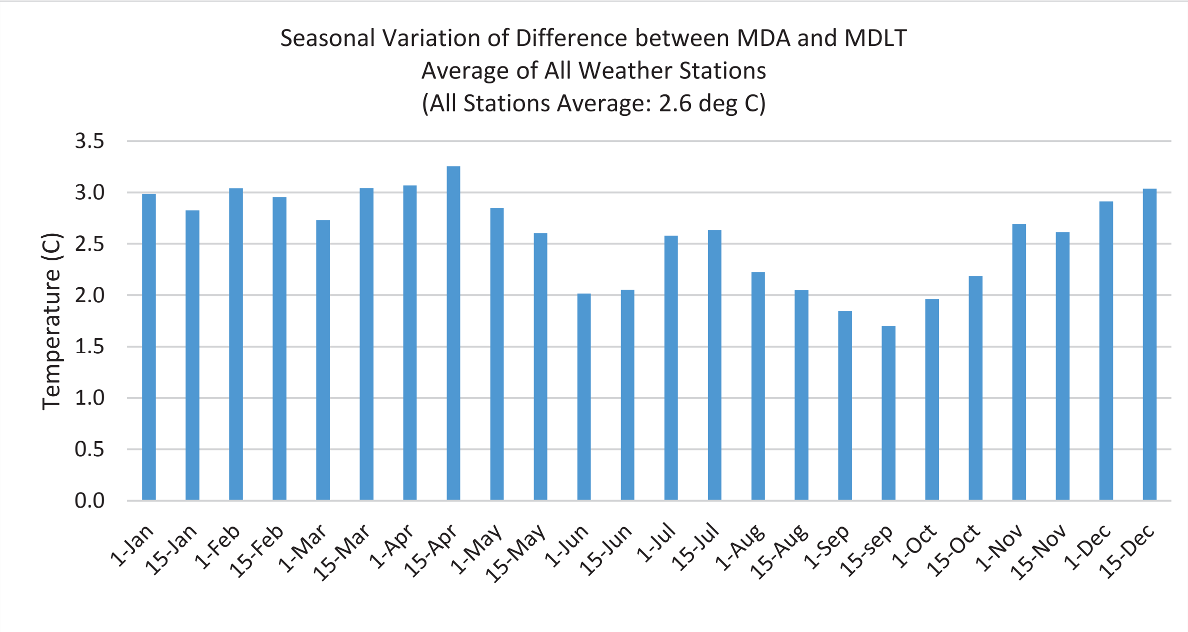

Figure 10 Seasonal variation of difference between MDAT and MDLT, ABS LTE Guide

5. Conclusion and Recommendations

Results from all three data sources, Canadian, Argentinian and ABS, showed the difference between the mean daily average temperature (MDAT) and the mean daily low temperature (MDLT) is in the range of 2.5°C to 3.0°C

- 2.8°C – Canadian Data
- 2.5°C – Argentinian Data
- 2.6°C – ABS Data

It has been demonstrated that the nominal difference between the MDAT and MDLT in the Polar regions can be considered 3°C. This implies that the MDAT can be 13°C higher than the Polar Service Temperature (PST).

A. Recommendation for changes of UR S6.3

It is recommended to add the following statement in UR S6.3.

1) "For the purpose of issuing the Polar Ship Certificate in accordance with the Polar Code, the design temperature t_D shall be no more than 13°C higher than the Polar Service Temperature (PST) of the ship".
2) "In the Arctic region, the statistical mean over observation period is to be determined for a period of at least 10 years".

Associated with point 2) above it is recommended that the requirement for a statistical mean of at least 20 years in S6.3 be removed by deleting "at least 20 years" in the parenthesis at the end of the Mean definition.

Furthermore, it is recommended that Fig 2. of UR S6.3 be updated to include identification of the lowest mean daily lowest temperature. It is recommended that the figure contained in Part IB of the Polar Code be used for consistency.

B. Recommendations to IACS panels and working groups

1) The list of Polar Service Temperature (PST) related clauses in Section 3. C of this report should be reviewed by relevant IACS Panel or working group to develop the implementation plans, if necessary. Specific attention should be given to the reference to UR S6.3 for approval of materials of machinery systems and materials used in fire protection systems

2) It should be noted that the polar code makes reference to UR S6.3 for materials of hull structures, machinery, and fire protection systems. UR S6.3 was originally only intended for materials of steel hull structures. The application to machinery and FP systems may fall out of the intended scope of the UR. This issue should be raised with other IACS safety and machinery panels.

3) In addition, IACS should be prepared to assign a Polar Service Temperature (PST) on the Polar Ship Certificate for existing vessels of which materials have been certified under UR S6.

End of Document

Technical Background (TB) document for UR S6 (Rev.9 July 2018)

1. Scope and objectives

This revision of UR S6 addresses two topics handled by the hull panel upon request from members.

Limiting temperature UR S6.1:

The material requirements in CSR and UR S6.1 apply for design temperature down to -10ºC and low temperature requirements in S6.2 apply for design temperature below -20ºC. This leave a gap with no clear requirements to material for ships having a design ambient temperature between -10ºC and -20ºC degrees. It was agreed to develop unified requirements to close this gap. (Hull Panel ref PH16010)

Cold Cargo:

CSR OT and CSR BC&OT include an assumption about cargo temperature between 0ºC and 80ºC, ref. CSR Pt 1 Ch 1 Sec 1 [1.3.2]. In general bulk carriers and tanker are occasionally loading cargos with temperature below 0ºC, and it has been questioned if additional requirements should apply. The Hull Panel therefore agreed to develop unified requirements for cold cargoes for introduction in UR S6 (Hull Panel ref. PH14005)

2. Engineering background for technical basis and rationale

UR S6.1& S6.2 Limiting temperature:

It was decided to update UR S6 to be consistent with CSR and clarify that S6.1 applies for temperature -10ºC and above. In addition it was decided to close the gap between S6.1 and S6.2 by expanding the low temperature requirements in S6.2 to cover temperatures in the range between -10ºC and -20ºC.

The column which previously covered -20/-25ºC has been expanded to cover the temperature range -16/-25ºC, 10 degrees difference, similar to columns for lower design temperatures.

In addition a column was added to cover the range -11/-15ºC. The applicable material grades were determined using the diagram from DNV Rules for Ships Pt.3 Ch.5 Sec.7 Jan 2015 version as inserted below. The diagram is based on IACS Rec.7 (Guide for the use of hull structural steels for prolonged exposure to low service temperatures - Deleted July 2003). The low temperature requirements in UR S6 are found consistent with the diagram.

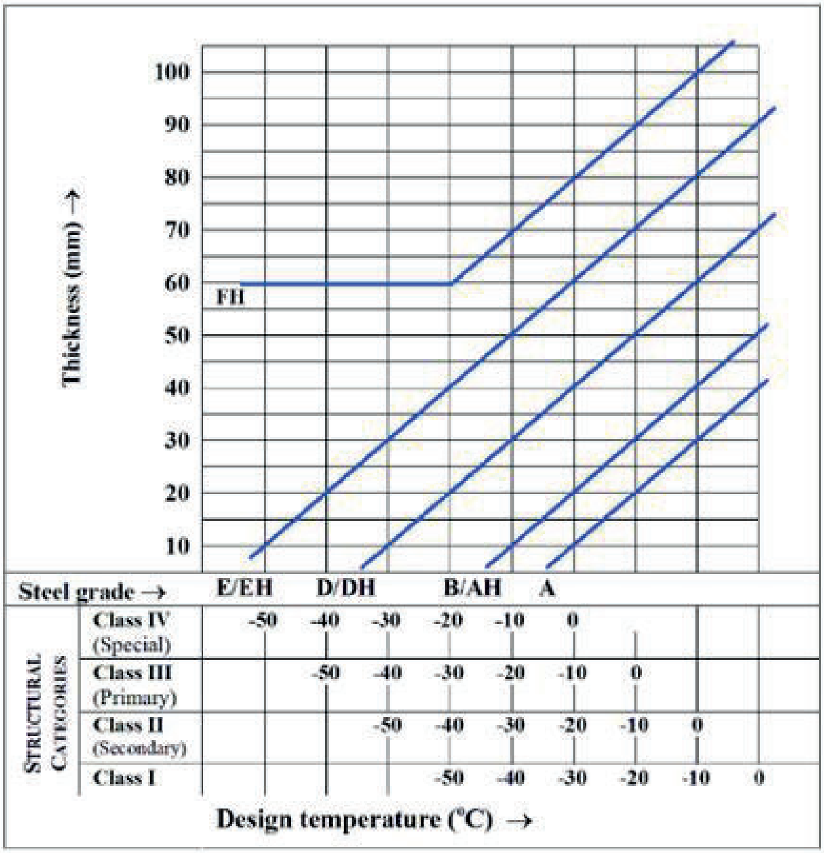
It is clarified that S6.2 is applicable to ships intended to operate in low air temperature (below -10°C) and the cargo tank boundary of ships intended to carry cargo at low temperature as defined in S6.4.

The S6.2 covers:

- the external structural members directly exposed to low air temperature,

- the internal members made of the plating of longitudinal or transvers bulkheads attached to hull envelope plating exposed to low air temperature (At least one strake is to be considered in the same way as exposed plating and the strake width is to be at least 600 mm.)

- The cargo tank boundary plating of cold cargo as defined in S6.4.



The diagram above is based on DNV rules having 4 different material classes. The "Special", "Primary" and "Secondary" structural categories correspond to Class III, II and I respectively in UR S6.

UR S6.4 Cold Cargo for ships other than liquefied gas carriers:

The design basis in CSR assumes cargo temperature between 0ºC and 80ºC. It was not part of scope when developing CSR to consider possible carriage of cargoes with temperatures outside of this range. Such temperatures should trigger additional considerations and do not mean that ships other than liquefied gas carriers are not fit for loading cargos with temperature outside of this range.

Some class societies accept cargo temperature down to -10ºC without further consideration and cargos with even lower temperatures have been loaded based on operator's judgement. Operational precautions may sometimes be taken like e.g.

filling of adjacent ballast tanks before commencement of loading in case of cold cargos.

Carriage of cargo with temperature less than 0ºC is not new and operational experience is available. Hull Panel members were therefore requested to collected damage experience related to cold cargo from ships in their class. None of the members could trace information about damages which can be related to cold cargo and this leave some confidence that ships built according to current rules may be used for this purpose.

When determining the material requirement for cold cargo, comparison was done with the requirements already in place in S6.2. These requirements have been verified through extensive service experience and apply to outer shell. Comparing tank boundaries with the outer shell it may be noted that outer shell:

- Will experience a wider range of temperatures (Polar service temperature is 13 degrees lower than the design temperature)

- Is more prone to impact loads from ice, tug, quay, falling objects etc.

- Has higher hull girder stresses

- Is assigned Class I, II or III in UR S6 Table 1 while no class is assigned to inner bottom, transverse bulkhead or longitudinal bulkhead outside of 0.4*L*

On the other hand, cargo hold boundaries are exposed to low temperature for a long time. Still comparing with outer shell for which cold temperature requirements are available, the low temperature on cargo tank boundaries is considered less critical. It was therefore concluded that we are on the conservative side making temperature requirements equivalent to requirements for outer shell using “Category I” which apply for structure with moderate hull girder loads.

The requirement to cold cargo is only applied for liquid cargo which will efficiently cool down the tank boundaries. Additional material requirement for loading of cold bulk cargo is not found necessary as the heat transfer between the cargo hold boundary plating and the dry cargo is considered to be less than for liquids. It will also be less dynamic loading on dry cargo hold boundaries than on cargo tank boundaries during voyage.

It is advisable that before the loading operation, the Master pays attention to the possible risk of thermal shock the cargo hold structural members may suffer resulting from the temperature difference between the liquid cargo and the cargo hold surface.

3. Source/derivation of the proposed IACS Resolution

None

4. Summary of Changes intended for the revised Resolution:

S6.2 Table 8 : Cargo tank boundaries include in Category I and footnote 6 added.
S6.2 Table 9 : Updated to include -11/-15ºC degrees and -16/-25ºC
S6.4 : New paragraph added to address cold cargo

5. Points of discussions or possible discussions

It was discussed to introduce an operational requirement to max temperature difference, 30 degrees, between the cargo and the tank boundary plating. Some considered this requirement to be not satisfactorily justified and therefore not necessary. This point is mentioned in this TB for the paragraph relative to UR S6.4.

6. Attachments if any

None

Rev.1 (1976)	*No record*	-
NEW (1973)	*No record*	-

- **Rev.4 (May 2010)**

.1 Origin for Change:

☑ Based on IACS Requirement *(Common Structural Rules for Bulk Carriers and Double Hull Oil Tankers)*

.2 Main Reason for Change:

Following the introduction of the IACS Common Structural Rules for Bulk Carriers and Double Hull Oil Tankers, Hull Panel were tasked to review all the UR S files to consider whether or not they are applicable to ships covered by the CSR.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None.

.4 History of Decisions Made:

After review it was decided that for CSR ships the requirements of UR S7 are superseded by those of the Common Structural Rules and therefore do not apply.

Additionally the opportunity was taken to correct an alignment error in S7.1.

.5 Other Resolutions Changes

All UR S files, except UR S8, S9, S15, S16, S19, S22, S23, S30 and S31.

.6 Dates:

Original proposal: *2007, made by Hull Panel Task 50*
Panel submission to GPG: *19 April 2010*
GPG Approval: *24 May 2010 (Ref. 10051_IGd)*

UR S8 "Bow Doors and Inner Doors"

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev. 4 (Dec. 2010)	13 December 2010	1 January 2012
Rev. 3 (Nov 2003)	7 November 2003	-
Corr. (1997)	*No record*	-
Rev. 2 (1995)	*No record*	-
New (1982)	*No record*	-

- ### Rev.4 (Dec 2010)

.1 Origin of Change:

☑ Request by Hull Panel

.2 Main Reason for Change:

Since the manual mentioned in Rev.3 S8.8.1 to be kept on board the vessel was required to include a copy of the certificate, each time the certificate was renewed the whole manual also had to be updated. However, noting that the vessel also has to have a copy of the certificate on board it was deemed to be a duplication of information and not necessary to keep updating the whole manual just to include a copy of the certificate that is already available on board.

In addition, Statutory Panel Chairman suggested the editorial amendment to UR S8.1.2b, to make it in line with the SOLAS 2005 Amendments adopted by MSC.194(80).

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

The Hull Panel agreed to the proposal and created the modifications to no longer require a copy of the certificate in the manuals. This was in turn agreed by the GPG.

Editorial amendment to UR S8.1.2b, which was unanimously agreed by Statutory Panel members was approved by GPG

.5 Other Resolutions Changes

UR S9

.6 Dates:

Original Proposal: *14 November 2008*
Panel Approval: *14 October 2010*
GPG Approval: *13 December 2010 (Ref: 10146_IGc)*

- **Rev. 3 (Nov. 2003)**

According to CG/RRS Task 98-1, CG/RRS prepared draft amendments to S8 /S9 /S15 /S16 (also IG No.8) which were then revised by WP/S. The scope of application in S8 /S9 /S15 /S16 were revised and confirmed by GPG and Council (2081a).

No TB document available.

- **Corr. (1997)**

Minor editorial corrections - S.8.2.1c ‘normal’ to ‘nominal’; S8.7.2d ‘indiction’ to ‘indication’.

Note: There are no separate Technical Background (TB) documents available for New (1982), Rev.2 (1995), Corr.1 (1997) and Rev.3 (Nov 2003).

Technical Background for UR S8 Rev.4, Dec 2010

1. Scope and objectives

To address the issue that since the list of information to be placed in the Manual for bow, inner, side and stern doors includes the Certificate, if the Certificate change then the Manual has to be updated.

In addition, Statutory Panel Chairman suggested the editorial amendment to UR S8.1.2b, to make it in line with the SOLAS 2005 Amendments adopted by MSC.194(80).

2. Engineering background for technical basis and rationale

Since the manual mentioned in Rev.3 S8.8.1 to be kept on board the vessel was required to include a copy of the certificate, each time the certificate was renewed the whole manual also had to be updated. However, noting that the vessel also has to have a copy of the certificate on board it was deemed to be a duplication of information and not necessary to keep updating the whole manual just to include a copy of the certificate that is already available on board. The Hull Panel agreed to the proposal and created the modifications to no longer require a copy of the certificate in the manuals.

3. Source/derivation of the proposed IACS Resolution

UR S8 Rev.3 (Nov 2003)
SOLAS 2005 Amendments adopted by MSC.194(80).

4. Summary of Changes intended for the revised Resolution:

S8.1.2b An inner door is to be fitted. The inner door is to be part of the collision bulkhead. The inner door needs not be fitted directly above the bulkhead below, provided it is located within the limits specified for the position of the collision bulkhead, refer to regulation II-1/12 ~~II-1/10 or II-1/11~~ of the SOLAS Convention~~, as appropriate to the type of ship~~. A vehicle ramp may be arranged for this purpose, provided its position complies with regulation II-1/12 ~~II-1/10 or II-1/11~~ of the SOLAS Convention~~, as appropriate to the type of ship~~. If this is not possible a separate inner weathertight door is to be installed, as far as practicable within the limits specified for the position of the collision bulkhead.

S8.8.1 An Operating and Maintenance Manual for the bow door and inner door is to be provided on board and is to contain necessary information on:

- *main particulars and design drawings*
  special safety precautions
  details of vessel~~, class, statutory certificates~~
  equipment and design loading (for ramps)
  key plan of equipment (doors and ramps)
  manufacturer's recommended testing for equipment
  description of equipment for

bow doors
inner bow doors
bow ramp/doors
side doors
stern doors
central power pack
bridge panel
engine control room panel

5. Points of discussions or possible discussions

The necessity of reporting the revision to IMO was considered since IMO resolutions and documents referred to IACS URs S8 and S9. Finally it was agreed not to submit the revision to URs S8 and S9 to IMO.

UR S11 "Longitudinal Strength Standard"

Summary

Based on original document Rec.97, this UR S11 Annex 1 is formulated considering few technical changes and clarifications keeping the application scope same as of UR S11, i.e. excluding CSR BC&OT vessels and container ships. This UR S11 Annex is considered to replace the Rec.97.

***** Note:**
For bulk carriers with notation BC-A, BC-B or BC-C, as defined in UR S25, UR S11 is to be complied with by ships contracted for construction on or after 1 July 2003. For other ships, this revision of UR S11 is to be complied with by ships contracted for construction on or after 1 July 2004.

- ## Rev.10 (Dec 2020)

.1 Origin of Change:

☒ Suggestion by IACS member

.2 Main Reason for Change:

The GPG tasked the Hull Panel to identify the IACS resolutions & recommendations, which have not been updated in the past ten years and to determine the documents that need revision.

The Hull Panel concluded that Rec.97 provides a recommendation to designers for obtaining operational flexibility as regards to the filling level of WBT for the application of UR S11.2.1.3. However, UR S11 is applicable to steel ships over 90m in length excluding CSR BC&OT vessels and container ships. Accordingly, Rec.97 should have the same scope of application as S11 and so, should not be applicable to CSR BC&OT and container ships. In view of this, the CSR BC&OT and the container ships cannot refer to Rec.97 giving interpretation of a requirement that is not applicable to them.

This recommendation is not applicable to passenger ships and is not useful for ro-ro ships for which the ballast loading conditions are not generally the most critical ones from the structural point of view.

Currently, typical conventional ore carriers are arranged with 7 cargo holds. In order to meet the technical changes, the illustrations related to ore carriers in relevant Figures are updated with 7 cargo holds and bow shapes are also corrected to be representative of ore carriers.

.3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

N/A

.4 History of Decisions Made:

During the HP30 Meeting, the Hull Panel Members confirmed their agreement to update the Rec 97.

One Member proposed updating the references made to the IACS Resolutions since these resolutions were amended.

The Hull Panel discussed the subject via correspondence and unanimously agreed to delete the revision numbers of the relevant URs in order to avoid updates due to simple revisions of these resolutions.

In addition, the references to the "Common Structural Rules for Bulk Carriers" and "Common Structural Rules for Oil Tankers" were superseded by the "Common Structural Rules for Bulk Carriers and Oil Tankers". Therefore, the references in the text were updated accordingly.

Noting that Rec 97 content is also applicable to CSR, one Member proposed to modify the recommendation title. This proposal has been agreed by the Hull Panel.

During the HP31 Meeting, the Hull Panel decided that Rec.97 should have the same scope of application as S11 and so, should not be applicable to CSR BC&OT and container ships. In view of this, the CSR BC&OT and the container ships cannot refer to Rec.97 giving interpretation of a requirement which is not applicable to them. In addition, the definition of Case A, B and C for ship type should be clarified and the figures with scenarios of conventional ore carriers should be amended.

.5 Other Resolutions Changes:

None

.6 Any hindrance to MASS, including any other new technologies:

None

.7 Dates:

Original Proposal: June 2019 (Made by: Hull Panel)

Panel Approval: 16 November 2020 (Ref: 19232_PHd)
GPG Approval: 10 December 2020 (Ref: 19232_IGg)

- **Rev.9 (June 2019)**

.1 Origin for Change:

☒ Suggestion by IACS member (PT56)

.2 Main Reason for Change:

References to UR S25 for BC-A, B and C remained in the text while UR S25 has been deleted in May 2010. UR S11A has been developed for covering the Longitudinal Strength Standard for containerships. However, some requirements of UR S11 were still referring to containerships; those references are removed. For text simplicity (to avoid text repetitions), the update of S11A in progress will refer to particular paragraphs of S11. For allowing this exception, the scope of application of S11 has been modified by adding the expression "except otherwise mentioned".

Correction of a typo in S11.5.2.1: a square is missing in the ☐□ expression of the ideal elastic buckling stress in compression of plates.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

The decision to revise UR S11 is an outcome of the work of PT56.

.5 Other Resolutions Changes

UR S11A (newly introduced)

.6 Any hindrance to MASS, including any other new technologies:

None

.7 Dates:

Original proposal:	April 2015	Made by: IACS PT56
Panel Approval:	11 June 2019 (Ref: 19093_PHb)	
GPG Approval:	27 June 2019 (Ref: 19093_IGd)	

- **Rev.8 (June 2015)**

.1 Origin for Change:

❒ Suggestion by an IACS member

.2 Main Reason for Change:

UR S11A "Longitudinal Strength Standard for Container Ships" has been introduced which supersedes the requirements of UR S11 with respect to container ships. Hence, the application of UR S11 has been amended such that it does not apply to container ships to which UR S11A is applicable.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

The decision to revise UR S11 is an outcome of the work of PT56.

.5 Other Resolutions Changes

UR S11A (newly introduced)

.6 Dates:

Original proposal: April 2015 Made by: An IACS member Panel Approval: 21 May 2015 by Hull Panel
GPG Approval: 02 June 2015 (Ref: 8566_IGzn)

- **Rev.7 (Nov 2010)**

.1 Origin for Change:

❒ Suggestion by an IACS member *(Action initiated to address UK MAIB recommendations following the MSC Napoli incident)*

.2 Main Reason for Change:

The main technical reason for the change is to clarify strength requirements during sequential ballast water exchange and to include recommendations made in the UK MAIB report on the MSC Napoli incident.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

The revisions were made through discussions and e-mails within the Hull Panel. ABS incorporated the comments and drafted a final revision. The remainder of the Hull Panel members reviewed and accepted the revisions.

.5 Other Resolutions Changes

None

.6 Dates:

Original proposal: *12 April 2010 Made by: An IACS member*
Panel Approval: *5 October 2010*
GPG Approval: *16 November 2010 (Ref. 8566_IGq)*

- **Rev.6 (May 2010)**

.1 Origin for Change:

- ❒ Based on IACS Requirement *(Common Structural Rules for Bulk Carriers and Double Hull Oil Tankers)*

.2 Main Reason for Change:

Following the introduction of the IACS Common Structural Rules for Bulk Carriers and Double Hull Oil Tankers, Hull Panel were tasked to review all the UR S files to consider whether or not they are applicable to ships covered by the CSR.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None.

.4 History of Decisions Made:

After review it was decided that for CSR ships the requirements of UR S11 are superseded by those of the Common Structural Rules and therefore do not apply.

.5 Other Resolutions Changes

All UR S files, except UR S8, S9, S15, S16, S19, S22, S23, S30 and S31.

.6 Dates:

Original proposal: *2007, made by Hull Panel Task 50*

Note: *There are no separate Technical Background (TB) documents for the original resolution (1989), Rev.1 (1993), Rev.4 (July 2004), Rev.6 (May 2010), Rev.8 (June 2015) and Rev.9 (June 2019).*

Technical Background to changes proposed with respect to UR S1A & S11

The objective of the attached proposals is to prohibit the practice of using partially filled ballast tanks, in design conditions, to control longitudinal strength. To accomplish this, it is proposed that appropriate changes be incorporated into the portion of UR S11.2.1.2 that describes items related to the load conditions that are considered in longitudinal strength calculations. This change also necessitates deletion of a conflicting reference in S1A.3c), which deals with partial filling of peak tanks.

The change was agreed unanimously and no unresolved issues remain.

Submitted by WP/S Chairman on 28 August 2001.

Technical background of UR S11 rev. 3(June 2003)

S11.1 Application

As S11 applies to other ship types than bulk carriers with notation BC-A, BC-B or BC-C, two application dates are specified for the requirements in the new revision of UR S11: for the bulks with notation BC-A, BC-B or BC-C, the application date is 1 July 2003, for other ships is 1 July 2004.

S11.2.1.2 Design loading Conditions

In addition to departure and arrival conditions, transitory conditions are to be considered, where the amount and disposition of consumables are considered more severe.

The objective is to increase the safety at the design stage, reducing the risk to have loading conditions during the voyage that could be critical for the longitudinal strength.

The WP/S agreed that, as the possibilities of transitory loading conditions can be very many, only those supposed to be more critical are to be checked at the design stage. The matter of safe operations must be left to the ship staff after ensuring that the operational limits fixed at the design stage are not too narrow or impractical.

Nevertheless, the safety at the design stage can be increased, requiring checks and planning of ballast change during the transitory conditions between the departure and arrival conditions. Therefore calculations of longitudinal strength of the intermediate conditions just before and just after ballasting and/or deballasting any ballast tank are required.

Loading conditions according to UR S25 are explicitly included.

S11.2.1.3 Partially filled ballast tanks in ballast loading conditions

The old revision was not clear about the applicability of UR S17 to the ballast conditions, involving partially filling tanks. The text in revision 3 clarifies that these conditions can be used as design conditions provided that UR S17, as applicable, is complied with.

It is also clarified that the ballast conditions, involving partially filling tanks, can be used as design conditions, provided that calculations of longitudinal strength are performed for all filling levels between empty and full

In order to have a manageable number of investigations, for the purpose of design, it is sufficient that the partially filled tanks are assumed to be empty and full, in departure, arrival conditions and any other condition required in S11.2.1.2.

S11.2.1.4 Partially filled ballast tanks in cargo loading conditions

The requirements for the partial filling are extended to cargo loading condition and not only to ballast condition, as cargo loading conditions involving partially filled peak tanks are to be well controlled in terms of hull girder strength.

Notes by the IACS Permanent Secretariat.

1) Council agreed that the last sentence of S11.1 be revised to read for clarity: "For other ships ~~types~~, this revision of this UR is to be….".

2) Council decided that the implementation date of S11(Rev.3) and S17(Rev.5) should be aligned with that of UR S25 – 1 July 2003. NK will implement UR S25 from 1 January 2004. In the interim period between 1 July 2003 and 1 January 2004 NK will recommend that Owners/Builders stipulate in their contract compliance with URs S11 Rev.3 and S17 Rev.5 when UR S25 is applied.

Adopted on 20 June 2003.

Technical Background

UR S11 (**Rev.5**, Jan 2006)

1. Scope and objective

1.1 Application of UR S11.2.1.3 and S11.2.1.4 to Ballast Water Exchange

Ballast water exchange sequences are to be included in the LM as per UR S1, UR S1A and S11.2.1.2 and are to be approved. However there is no need to check that the longitudinal strength is complied with for any filling levels between full and empty.

Therefore IACS Hull Panel proposes to insert a new sub-section S11.2.1.5 in order to clarify the application of UR S11.2.1.3 and UR S11.2.1.4 with regard to sequential ballast water exchange.

1.2 Application of UR S11.2.1.3 and S11.2.1.4 to Ore carrier

In case of ore carriers defined in UR Z11.2.3 as given below, which have large wing ballast tanks, design loading conditions may include two pairs of partially filled ballast tanks. There are loading limits, other than full and empty, due to reasons other than longitudinal strength such as propeller immersion and bridge visibility. Where these limits exist, they will serve as alternate limits to full or empty condition in S11.2.1.3. The current text of S11.2.1.3 and S11.2.1.4 might require longitudinal strength check for the unrealistic virtual ballast/cargo loading conditions, which are far beyond the above-mentioned limits. Therefore IACS Hull Panel proposes to modify sub-section S11.2.1.3 to solve this problem by introducing criteria which give the thresholds of loading conditions.

Z11.2.3 Ore Carrier

The ship type notation "ORE CARRIER", or equivalent, and the notation "ESP" shall be assigned to sea going self-propelled single deck ships having two longitudinal bulkheads and a double bottom throughout the cargo region and intended for the carriage of ore cargoes in the centre holds only. A typical midship section is given in Figure 3.

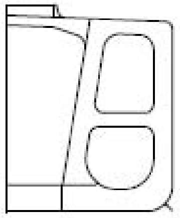

Fig. 3

2. Points of discussions or possible discussions

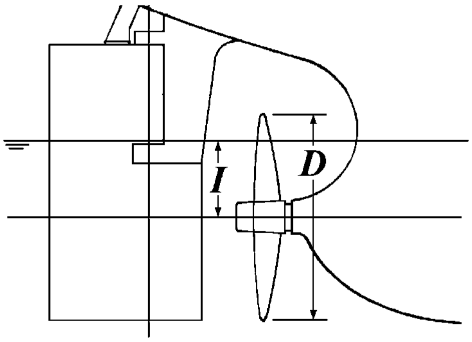
2.1 Application of UR S11.2.1.3 and S11.2.1.4 to Ballast Water Exchange

Review the applicability of S11.2.1.3 and S11.2.1.4 to ballast tank during ballast water exchange and resolve the problem arising from the current text.

2.2 Application of UR S11.2.1.3 and S11.2.1.4 to Ore carrier

When the design stress limit cannot be achieved with empty / full condition for one or two pairs of Wing Ballast Tanks, the longitudinal strength check is performed for partial filling of these tanks within the filling limitations. The pair of tanks is understood to be similar and symmetrical along the centre line. The filling limitations correspond to 3 extreme conditions of trim as follows:

- Trim by stern of 3% of ship's length
- Trim by bow of 1.5% of ship's length
- Any trim that cannot maintain propeller immersion (I/D) not less than 25%, where;
  I = the distance from propeller centerline to the waterline
  D = propeller diameter
  (see the following figure)



3. Source/ derivation of proposed requirement

Hull Panel

4. Decision by voting

N.A.

Submitted by Hull Panel Chairman

26 Oct 2005

Technical Background for UR S11 Rev.7, Nov 2010

1. Scope and objectives

Revisions are being made to clarify documentation of hull girder strength during sequential ballast water exchange and to incorporate recommendations made by the UK MAIB in their report on the investigation into the structural failure of the MSC Napoli.

2. Engineering background for technical basis and rationale

Evaluation of hull girder longitudinal strength during a sequential ballast water exchange process and the inclusion of this information in the loading manual or ballast water management plan are considered important and necessary.

Among the recommendations from the UK MAIB investigations into the MSC Napoli incident, it asks for a review of UR S11 to ensure that hull girder and buckling strength checks are carried out at all critical sections along the entire length of a vessel.

3. Source / derivation of the proposed IACS Resolution

The source of the information was obtained through the input of the Hull Panel members.

4. Summary of Changes intended for the revised Resolution:

New text describing requirements covering items mentioned in 2 above are introduced in this revision of the UR.

5. Points of discussions or possible discussions

The revisions were made through discussions and e-mails within the Hull Panel which involved mainly incorporating individual comments and accepting the consolidated text.

6. Attachments if any

None

Technical Background (TB) document of UR S11 (Rev.10 Dec 2020)

Addition of Annex 1 Recommendation for UR S11.2.1.3 for cargo vessels

1 Scope and objectives

Original version(Rec.97,2007) was made to provide the guidance and interpretation of UR S11.2.1.3 "Partially filled ballast tanks in ballast loading conditions" for the cargo ships including CSR BC & OT and Ore Carriers & container ships. During technical review within the Hull Panel it was concluded that Rec.97 should be applicable for only Steel ships which are under the scope of application of UR S11 and should not be applicable to CSR BC & OT and container vessels. In this regard, the contents of Rec.97 should be updated and the document will be replaced with new Annex 1 of UR S11 accordingly.

2 Engineering background for technical basis and rationale

2.1 Identify ships needing recommendation on "Partially filled ballast tanks in ballast loading conditions" stated in S11.2.1.3

Technically, any cargo vessel (such as general cargo ships, bulk carriers and oil & chemical tankers as well as ore carriers etc.), which might have one BW Tank (or one pair of BW Tanks) partially filled, might have the loading scenarios of "Partially filled ballast tanks in ballast loading conditions" for adjusting its real draught. Therefore, this recommendation applies to any cargo vessel with one BW Tank (or one pair of BW Tanks) partially filled, which might operate with "partially filled ballast tanks in ballast loading conditions".

2.2 The definition of Case A, B and C

From 2.1 above, the original text for describing Case A and B are suggested to be kept, i.e. "Case A and B are generally applicable for ballast loading conditions for any cargo vessel which might have one BW Tank (or one pair of BW Tanks) partially filled."
Case A has no limitation on % consumables for filling the partial ballast tank, whereas Case B has limitation to fill partial ballast tank in terms of certain % of consumables.
For Case C, i.e. "no partial filling of ballast tank is allowed during ballast voyage", it might be misleading since it is out of the scope of this recommendation concerning "partially filled ballast tanks". In addition, Case C can be also referred to UR S11.2.1.2. In view of that, Case C is suggested to be deleted in this recommendation, and original Case D will be changed as new Case C in the new document due to renumbering.

2.3 Update for conventional ore carrier with two pairs of partially filled ballast water tanks

Currently, typical conventional ore carriers are arranged with 7 cargo holds. In order to meet the technical changes, the illustrations related to ore carriers in relevant Figures are updated with 7 cargo holds and bow shapes are also corrected to be representative of ore carriers'.

3 Source/derivation of the proposed IACS Resolution

The source of the information was obtained through the working group from some IACS members supervised by the Hull Panel.

4 Summary of Changes intended for the revised Resolution

New Annex 1 added.

5 Points of discussions or possible discussions

1) The definition of Case A, B and C (objective or purpose and the scope of application;
2) Update the type of conventional ore carriers (increase the number of cargo holds in relevant Figures and modify bow shape for ore carriers' etc,);
3) Delete original Case C;
4) Give the requirement for "peak tank" instead of referring to CSR.

6 Attachments if any

None.

UR S10 "Rudders, sole pieces and rudder horns"

Summary

The Rev. 7 Corr.2 of UR S10 has been prepared to correct the editorial errors with respect to formulas for semi spade rudder with 2-conjugate elastic support stipulated in Annex S10.6.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Corr.2 (May 2024)	14 May 2024	-
Corr.1 (June 2023)	20 June 2023	-
Rev.7 (Feb 2023)	16 February 2023	1 July 2024
Rev.6 (Sep 2019)	20 Sep 2019	1 January 2021
Rev.5 (May 2018)	16 May 2018	1 July 2019
Corr.1 (Dec 2015)	22 December 2015	-
Rev.4 (Apr 2015)	3 April 2015	1 July 2016
Corr.1 (Apr 2015)	14 April 2015	-
Rev.3 (Mar 2012)	15 March 2012	1 January 2013
Rev.2 (May 2010)	24 May 2010	-
Corr.2 (July 2003)	16 July 2003	-
Corr.1 (July 1999)	13 July 1999	-
Rev.1 (1990)	*No record*	-
NEW (1986)	*No record*	-

- **Rev.7 Corr.2 (May 2024)**

1 Origin for Change:

☑ Suggestion by IACS Members

2 Main Reason for Change:

An IACS member found editorial errors on formulas for semi spade rudder with 2-conjugate elastic support stipulated in Annex S10.6.

Having compared with the formulas of k_{12} and k_{22} in the UR S10 TB as shown below, it should be modified that the first formula above is for K_{12}, and the second one for K_{22},.

$$k_{12} = k_{21} = 1.3\,.\left[\frac{l_1^3}{3EJ_{1h}} + \frac{l_1^2.(d-l_1)}{2EJ_{1h}}\right] + \frac{l_1.e^2}{GJ_{th}} \qquad (18b)$$

$$k_{22} = 1.3\,.\left[\frac{l_1^3}{3EJ_{1h}} + \frac{l_1^2.(d-l_1)}{EJ_{1h}} + \frac{l_1.(d-l_1)^2}{EJ_{1h}} + \frac{(d-l_1)^3}{3EJ_{2h}}\right] + \frac{d.e^2}{GJ_{th}} \qquad (18c)$$

In this regard, Hull Panel confirmed that it should be corrected, and the formulas are modified as below.

$$K_{\cancel{22}\,\underline{12}} = 1.3\left[\frac{\lambda^3}{3EJ_{1h}} + \frac{\lambda^2(d-\lambda)}{2EJ_{1h}}\right] + \frac{e^2\lambda}{GJ_{th}}$$

$$K_{\cancel{12}\,\underline{22}} = 1.3\left[\frac{\lambda^3}{3EJ_{1h}} + \frac{\lambda^2(d-\lambda)}{EJ_{1h}} + \frac{\lambda(d-\lambda)^2}{EJ_{1h}} + \frac{(d-\lambda)^3}{3EJ_{2h}}\right] + \frac{e^2 d}{GJ_{th}}$$

3 Surveyability review of UR and Auditability review of PR

None

4 List of non-IACS Member Classification Societies contributing or participating in IACS Working Group:

None

5 History of Decisions Made:

Editorial errors with respect to the formulas for semi spade rudder with 2-conjugate elastic support in Annex S10.6 are found by an IACS member. The corrected formulas are checked by the member as well as Hull Panel Chair.

It is proposed to be corrected as a corrigendum and it is confirmed through discussion within hull panel.

6 Other Resolutions Changes:

None

7 Any hinderance to MASS, including any other new technologies:

None

8 Dates:

Original proposal	: 27 February 2024	(Made by IACS Member)
Panel Approval	: 26 April 2024	(Ref: PH24008_IHd)
GPG Approval	: 14 May 2024	(Ref: 22203_IGg)

- **Rev.7 Corr.1 (June 2023)**

1 Origin for Change:

☑ Suggestion by IACS Members

2 Main Reason for Change:

An IACS member found an editorial error about the rudder stock diameter's formula stipulated in S10.4.2.

The Rev.7 stipulates the following formula.

$$d_c = d_t \sqrt[6]{1 + \frac{4}{3(M/Q_R)^2}} \quad \text{[mm]}$$

On the other hand, the previous version Rev.6 stipulates the following formula.

$$d_c = d_t \sqrt[6]{1 + 4/3(M/Q_R)^2} \quad \text{[mm]}$$

Though this part is not modified in the rev.7, this formula is changed.

And it considers that the following formula is correct intention in this UR.

$$d_c = d_t \sqrt[6]{1 + \frac{4}{3}\left(\frac{M}{Q_R}\right)^2} \text{[mm]}$$

It is regarded as an editorial error and is corrected as a corrigendum.

3 List of non-IACS Member Classification Societies contributing or participating in IACS Working Group:

None

4 History of Decisions Made:

An editorial error with respect to the rudder stock diameter's formula in S10.4.2 is found by an IACS member. The corrected formula is checked by the member as well as Hull Panel Chair.

It is proposed to be corrected as a corrigendum and it is confirmed through discussion within hull panel.

5 Other Resolutions Changes:

None

6 Any hinderance to MASS, including any other new technologies:

None

7 Dates:

Original proposal	: 21 April 2021	(Made by IACS Member)
Panel Approval	: 05 June 2023	(Ref: PH21023_IHt)
GPG Approval	: 20 June 2023	(Ref: 22203_IGe)

- **Rev.7 (Feb 2023)**

1 Origin for Change:

☑ Suggestion by IACS Members

2 Main Reason for Change:

IACS Members have been contacted by industry partners in view of the requirements to sealing equipment and the requirements related to the push-up lengths in case of cone couplings mainly for pintles.

Additionally, the Hull Panel considered further input of its members in view of improving the IACS requirements.

3 List of non-IACS Member Classification Societies contributing through the TC Forum and/or participating in IACS Working Group:

None

4 History of Decisions Made:

Discussion related to changes of UR S10 started in August 2021 related to the formulations regarding sealing requirements in UR S10 1.2.3.

During the following discussions further issues with the requirements in UR S10 were identified and change proposals were discussed. The Hull Panel decided via correspondence and discussion during the regular HP meetings to implement the following modifications:

- clarify the application of UR in 1.1.2 (for ships with $L \geq 24m$
- clarify the requirement regarding sealing equipment in 1.2.3 including the definition of the waterline to be applied
- clarify the welding requirements for rudder side plating and between plates and heavy pieces in 1.4.3
- clarify and align the speed in astern condition with SOLAS II-1/3.15
- clarify the bending forces and moments for spade rudder with trunk extending inside the rudder in Annex S10.3 and subsequent requirements n 4.2 and 6.4.2
- clarify and improve the push-up pressure and push-up length requirements for pintle cone couplings in 7.2.2
- Clarify the requirements of fittings of liners for rudder stocks having diameter less than 200 mm in 8.1.1

- clarification for the requirements for fillet shoulder radius in case of trunks extending below shell or skeg in 9.3
- furthermore, editorial changes and renumbering of figures

5 Other Resolutions Changes

None

6 Any hinderance to MASS, including any other new technologies:

None

7 Dates:

Original proposal	: 16 August 2021	(Made by IACS Member)
Panel Approval	: 20 December 2022	(Ref: PH21023_IHq)
GPG Approval	: 16 February 2023	(22203_IGc)

- **Rev.6 (Sep 2019)**

1 Origin for Change:

☑ Suggestion by IACS Members

2 Main Reason for Change:

IACS Members have been contacted by industry partners in view of updating the UR S10 considering the ultimate technology applied to the construction of rudder, sole pieces and horns.
Additionally the Hull Panel considered the practical experience of its Members damage reports in view of improving the IACS requirements.

3 List of non-IACS Member Classification Societies contributing through the TC Forum and/or participating in IACS Working Group:

None

4 History of Decisions Made:

During Hull Panel Meeting 30th the Members decided to evaluate the UR S10 in view of identifying possible modifications to be implemented in this resolution.

The Hull Panel decided via correspondence to implement the following modifications:

- clarify the application of the required radii in way of the solid part in cast steel
- address vague text “to be specially considered; if not known:” in Table 1
- clarify the definition of Rudder areas “A_1 and A_2” used for calculating the rudder forces and torques

- indicate the radius in the critical corners of cover plates in figure 3
- make the definition "ℓ" used for calculating the push-up pressure of cone coupling more appropriate
- clarify the definition of outer diameter of gudgeon (d_a) used in the permissible push up pressure
- clarify that synthetic material with hardness greater than 70 Shore D is accepted as a rudder bearing material
- correct a misprint in figure 7
- make the application of rudder trunk requirements more appropriate
- the minimum specified yield stress σ_F symbol has been replaced by ReH adopting a consistent approach within the different IACS documents
- the different symbols utilized in the formulas have been modified to Italic font and the text updated where appropriate

5 Other Resolutions Changes

None

6 Any hinderance to MASS, including any other new technologies:

None

7 Dates:

Original proposal: 9 November 2018 made by IACS Member
Panel Approval: 22 August 2019 (Ref: PH18023_IHp)
GPG Approval: 20 September 2019 (Ref: 19158_IGb)

- **Rev.5 (May 2018)**

.1 Origin for Change:

☑ Suggestion by IACS Members

.2 Main Reason for Change:

To correct inconsistences and/or clarify requirements identified in the text of Rev. 4 and Annexes.

To improve the requirements for dimension of gudgeon and cone coupling push-up length.

.3 List of non-IACS Member Classification Societies contributing through the TC Forum and/or participating in IACS Working Group:

None.

.4 History of Decisions Made:

Some corrections, missing definitions and clarifications have been identified in the UR text Rev. 4 Corr.1 and the Hull Panel decided to issue a new Revision to solve these issues, namely: S.10.5.1a), S.10.5.3.1, S.10.5.3.3, S.10.6.4.3, S.10.7.2.2, S.10.9.3.1, Annexes S10.3 and S10.6.

Additionally, improvement of gudgeon and cone push-up length dimensioning formulas have been introduced in S.10.6.4.2, S.10.6.4.3.
Removal of the minimum push-up length further to a Member request.

For detailed information regarding the different modifications introduced in this revision please refer to the TB section (Annex 3).

.5 Other Resolutions Changes

None.

.6 Dates:

Original proposal: 18 August 2016 made by IACS Member
Panel Approval: 19 April 2018 (Ref: PH16025)
GPG Approval: 16 May 2018 (Ref: 12121aIGh)

- ## Rev.4 Corr.1 (Dec 2015)

.1 Origin for Change:

☑ Suggestion by IACS member

.2 Main Reason for Change:

To correct the identified inconsistencies and errata in Rev.4 of the document.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None.

.4 History of Decisions Made:

PM of the PT62 and Hull Panel Members identified some consistencies and errata in Rev.4 of UR S10. It was decided to issue a Corr.1 of the document. Implementation date of version will be aligned with the implementation date of Rev. 4, i.e. 1 July 2016.

.5 Other Resolutions Changes

None.

.6 Dates:

Original proposal: 13 August 2015

Panel Approval: 30 November 2015 (Ref: PH11031)
GPG Approval: 22 December 2015 (Ref: 12121_IGn)

- **Rev.4 (Apr 2015)**

.1 Origin for Change:

☑ Suggestion by IACS member

.2 Main Reason for Change:

Since UR S10 was first issued in 1986, only minor changes have been carried out. In 2006, more comprehensive and modern rudder requirements were introduced for CSR-BC. It was subsequently decided that the rudder requirements in CSR-BC would not be continued in CSR-BC & OT but that it was desirable to retain the improvements introduced in CSR-BC by updating UR S10.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None.

.4 History of Decisions Made:

Please see Part B, Technical Background, Annex 2 for a detailed summary table of the decisions made.

.5 Other Resolutions Changes

None.

.6 Dates:

Original proposal: 05 July 2012
Panel submission to GPG: 10 Feb 2015 by Hull Panel
GPG Approval: 3 April 2015 (Ref: 12121_IGk)

- **Rev.3 Corr.1 (Apr 2015)**

.1 Origin for Change:

☑ Suggestion by IACS member

.2 Main Reason for Change:

To clarify that bulk carriers contracted for construction between 1 July 2015 and 30 June 2016 are subject to CSR-BC.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None.

.4 History of Decisions Made:

A Member proposed to add a footnote "Bulk carriers contracted for construction between 1 July 2015 and 30 June 2016 are subject to CSR-BC" into UR S10 Rev .4. However, Rev. 4 will be applicable only from 1 July 2016 and the users of the UR will not be able to see the footnote until 1 July 2016. It was proposed that the footnote could be included in UR S10 Rev. 3 through a corrigendum (Ref: 12121_RId). GPG agreed to this proposal and tasked the Permanent Secretariat to issue a Corrigendum for UR S10 (Rev.3).

.5 Other Resolutions Changes

None.

.6 Dates:

Original proposal: 7 April 2015 by a Member
GPG Approval: 14 April 2015 (Ref. 12121_IGl)

- **Rev.3 (Mar 2012)**

.1 Origin for Change:

☑ Suggestion by IACS member

.2 Main Reason for Change:

Members have been contacted a number of times by designers who asked if the bearing clearance of S10.8.3 could be smaller for non-metallic bearings. Designers noted that some IACS societies had approved smaller clearances based on special considerations.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None.

.4 History of Decisions Made:

After review it was decided by the Hull Panel that for non-metallic bearing materials a smaller clearance could be considered.

.5 Other Resolutions Changes

None.

.6 Dates:

Original proposal: *15th Hull Panel meeting (October 2011)*

Panel submission to GPG: *02 December 2011*
GPG Approval: *15 March 2012 (Ref. 12027_IGc)*

- **Rev.2 (May 2010)**

.1 Origin for Change:

☑ Based on IACS Requirement *(Common Structural Rules for Bulk Carriers and Double Hull Oil Tankers)*

.2 Main Reason for Change:

Following the introduction of the IACS Common Structural Rules for Bulk Carriers and Double Hull Oil Tankers, Hull Panel were tasked to review all the UR S files to consider whether or not they are applicable to ships covered by the CSR.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None.

.4 History of Decisions Made:

After review it was decided that for CSR bulk carriers the requirements of UR S10 are superseded by those of the Common Structural Rules and therefore do not apply. However for CSR oil tankers the requirements of UR S10 are still valid.

Additionally the opportunity was taken to correct a couple of equations in S10.1 and S10.3.

.5 Other Resolutions Changes

All UR S files, except UR S8, S9, S15, S16, S19, S22, S23, S30 and S31.

.6 Dates:

Original proposal: *2007, made by Hull Panel Task 50*
Panel submission to GPG: *19 April 2010*
GPG Approval: *24 May 2010 (Ref. 10051_IGd)*

- **Corr.2 (July 2003)**

No TB document available.

- **Corr.1 (July 1999)**

Editorial correction to equation for d_t in Section S10.3 – no TB document available.

- **Rev.1 (1990)**

No TB document available.

- **New (1986)**

No TB document available.

Part B. Technical Background

List of Technical Background (TB) documents for UR S10:

Annex 1. **TB for Rev.3 (Mar 2012)**

See separate TB document in Annex 1.

Annex 2. **TB for Rev.4 (Apr 2015)**

See separate TB document in Annex 2.

Annex 3 **TB for Rev.5 (May 2018)**

See separate TB document in Annex 3.

Annex 4 **TB for Rev.6 (Sep 2019)**

See separate TB document in Annex 4.

Annex 5 **TB for Rev.7 (Feb 2023)**

See separate TB document in Annex 5.

Note: *There are no separate Technical Background (TB) documents for the original resolution (1986), Rev.1 (1990), Corr.1 (July 1999), Corr.2 (July 2003), Rev.2 (May 2010), Corr.1 (Apr 2015), Corr.1 (Dec 2015), Corr.1 (June 2023) and Corr.2 (May 2024).*

Technical Background for UR S10 Rev.3, March 2012

1. Scope and objectives

This revision is limited to S10.8.3 and the change in bearing clearance associated with non-metallic bearing materials. The consequence of this change is that reduced bearing clearances may be seen for non-metallic bearings.

2. Engineering background for technical basis and rationale

As stated in the S10.8.3, smaller clearances may be permitted considering the material's swelling and thermal expansion properties upon the discretion of the Society, when supported by the manufacturer's recommendation and documented evidence of satisfactory service history with reduced clearances.

3. Source/derivation of the proposed IACS Resolution

None.

4. Summary of Changes intended for the revised Resolution:

The change to S10.8.3 entails deleting the text "in no way" from the third sentence and adding the fourth sentence.

5. Points of discussions or possible discussions

This change was agreed by the Hull Panel during the 13th and 14th meetings which took place in late 2010 and early 2011.

6. Attachments if any

None

Technical Background for UR S10 Rev.4, Apr 2015

1. Scope and objectives

UR S10 shall be updated based on more modern and comprehensive requirements in CSR BC.

2. Engineering background for technical basis and rationale

Please refer to detailed technical background document.

3. Source / derivation of the proposed IACS Resolution

The source of the information was obtained through work performed by a dedicated project team.

4. Summary of Changes intended for the revised Resolution:

Please refer to attached Summary of changes in table format.

5. Points of discussions or possible discussions

None

Detailed technical background

The following provides technical background to the rule modifications identified as "technical" in the summary of changes, and the items that are new or based on CSR BC rules.

1.4.1
Slot welds are to be avoided in highly stressed areas, since the area of the plate material will be reduced due to the slots. Slots shall not be filled with weld, since this will make it difficult to detect cracks or loss of contact with the inside web.

1.4.2
The rudder horn recess is prone to cracking. The requirements have been introduced to make a design standard with less stress concentrations and hence less fatigue problems.

1.4.3
Welding requirement has been introduced to provide a good connection between plates and castings or very thick plating.

1.5
1.5.1 to 1.5.4 specify principles for equivalence considerations.

2.1.1
The thrust factor K_{th} has been deleted, since the thrust coefficient is normally not known in the approval phase. Taking account of K_{th} larger than 1 should be the responsibility of the designer.

Coefficients for high lift rudders, fish tail, single plate and mixed profiles (e.g. HSVA) have been added in line with CSR BC rules.

Coefficients for High lift rudders and Fish tail are from the comparison between High lift rudder, the fish tail type schilling rudder and a conventional rudder (NACA0020) based on circulatory water tunnel tests and strain gauge readings on actual rudders. According to the test results, it has shown that the CL lift coefficients are:

High Lift Rudders(Rudder with flaps)	-	1.77
Schilling rudder	-	1.30
Conventional NACA0020	-	1.15

It indicates that "y" peak force on the high lift rudders and the schilling rudder is about 54 (1.77/1.15) and 13 (1.30/1.15) per cent higher than force on a conventional rudder of the NACA 0020 form. Considering the above with safety factor, coefficients K_2 are given as below

High Lift Rudders(Rudder with flaps)	K_2= 1.1(NACA-00) x 1.54= 1.69 ⇒ 1.7
Fish tail(Schilling rudder)	K_2= 1.1(NACA-00) x 1.13= 1.24 ⇒ 1.4

Coefficients for Mixed side profiles are taken from C.1.1, Sec.14, Chapter 1, Part 1 of the GL Rules.

Coefficients for Single plate are standard basis.

5.1
It has been clarified that material factor k should be included in the stress criteria. However, in way of the recess for the rudder horn pintle on semi-spade rudders no credit for high tensile steel is given, since the given stress criteria are considered necessary to avoid fatigue cracks. The fatigue resistance properties of high tensile steel are similar to mild steel.

Reference is made to Appendix 1.

5.3.2
Based on CSR BC. No TB available.

5.3.3
Solid parts, in forged or cast steel, used for the housing of either the rudder stock or of the rudder pintle are connected to the rudder blade by means of horizontal and vertical web plates, as shown in figure 1, here below. The solid part is located either below the lower rudder stock-bearing, or below the lower pintle-bearing.

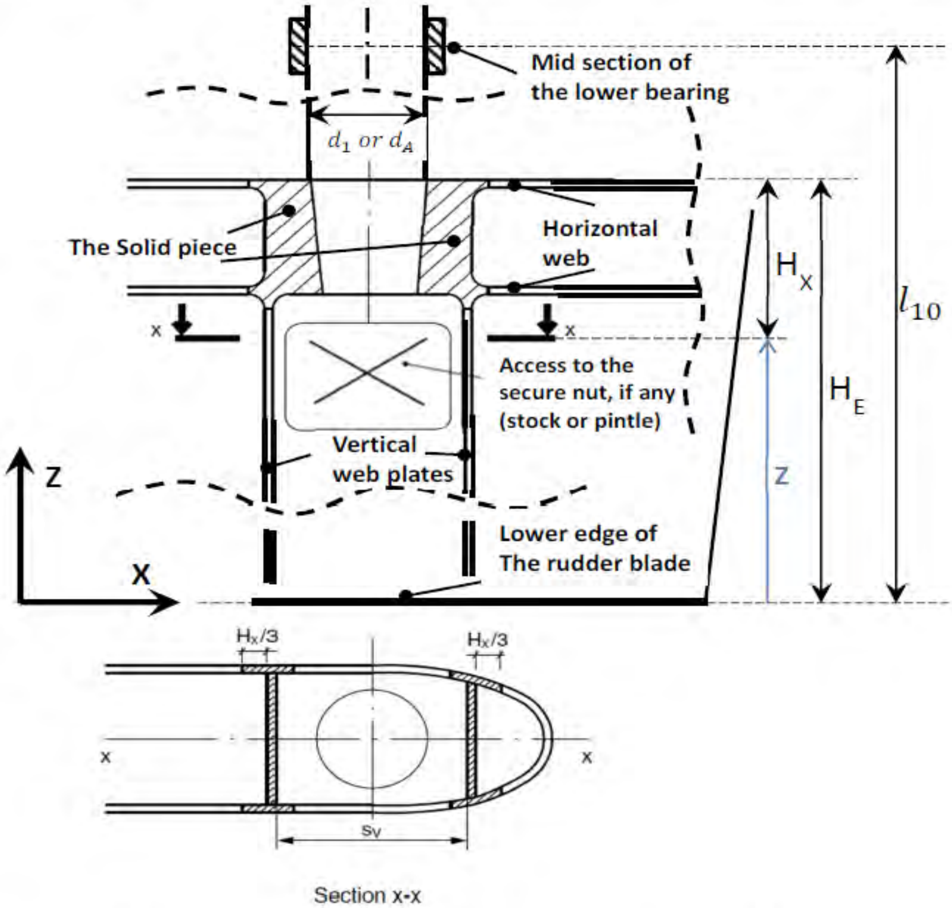

Figure 1 : Section modulus in the area below stock or pintle

The section modulus of the cross-section of the structure of the rudder blade, formed by vertical web plates and rudder body plating, is to be enough stiff to withstand bending moment acting on this area.

The objective is to provide the technical background for the following formula:

$$W_s = c_s\, d_1^3 \left(\frac{H_E - H_X}{H_E}\right)^2 \frac{k}{k_1} 10^{-4} \qquad (1)$$

Bending moment acting below the solid part:

Two rudder systems are considered in the scope of this technical note: spade rudders and semi-spade rudders. Bending moment diagrams from the lower edge of the blade till the lower bearing area of the rudder system can be written, as follows:

- For spade rudders

$$M_z = -p_{R10}\frac{z^2}{2} - \left(\frac{p_{R20} - p_{R10}}{l_{10}}\right)\frac{z^3}{6} \qquad (2a)$$

- For semi-spade rudders:

$$M_z = -p_{R10}\frac{z^2}{2} \qquad (2b)$$

where:

z is the distance, in m, from the lower edge of the rudder blade till its cross-section submitted to the bending moment M_Z

p_{R10} is the force per unit length, in N/m, obtained for z equal to zero (at rudder-blade bottom edge)

p_{R20} is the force per unit length, in N/m, obtained for z equal to l_{10} (location of the lower bearing, mid-section)

Note that in case of spade-rudders, $p_{R10} = p_{R20} = constant$, and the cubic term of equation (2a), becomes zero.

For both formulae (2a) and (2b), the minimum bending moment, $M_Z = 0$ is obtained for $z = 0$ and the maximum bending moment, M_Z is obtained for $z = l_{10}$.

At the lower bearing position, for $z = l_{10}$, the section modulus of the structure is mainly given either by:

- Cross-section of the rudder stock, with diameter d_1, in mm, calculated for a solid circle, as follows:

$$W_s = \frac{I}{\left(\frac{d_1}{2}\right)} = \frac{\pi d_1^3}{32} \approx \frac{d_1^3}{10}, which\ is\ valid\ for\ a\ material\ with\ a\ coefficient = k_1 \qquad (2c)$$

or by

- Cross-section of the rudder pintle, with diameter d_A, in mm, calculated for a solid circle, as follows:

$$W_p = \frac{I}{\left(\frac{d_A}{2}\right)} = \frac{\pi d_A^3}{32} \approx \frac{d_A^3}{10}, which\ is\ valid\ for\ a\ material\ with\ a\ coefficient = k_1 \qquad (2d)$$

Equations (2c) and (2d) may be written in cm^3, as follows:

$$W_s = d_1^3 10^{-4}\ cm^3 \qquad (2e)$$

$$W_p = d_A^3 10^{-4}\ cm^3 \qquad (2f)$$

The axial bending stress, σ_z, generated by the bending moment, M_z, is given by:

$$\sigma_z = \frac{M_z}{W_{sect}} \qquad (3a)$$

The normalized variable $u_z = \left(\frac{H_E - H_X}{H_E}\right)$ is defined, from figure 1, here above. By using it inside of equations (2a) and (2b), it can be seen that the bending moment will be decreasing from the value M_{H_E} till zero, when H_X varies from zero to H_E.

Section modulus below the solid part:

At $z = H_E \, or \, u_z = 1$, it can be said that, for a section modulus $W_{mec} = W_s \, or \, W_p$, the level of stress σ_{H_E}, acting on this section is acceptable, either based on the scantling of the rudder stock or on the scantling of the rudder pintle.

Based on the equation (3a), and assuming that the axial bending stress should be kept at most equal to σ_{H_E} inside of this transition zone, through the solid part thickness and beneath the lower edge of this part, the following can be written:

$$\sigma_{H_E} = \frac{M_{H_E}}{W_{mec}} \frac{u_z^2}{u_z^2} = constant \qquad (3b)$$

where $W_{mec} = d_v^3 10^{-4} \; cm^3 \text{ ,} with \; d_v \; either = d_1(rudder\ stock) \; or \; d_A(rudder\ pintle)$

Equation (3b) will make sure that the level of stress acting on a cross section (see figure 1, section at X-X) of the rudder blade is less than or equal to σ_{H_E}. Based on equation (3b), the section modulus at any cross section X-X, below the solid part, should be of a value, at least equal to W_{sect}, defined as follows:

$$W_{sect} = W_{mec} u_z^2 = d_v^3 10^{-4} \left(\frac{H_E - H_X}{H_E}\right)^2 \qquad (3c)$$

Equation (1) can be obtained from equation (3c) by adding:

1. a safety factor, c_s, to compensate the existence, or not of an opening in the considered cross section(*)
2. the ratio $\frac{k}{k_1}$, to make the difference of material properties of the stock (or pintle) with the web plates

From equation (3c), and considering the two above remarks, it can be written:

$$W_{sect} = c_s d_v^3 \left(\frac{H_E - H_X}{H_E}\right)^2 \frac{k}{k_1} \quad 10^{-4} \quad cm^3 \qquad (3d)$$

(*)Note that, the c_s coefficient is also considered to make possible the use of the same formula for the calculation of the actual section modulus for any cross section X-X, just in the region below the lower edge of the solid part (for both cases with or without an opening in the rudder plating). The breadth of the rudder plating to be considered for the calculation of this actual section modulus is to be not greater than that obtained, in m, from the following formula:

$$b = s_V + 2\frac{H_X}{m} \qquad (4)$$

where:

$s_V =$ *spacing, in m, between the two vertical webs (see figure 1)*

$H_X =$ *distance defined according to figure 1*

$m =$ *coefficient to be taken, in general, equal to 3.*

5.3.4

Based on CSR BC. (No TB available.)

5.3.5
Based on CSR BC. (No TB available.)

6.1.5
The bolts are to be of fitted type in order to efficiently transfer shear forces.

6.2.4
The bolts are to be of fitted type in order to efficiently transfer shear forces.

6.3.2
Based on CSR BC. (No TB available.)

6.3
Reference is made to Appendix 2.

6.3.5
There are designs where the key transmits all of the rudder torque, and in this case push-up pressure and length should be considered properly. However, it is considered outside the scope of this UR S10 update to develop detailed requirements.

6.3.4
Based on CSR BC. (No TB available.)

6.4
Reference is made to Appendix 2.

6.4.1
Based on CSR BC. (No TB available.)

6.4.2
Based on CSR BC. (No TB available.)

6.4.3
Based on CSR BC, with no TB available. In addition a push up length minimum requirement has been added

8.1.1
Based on CSR BC. (No TB available.)
Sentence regarding small ships deleted, since normally bushes are required, there is no definition for "small ships", and "suitably increased" is very vague.

8.1.2
Based on CSR BC. (No TB available.)

8.2
Maximum surface pressure for synthetic material has been limited to 10 N/mm^2.

9.2.2
Based on CSR BC. (No TB available.) Reference to rudder side plating removed, since the requirement based on length will normally be governing.

9.2.3
Based on CSR BC. (No TB available.) The following sentence is deleted, since the requirement is difficult to justify: "The thickness of these plate floors is to be increased by 50% above the bottom thickness determined according to Ch 6, Sec 1 or Ch 9, Sec 2."

Requirement to scallops added, in order to avoid crack initiation points in areas with high shear stress.

In order to achieve better connection with the hull structure brackets or stringers are to be fitted internally in horn in line with outside shell plate

Requirement to full penetration welding added to avoid cracking.

9.3.1
Based on CSR BC. (No TB available.)

9.3.2
Based on CSR BC. (No TB available.)

Annex 10.3
Reference is made to Appendix 3.

Annex 10.6
Reference is made to Appendix 4.

Appendix 1 Scantling of rudder blades with cut-outs (bending stress criterion)

GENERAL

The scantling of rudder blades takes into consideration bending and shear stresses, for both cases of rudder blades with and without cut-outs. It is noted that the presence of cut-outs will introduce geometrical discontinuities on the surface of the rudder blade, and will also decrease the real section area withstanding bending stress generated by the bending moment. An illustration of this is depicted in figures 1a, 1b, 1c and 1d, here below, which ones represent simplified views of plates and rudder blades, with and without cut-outs, subjected to a total force F uniformly distributed along the upper and bottom edges of the piece.

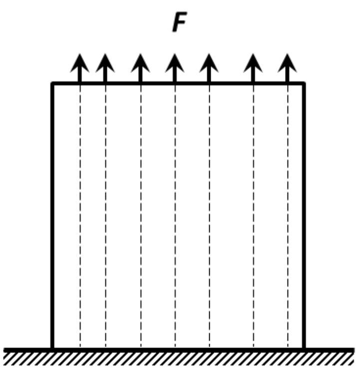

Figure 1a: *Force flow-lines through a plate without cut-outs*

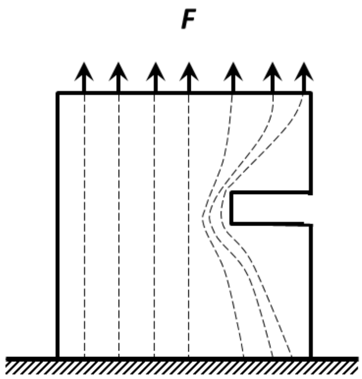

Figure 1b: *Force flow-lines through a plate with cut-outs*

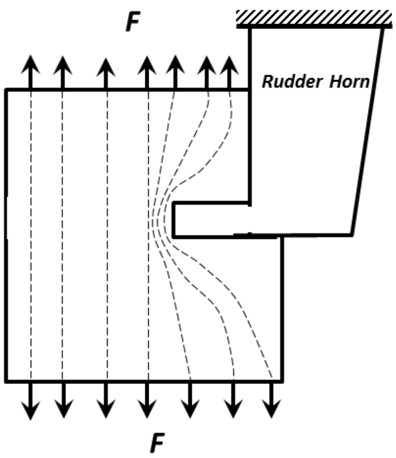

Figure 1c: *Force flow-lines through a rudder blade with cut-outs*

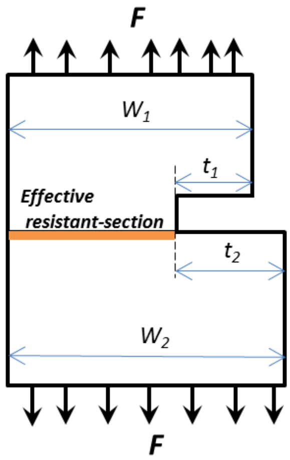

Figure 1d: *Main dimensions of the rudder blade and its effective resistant-section to the applied bending stress*

In addition to the section area reduction, these geometrical discontinuities also work as stress raisers, producing local stresses much higher than the nominal net section stress that would be calculated without considering stress concentration effects. The question addressed inside of this technical note is just referring to the value of "stress amplification" factor, sA_f, to be adopted in view of estimating the level of bending stress acting on a rudder blade with cut-outs. This note brings technical argumentation to be used on the choice of this "stress amplification" coefficient.

It is reminded that the bending stress scantling criterion of the rudder blade with cut-outs, according to URS10, can be considered as being a percentage of the maximum allowable bending stress for the rudder blade without cut-outs. That is why the "stress amplification-factor" may be considered, to make possible the definition of the maximum allowable bending stress of a rudder blade with cut-outs, $\boldsymbol{\sigma}_{\mathbf{allow\_cut}}$, as a function of the maximum allowable bending stress of a rudder blade without cut-outs, $\boldsymbol{\sigma}_{\mathbf{allow\_uncut}}$, as follows:

$$\sigma_{allow\_cut} = \frac{\sigma_{allow\_uncut}}{sA_f} \qquad (1a)$$

OBJECTIVE

To provide the technical background for the scantling criterion applicable for the bending stresses on the rudder blades with cut-outs. In other words, to justify the choice of the allowable bending stress for a rudder blade with cut-outs, based on:

- either:

$$sA_f = 1.22 \quad or \quad \sigma_{allow_{cut}} = \frac{\sigma_{allow_{uncut}}}{sA_f} = \frac{110}{1.22} = 90. \quad N/mm^2 \qquad (2a)$$

- or:

$$sA_f = 1.47 \quad or \quad \sigma_{allow_{cut}} = \frac{\sigma_{allow_{uncut}}}{sA_f} = \frac{110}{1.47} = 75. \quad N/mm^2 \qquad (2b)$$

STRESS FACTOR WITHOUT THE NOTCH EFFECT

The stress amplification factor, sA_f, can be calculated based on the effective resistant-section, as illustrated in the figure 1d here above, by using formulae as follows:

- Lower limit of sA_f:

$$sA_{fL} = \left(\frac{W_1}{W_1 - t_1}\right) \qquad (3a)$$

- Upper limit of sA_f:

$$sA_{fU} = \left(\frac{W_2}{W_2 - t_2}\right) \qquad (3b)$$

- Average value of sA_f:

$$sA_{fA} = \left(\frac{0.5 * [W_2 + W_1]}{W_1 - t_1}\right) = \left(\frac{0.5 * [W_2 + W_1]}{W_2 - t_2}\right) \qquad (3c)$$

This is a coarse and simplified approach which only takes into consideration the reduction of the effective resistant-section, due to the presence of the cut-out on the surface of the rudder blade.

Although this simplified method does:

- neither take into consideration the existence of several vertical and horizontal web plates, which reinforce different regions of the rudder blade, changing locally the section modulus of the blade
- nor considers any notch effect, very dependent on the smoothness of edges in the cut-out areas,

this approach can give a coarse estimation of the nominal stress acting on the resistant-section of the rudder-blade.

CASE SAMPLE

We have considered a case sample based on a very big rudder blade from our records, having a mean height of 13 m, and with the following geometrical parameters, as per figure 1d:

$$W_1 = 5.38\,m\ ; \quad W_2 = 6.90m; \quad t_1 = 1.27\,m\,; \quad t_2 = 2.79\,m\,;$$

Based on formulae (3a), (3b) and (3c), the following values are obtained:

$$sA_{fL} = 1.31\,; \quad sA_{fU} = 1.68; \quad and\ sA_{fA} = 1.49$$

The acceptance criteria can be obtained, as follows:

$$\sigma_{allow_{cut\_Max}} = \frac{\sigma_{allow_{uncut}}}{sA_{fL}} = \frac{110}{1.31} = 84. \quad N/mm^2 \qquad (3d)$$

$$\sigma_{allow_{cut\_Average}} = \frac{\sigma_{allow_{uncut}}}{sA_{fA}} = \frac{110}{1.49} = 74. \approx 75. \quad N/mm^2 \qquad (3e)$$

$$\sigma_{allow_{cut\_Min}} = \frac{\sigma_{allow_{uncut}}}{sA_{fU}} = \frac{110}{1.68} = 65.5 \quad N/mm^2 \qquad (3f)$$

CONCLUSION

Considering the results given for the case sample here above, the value of $\sigma_{allow_{cut}} = 75.\,N/mm^2$, as the scantling criterion applicable for the bending stresses on the rudder blades with cut-outs, is more appropriated than the one of 90.0 N/mm^2.

As a general criterion, the value of 75.0 N/mm^2 is to be considered inside of the URS10. Of course, the designer of the rudder system may always submit for approval, a FE calculation based on the real structure of the rudder blade, considering all horizontal and vertical web plates, and modeling in detail the cut-areas of the part. This FE analysis can provide a more relevant value for the stress amplification factor, sA_f, to consider on the evaluation of the allowable bending stress.

Appendix 2 Cone coupling assembly of steel rudder stock with the massive part

1. Introduction

1.1. General

The assembly process based on the tight tolerance fit of two mechanical parts, with axi-symmetrical geometries, assumes that relevant stress tensor is acting in a plane defined by the radial and circumferential directions. The strain component, ε_z, may be not negligible, and can be calculated from radial and circumferential stress-components, and engineering material constants.

1.2. Stress – strain relations, in a state of plane stress

In case of isotropic materials in plane stress, defined by the Young's Modulus, E, and the Poisson's ratio,ν, the following equation can be written:

$$\begin{Bmatrix} \varepsilon_r \\ \varepsilon_\theta \\ \varepsilon_z \\ \gamma_{r\theta} \\ 0 \\ 0 \end{Bmatrix} = \begin{bmatrix} \frac{1}{E} & \frac{-\nu}{E} & \frac{-\nu}{E} & 0 & 0 & 0 \\ \frac{-\nu}{E} & \frac{1}{E} & \frac{-\nu}{E} & 0 & 0 & 0 \\ \frac{-\nu}{E} & \frac{-\nu}{E} & \frac{1}{E} & 0 & 0 & 0 \\ 0 & 0 & 0 & \frac{1}{G} & 0 & 0 \\ 0 & 0 & 0 & 0 & \frac{1}{G} & 0 \\ 0 & 0 & 0 & 0 & 0 & \frac{1}{G} \end{bmatrix} \begin{Bmatrix} \sigma_r \\ \sigma_\theta \\ 0 \\ \tau_{r\theta} \\ 0 \\ 0 \end{Bmatrix} \qquad (1)$$

For each orthogonal direction, strain values can be calculated, as follows:

$$\varepsilon_r = \frac{1}{E}(\sigma_r - \nu\sigma_\theta) \qquad (1a)$$

$$\varepsilon_\theta = \frac{1}{E}(\sigma_\theta - \nu\sigma_r) \qquad (1b)$$

$$\varepsilon_z = -\frac{\nu}{E}(\sigma_r + \sigma_\theta) = -\frac{\nu}{1-\nu}(\varepsilon_r + \varepsilon_\theta) \qquad (1c)$$

$$\gamma = \left(\frac{1+\nu}{E}\right)\tau_{r\theta} \qquad (1d)$$

For the case of shrinking fit between two axi-symmetric parts (axi-symmetry related with geometry and loads), the following is also true:

$$\gamma_{r\theta} = \tau_{r\theta} = 0 \qquad (1e)$$

2. Objective of the study

The objective of this note is to describe the cone coupling assembly process for both key and keyless processes, by, amongst others, evaluating the contact pressure between the outer surface of the rudder stock and the inner surface of the massive part, at the end of the cone coupling assembly process. Relevant calculations are based on elastic formulae of thick-walled cylinders submitted to both internal and external pressures, p_i and p_e, respectively. Friction forces may be calculated at the contact surface between the rudder stock and the outer cone (massive part) by using a Coulomb friction model. Knowing the friction coefficient existing between contact surfaces, the contact pressure is adjusted in view of producing friction forces enough high to withstand bending and torsion moments in way of the cone coupling joint.

3. Formulae for thick-walled cylinders

3.1. Thick cylinders under internal and external loadings

Figure 1 shows a thick cylinder submitted to internal and external pressures.

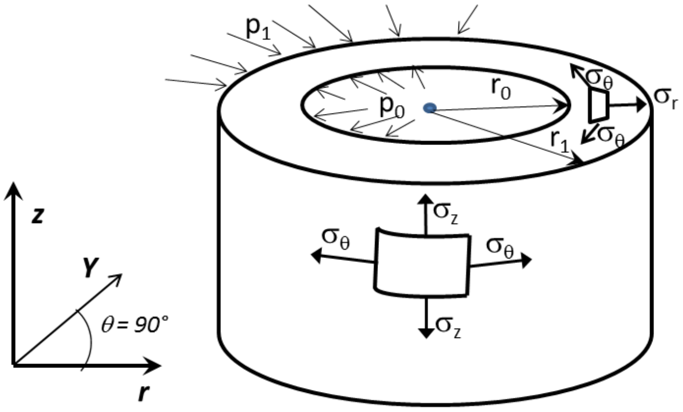

Figure 1 : Thick cylinder under internal and external pressure

The cylinder of figure 1 is submitted to:

- uniform internal radial pressure, p_0
- uniform external radial pressure, p_1

The longitudinal (OZ axis) component of stress, σ_z, is made equal to zero (end free condition).
Main stress axes, according to figure 1, are defined, as follows:

- radial direction, r
- circumferential direction, Y (or θ axis)
- longitudinal direction, Z

For $\sigma_z = 0$, the radial and circumferential components of stress, at a radial position, r, are given by the following formulae:

$$\sigma_r = p_0 \frac{r_0^2}{(r_1^2 - r_0^2)}\left[\frac{r^2 - r_1^2}{r^2}\right] - p_1 \frac{r_1^2}{(r_1^2 - r_0^2)}\left[\frac{r^2 - r_0^2}{r^2}\right] \qquad (3a)$$

$$\sigma_\theta = p_0 \frac{r_0^2}{(r_1^2 - r_0^2)}\left[\frac{r^2 + r_1^2}{r^2}\right] - p_1 \frac{r_1^2}{(r_1^2 - r_0^2)}\left[\frac{r^2 + r_0^2}{r^2}\right] \qquad (3b)$$

Where:

- r_0 = inner radius of the cylinder
- r_1 = outer radius of the cylinder
- r = radial position, where stress components, σ_r and σ_θ, are calculated

For the case of cylinders submitted only to an internal pressure, equations (3a) and (3b) would become:

$$\sigma_r = p_0 \frac{r_0^2}{(r_1^2 - r_0^2)}\left[1 - \left(\frac{r_1}{r}\right)^2\right] \qquad (< 0, compression) \qquad (3c)$$

$$\sigma_\theta = p_0 \frac{r_0^2}{(r_1^2 - r_0^2)}\left[1 + \left(\frac{r_1}{r}\right)^2\right] \qquad (> 0, tension) \qquad (3d)$$

For the case of cylinders submitted only to an external pressure, equations (3a) and (3b) would become:

$$\sigma_r = -p_1 \frac{r_1^2}{(r_1^2 - r_0^2)}\left[1 - \left(\frac{r_0}{r}\right)^2\right] \qquad (< 0, compression) \qquad (3e)$$

$$\sigma_\theta = -p_1 \frac{r_1^2}{(r_1^2 - r_0^2)}\left[1 + \left(\frac{r_0}{r}\right)^2\right] \qquad (< 0, compression) \qquad (3f)$$

For the case of full section cylinders ($r_0 = 0$), both stresses become identical ($\sigma_r = \sigma_\theta = -p1$).

4. Shrinking fit of a hole shaft with a hub

4.1. General

Figure 2, here below, shows two cylindrical steel parts, to be assembled together, by a shrinking fit process.

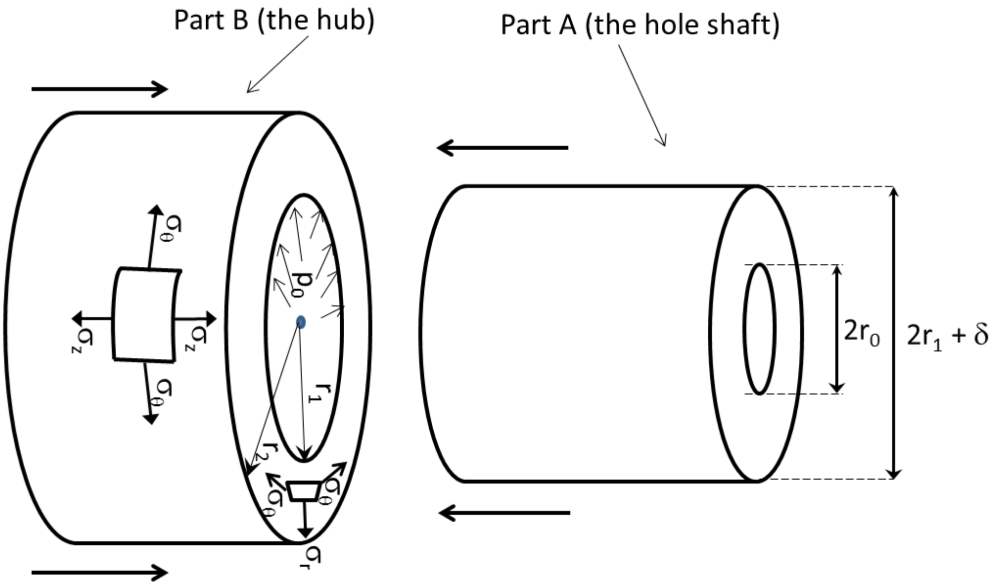

Figure 2 : Two thick cylindrical parts to be assembled by shrinking fit

At the equilibrium position, the outer surface of part A and the inner surface of part B will be in contact. The contact pressure at this equilibrium position, p_{eq}, is a function of the initial radial interference, δ.
The problem will consist on the calculation of a relevant value of δ necessary to generate a pressure, p_{eq}, required to withstand torque or both torque and bending moments to be transferred from B to A, or vice-versa.

4.2. The radial interference as a function of the contact pressure

Figure 3 shows a cut view of parts A and B of figure 2, at the final equilibrium position, after the assembly process.

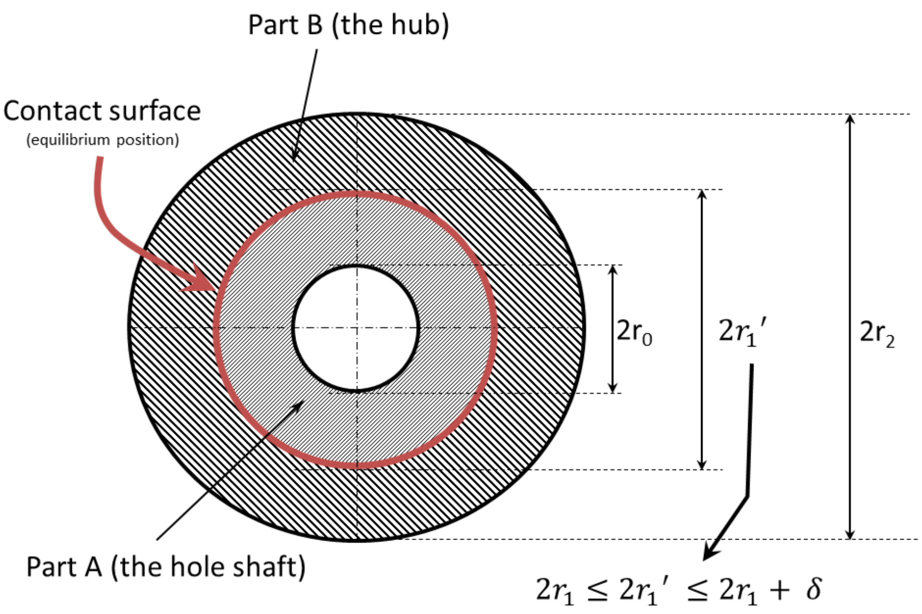

Figure 3 : Equilibrium position after assembly (shrinking fit)

It is assumed that, at the end of the shrinking fit process, radii r_0 and r_2 remain constant. At the equilibrium position, the radius of the contact surface between parts A and B can be calculated, as follows:

- For part A:

$$2r_1'\pi = (2r_1 + \delta)\pi + \varepsilon^A_{\theta(r=r_1)}(2r_1 + \delta)\pi \qquad (4a)$$

  Where the second term on the right side of equation (4a) represents the circumferential deformation of the "part A", over the length $(2r_1 + \delta)\pi,$ and caused by the external pressure, p_{eq}.

- For part B:

$$2r_1'\pi = 2r_1\pi + \varepsilon^B_{\theta(r=r_1)}\, 2r_1\pi \qquad (4b)$$

  Where the second term at the right side of equation (4b) represents the circumferential deformation of the "part B", over the length $2r_1\pi,$ and caused by the internal pressure, p_{eq}.

From equations (4a) and (4b), and assuming that the term $\varepsilon^A_\theta.\delta$ can be neglected, it follows:

$$\frac{\delta}{2r_1} = \varepsilon^B_\theta - \varepsilon^A_\theta \qquad (4c)$$

Assuming that parts A and B are made of materials A and B, respectively, and by using equation (1b) for these materials, it can be written:

$$\varepsilon^A_\theta = \frac{1}{E^A}\left(\sigma^A_\theta - \nu^A \sigma^A_r\right) \qquad (4c_1)$$

$$\varepsilon^B_\theta = \frac{1}{E^B}\left(\sigma^B_\theta - \nu^B \sigma^B_r\right) \qquad (4c_2)$$

Where:

- $E^j \; and \; \nu^j, for \; j = A \; or \; B$, are engineering constants, $E \; and \; \nu$, for the materials A and B, respectively.
- $\sigma^j_i \; , for \; i = r \; or \; \theta, and \; j = A \; or \; B$, are radial or circumferential stresses acting on either part A or on part B.

The values of σ_i^j can be calculated for materials A and B at $r = r_1$, by using equations (3a) and (3b), as follows:

- For part A, by making $p_0 = 0 \; and \; p_1 = p_{eq}$
- For part B, by making $p_0 = p_{eq} \; and \; p_1 = 0$

By replacing the calculated values of σ_i^j, on equations ($4c_1$) and ($4c_2$), $\varepsilon_\theta^A \; and \; \varepsilon_\theta^B$ can be expressed, as follows:

$$\varepsilon_\theta^A = \frac{-p_{eq}}{E^A}\left[\frac{(r_1^2 + r_0^2)}{(r_1^2 - r_0^2)} - \nu^A\right] \qquad (4c_3)$$

$$\varepsilon_\theta^B = \frac{p_{eq}}{E^B}\left[\frac{(r_1^2 + r_2^2)}{(r_2^2 - r_1^2)} + \nu^B\right] \qquad (4c_4)$$

By replacing the values of $\varepsilon_\theta^A \; and \; \varepsilon_\theta^B$ from equations ($4c_3$) and ($4c_4$) on to equation (4c), the following can be written:

$$\frac{\delta}{2r_1} = p_{eq}\left\{\frac{1}{E^B}\left[\frac{(r_1^2 + r_2^2)}{(r_2^2 - r_1^2)} + \nu^B\right] + \frac{1}{E^A}\left[\frac{(r_1^2 + r_0^2)}{(r_1^2 - r_0^2)} - \nu^A\right]\right\} \qquad (4d)$$

Equation (4d) relates the radial interference δ with the contact pressure, p_{eq}, at the end of the shrinking fit process. In other words, the contact pressure obtained at the end of the shrinking fit process can be adjusted based on equation (4d), by changing the value of δ. In case of tapered contact surfaces, an axial movement of part A against part B, by simply pushing part A on to part B, will induce variations of the radial interference, and consequently will change the contact pressure, p_{eq}. This is at the origin of the variable named "push-up" length, which associates the radial interference δ, to the axial relative displacement of parts A and B.

4.3. Relating radial shrinkage to push-up length

In the elastic domain, radial shrinkage of the rudder shaft may be associated to the push up length based on geometrical data, such as: the taper of conical coupling", **c**, measured on diameter, and the "slope" in this area, given by **c/2**).

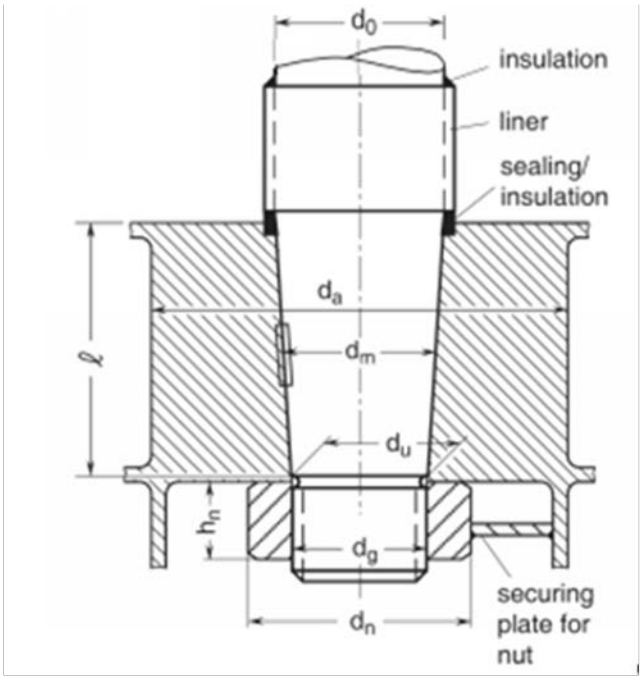

Figure 4: Geometry of cone coupling

These geometric data, according to figure 4, are defined, here below, as follows:

- $taper\ of\ conical\ coupling = \ c = \frac{(d_0 - d_u)}{l}$ $\qquad (4e)$
- $slope\ in\ the\ conical\ coupling\ area = \tan(angle) = \frac{\left(\frac{(d_0 - d_u)}{2}\right)}{l} = \frac{c}{2}$ $\qquad (4f)$

The "push up" length may be expressed as a function of the "shrinkage diameter" (radial interference$, \delta, of\ equation\ (4d), above)$, as follows:

$$\text{push-up}\ length = \ \Delta = \frac{diametral\ shrinkage\ (\delta)}{taper\ of\ conical\ coupling(c)} \qquad (4g)$$

5. Principles for Cone coupling design

5.1. Design basis

The cone coupling joint is designed to transmit loads from the rudder blade through the rudder stock, and vice-versa, by using friction forces to be generated between contact surfaces. The push-up pressure (related to a push-up length) has to be enough high to generate necessary friction forces able to withstand torsion and bending efforts passing through this joint, for both cases of keyed or keyless assemblies. These efforts are to be evaluated in the way of the cone coupling joint for the rudder mechanical system, on a case by case basis.

The term "push-up pressure"(or push-up length) is referring to the "equilibrium pressure" (or equilibrium “relative position of assembled parts”) obtained at the end of cone coupling assembly process. The “push-up” pressure is the required pressure existing between contact surfaces to keep the rudder blade fully tied to the rudder stock, allowing the "cone coupling joint" to withstand designed bending and torsion moments. The "equilibrium pressure" is valid only for a given friction coefficient (assumed as 0.15 for steel-steel surfaces and 0.13 for steel-SG iron surfaces).

A safety coefficient is included on the design of a cone coupling joint, by either considering a key as a safety device, or by designing a higher value of “push-up pressure”. For both cases, friction forces have to be generated at contact surfaces to a level sufficiently high to ensure the safety transmission of bending and torsion efforts from the rudder blade to the rudder stock, and vice-versa.

Special care is to be drawn for the calculation of threshold limit stress acting on the outer cone of the cone coupling joint, to avoid this part to burst, and being definitely damaged.

5.2. Scantling the cone coupling joint

The design of the cone coupling assembly is based on the calculation of:

1. minimum values of push-up pressure and push-up length based on either design yield moment of the rudder stock or the bending moment in the cone coupling (the one producing maximum 'push-up' pressure , and push-up length, as well, is taken)
2. the torsion moment, expressed by Q_F, also known as the design yield moment of the stock, which is calculated based on the rudder torque value, Q_R
3. key dimensions required for the cone coupling joints with a key, by assuming that 50% of Q_F is supported by friction force and remaining 50% by the key. In this case the safety margin is provided by the key. Under normal conditions, the key is not designed to ensure the transmission of the torsion: it is supposed to work only when friction forces are not enough high to withstand the rudder torque, Q_R
4. friction forces required for the cone coupling joints without key, by assuming that 100% of Q_F is supported by friction forces acting between contact surfaces of the rudder body and rudder stock. In this case the safety margin is ensured by the increase of the friction forces, which are taken twice those calculated for cone coupling joints with key)
5. maximum acceptable values of push-up pressure and push-up length to avoid any damage caused to the massive part (the outer cone)

Cone coupling push-up pressure and push-up length are calculated based on a plane state of stress acting between the rudder stock and the massive part of the rudder blade, as previously described inside of chapters 1, 3 and 4 of this document.

5.3. Bases for calculating the design yield moment

For the cross section of a round shaft the maximum shear stress acting on the cylindrical surface of the shaft may be calculated, as follows:

$$\tau = \frac{16\ Q_F}{\pi d_{shaft}^3} \qquad (5.1a)$$

Where:

Q_F
: *is the twisting or torsion moment, in N .mm (also known as the design yield moment)*
d_{shaft} : *is the diameter of the shaft*, in mm

The maximum shear stress may also be written as a function of the material yield stress based on the von Mises criterion (also known as the distortion-energy theory of yielding), as follows:

$$\tau = \frac{R_{eH}}{\sqrt{3}} \qquad (5.1b)$$

Based on equations (5.1a) and (5.1b), the design yield moment, Q_F, can be expressed by:

$$Q_F = \frac{\pi d_{shaft}^3}{16\sqrt{3}} R_{eH} \approx 0.2\, d_{shaft}^3 \frac{R_{eH}}{\sqrt{3}} \qquad (5.1c)$$

By introducing the material factor, k_s, and assuming the reference value $R_{eH} = 235 \frac{N}{mm^2}$, equation (5.1c) becomes:

$$Q_F = 26.64\, d_{shaft}^3 \,.k_s \ \text{in } N\,.mm \qquad (5.1d) \quad or$$

$$Q_F = 0.02664\, d_{shaft}^3 \,.k_s \ \text{in } N.m \qquad (5.1e)$$

For safety reasons, the design yield moment Q_F, is taken twice the value of, Q_R, the torsion moment taken for the design of the rudder stock, in such way to have the following relation: $Q_F = 2\,.Q_R$

By using the above relation between Q_F and Q_R and equation (5.1d), the rudder stock diameter, in mm, may be calculated from equations (5.2a) and (5.2b), as follows:

$$2\,Q_R = 26.64\, d_{shaft}^3 \,.k_s \qquad (5.1f) \ , \ or$$

$$Q_R = 13.32\, d_{shaft}^3 \,.k_s \quad \text{in } N\,.mm \qquad (5.1g)$$

$$Q_R = 0.01332\, d_{shaft}^3 \,.k_s \quad \text{in } N\,.m \qquad (5.1g\_bis)$$

$$d_{shaft} = \sqrt[3]{\frac{Q_R}{13.32\,k_s}} = 0.42\sqrt[3]{\frac{Q_R}{k_s}}, \qquad \text{with } Q_R \text{ expressed in } N\,.mm \qquad (5.2a)$$

By expressing the torsion moment, Q_R, in $N\,.m$, equation (5.2a) becomes:

$$d_{shaft} = 4.2\sqrt[3]{\frac{Q_R}{k_s}}, \qquad \text{with } Q_R \text{ expressed in } N\,.m \qquad (5.2b)$$

5.4. Design yield moment and its maximum value

The design yield moment of the rudder stock Q_F, *in N.m*, is to be calculated by using equation (5.1e), as follows:

$$Q_F = 0.02664\, d_{tActual}^3 \,.k_s \ \text{in } N.m \qquad (5.2c)$$

Where:

$d_{tActual}$: is the actual value of the rudder stock diameter, in mm, which must be $\geq d_{shaft}$.

d_{shaft} : is the rudder stock diameter, in mm, calculated based on the rudder stock torsion moment, Q_R, according to equation (5.2b).

For the calculation of Q_F according to equation (5.2c), the actual value of the rudder stock diameter, $d_{tActual}$, shall not be taken greater than $1.145\ d_{shaft}$. According to equation (5.3d) here below, this upper limit value is obtained by adopting the following procedure:

1. Definition of Q_{Fmax} , by using equation (5.1g_bis):

$$Q_{Fmax} = 3\,.Q_R = 3\,.\;0.01332\;d_{tActual}^3\,.k_s = 0.03996\;d_{tActual}^3\,.k_s \qquad (5.3a)$$

2. Calculating the “highest” value d_{tMax} , to be used in “the modified” equation (5.2c) in such way to obtain:

$$Q_{Fmax} = 3\,.Q_R = 0.02664\,d_{tMax}^3\,.k_s \qquad (5.3b)$$

3. Dividing equation (5.3a) by equation (5.3b):

$$\frac{Eq.(5.3a)}{Eq.(5.3b)} = \frac{Q_{Fmax}}{Q_{Fmax}} = \frac{0.03996\;d_{tActual}^3\,.k_s}{0.02664\;d_{tMax}^3\,.k_s} \qquad (5.3c)$$

4. To obtain:

$$\frac{d_{tMax}}{d_{tActual}} = \sqrt[3]{\frac{0.03996}{0.02664}} = \sqrt[3]{1.5} = 1.145 \qquad (5.3d)$$

6. Cone coupling with key

6.1. *Push–up pressure and friction forces to withstand $0.5\;Q_F$*

The required friction force acting between contact surfaces may be calculated based on the “equilibrium” pressure p_{req1} required to generate a friction force $,F_{fric\_Key},$ able to withstand 50% of the design yield moment, $,Q_F\;,in\;N.m.$ Based on this statement following equations may be written:

$$F_{fric\_Key} * \frac{d_m}{2} = \frac{Q_F}{2} \qquad (6.1a)$$

$$F_{fric\_Key} = F_N * \mu_0 = p_{req1} * Area_{Contact} * \mu_0 \qquad (6.1b)$$

$$Area_{Contact} = 2\pi * \frac{d_m}{2} * l \qquad (6.1c)$$

To obtain:

$$p_{req1} = \frac{F_{fric\_Key}}{Area_{Contact} * \mu_0} = \frac{Q_F}{d_m^2 * \pi * l * \mu_0} * 10^3 \qquad (6.1d)$$

$$F_{fric\_Key} = \frac{Q_F}{d_m} \qquad (6.1e)$$

Where:

d_m : Mean cone diameter, in mm, as shown in figure 4

F_N : Normal force to the contact surface between the rudder stock and outer cone, in N

F_{fric_Key} : Required friction force, in N, for a cone coupling connection with key

$Area_{Contact}$: Area of contact surface between the rudder stock and outer cone, mm^2

μ_0 : Friction coefficient, equal to about 0.15

l : Height, in mm, of the massive part (the outer cone, according to figure 4)

6.2. *Push-up length to withstand $0.5\;Q_F$*

The minimum push-up length necessary to withstand $0.5 * Q_F$, may be calculated by using equations (4g), (4d) and (4e), as follows:

1. Calculation of taper of conical coupling, c, with equation (4e) and geometrical data, in accordance to figure 4.

$$taper\ of\ conical\ coupling = \ c = \frac{(d_0 - d_u)}{l} \qquad (4e)\ \ or\ (6.2a)$$

2. Calculation of diametrical shrinkage , δ , based on equation (4d) by using: geometrical data from figures 2, 3 and 4; material properties with $\nu^B = \nu^A = \nu = 0.3$, $E^A = E^B = E$, and $p_{eq} = p_{req1}$, calculated according to equation (6.1d), here above.

$$\frac{\delta}{2r_1} = p_{eq}\left\{\frac{1}{E^B}\left[\frac{(r_1^2 + r_2^2)}{(r_2^2 - r_1^2)} + \nu^B\right] + \frac{1}{E^A}\left[\frac{(r_1^2 + r_0^2)}{(r_1^2 - r_0^2)} - \nu^A\right]\right\} \qquad (4d)\ or\ (6.2b)$$

3. Calculation of push-up length by replacing values of , δ and c , calculated in 2 and 1, respectively, on the equation (4g)

$$\text{push-up}\ length = \ \Delta_{req1} = \frac{diametral\ shrinkage\ (\delta)}{taper\ of\ conical\ coupling(c)} \qquad (4g)\ or\ \ (6.2c)$$

6.3. Push–up pressure & push length to withstand bending moment

The minimum push-up pressure , p_{req2} , $in\ N/mm^2$ necessary to withstand the bending moment , M_B, $in\ N.m$, is taken equal to the axial bending stress in way of the cone coupling joint, calculated, as follows:

$$p_{req2} = \sigma_{axial} = \frac{M_B}{W_{sect}} \qquad (6.3a)$$

Where W_{sect} = the section modulus of the massive part in way of the cone coupling joint, calculated based on geometrical data shown in figure 4:

$$W_{sect} = \frac{l^2 * d_m}{6} \qquad (6.3b)$$

To obtain:

$$p_{req2} = \frac{6 * M_B}{l^2 * d_m} 10^3, \quad in\ N/mm^2 \qquad (6.3c)$$

The calculation of push-up length , Δ_{req2} , associated to the push-up pressure may be performed by following the same procedure presented under [6.2], *push-up length necessary to withstand* $0.5 * Q_F$, by only changing the value of p_{eq} , by p_{req2} .

6.4. Minimum push–up pressure and push–up length

The minimum value of push-up pressure is selected by taking the maximum of $p_{req1} and \ p_{req2}$:

$$p_{req} = Max\left(p_{req1}, p_{req2}\right) \qquad (6.4a)$$

The minimum value of push-up length is selected by taking the maximum of $\Delta_{req1} and\ \Delta_{req2}$:

$$\Delta_{req} = Max\left(\Delta_{req1}, \Delta_{req2}\right) \qquad (6.4b)$$

6.5. Maximum push-up pressure and push-up length

The maximum allowable push-up pressure acting on the inner surface of the outer cone (the massive part) in the way of the cone coupling is based on von Mises equivalent stress, calculated for a biaxial state of stress $\sigma_r and\ \sigma_\theta$, as follows:

$$\sigma_{eq} = \sqrt{(\sigma_r - \sigma_\theta)^2 + \sigma_r^2 + \sigma_\theta^2} = \sqrt{2 * \sigma_r^2 + 2 * \sigma_\theta^2 - 2 * \sigma_r\ \sigma_\theta} \leq 0.8 * R_{eH} \qquad (6.5a)$$

Where $\sigma_r and\ \sigma_\theta$ are the radial and circumferential normal stresses acting on the inner surface of a thick walled cylinder, as described in chapter [3].

The upper stress limit of equation (6.5a) is taken $\leq 0.8 * R_{eH}$ and values of $\sigma_r and\ \sigma_\theta$ at the inner surface of the massive part may be calculated from equations (3c) and (3d) of chapter [3], by making $p_0 = p_{max}$, and $r = r_1$, as follows:

$$\sigma_r = p_{max} \frac{r_1^2}{(r_2^2 - r_1^2)}\left[1 - \left(\frac{r_2}{r_1}\right)^2\right] = -p_{max} \quad (< 0, compression) \qquad (6.5b)$$

$$\sigma_\theta = p_{max} \frac{r_1^2}{(r_2^2 - r_1^2)}\left[1 + \left(\frac{r_2}{r_1}\right)^2\right] = p_{max} * \frac{r_1^2 + r_2^2}{(r_2^2 - r_1^2)} \qquad (> 0, tension) \qquad (6.5c)$$

By making $r_1 = \frac{d_m}{2}$, and $r_2 = \frac{d_a}{2}$, in equation (6.5c) σ_θ may be written:

$$\sigma_\theta = p_{max} * \frac{(d_m^2 + d_a^2)}{(d_a^2 - d_m^2)} \qquad (> 0, tension) \qquad (6.5d)$$

The maximum allowable push-up pressure, p_{max}, may be calculated from equation (6.5a) by using equations (6.4b) and (6.4d), to obtain:

$$p_{max} \leq \frac{0.8 * R_{eH}}{\sqrt{2} * \sqrt{1 + \left[\frac{(d_m^2 + d_a^2)}{(d_a^2 - d_m^2)}\right]^2 + \left[\frac{(d_m^2 + d_a^2)}{(d_a^2 - d_m^2)}\right]}} \qquad (6.5e)$$

The calculation of the maximum push-up length, Δ_{max}, associated to the maximum push-up pressure, p_{max}, may be performed by following the same procedure presented under [6.2], by only changing the value of p_{eq}, by p_{max}.

6.6. Dimensions of key

A top cut view of the contact area of the cone coupling joint pointing out a rudder stock section with diameter d_K, which is designed a key as shown in figure 5a, here below. Figure 5b corresponds to a vertical cut view of the key, pointing out its shear section.

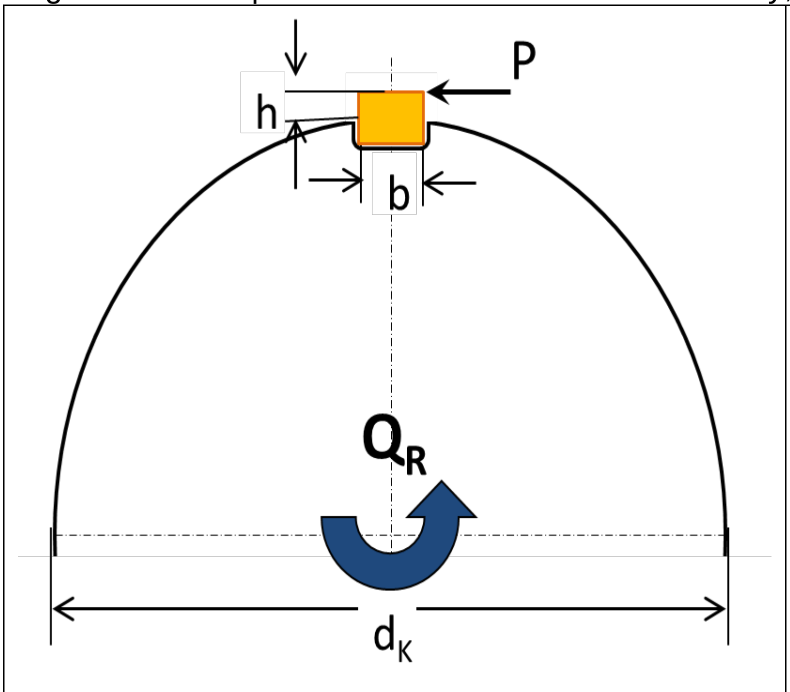

Figure 5a: A cut view of rudder stock with a key

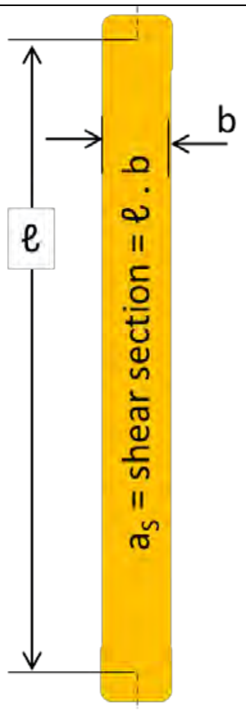

Figure 5b: The shear area of the key

The key is designed to support the shear force, P, in N, produced by , Q_R , in the way of the cone coupling joint. (Q_R , is the torsion moment taken for the design of the rudder stock, expressed in N m). The following relations between Q_R *and* P , and between τ_p *and* P , exist:

$$P\ [N] * \frac{d_K[mm]}{2} = Q_R\ [N\,m] * 10^3 \left[\frac{mm}{m}\right] \qquad (6.5a)$$

$$\tau_p \left[\frac{N}{mm^2}\right] = \frac{P\ [N]}{a_s[cm^2] * 10^2 \left[\frac{mm^2}{cm^2}\right]} \qquad (6.5b)$$

$$R_{eH\_min} \left[\frac{N}{mm^2}\right] = \frac{P\ [N]}{a_K[cm^2] * 10^2 \left[\frac{mm^2}{cm^2}\right]} \qquad (6.5c)$$

Where:

d_K : is the rudder stock diameter taken at the cut plane, in mm (for a conical surface, the mean diameter is taken)

a_s : is the minimum key shear area, in cm^2 , required to resist the shear force, P, generated by the torsion moment , Q_R , in N m .

a_K : is the minimum normal section area, in cm^2 , required to resist the force, P. This force, is first transmitted from the rudder stock to the key, and then from the key to the outer cone.

$R_{eH\_min} = Min\left(R_{eH\_key}, R_{eH\_stock}, R_{eH\_outerCone}\right)$: is the minimum yield stress, in N/mm^2, among the yield stress values obtained for the relevant materials.

The minimum shear area of the key may be calculated by using equations (6.5a) and (6.5b), the relation $Q_F = 2 . Q_R$, and by assuming the von Mises quadratic theory to relate the maximum shear to the yield stress value, as follows:

$$\tau_p = \frac{R_{eH\_key}}{2*\sqrt{3}} \qquad (6.5d)\text{: according to Mises theory with a safety factor of 2}$$

$$a_s = \frac{2 * Q_R\ [N\ m] * 10^3 \left[\frac{mm}{m}\right]}{d_K * \tau_p \left[\frac{N}{mm^2}\right] * 10^2 \left[\frac{mm^2}{cm^2}\right]} = \frac{2 * Q_R * 10}{d_K * \frac{R_{eH\_key}}{2*\sqrt{3}}} = \frac{Q_F * 34.64}{d_K * R_{eH\_key}}\ cm^2 \qquad (6.5e)$$

The minimum normal section area , a_K , in cm^2, may be calculated by using equations (6.5c) and (6.5a) and the relation $Q_F = 2 . Q_R$, to obtain:

$$a_K = \frac{2 * Q_R\ [N\ m] * 10^3 \left[\frac{mm}{m}\right]}{d_K * R_{eH\_min} \left[\frac{N}{mm^2}\right] * 10^2 \left[\frac{mm^2}{cm^2}\right]} = \frac{Q_F * 10}{d_K * R_{eH\_min}}\ cm^2 \qquad (6.5f)$$

According to design basis for cone coupling joints with a key, it is assumed that 50% of Q_F is supported by friction force and remaining 50% by the key. Consequently previous equations (6.5e) and (6.5f) may be rewritten for $0.50 * Q_F$, as follows:

$$a_s = \frac{0.50 * Q_F * 34.64}{d_K * R_{eH\_key}} \approx \frac{Q_F * 17.32}{d_K * R_{eH_{key}}}\ cm^2 \qquad (6.5e\_bis)$$

$$a_K = \frac{0.50 * Q_F * 10}{d_K * R_{eH\_min}} = \frac{Q_F * 5}{d_K * R_{eH\_min}} cm^2 \qquad (6.5f\_bis)$$

7. Cone coupling without key

7.1. Push-up pressure and push-up length to withstand Q_F

The same calculation procedure used under [6.1] may be adopted for the calculation of p_{req1_kLess} , for a cone coupling connection without key, by just replacing Q_F by $2Q_F$ inside of equation (6.1d), to obtain:

$$p_{req1\_kLess} = \frac{F_{fric}}{Area_{Contact} * \mu_0} = \frac{2Q_F}{d_m^2 * \pi * l * \mu_0} * 10^3 \qquad (7.1a)$$

The calculation of push-up length , Δ_{req1_kLess} , associated to the push-up pressure may be performed by following the same procedure presented under [6.2], by only changing the value of p_{eq} , by p_{req1_kLess} , to obtain:

$$\Delta_{req1\_kLess} = \frac{\delta_{p_{req1\_kLess}}}{c} \qquad (7.1b)$$

7.2. Push-up pressure and push-up length to withstand M_B

The same calculation procedure used under [6.3] may be adopted for the calculation of p_{req2_kLess}, for a cone coupling connection without key. The push-up pressure for a keyless cone coupling assembly to resist the bending moment may be calculated by the same formula (6.3c) by just inputting the right geometric data and the M_B value, to obtain:

$$p_{req2\_kLess} = \frac{6 * M_B}{l^2 * d_m} 10^3, \quad in\ N/mm^2 \qquad (7.2a)$$

The calculation of push-up length , Δ_{req2_kLess} , associated to the push-up pressure may be performed by following the same procedure presented under [6.2], but using $p_{req2_{kLess}}$ as a substitute for p_{eq} , to obtain:

$$\Delta_{req2\_kLess} = \frac{\delta_{p_{req2\_kLess}}}{c} \quad , \qquad in\ mm \qquad (7.2b)$$

7.3. Minimum push–up pressure and push–up length

The minimum value of push-up pressure is selected by taking the maximum of $p_{req1_{kLess}}$ and p_{req2_kLess} , to obtain:

$$p_{req\_kLess} = Max\left(p_{req1\_kLess}, p_{req2\_kLess}\right) \qquad (7.3a)$$

The minimum value of push-up length is selected by taking the maximum of $\Delta_{req1_{kLess}}$ and $\Delta_{req2_{kLess}}$, to obtain:

$$\Delta_{req\_kLess} = Max\left(\Delta_{req1\_kLess}, \Delta_{req2\_kLess}\right) \qquad (7.3b)$$

7.4. Maximum push-up pressure and push-up length

The maximum allowable push-up pressure , $p_{\max\_kLess}$, may be calculated from equation (6.5e) by using relevant material properties and geometric data, to obtain:

$$p_{\max\_kLess} \leq \frac{0.8 * R_{eH}}{\sqrt{2} * \sqrt{1 + \left[\frac{(d_m^2 + d_a^2)}{(d_a^2 - d_m^2)}\right]^2 + \left[\frac{(d_m^2 + d_a^2)}{(d_a^2 - d_m^2)}\right]}} \qquad (7.4)$$

The calculation of the maximum push-up length , $\Delta_{\max\_kLess}$, associated to the maximum push-up pressure , p_{max}_kLess , may be performed by following the same procedure presented under [6.2], by only changing the value of p_{eq} , by $p_{\max\_kLess}$.

8. Cone coupling by Direct calculation

8.1. FE analyses with axisymmetric models

A schematic view illustrating the cone coupling assembly process based on axisymmetric elements, with twist, is shown in figure 6. The assembly procedure of figure 6 refers to a cone coupling assembly process using hydraulic pressure. The FE analysis may be run by splitting the problem into 4 steps, as follows:

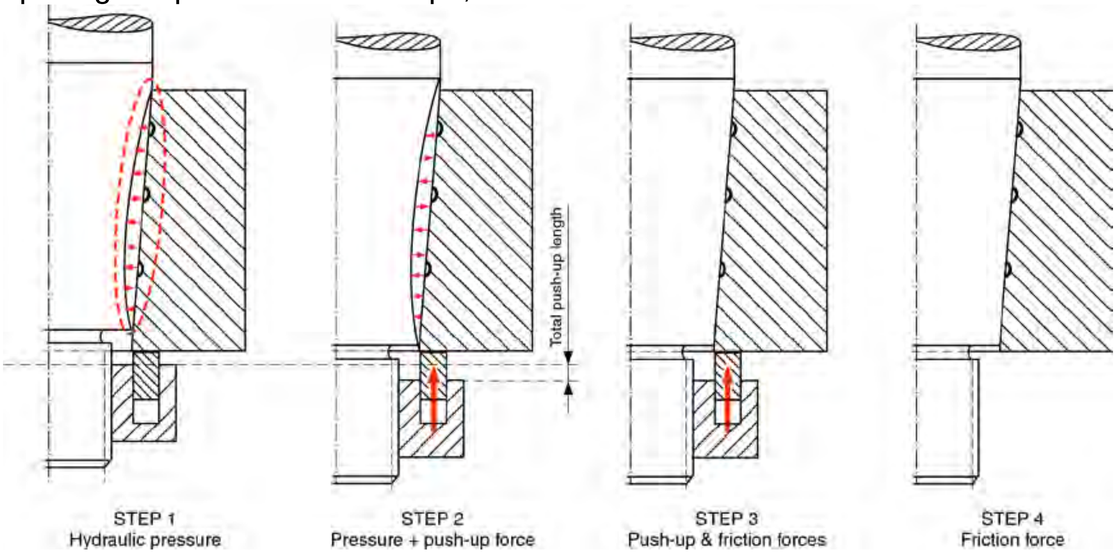

Figure 6: Steps for the numerical simulation of cone coupling process (with oil pressure)

These steps are listed here below:
Step 1: Hydraulic pressure allowing the increase of gap between contact surfaces of stock and hub (no friction coefficient is taken into account, during this step).
Step 2: Additional axial force is applied to generate a relative movement between parts, until a push-up distance is reached. A very low friction coefficient is used.
Step 3: The hydraulic pressure is removed and the friction coefficient is set to a value being close to reality.
Step 4: The push-up force is removed.
The assembled joint, at the end of step 4, can be tested against a torsion moment, by constraining the outer surface of the hub (the outer cone) against rotation around its longitudinal axis and by applying a torsion moment (around this same axis) to the rudder stock.
Only torsion moment may be tested based on axisymmetric approach

8.2. FE analyses with 3D continuum elements

FE modelling based on 3D continuum elements can also permit the application of bending moment at the end of the cone coupling assembly process, in view of testing the capacity of the joint to withstand the bending effort.
In case of the numerical simulation of a cone coupling with hydraulic arrangements, the same sketch presented in figure 6 can be used. When dealing with 3D models, some new challenges are to be considered, such as:

- The increase of the model size requiring huge computer capabilities
- Convergence problems, related to contact interactions between 3D surfaces
- Increase of complexities for pre and post treatment operations.

Direct calculations can be adapted on a case by case basis, to make possible the modelling of any specific procedure for the cone coupling assembly process.

Appendix 3 Spade Direct calculations of spade rudders with a rudder trunk - accounting for stiffness of the neck bearing-support

1. General

This technical background is dedicated to the direct calculations of spade rudders with a rudder trunk, by considering the following configuration for the mechanical system:

1. A simply supported beam, with 1-rigid support in way of the steering gear and a “spring-support” in the way of the neck-bearing.

The configuration assuming 2-rigid bearing supports corresponds to a simply supported isostatic beam, and may be calculated directly by considering the equilibrium of forces and moments. The solution of this problem does not depend on the geometrical properties of rudder stock beam sections. For this approach, named as “classical approach”, the trunk is assumed infinitely rigid (no displacements in way of supports).

The approach considered inside of this technical note is named an “alternative approach” and requires further calculations to evaluate, for example, the support-stiffness in way of neck-bearing, calculated based on displacements of the rudder trunk at this location. The steering gear-support is assumed as completely rigid. It is assumed that the theory of small displacements and small rotations remains valid inside of this technical background.

2. Objective of the study

The objective of this technical note is to present an alternative method, as compared with the “classical method”, for direct calculations of spade rudder mechanical systems.

3. Forces, bending moment, slopes and deflections

3.1. Overview of main components of the rudder system

Figure 1, here below shows a schematic view of the rudder mechanical system, with its main components, such as: the rudder blade, the rudder stock, the trunk and supports (at steering gear and neck bearing).

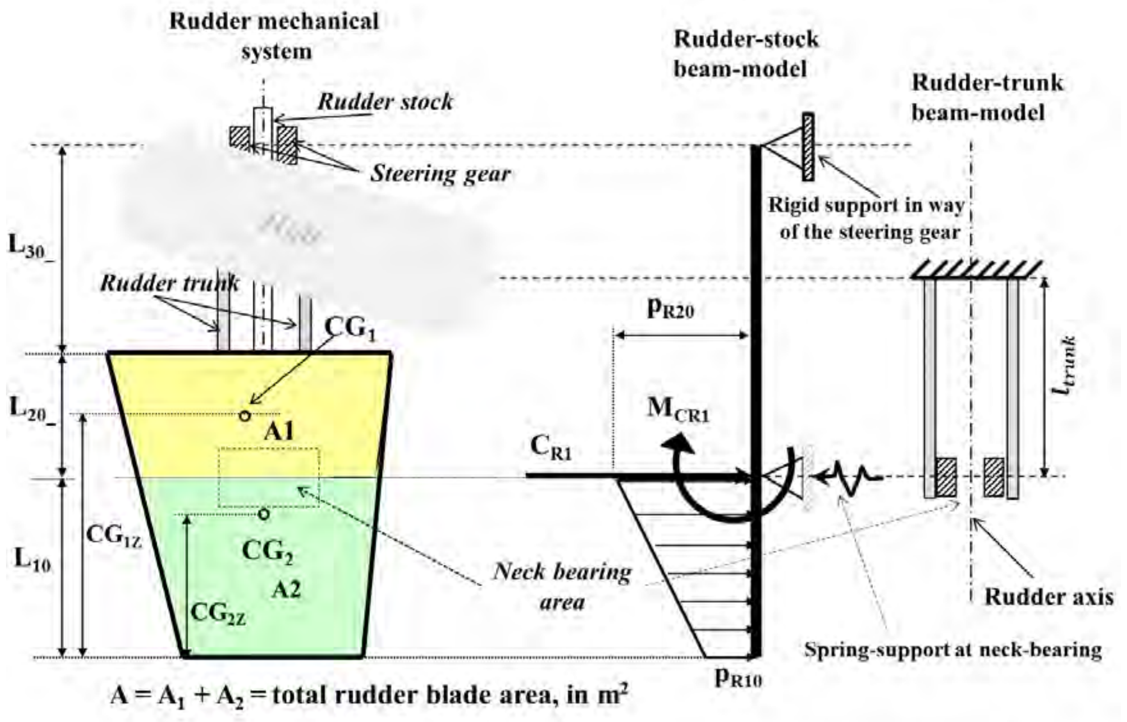

Figure 1: forces and bending moment on the rudder system

Resultant forces acting on areas A_1 and A_2 of the rudder blade (see figure 1, in yellow and green colors) are calculated, as follows:

$$C_{R1} = C_R \frac{A_1}{A_1 + A_2} \quad (1a)$$

$$C_{R2} = C_R \frac{A_2}{A_1 + A_2} \quad (1b)$$

where C_R is the rules total rudder-force, in N, acting on rudder blade area, $A = A_1 + A_2$ expressed in m^2.

3.2. *Forces per unit length on the rudder body*

The force per unit length p_{RZ}, acting on the lower part of the rudder body (area A_2 of figure 1), is to be obtained, in N/m, from the following formula:

$$p_{R_Z} = p_{R10} + \left(\frac{p_{R20} - p_{R10}}{l_{10}}\right) z \quad (1c)$$

where:

z is the position of the rudder blade section, in m, taken over the rudder blade height

p_{RZ} is the force per unit length, in N/m, obtained at the z position

p_{R10} is the force per unit length, in N/m, obtained for z equal to zero (rudder-blade bottom level)

p_{R20} is the force per unit length, in N/m, obtained for z equal to l_{10}

NOTA – Equation (1c) is defined for the range $0 \leq z \leq l_{10}$. However, for the rudder blade scantlings it could also be extended for the range $l_{10} \leq z \leq l_{10} + l_{20}$, if the slope of the straight line defined in equation (1c) remains constant inside of the range $0 \leq z \leq l_{10} + l_{20}$.

3.3. Calculating p_{R10} and p_{R20} values

Forces per unit length, p_{R10} and p_{R20}, are calculated based on the following formulae:

$$C_{R2} = \frac{(p_{R10} + p_{R20})}{2} l_{10} \qquad (2a)$$

$$\frac{(p_{R10} + p_{R20})}{2} l_{10}(l_{10} - CG_{2Z}) = (p_{R20} - p_{R10}) \frac{l_{10}}{2}\frac{l_{10}}{3} + p_{R10} l_{10} \frac{l_{10}}{2} \qquad (2b)$$

Equation (2a) is related to the area of a trapezoid with parallel sides equal to p_{R10} and p_{R20}, and a height l_{10}.
Equation (2b) comes from the statement that the global static moment about an axis is equal to the sum of static moments of all constitutive 'elementary components' about the same axis. Figure 2 here below, presents schematic explanations for these 2-formulae.

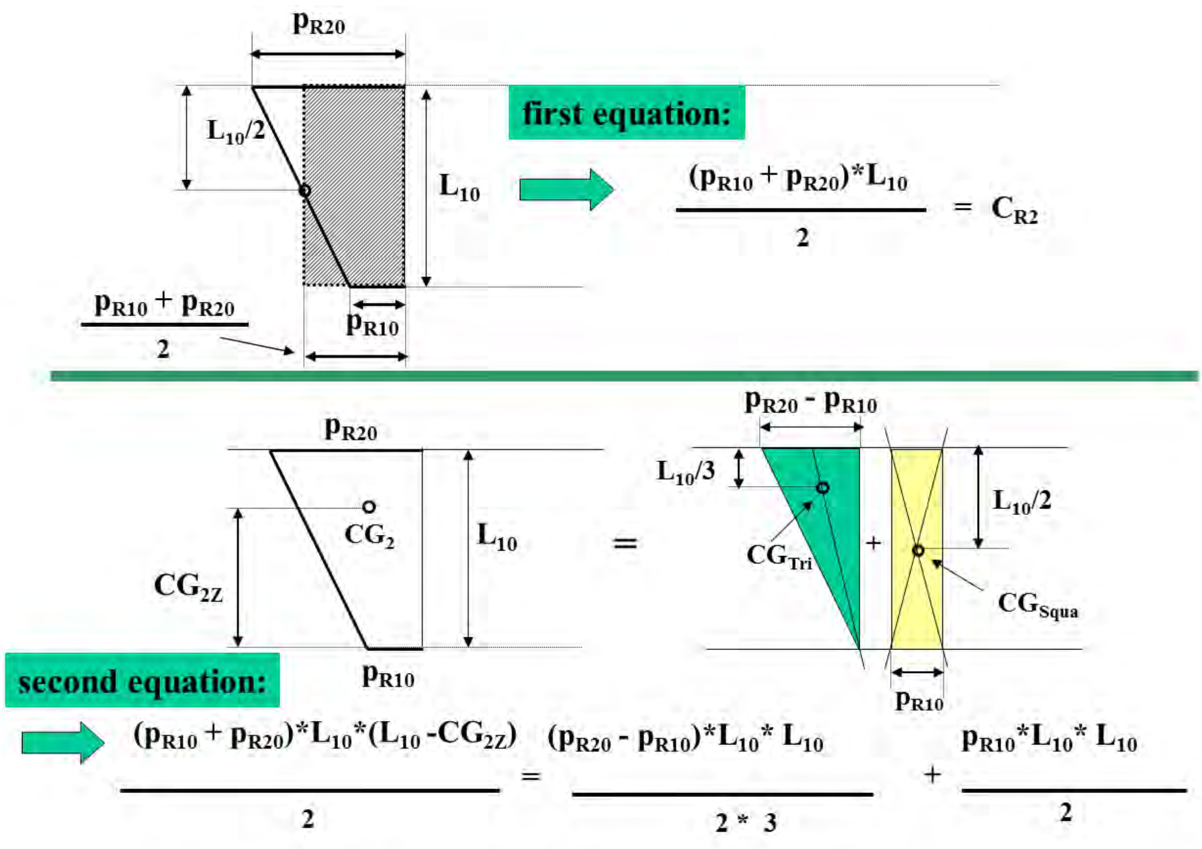

Figure 2: calculation of p_{R10} and p_{R20} - schematic explanation

Final expressions for p_{R10} and p_{R20} are obtained from equations (2a) and (2b), and are written as follows:

$$p_{R10} = \frac{2C_{R2}(2l_{10} - 3CG_{2Z})}{l_{10}^2} \qquad (2c)$$

$$p_{R20} = \frac{2C_{R2}(3CG_{2z} - l_{10})}{l_{10}^2} \qquad (2d)$$

3.4. Rudder stock with a spring-support: general calculation formulae

Figure 3 here below is extracted from figure 1 to represent the rudder-stock beam model in terms of 2-basic spans that will be used for direct calculations of the rudder stock (spans AB and BC).
For any cross section of the beam shown in figure 3, as a general condition of equilibrium, the following assumptions are to be true:

1. the sum of tensile stresses in Z direction = sum of compressive stresses in Z direction
2. the resisting shear force = sum of shear forces
3. the resisting bending moment = sum of bending moments
4. there should be continuity of:
   - slopes at points shared by 2 adjacent-spans
   - displacements (deflections) at points shared by 2 adjacent-spans

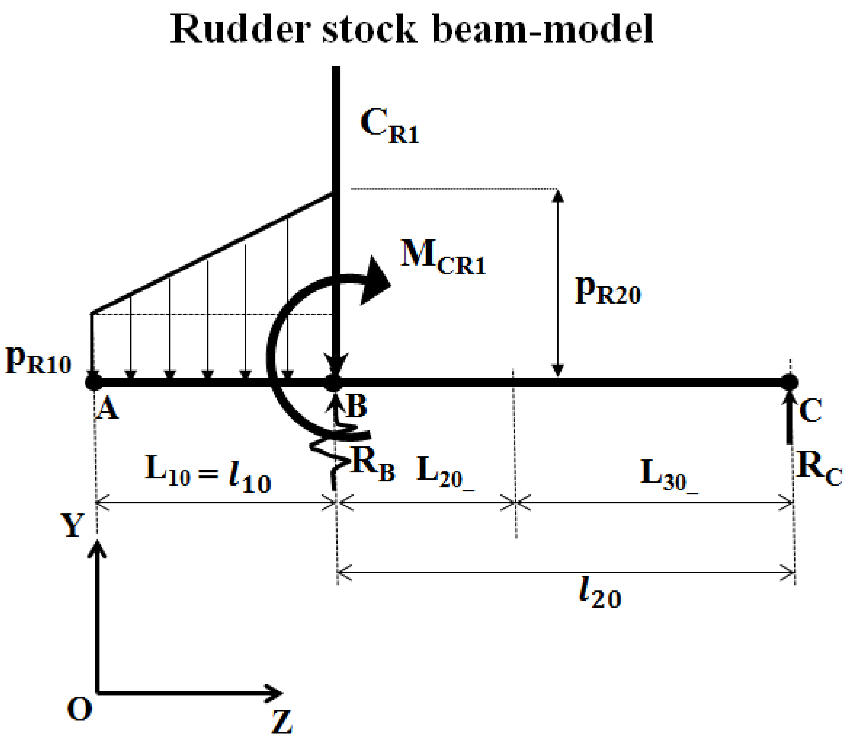

Figure 3: shear forces and bending moment

From figure 3 here above, shear forces can be written from the most left-side of the model, till its most right-side, for every span of the beam, as follows:

- for the span AB ($0 \leq Z < l_{10}$ or $0 \leq z < l_{10}$)

$$S_z = S_A - p_{R10}\,z - \left[\left(\frac{p_{R20} - p_{R10}}{l_{10}}\right)\frac{z}{2}\right] z \qquad (3a)$$

- for the span BC ($l_{10} < Z \leq l_{10} + l_{20}$ or $0 < z \leq l_{20}$)

$$S_z = S_{B\_} - C_{R1} + R_B \qquad (3b)$$

The reaction force R_B is calculated based on the stiffness of the trunk in way of the neck-bearing, by using the following formulae:

$$R_B = -K_{trunk} y_B \qquad (3a_1)$$

$$K_{trunk} = \frac{3EJ_{trunk}}{1.3 l_{trunk}^3} \qquad (3a_2)$$

where:

K_{trunk} is the spring constant, in N/m, at the cross section of the trunk in way of the neck bearing

y_B is the deflection of the rudder stock beam, in m, calculated at point B

l_{trunk} is the length of the trunk, in m, from its built-in section till the neck bearing mid-section

J_{trunk} is the moment of inertia of the trunk, in m^4, and E is the Young's modulus, in N/m^2

S_Z is the shear force, in N, acting on a cross section located at a distance Z from the origin O

S_A is the shear force, in N, acting on a cross section located at point A ($Z = 0$)

$S_{B\_}$ is the shear force, in N, inside of span AB, acting on a cross section close to point B ($Z \approx l_{10}$)

R_B is the reaction force, in N, at point B ($Z = l_{10}$), which depends on the support stiffness

R_C is the reaction force, in N, acting at point C ($Z = l_{10} + l_{20}$)

Expressions for bending moments, in N.m, acting on any cross-section of the beam, from the most-left to the right, may be obtained by integrating equations (3a) and (3b) from 0 to z (inside of each span):

- for the span AB:

$$M_z = M_A + S_A z - p_{R10}\frac{z^2}{2} - \left(\frac{p_{R20} - p_{R10}}{l_{10}}\right)\frac{z^3}{6} \qquad (3c0)$$

By assuming $S_A = M_A = 0$, equation $(3c0)$ becomes:

$$M_z = -p_{R10}\frac{z^2}{2} - \left(\frac{p_{R20} - p_{R10}}{l_{10}}\right)\frac{z^3}{6} \qquad (3c)$$

- for the span BC:

$$M_z = M_{B\_} + M_{CR1} + \int_0^z (S_{B\_} - C_{R1} + R_B)dz \qquad (3d0) \qquad or$$

$$M_z = M_{B\_} + M_{CR1} + S_{B\_} z - C_{R1} z + R_B z \qquad (3d)$$

where:

$M_{B\_}$ = the bending moment at the end of span AB (equation 3c, for z = $Z \approx l_{10}$)

M_{CR1} = the bending moment at the beginning of span BC (C_{R1}, with a lever arm = $CG_{1Z} - l_{10}$)

In the elastic domain, and for small deflections of the beam, the following differential equations (4a) and (4b), may apply at any section of the elastic beam:

$$EJ\left(\frac{d^2y}{dz^2}\right) = M \qquad (4a) \quad ; \qquad or \qquad \left(\frac{d^2y}{dz^2}\right) = \frac{M}{EJ} \qquad (4b);$$

Where: E = modulus of elasticity of the material, in N/m^2, J = moment of inertia of the cross section, in m^4, M is the bending moment, in N.m, and y is the deflection of the beam cross-section at a position z.
Expressions of slopes, θ_z , for any cross section of the beam, may be calculated by substituting equations (3c) and (3d), expressing bending moments over spans AB and BC, respectively, in equation (4b), and by integrating these resultant equations inside of each span:

- for span AB:

$$\theta_z = \left(\frac{dy}{dz}\right)_z = \theta_A - p_{R10}\frac{z^3}{6EJ_1} - \left(\frac{p_{R20}-p_{R10}}{l_{10}}\right)\frac{z^4}{24EJ_1} \qquad (5a)$$

- for span BC:

$$\theta_z = \left(\frac{dy}{dz}\right)_z = \theta_B + \frac{M_{B\_}\,z}{EJ_2} + \frac{M_{CR1}z}{EJ_2} + \frac{S_{B\_}z^2}{2EJ_2} - \frac{C_{R1}z^2}{2EJ_2} + \frac{R_B z^2}{2EJ_2} \qquad (5b)$$

where:

$\theta_{z\_} = \theta_{z_+} = \theta_z$ is the beam slope at any cross section (continuity of slopes)
J_1 is the moment of inertia of the cross section for the span AB
J_2 is the moment of inertia of the cross section for the span BC

Deflections of the beam cross section, y_z $(where\ y_{z\_} = y_{z_+} = y_z{:}continuity\ of\ deflections)$, in m, may be calculated at the neutral fiber of the beam, by integrating equations (5a) and (5b) inside of spans AB and BC, respectively:

- for span AB:

$$y_z = y_A + \theta_A z - p_{R10}\frac{z^4}{24EJ_1} - \left(\frac{p_{R20}-p_{R10}}{l_{10}}\right)\frac{z^5}{120EJ_1} \qquad (6a)$$

- for span BC:

$$y_z = y_B + \theta_B z + \frac{M_{B\_}z^2}{2EJ_2} + \frac{M_{CR1}z^2}{2EJ_2} + \frac{S_{B\_}z^3}{6EJ_2} - \frac{C_{R1}z^3}{6EJ_2} + \frac{R_B z^3}{6EJ_2} \qquad (6b)$$

3.5. Rudder stock beam-model: calculation formulae close to supports

Based on general calculation formulae described in 3.4, shear forces, bending moments, slopes and deflection at points B and C of figure 3 may be defined.

- from equation 3a, for $z = Z \approx l_{10}$, it follows:

$$S_{B\_} = -p_{R10}l_{10} - \left[\left(\frac{p_{R20}-p_{R10}}{2}\right)l_{10}\right] \qquad (7a)$$

- from equation 3b, for $z = l_{20}\ or\ Z = l_{10} + l_{20}$, it follows:

$$S_C = S_{B\_} - C_{R1} + R_B \qquad (7b)$$

According to equations 3b and 7b it can be noted that shear forces all along BC span have a constant value with z, equal to S_C. Consequently, $R_C = S_C$ $\qquad (7b_1)$

- from equation 3c, for $z = Z \approx l_{10}$, it follows:

$$M_{B\_} = -\left(\frac{2p_{R10} + p_{R20}}{6}\right) l_{10}^2 \quad and \quad M_{CR1} = C_{R1}(CG_{1z} - l_{10}) \qquad (7c)$$

- from equation 3d, for $z = l_{20}$ $(or\, Z = l_{10} + l_{20})$, it follows:

$$M_C = M_{B\_} + M_{CR1} + S_{B\_} l_{20} - C_{R1} l_{20} + R_B l_{20} \qquad (7d)$$

- from equations 5a and 6a, for $z = Z \approx l_{10}$, it follows (span AB):

$$\theta_B = \theta_A - p_{R10} \frac{l_{10}^3}{6EJ_1} - \left(\frac{p_{R20} - p_{R10}}{24}\right) \frac{l_{10}^3}{EJ_1} \qquad (7e0) \quad or$$

$$\theta_B = \theta_A - \frac{3p_{R10} l_{10}^3 + p_{R20} l_{10}^3}{24EJ_1} \qquad (7e1)$$

$$y_B = y_A + \theta_A l_{10} - p_{R10} \frac{l_{10}^4}{24EJ_1} - \left(\frac{p_{R20} - p_{R10}}{l_{10}}\right) \frac{l_{10}^5}{120EJ_1} \qquad (7e2) \quad or$$

$$\theta_A = \frac{y_B - y_A}{l_{10}} + \frac{4p_{R10} l_{10}^3}{120EJ_1} + \frac{p_{R20} l_{10}^3}{120EJ_1} \qquad (7e3)$$

- from equations 5b and 6b, for $z = l_{20}$ $(or\, Z = l_{10} + l_{20})$, it follows:

$$\theta_C = \theta_B + \frac{M_{B\_} l_{20}}{EJ_2} + \frac{M_{CR1} l_{20}}{EJ_2} + \frac{S_{B\_} l_{20}^2}{2EJ_2} - \frac{C_{R1} l_{20}^2}{2EJ_2} + \frac{R_B l_{20}^2}{2EJ_2} \qquad (7e4)$$

$$y_C = y_B + \theta_B l_{20} + \frac{M_{B\_} l_{20}^2}{2EJ_2} + \frac{M_{CR1} l_{20}^2}{2EJ_2} + \frac{S_{B\_} l_{20}^3}{6EJ_2} - \frac{C_{R1} l_{20}^3}{6EJ_2} + \frac{R_B l_{20}^3}{6EJ_2} \qquad (7e5)$$

$$\theta_B = \frac{y_C - y_B}{l_{20}} - \frac{M_{B\_} l_{20}}{2EJ_2} - \frac{M_{CR1} l_{20}}{2EJ_2} - \frac{S_{B\_} l_{20}^2}{6EJ_2} + \frac{C_{R1} l_{20}^2}{6EJ_2} - \frac{R_B l_{20}^2}{6EJ_2} \qquad (7e6)$$

4. Reaction forces, slopes and displacements at points A, B and C

4.1. Calculation of reaction forces at points B and C

Assuming that the bending moment $M_C = 0$, the reaction force, R_B, can be calculated from equation 7d, as follows:

$$R_B = \frac{-(M_{B\_} + M_{CR1})}{l_{20}} - S_{B\_} + C_{R1} \qquad (8a)$$

where:

$M_{B\_}$ *and* M_{CR1} are calculated from equations given in 7c
C_{R1} *and* C_{R2} are calculated from equations 1a and 1b
p_{R10} *and* p_{R20} are calculated from equations 2c and 2d
$S_{B\_}$ is calculated from equation 7a

After the calculation of R_B, the reaction force R_C, can be obtained directly from equations 7b and $7b_1$.

4.2. Slopes and displacements at points A, B and C

From equations $3a_1$ and $3a_2$, the displacement at point B, y_B, can be calculated, as follows:

$$y_B = -\frac{R_B}{K_{trunk}} \qquad (8b)$$

where:

K_{trunk} is calculated, in N/m, from equation $3a_2$

The moment of inertia of the rudder trunk, J_{trunk}, in m^4, is calculated, as follows:

$$J_{trunk} = \frac{\pi(d_{out}^4 - d_{in}^4)}{64} \qquad (8c)$$

where:

d_{out} and d_{in} are the outer and inner diameters of the rudder trunk, in m

The slope at point B, θ_B, can be calculated from equation $7e_6$, by making the displacement at point C, $y_C = 0$.

The slope at point A, θ_A, can be calculated from equation $7e_1$, by assuming the continuity of slopes at point B of the beam, $\theta_{B\_ (span\ AB)} = \theta_{B_+ (span\ BC)} = \theta_B$.

Finally, based on all calculated values of slopes and displacements, the displacement at point A, y_A, can be calculated from equation $7e_2$.

Appendix 4 Concept of 2-conjugate elastic supports

1. General

This concept is applicable to semi-spade rudders with two pintle bearings, shared by both the rudder beam and the rudder horn.
The rudder beam is a mechanical system constituted by the rudder stock and the rudder blade, represented as a simply supported beam model, with three supports as follows:

- A rigid top bearing (in way of the steering gear),
- 2-pintle bearings, with stiffnesses calculated based on the rudder-horn section properties

The rudder horn is represented by a cantilever beam, with the top side completely built-in on the ship hull.
Torsion and bending effects are considered separately, and superposition principle is applied at the end, to account for these two effects.

2. Objective of the study

The objective of this technical note is to express the stiffness of 2-pintle supports in terms of section properties of the rudder horn. The final expression will take into consideration both bending and torsion terms.

3. Beam models

3.1. Models overview

Figures 1a and 1b illustrate the rudder and rudder-horn beams that are used for the modeling of both the rudder beam and the rudder-horn mechanical systems. They also show how beam models are connected between themselves. Figures 2 and 3 are showing different views of the rudder-horn mechanical system.

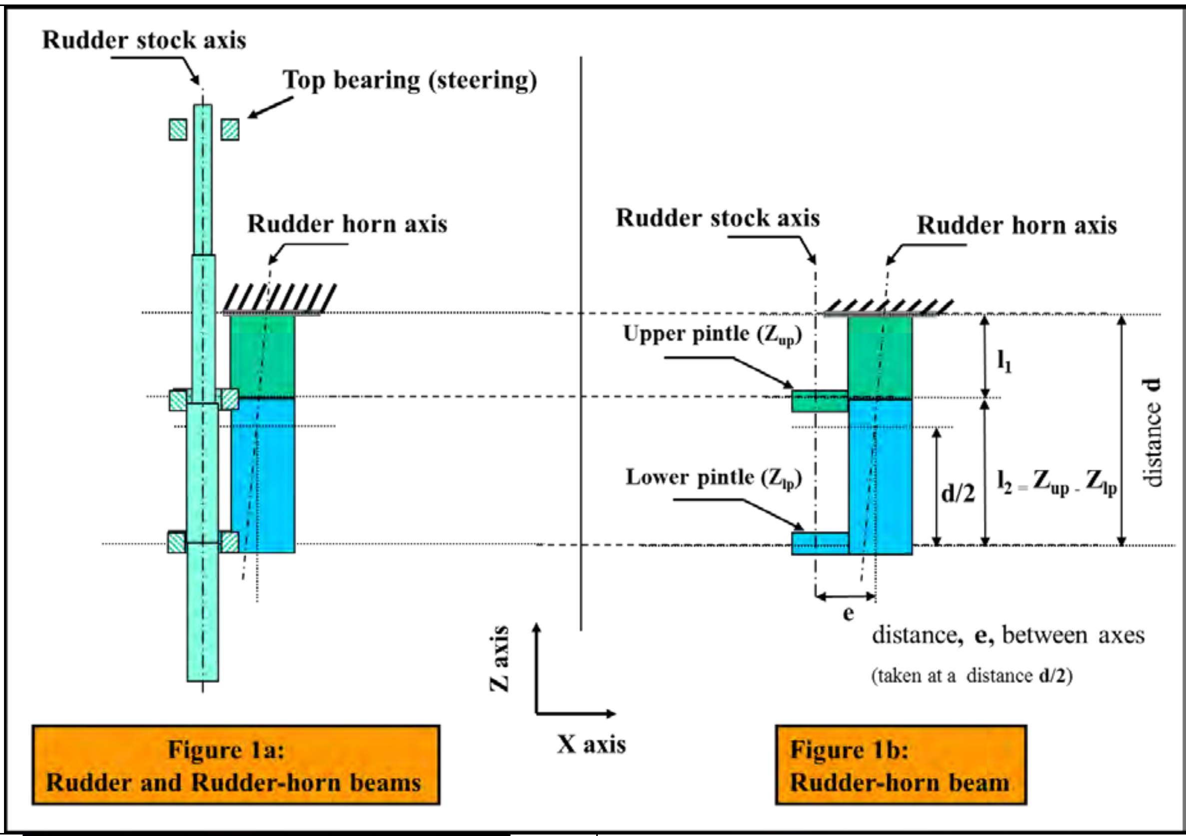

Figure 1a: Rudder and Rudder-horn beams

Figure 1b: Rudder-horn beam

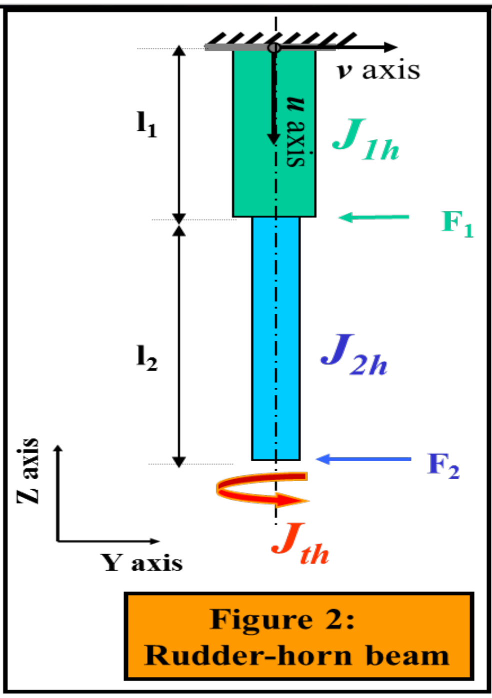

Figure 2: Rudder-horn beam

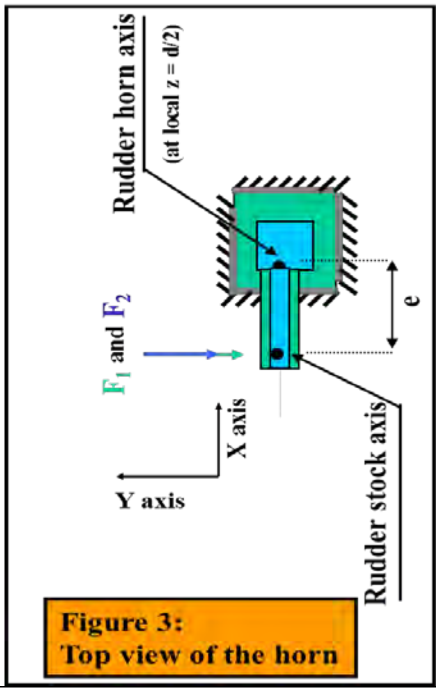

Figure 3: Top view of the horn

According to figures 1 to 3 the rudder-horn structure is submitted to bending and torsion caused by forces F_1 and F_2, which are support forces acting on the upper and lower pintle-bearings, respectively. These support forces are obtained from direct calculation of the rudder beam, by considering the unit length forces acting on the lower and upper areas of the rudder blade, as described in 3.2.

The following parameters are required for the calculation of the “support-stiffnesses”:

- the moment of inertia of the rudder-horn about the x-axis, J_{1h} , for the 1rst span, given in m^4
- the moment of inertia of the rudder-horn about the x-axis, J_{2h} , for the 2nd span, given in m^4

- the torsional stiffness factor of the rudder-horn, J_{th} , in m^4 , which depends on the shape and dimensions of the rudder-horn cross section
- geometric parameters, in m, such as: distances d and e, span lengths l_1 and l_2, etc.

3.2. Forces per unit length on the rudder body

The forces per unit length P_{R10} and P_{R20} acting on the rudder body are to be obtained, in N/m, from the following formulae:

- for the rudder blade area below the lower pintle, defined as area A_2

$$P_{R10} = \frac{C_{R2}}{l_{lower}} \qquad (1a)$$

- for the rudder blade area above the lower pintle, defined as area A_1

$$P_{R20} = \frac{C_{R1}}{l_{upper}} \qquad (1b)$$

where:

C_{R1} and C_{R2} are rudder forces, in N, acting on each part A_1 and A_2 of the rudder blade, respectively

l_{lower} is the relevant height, in m, of the lower rudder blade area, A_2

l_{upper} is the relevant height, in m, of the upper rudder blade area, A_1

4. Calculation procedure

4.1. Displacements and forces in way of pintle-bearings

A local system of axes, with unit vectors u and v, is defined for the cantilever beam of figure 2, as follows:

- origin of the system is taken at the built-in point of the rudder-horn axis
- u vector taken parallel to –Z axis
- v vector taken parallel to Y axis

Displacements of the rudder-horn beam, v_{upper} and v_{lower}, in way of upper and lower pintle-bearings, are related to support forces F_1 and F_2, at upper and lower pintle-bearings, respectively, by the following matrix expression:

$$\begin{Bmatrix} v_{upper} \\ v_{lower} \end{Bmatrix} = [Compli]_{horn} \begin{Bmatrix} F_1 \\ F_2 \end{Bmatrix} \qquad (2a)$$

The compliance matrix of the rudder-horn is written, as follows:

$$[Compli]_{horn} = \begin{bmatrix} -k_{11} & -k_{12} \\ -k_{21} & -k_{22} \end{bmatrix} \qquad (2b)$$

Equation (2a) may also be written, as follows:

$$\begin{Bmatrix} v_{upper} \\ v_{lower} \end{Bmatrix} = \begin{bmatrix} -k_{11} & -k_{12} \\ -k_{21} & -k_{22} \end{bmatrix} \begin{Bmatrix} F_1 \\ F_2 \end{Bmatrix} \qquad (2c)$$

The following remarks apply to the rudder-horn matrix-terms:

- k_{11} and k_{21}relate to components of displacements on points 1 and 2, respectively, caused by force F_1

- k_{12} and k_{22}relate to components of displacements on points 1 and 2, respectively, caused by force F_2

The negative signs of compliance matrix-terms are to compensate opposite signs of forces acting on the rudder blade when compared with those of support forces (reaction forces).
Every compliance matrix-term has 2 categories of components: those referring to bending effects and those related with torsion (axes of the rudder beam and rudder-horn beam are considered as parallel, at a distance of "e" meters, as shown in figure 3). As the superposition principle applies for elastic beams, submitted to small displacements, the bending and torsion contributions will be first considered separately, under 4.2 and 4.3., respectively. Final expressions of compliance matrix-terms, including both bending and torsion effects, are presented under 4.4.

4.2. Components of compliance matrix-terms due to bending

The algebraic sum of the moments of the external forces that lie to the "bottom" side of any cross section of the cantilever "rudder-horn" beam of figure 2 is accounted for each beam span, starting from the built-in cross-section till the free end cross-section of this beam.
Adopting a local system of axes based on the unit vectors u and v, as defined in 4.1, the bending moment equation for any cross-section taken within the first beam span ($0 \le u \le l_1$), may be written as follows:

$$M_u = -F_1(l_1 - u) - F_2(l_1 + l_2 - u) \qquad (3)$$

In the elastic domain, and for small deflections of the beam, the following differential equations (4a) and (4b), may apply at any section of the elastic beam:

$$EJ\left(\frac{d^2v}{du^2}\right) = M \qquad (4a)\,; \qquad \text{or} \qquad \left(\frac{d^2v}{du^2}\right) = \frac{M}{EJ} \qquad (4b)\,;$$

Where: E = modulus of elasticity of the material, J = moment of inertia of the cross section, *M* is the bending moment, and v is the deflection of the beam cross-section at a position u.
By substituting equation (3) in equation (4b), and by integrating this resultant equation, it lies:

$$\frac{dv}{du} = -\frac{1}{EJ_{1h}}\int [F_1(l_1 - u) + F_2(l_1 + l_2 - u)]du + C_{11} \qquad (5a)$$

$$\frac{dv}{du} = -\frac{1}{EJ_{1h}}\left[F_1\left(l_1u - \frac{u^2}{2}\right) + F_2\left(l_1u + l_2u - \frac{u^2}{2}\right)\right] + C_{11} \qquad (5b)$$

$\frac{dv}{du}$ is the slope of the beam at position u ($0 \le u \le l_1$). At u = 0, the slope is zero, and consequently, C_{11} = 0, and equation (5b) becomes equation (5c), as follows:

$$\frac{dv}{du} = -\frac{1}{EJ_{1h}}\left[F_1\left(l_1u - \frac{u^2}{2}\right) + F_2\left(l_1u + l_2u - \frac{u^2}{2}\right)\right] \qquad (5c)$$

Equation (5d) is obtained by taking $u = l_1$ in equation (5c), as follows:

$$\left.\frac{dv}{du}\right]_{l1} = -\frac{l_1}{EJ_{1h}}\left[F_1\left(l_1 - \frac{l_1}{2}\right) + F_2\left(l_1 + l_2 - \frac{l_1}{2}\right)\right] \qquad (5d)$$

The integration of equation (5c) gives the expression of the beam deflection at position u, as follows:

$$v_u = -\frac{1}{EJ_{1h}}\left[F_1\left(l_1\frac{u^2}{2}-\frac{u^3}{6}\right)+F_2\left(l_1\frac{u^2}{2}+l_2\frac{u^2}{2}-\frac{u^3}{6}\right)\right]+C_{12} \qquad (6a)$$

At $u = 0$, the deflection of the beam, $v_0 = 0.$, and consequently, $C_{12} = 0$.

Equation (6a) can be written for $u = l_1$, as follows:

$$v_{l_1} = -\frac{l_1^2}{2EJ_{1h}}\left[F_1\left(l_1-\frac{l_1}{3}\right)+F_2\left(l_1+l_2-\frac{l_1}{3}\right)\right] \qquad (6b)$$

For the second beam span ($l_1 \leq u \leq l_1 + l_2$) the algebraic sum of the moments of the external forces that lie to the "bottom" side of any cross section of the cantilever "rudder-horn" beam of figure 2 is written, as follows:

$$M_u = -F_2.(l_1+l_2-u) \qquad (7)$$

By repeating operations from equation (3) to equation (5b), but now starting from equation (7), the following expression can be written for $l_1 \leq u \leq l_1 + l_2$:

$$\frac{dv}{du} = -\frac{1}{EJ_{2h}}\left[F_2\left(l_1u+l_2u-\frac{u^2}{2}\right)\right]+C_{21} \qquad (8b)$$

C_{21} can be calculated by making $u = l_1$ in equation (8b), and by comparing this resultant equation with equation (5d), to obtain the following expression:

$$C_{21} = -\frac{l_1}{EJ_{1h}}\left[F_1\left(l_1-\frac{l_1}{2}\right)+F_2\left(l_1+l_2-\frac{l_1}{2}\right)\right] - \frac{l_1}{EJ_{2h}}\left[F_2\left(-l_1-l_2+\frac{l_1}{2}\right)\right] \qquad (8c)$$

By substituting equation (8c) in equation (8b), and by integrating the resultant equation, the expression of beam deflection can be written, as follows:

$$v_u = -\frac{1}{EJ_{1h}}\left\{\sum_{i=1}^{2}F_i\left[\left(\sum_{k=1}^{i}l_k\right)l_1u-\frac{l_1^2}{2}u\right]\right\}-\frac{1}{EJ_{2h}}\left\{F_2\left[\left(\sum_{k=1}^{2}l_k\right)\left(\frac{u^2}{2}-l_1u\right)+\frac{l_1^2}{2}u-\frac{u^3}{6}\right]\right\} + C_{22} \qquad (9a)$$

Equation (9a) can be written for $u = l_1$, as follows:

$$v_{l_1} = -\frac{l_1^2}{EJ_{1h}}\left\{\sum_{i=1}^{2}F_i\left[\left(\sum_{k=1}^{i}l_k\right)-\frac{l_1}{2}\right]\right\}-\frac{l_1^2}{EJ_{2h}}\left\{F_2\left[\left(\sum_{k=1}^{2}\frac{-l_k}{2}\right)+\frac{2l_1}{3}\right]\right\}+C_{22} \qquad (9b)$$

C_{22} is calculated by substituting equation (9b) in equation (6b), to obtain:

$$C_{22} = -\frac{l_1^2}{EJ_{1h}}\left\{\sum_{i=1}^{2}F_i\left[\left(\sum_{k=1}^{i}\frac{-l_k}{2}\right)+\frac{l_1}{3}\right]\right\}-\frac{l_1^2}{EJ_{2h}}\left\{F_2\left[\left(\sum_{k=1}^{2}\frac{l_k}{2}\right)-\frac{l_1}{3}\right]\right\} \qquad (9c)$$

$$C_{22} = -\frac{1}{EJ_{1h}}\left\{\sum_{i=1}^{2} F_i\left[\left(\sum_{k=1}^{i}\frac{-l_k . l_1^2}{2}\right) + \frac{l_1^3}{3}\right]\right\} - \frac{1}{EJ_{2h}}\left\{F_2\left[\left(\sum_{k=1}^{2}\frac{l_k . l_1^2}{2}\right) - \frac{l_1^3}{3}\right]\right\} \qquad (9d)$$

By replacing C_{22} in equation (9a), it can be written:

- For terms multiplying $\frac{1}{EJ_{1h}}$:

$$v_u = -\frac{1}{EJ_{1h}}\left\{\sum_{i=1}^{2} F_i\left[\left(\sum_{k=1}^{i} l_k\right)\left(l_1 u - \frac{l_1^2}{2}\right) - \frac{l_1^2}{2}u + \frac{l_1^3}{3}\right]\right\} \qquad (10a)$$

- For terms multiplying $\frac{1}{EJ_{2h}}$:

$$v_u = -\frac{1}{EJ_{2h}}\left\{F_2\left[\left(\sum_{k=1}^{2} l_k\right)\left(\frac{u^2}{2} - l_1 u + \frac{l_1^2}{2}\right) + \frac{l_1^2}{2}u - \frac{u^3}{6} - \frac{l_1^3}{3}\right]\right\} \qquad (10b)$$

For $u = l_1 + l_2$, equations (10a) and (10b) become equations (11a) and (11b), respectively:

- For terms multiplying $\frac{1}{EJ_{1h}}$:

$$v_{l_1+l_2} = -\frac{1}{EJ_{1h}}\left\{\sum_{i=1}^{2} F_i\left[\left(\sum_{k=1}^{i} l_k\right)\left(l_1(l_1+l_2) - \frac{l_1^2}{2}\right) - \frac{l_1^2}{2}(l_1+l_2) + \frac{l_1^3}{3}\right]\right\} \qquad (11a)$$

- For terms multiplying $\frac{1}{EJ_{2h}}$:

$$v_{l_1+l_2} = -\frac{1}{EJ_{2h}}\left\{F_2\left[\left(\sum_{k=1}^{2} l_k\right)\left(\frac{(l_1+l_2)^2}{2} - l_1(l_1+l_2) + \frac{l_1^2}{2}\right) + \frac{l_1^2}{2}(l_1+l_2) - \frac{(l_1+l_2)^3}{6} - \frac{l_1^3}{3}\right]\right\} \qquad (11b)$$

Compliance matrix-terms due to bending may be calculated based on equation (2c), by associating this equation with:

- equation (6b), for the calculation of k_{11} and k_{12}, which are related to displacements of point 1 caused by forces F_1 and F_2, respectively
- equations (11a) and (11b), for the calculation of k_{21} and k_{22}, which are related to displacements of point 2 caused by forces F_1 and F_2, respectively.

Bending components are written, as follows:

$$k_{11_{bend}} = \frac{l_1^3}{3EJ_{1h}} \qquad (12a)$$

$$k_{12_{bend}} = k_{21_{bend}} = \frac{l_1^3}{3EJ_{1h}} + \frac{l_1^2(d-l_1)}{2EJ_{1h}} \qquad (12b)$$

$$k_{22_{bend}} = \frac{l_1^3}{3EJ_{1h}} + \frac{l_1^2(d-l_1)}{EJ_{1h}} + \frac{l_1(d-l_1)^2}{EJ_{1h}} + \frac{(d-l_1)^3}{3EJ_{2h}} \qquad (12c)$$

where $l_2 = (d - l_1)$, can be read from figure 1b.

For $l_1 = 0.$, the 2-conjugate elastic support becomes the 1-elastic support. To keep consistency between formulae given in equations (12a), (12b), (12c) and that one of the spring constant of 1-elastic support, the factor of 1.3 is applied to equations (12..), to obtain:

$$k_{11_{bend}} = 1.3\,\frac{l_1^3}{3EJ_{1h}} \qquad (13a)$$

$$k_{12_{bend}} = k_{21_{bend}} = 1.3\left[\frac{l_1^3}{3EJ_{1h}} + \frac{l_1^2(d-l_1)}{2EJ_{1h}}\right] \qquad (13b)$$

$$k_{22_{bend}} = 1.3\left[\frac{l_1^3}{3EJ_{1h}} + \frac{l_1^2(d-l_1)}{EJ_{1h}} + \frac{l_1(d-l_1)^2}{EJ_{1h}} + \frac{(d-l_1)^3}{3EJ_{2h}}\right] \qquad (13c)$$

4.3. Components of compliance matrix-terms due to torsion

The compliance matrix-terms due to torsion are calculated by assuming the rudder beam axis is parallel to the rudder-horn axis, and is located at a distance “e”, in m, of the latter axis. Calculations are based on the following equation, which are valid for the torsion of thin-wall closed sections:

$$\frac{\theta}{L} = \frac{T}{GJ} \quad (14a) \qquad or \qquad \theta = \frac{L\,T}{G\,J} \quad (14b)$$

Where:

$\theta = angle\ of\ twist, in\ radians;$ $L = length\ in\ axial\ direction, in\ m\,;$
$T = twisting\ moment, in\ N.m;$ $G = shear\ elasticity\ modulus, in\ N/m^2;$
$J = polar\ moment\ of\ inertia, in\ m^4;$

The equation (14c) is obtained from equation (14b) by considering the thin-wall closed section of the rudder horn illustrated in figures 2 and 3:

$$\theta_i = \frac{L_i\,F_i\,e}{G\,J_{th}} \qquad (14c)$$

Where:

$L_i = l_1\ or\ l_1 + l_2, in\ m;$ $F_i = F_1\ or\ F_2\ , in\ N;$ $e = distance\ between\ axes, in\ m$

Displacements of the rudder horn caused by torsion are calculated based on the product of the angle of twist by the gyration radius, e, as follows:

$$v_{torsion} = v_{t_i} = e.\theta_i \qquad (15a)$$

By replacing equation (14c) in equation (15a), displacements of the rudder horn by torsion may be calculated, as follows:

$$v_{t_i} = \frac{L_i\, F_i\, e^2}{G\, J_{th}} \qquad (15b)$$

Compliance matrix-terms due to torsion may be calculated based on equations (2c) and (15b), as follows:

$$v_{t_1} = \frac{l_1\, F_1\, e^2}{G\, J_{th}} + \frac{l_1\, F_2\, e^2}{G\, J_{th}} \qquad (16a)$$

$$k_{11_{tors}} = \frac{l_1.e^2}{GJ_{th}} \qquad (16b)$$

$$k_{12_{tors}} = \frac{l_1.e^2}{GJ_{th}} \qquad (16c)$$

$$v_{t_2} = \frac{l_1\, F_1\, e^2}{G\, J_{th}} + \frac{(l_1 + l_2)\, F_2\, e^2}{G\, J_{th}} \qquad (17a)$$

$$k_{21_{tors}} = \frac{l_1.e^2}{GJ_{th}} \qquad (17b)$$

$$k_{22_{tors}} = \frac{(l_1 + l_2).e^2}{GJ_{th}} \qquad (17c)$$

From equations (16c) and (17b), we notice that: $k_{12_{tors}} = k_{21_{tors}} \qquad (17d)$

4.4. Compliance matrix-terms, including bending and torsion

Based on results presented under 4.2 and 4.3, the compliance matrix-terms, for both bending and torsion, are the following:

$$k_{11} = 1.3\,.\frac{l_1^3}{3EJ_{1h}} + \frac{l_1.e^2}{GJ_{th}} \qquad (18a)$$

$$k_{12} = k_{21} = 1.3\,.\left[\frac{l_1^3}{3EJ_{1h}} + \frac{l_1^2.(d - l_1)}{2EJ_{1h}}\right] + \frac{l_1.e^2}{GJ_{th}} \qquad (18b)$$

$$k_{22} = 1.3\,.\left[\frac{l_1^3}{3EJ_{1h}} + \frac{l_1^2.(d - l_1)}{EJ_{1h}} + \frac{l_1.(d - l_1)^2}{EJ_{1h}} + \frac{(d - l_1)^3}{3EJ_{2h}}\right] + \frac{d.e^2}{GJ_{th}} \qquad (18c)$$

In equation (18c), the term due to torsion is expressed with $d, as\ l_1 + l_2 = d, according\ to\ figure\ 1b.$

Technical Background (TB) document for UR S10 (Rev.5 May 2018)

Requirement S10.5.1a and S10.5.3.1

1. Scope and objectives

The scope of this revision is the clarification of the formulas utilization in S.10.5.1 a) and b); clarification of applicability of protrusions in the connections of rudder blade structures with solid parts in S.10.5.3.1.

2. Engineering background for technical basis and rationale

S.10.5.1 a) – Clarification in the text has been introduced in order to reflect the exclusive nature of the requirements a) and b) as originally proposed in this UR and the application by IACS Members and Industry.

S.10.5.3.1 – IACS Members have reported rudder causalities in rudder constructions where protrusions have not been applied.

3. Source / derivation of the proposed IACS Resolution

None.

4. Summary of Changes intended for the revised Resolution:

S.10.5.1 a) – "a) In general except in way of rudder recess sections where b) applies."

S.10.5.3.1 – "Solid parts in forged or cast steel, which house the rudder stock or the pintle, are ~~normally~~ to be provided with protrusions, except where not required as indicated below."

5. Points of discussions or possible discussions

Regarding the clarifications applied in S.10.5.1, two Members proposed to introduce a material factor coefficient (k) in subparagraph b) for cast steel materials with yield stress below 235 N/mm^2 which has not been supported by the other Members since the nature of subparagraph b) is explained in the TB Appendix 1 Scantling of rudder blades with cut-outs (bending stress criterion) as derived simply from an average stress amplification factor.

6. Attachments, if any

None.

Requirement S10.5.3.3

1. Scope and objectives

The scope of this revision is to correct a typo in the minimum section modulus formulation. The term between brackets shall be squared.

2. Engineering background for technical basis and rationale

The TB Annex 2 for Rev.4 (Apr 2015) remains valid for this formula.

$$W_s = c_s d_c^{\,3} \left(\frac{H_E - H_x}{H_E} \right)^2 \frac{k}{k_s} 10^{-4} \text{ [cm}^3\text{]}$$

Solid parts, in forged or cast steel, used for the housing of either the rudder stock or of the rudder pintle are connected to the rudder blade by means of horizontal and vertical web plates, as shown in figure 1, here below. The solid part is located either below the lower rudder stock-bearing, or below the lower pintle-bearing.

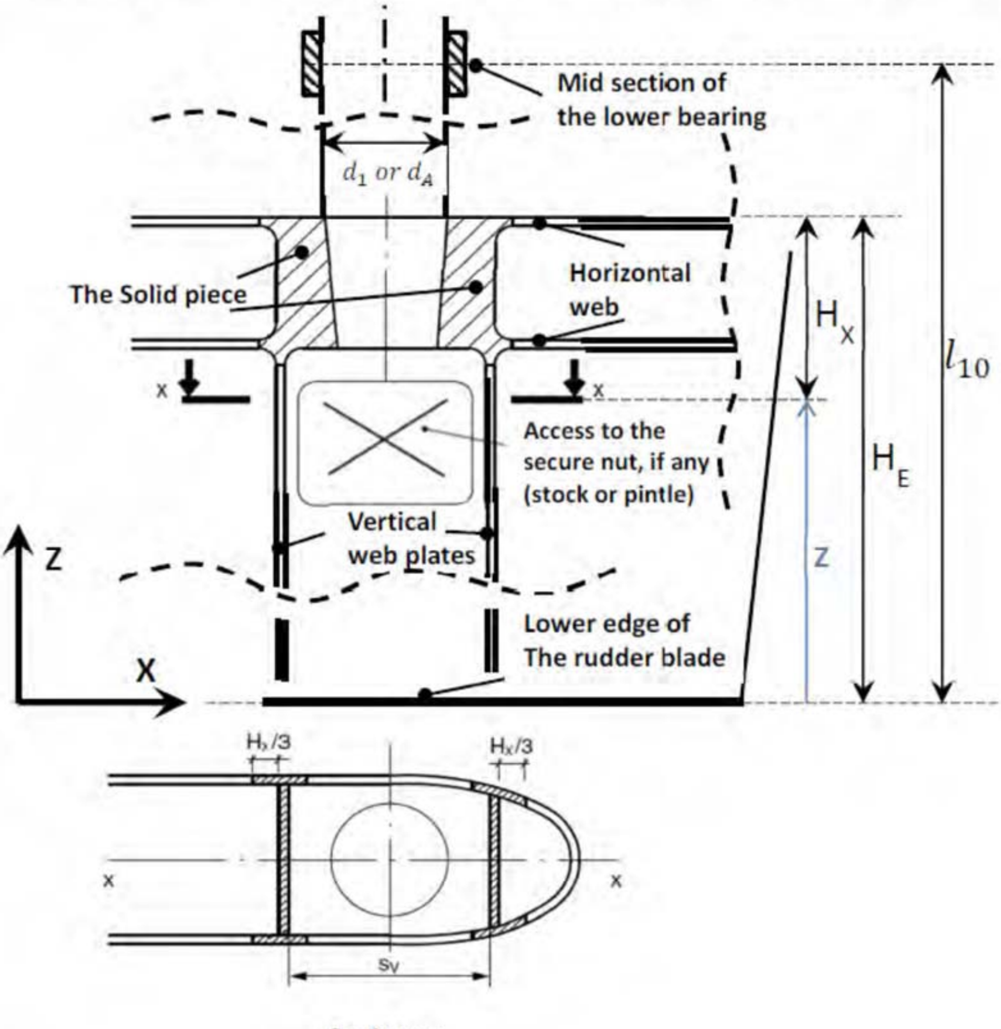

Figure 1 : Section modulus in the area below stock or pintle

The section modulus of the cross-section of the structure of the rudder blade, formed by vertical web plates and rudder body plating, is to be enough stiff to withstand bending moment acting on this area.

The objective is to provide the technical background for the following formula:

$$W_s = c_s\, d_1^3 \left(\frac{H_E - H_X}{H_E}\right)^2 \frac{k}{k_1} 10^{-4} \qquad (1)$$

Bending moment acting below the solid part:

Two rudder systems are considered in the scope of this technical note: spade rudders and semi-spade rudders. Bending moment diagrams from the lower edge of the blade till the lower bearing area of the rudder system can be written, as follows:

- For spade rudders

$$M_z = -p_{R10}\frac{z^2}{2} - \left(\frac{p_{R20} - p_{R10}}{l_{10}}\right)\frac{z^3}{6} \qquad (2a)$$

- For semi-spade rudders:

$$M_z = -p_{R10}\frac{z^2}{2} \qquad (2b)$$

where:

z is the distance, in m, from the lower edge of the rudder blade till its cross-section submitted to the bending moment M_Z

p_{R10} is the force per unit length, in N/m, obtained for z equal to zero (at rudder-blade bottom edge)

p_{R20} is the force per unit length, in N/m, obtained for z equal to l_{10} (location of the lower bearing, mid-section)

Note that in case of spade-rudders, $p_{R10} = p_{R20} = constant$, and the cubic term of equation (2a), becomes zero.

For both formulae (2a) and (2b), the minimum bending moment, $M_Z = 0$ is obtained for $z = 0$ and the maximum bending moment, M_Z is obtained for $z = l_{10}$.

At the lower bearing position, for $z = l_{10}$, the section modulus of the structure is mainly given either by:

- Cross-section of the rudder stock, with diameter d_1, in mm, calculated for a solid circle, as follows:

$$W_s = \frac{I}{\left(\frac{d_1}{2}\right)} = \frac{\pi d_1^3}{32} \approx \frac{d_1^3}{10}, which\ is\ valid\ for\ a\ material\ with\ a\ coefficient = k_1 \qquad (2c)$$

or by

- Cross-section of the rudder pintle, with diameter d_A, in mm, calculated for a solid circle, as follows:

$$W_p = \frac{I}{\left(\frac{d_A}{2}\right)} = \frac{\pi d_A^3}{32} \approx \frac{d_A^3}{10}, which\ is\ valid\ for\ a\ material\ with\ a\ coefficient = k_1 \qquad (2d)$$

Equations (2c) and (2d) may be written in cm^3, as follows:

$$W_s = d_1^3 10^{-4}\ cm^3 \qquad (2e)$$

$$W_p = d_A^3 10^{-4}\ cm^3 \qquad (2f)$$

The axial bending stress, σ_z, generated by the bending moment, M_z, is given by:

$$\sigma_z = \frac{M_z}{W_{sect}} \qquad (3a)$$

The normalized variable $u_z = \left(\frac{H_E - H_X}{H_E}\right)$ is defined, from figure 1, here above. By using it inside of equations (2a) and (2b), it can be seen that the bending moment will be decreasing from the value M_{H_E} till zero, when H_X varies from zero to H_E.

Section modulus below the solid part:

At $z = H_E$ or $u_z = 1$, it can be said that, for a section modulus $W_{mec} = W_s$ or W_p , the level of stress σ_{H_E}, acting on this section is acceptable, either based on the scantling of the rudder stock or on the scantling of the rudder pintle.

Based on the equation (3a), and assuming that the axial bending stress should be kept at most equal to σ_{H_E} inside of this transition zone, through the solid part thickness and beneath the lower edge of this part, the following can be written:

$$\sigma_{H_E} = \frac{M_{H_E}}{W_{mec}} \frac{u_z^2}{u_z^2} = constant \qquad (3b)$$

where $W_{mec} = d_v^3 10^{-4}\ cm^3$, with d_v either $= d_1$(rudder stock) or d_A(rudder pintle)

Equation (3b) will make sure that the level of stress acting on a cross section (see figure 1, section at X-X) of the rudder blade is less than or equal to σ_{H_E}. Based on equation (3b), the section modulus at any cross section X-X, below the solid part, should be of a value, at least equal to W_{sect}, defined as follows:

$$W_{sect} = W_{mec} u_z^2 = d_v^3 10^{-4} \left(\frac{H_E - H_X}{H_E}\right)^2 \qquad (3c)$$

Equation (1) can be obtained from equation (3c) by adding:

1. a safety factor, c_s, to compensate the existence, or not of an opening in the considered cross section(*)
2. the ratio $\frac{k}{k_1}$, to make the difference of material properties of the stock (or pintle) with the web plates

From equation (3c), and considering the two above remarks, it can be written:

$$W_{sect} = c_s d_v^3 \left(\frac{H_E - H_X}{H_E}\right)^2 \frac{k}{k_1} \quad 10^{-4} \quad cm^3 \qquad (3d)$$

(*)Note that, the c_s coefficient is also considered to make possible the use of the same formula for the calculation of the actual section modulus for any cross section X-X, just in the region below the lower edge of the solid part (for both cases with or without an opening in the rudder plating). The breadth of the rudder plating to be considered for the calculation of this actual section modulus is to be not greater than that obtained, in m, from the following formula:

$$b = s_V + 2\frac{H_X}{m} \qquad (4)$$

where:

$s_V =$ spacing, in m, between the two vertical webs (see figure 1)

$H_X =$ distance defined according to figure 1

$m =$ coefficient to be taken, in general, equal to 3.

In conclusion, it is clear established in the above (3d) formula the square of the term between bracket.

3. Source / derivation of the proposed IACS Resolution

None.

4. Summary of Changes intended for the revised Resolution:

The Rev.4 contain this following formula with the missing square coefficient of the bracket term:

$$\mathrm{W_s} = c_s d_c{}^3 \left(\frac{H_E - H_x}{H_E} \right) \frac{k}{k_s} 10^{-4}$$

The missing square symbol shall be introduced in the formulation of the rev.5:

$$\mathrm{W_s} = c_s d_c{}^3 \left(\frac{H_E - H_x}{H_E} \right)^2 \frac{k}{k_s} 10^{-4} \text{ [cm}^3\text{]}$$

5. Points of discussions or possible discussions

None

6. Attachments, if any

None.

Requirements S10.6.4.2 and S10.6.4.3

1. Scope and objectives

The scope of this revision is a modification to UR S10 6.4.2 and 6.4.3. The objective is to improve the requirements for dimension of gudgeon and cone coupling push-up length.

2. Engineering background for technical basis and rationale

In UR S10 Rev.4 it was introduced a requirement, copied from CSR BC, saying that the outer diameter of the gudgeon was not to be less than 1.5 times the mean cone diameter.

After applying UR S10 Rev.4 to other vessel types than Bulk Carriers, the feedback from the industry is that it is necessary to increase the breadth of standard rudder designs to comply with the gudgeon diameter requirement, and this will result in increased fuel consumption. It is argued that the experience with gudgeon in current designs is positive. From DNV GL side it is confirmed that there are no registered rudder damages which can justify the gudgeon diameter requirement. To avoid having to modify existing rudder designs, UR S10 is updated in line with previous DNV rules, which had a more relaxed requirement to the gudgeon diameter, but a more accurate and conservative calculation of the loads on the gudgeon.

The additional push-up length limitation has been introduced in the Rev.3. However, there is no technical justification in the appendix 2 "Cone coupling assembly of steel rudder stock with the massive part" of this revision for this minimum push-up length of 2 mm.

3. Source / derivation of the proposed IACS Resolution

The proposed modifications are based on DNV Rules for ships, January 2015, Part 3 Chapter 3 Section 2 G200.

The formula for allowable surface pressure p_{perm} in 6.4.2 is modified to include the contribution to the surface pressure from bending of the rudder stock. As the surface pressure calculation is including more load components, the allowable stress is increased from 0.8 R_{eH} to 0.95 R_{eH}.

For cylinder-cylinder contact where the clearance is negligible, there are two common calculation models to estimate the bearing pressure.

The first model assumes that the parts are rigid bodies. In this model the pressure is a uniform, radial pressure given by the following equation:

$$p = \frac{F}{d_m \ell}$$

where F is the force.

The second model assumes that the parts are elastic bodies. The pressure is now sinusoidal, and may be written as:

$$p(\theta) = \frac{4}{\pi} \frac{F}{d_m \ell} \cos\theta$$

The maximum pressure is 4/π ≃ 1.27 times bigger than with the rigid body assumption.

The conical coupling of rudder stock with rudder gudgeon is assumed to be neither fully rigid nor fully elastic, but something in between. As shown below, in the rule formula for p_b the local pressure p_b correspond to 1.17 times the pressure with rigid body assumption and uniform distribution.
Along the length of the cone, the surface pressure due to a bending moment in the stock has been assumed to have a triangular distribution with maximum pressure at the ends of the bore.

Figure 1 shows the principles of the assumed model of the connection. Please note that only a projection of the radial pressure is shown.

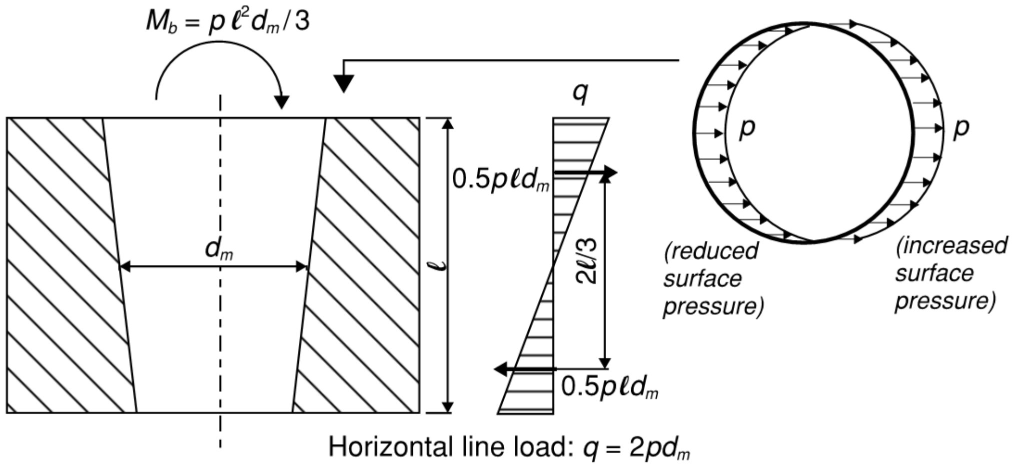

Figure 1 Bending moment in the stock assuming uniform surface pressure *p*

Thus, considering a ratio between uniform to peak pressure of p_b = 1.17p, the bending moment given by this pressure is approximated to:

$$M_b = \frac{p_b}{1.17} d_m \frac{\ell}{2} \frac{2\ell}{3}$$

Rearranging and correcting for units:

$$p_b = \frac{3.5 M_b}{d_m \ell^2} 10^3$$

In the boss, which may be considered as a hollow cylinder with an internal pressure $p = p_r + p_b$, using formulas for thick-walled cylinder the maximum tangential stress will be: $\sigma_t = p\frac{1+\alpha^2}{1-\alpha^2}$ and the radial stress will be: $\sigma_r = -p$. Thus, the equivalent stress becomes:

$$\sigma_e = \sqrt{\sigma_t^2 + \sigma_r^2 - \sigma_t\sigma_r} = \left(p_r + p_b\right)\frac{\sqrt{3+\alpha^4}}{1-\alpha^2}$$

With allowable stress of $0.95R_{eH}$ the formula for the allowable push-up pressure p_{perm} becomes:

$$p_{perm} = \frac{0.95R_{eH}\left(1-\alpha^2\right)}{\sqrt{3+\alpha^4}} - p_b$$

For a solid shaft in a boss of the same material the effective grip (mutual compression of the mating surfaces) is given by:

$$\delta = \frac{2p_r d_m}{E\left(1-\alpha^2\right)}$$

The push-up length is given by:

$$\Delta\ell = \frac{\delta + 0.8R_{tm}}{c}$$

where $0.8R_{tm}$ represents the compression of the surface irregularities.

Rearranging:
$\delta = \Delta\ell c - 0.8R_{tm}$

Equating δ and rearranging gives the following equation for the maximum permissible push-up length:

$$\Delta\ell_2 = \frac{p_{perm}d_m}{E\left(\frac{1-\alpha^2}{2}\right)c} + \frac{0.8R_{tm}}{c}$$

The minimum push-up length of 2 mm has been introduced in the Rev.3 without technical justification. A rudder manufacturer raised the question. Moreover, in the Rev.3 Appendix 2, paragraph 5.2, the user attention is drawn on the risk related to a push-up value over the maximum acceptable pressure or length: "maximum acceptable values of push-up pressure and push-up length to avoid any damage caused to the massive part (the outer cone)". This is the reason why the sentence "*Notwithstanding the above, the push up length is not to be less than 2 mm.*" is removed.

4. Summary of Changes intended for the revised Resolution:

The prescriptive requirement for outer diameter of the gudgeon is reduced from 1.5 times the mean diameter to 1.25 times the maximum cone diameter which means the minimum diameter will normally be limited by the yield strength criteria.
The formula for allowable surface pressure p_{perm} in 6.4.2 is modified to include the contribution to the surface pressure from bending of the rudder stock. As the surface pressure calculation is including more load components, the allowable stress is increased from 0.8 R_{eH} to 0.95 R_{eH}.

The formula for Δl2 is simplified to use p_{perm} as input.

5. Points of discussions or possible discussions

Requirement S10.7.2.2

1. Scope and objectives

The scope of this revision is the clarification of coupling and push-up requirements in S.7.2.2.

2. Engineering background for technical basis and rationale

Noting that bearing" means not a coupling part but a sliding part the word bearing may be deleted from "pintle bearing".

3. Source / derivation of the proposed IACS Resolution

None.

4. Summary of Changes intended for the revised Resolution:

7.2.2 Push-up pressure for pintle ~~bearings~~

The required push-up pressure for pintle ~~bearing~~, in N/mm², is to be determined by the following formula:

$$p_{req} = 0.4 \frac{B_1 d_0}{d_m^2 \ell} \qquad \text{[N/mm}^2\text{]}$$

where:

B_1 = Supporting force in the pintle ~~bearing~~, in [N]

d_0 = Pintle diameter, in [mm], see Figure 5

The push-up length is to be calculated similarly as in S10.6.4.3, using required push-up pressure and properties for the pintle ~~bearing~~.

Requirement S10.9.3.1

1. Scope and objectives

The scope of this revision is the clarification of rudder trunk material chemical composition in S.10.9.3.1.

2. Engineering background for technical basis and rationale

S.10.9.3.1 – Clarification on materials chemical composition have been introduced to align this UR with other IACS unified requirements.

3. Source / derivation of the proposed IACS Resolution

None.

4. Summary of Changes intended for the revised Resolution:

S.10.9.3.1 – "The steel used for the rudder trunk is to be of weldable quality, with a carbon content not exceeding 0.23% on ladle analysis ~~and~~ or a carbon equivalent CEQ not exceeding 0.41%."

5. Points of discussions or possible discussions

None

6. Attachments, if any

Requirement in Annex S10.3 and Annex S10.6

1 Scope and objectives

Annex S10.3, spade rudder with trunk and Annex S10.6 for the rudder horn shear stress calculation.

The objective is to bring clarification in some equations and the corresponding figure A2 for better understanding for Annex S10.3 and to correct magnitude of the torsional stress in Annex S10.6.

2 Engineering background for technical basis and rationale

2.1 Annex S10.3, spade rudder with trunk

2.1.1 Clarification is brought by detailing the subscript of bending moments acting in the upper (A_1) and lower (A_2) parts of the rudder blade, M_{CR1} and M_{CR2} respectively.

2.1.2 It is clarified that the total force acting on the blade, C_R, is the sum of the forces acting on the upper and lower parts, C_{R1} and C_{R2}.

2.1.3 The bending moment and shear force acting on the rudder blade at the level of the lower bearing are defined respectively as:

- For the upper part (A_1)
  $M_{CR1} = C_{R1} (CG_{1Z} – \ell_{10})$
  C_{R1} = Rudder force over the rudder blade area A_1.

- For the lower part (A_2)
  $M_{CR2} = C_{R2} (\ell_{10} – CG_{2Z})$
  C_{R2} = Rudder force over the rudder blade area A_2

2.1.4 The bending moment acting on the rudderstock at the level of the lower bearing is $M_{CR2} − M_{CR1}$
and the correspondent shear force in the rudder stock is defined as
$B_3 = (M_{CR2} - M_{CR1}) / (\ell_{20} + \ell_{30})$

2.1.5 The definitions of CG_{1Z} and CG_{2Z} have been clarified by adding from which point the distance is measured.

2.1.6 The Figure A2 shows for simplicity the equivalent pressure, a distributed load acting on the upper part of the rudder blade, i.e. on the l_{20} part is represented as a concentrated load and moment acting on the rudder blade at the level of the lower bearing, although they are considered in the equations for the correct forces balance on the complete system.

2.2 Annex S10.6, rudder horn shear stress calculation
In the formulae of the torsional stress a coefficient of 10^3 was introduced instead of 10^{-3}. This editorial correction was made to correct the magnitude of the stress.

3 Source / derivation of the proposed IACS Resolution

None.

4 Summary of Changes intended for the revised Resolution:

- In Annex S10.3:

The formulae of M_{CR1}, M_{CR2} and B_3 have been modified.
The definitions of CG_{1Z} and CG_{2Z} have been modified
The Figure A2 has been modified to correspond to the equations.

- In annex S10.6:

The 2 torsion stress formulae were corrected with coefficient 10^{-3}.

5 Points of discussions or possible discussions

These changes were agreed by the Hull Panel in 2017 and the figure by GPG in July 2017.

Technical Background for UR S10 Rev.6 Sep 2019

Requirements S10.1.4.2

1. Scope and objectives

The scope of this revision is to clarify the application of the required radii in way of the solid part in cast steel.

2. Engineering background for technical basis and rationale

The required radii of 100mm is not applicable to solid parts in cast steel and smaller radii may be accepted. As shown in Recommendation No.76 IACS Guidelines for Surveys, Assessment and Repair of Hull Structure – Bulk Carriers, Example Nos. 4, 5 & 6 of structural detail failures and repairs - Area 3, fractures occurred in way of small radii in plating or welding seam. Where steel cast pieces having three-dimensional smooth profile are extended beyond the end of radii, fractures in way of radii have not been reported.

3. Source / derivation of the proposed IACS Resolution

None.

4. Summary of Changes intended for the revised Resolution:

The underlined phrase is added:

[quote]
1.4.2 In way of the rudder horn recess of semi-spade rudders, the radii in the rudder plating <u>except in way of solid part in cast steel</u> are not to be less than 5 times the plate thickness, but in no case less than 100 mm. Welding in side plate is to be avoided in or at the end of the radii. Edges of side plate and weld adjacent to radii are to be ground smooth.
[unquote]

5. Points of discussions or possible discussions

The last sentence in item 2 above should be confirmed by Hull Panel Members, i.e.:
[quote]
Where steel cast pieces having three-dimensional smooth profile are extended beyond the end of radii, fractures in way of radii have not been reported.
[unquote]

6. Attachments, if any

None.

Requirements S10.2.1.1

1. Scope and objectives

The scope of this revision is to address the vague text “to be specially considered; if not known:” in Table 1.

2. Engineering background for technical basis and rationale

Text “to be specially considered; if not known:” for high lift rudders in Table 1 is vague and lacks details.

For rudder torque: $Q_R=C_R \bullet r= C_R \bullet c(\alpha-k_f)$, where $C_R=K_1 \bullet K_2 \bullet K_3 \bullet 132 \bullet A \bullet V^2$, $\alpha=0.33$ for ahead condition while $\alpha=0.66$ for astern condition. It is noted that the flap rudder balance coefficient k_f is normally around 0.33~0.46, then $(\alpha-k_f)$ ratio for astern/ahead will be less than 4. Considering C_R at the astern is quarter of the ahead C_R since the astern speed is half of ahead speed normally, the rudder torque at ahead is larger than astern which is same as rudder force. Hence, there is no need to give special consideration for at astern conditions.

3. Source / derivation of the proposed IACS Resolution

None.

4. Summary of Changes intended for the revised Resolution:

Remove the vague text "to be specially considered; if not known:" in Table 1 of UR S10.2.1.1.

5. Points of discussions or possible discussions

None

6. Attachments, if any

None.

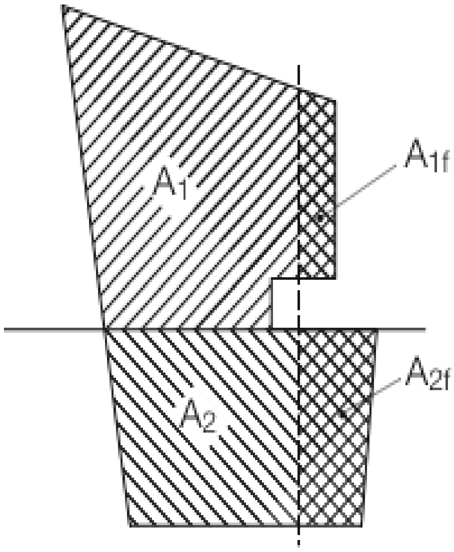
Requirements S10.2.2

1. Scope and objectives

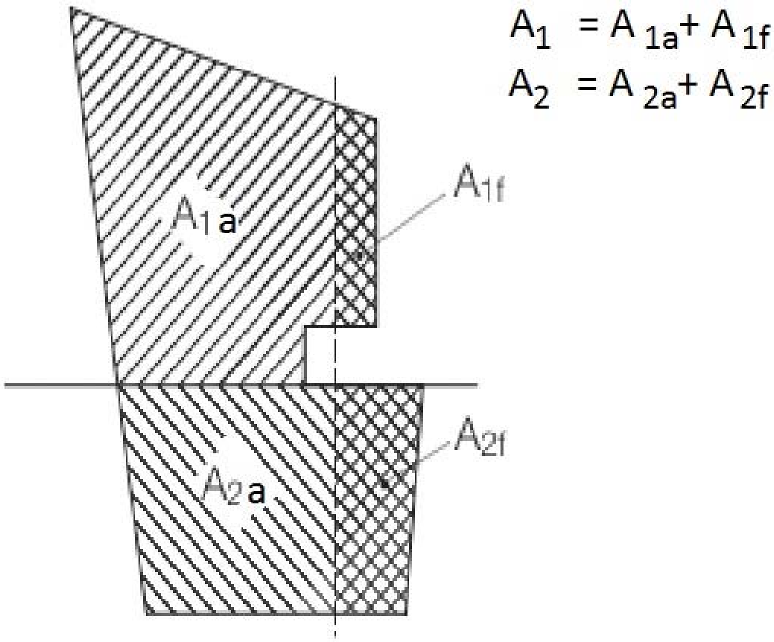
The scope of this revision is to make the definition of Rudder areas "A_1 and A_2" clearer, which are used for calculating the rudder forces and torques of semi-spade rudders.

2. Engineering background for technical basis and rationale

The rudder area A is defined as the sum of two rectangular or trapezoidal parts A1 and A2 for a semi-spade rudder. The original figure given in Rev. 5 (2018) of this UR is as given below:



It is not clear from the above figure, whether A_{1f} and A_{2f} are part of A_1 and A_2.
Hence it is suggested to include the following figure and the definitions in the UR for more clarity.



A_{1f} = portion of A_1 situated ahead of the centre line of the rudder stock

A_{1a} = portion of A_1 situated aft of the centre line of the rudder stock

A_{2f} = portion of A_2 situated ahead of the centre line of the rudder stock

A_{2a} = portion of A_2 situated aft of the centre line of the rudder stock

3. Source / derivation of the proposed IACS Resolution

None

4. Summary of Changes intended for the revised Resolution:

The figure 2 in UR S10 is edited for more clarity

5. Points of discussions or possible discussions

None

6. Attachments, if any

None

Requirements S10.5.3 Fig.3

1. Scope and objectives

The scope of this revision is to indicate the radius in the critical corners of cover plates or openings in rudder plates as shown in figure 3.

2. Engineering background for technical basis and rationale

Cover plate - One side welding against permanent steel backing

Welding against permanent steel backing:
1) Often root defects are not possible/difficult to detect;
2) Sometimes serious weld defects are found during operation;
3) Fatigue cracking from cover plate welding may propagate over the width of the blade causing serious damage
4) Removing and re-welding the cover plates in service will increase the crack probability
5) Poor fatigue strength, i.e. low SN-curve

Bolted cover and radius corners are considered better solutions for cover plates
In any case all cover plates and openings need to have radiused corners.

3. Source / derivation of the proposed IACS Resolution

None.

4. Summary of Changes intended for the revised Resolution:

The current figure 3 provided in UR S10 Rev 5 has been replaced by the following updated figure 3.

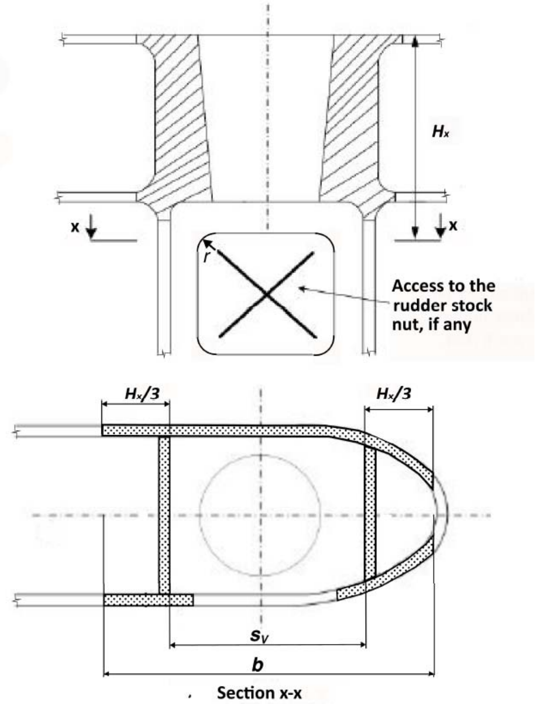


Figure 3 Cross-section of the connection between rudder blade structure and rudder stock housing, example with opening in only one side shown

5. Points of discussions or possible discussions

None.

6. Attachments, if any

Requirements S10.6.4.2 and S10.7.2.2

1. Scope and objectives

The scope of this revision is to make the definition "ℓ" used for calculating the push-up pressure of cone coupling more appropriate.

In addition to clarify the definition of outer diameter of Gudgeon(d_a) used in the permissible push up pressure clearer.

2. Engineering background for technical basis and rationale

The length "ℓ" is defined in S10.6.4.2 as a cone length and this parameter is used to calculate a taper "c" in S10.6.3.1 and push-up pressure in S10.6.4.2 and S10.7.2.2.

To use a cone length for calculation of a taper "c" is considered appropriate.

On the other hand, in the equation of the push-up pressure, area of contact surface between a cone and gudgeon is taken into consideration. Therefore, it is considered that the contact length of a cone and gudgeon should be used instead of the cone length when calculating the push-up pressure (See below figure). As a cone length is generally greater than a contact length, the result of push-up pressure calculation with cone length may be dangerous side by overestimating the area of contact surface.

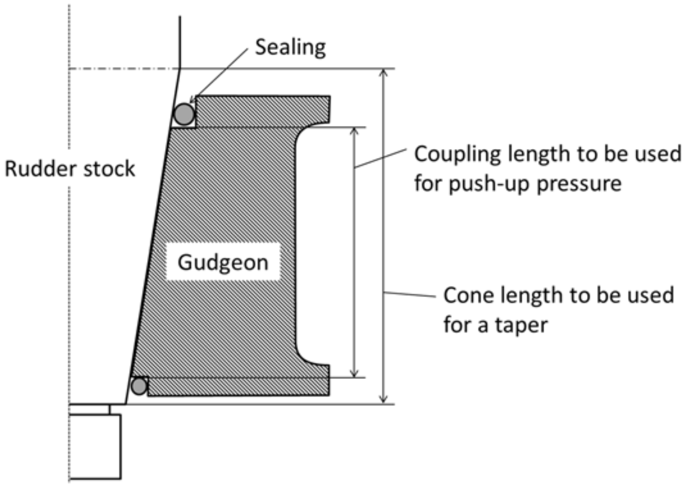

Figure 5 of UR S10 Rev 5 shows d_a as the outer diameter of Gudgeon. However, it is not clear whether it is to be measured along the breadth of the rudder or along the transverse direction. A typical configuration like below, may mislead the designer/class societies to take the largest diameter/distance:

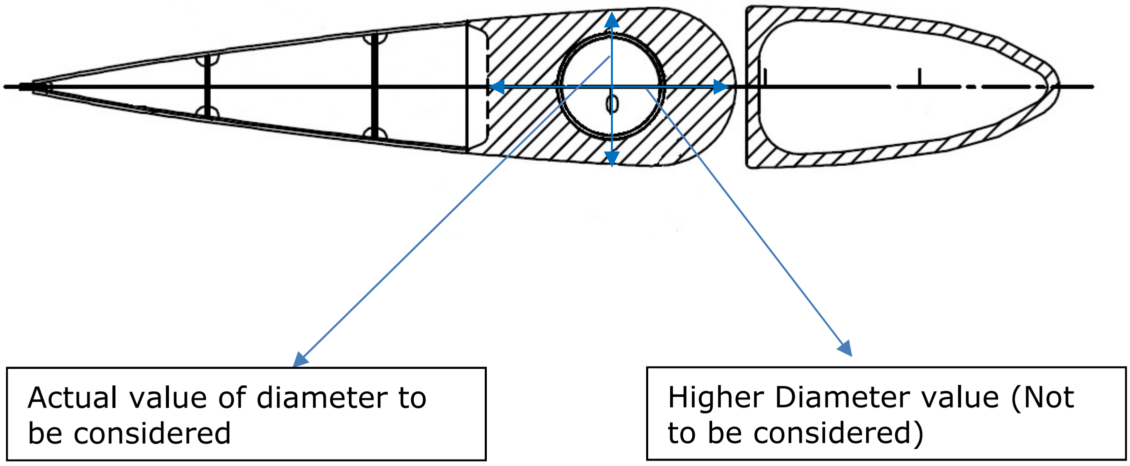

Considering a higher diameter would result in a higher permissible surface pressure value, where the actual highest permissible pressure is as calculated for the least diameter in the transverse direction. It is recommended to take this value at the same plane in which the value of d_m is measured.

The following editorial corrections are proposed:

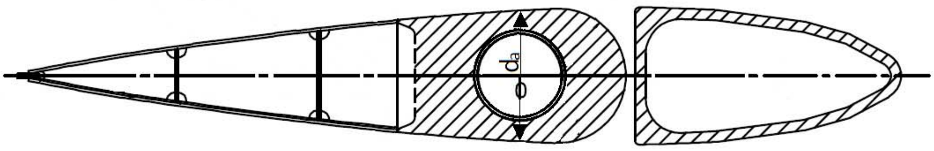

Figure 5a – Gudgeon outer diameter(d_a) measurement

d_a = outer diameter of the gudgeon, in [mm], see Figure 5 and Figure 5a. (The least diameter is to be considered).

3. Source / derivation of the proposed IACS Resolution

None

4. Summary of Changes intended for the revised Resolution:

A new coefficient "ℓ_c" is introduced as a cone length and just used to calculate a taper "c". A coupling length "ℓ" used as a contact length mentioned above to calculate a push-up pressure is clearly determined by Figure 5b.

A new figure (Figure 5a) is proposed for more clarity on the definition of the outer diameter of the gudgeon.

5. Points of discussions or possible discussions

None

6. Attachments, if any

None

Requirements S10.8.2 Table 3

1. Scope and objectives

The scope of this revision is the clarification of use of synthetic materials with hardness greater than 70 Shore D.

2. Engineering background for technical basis and rationale

The description "with hardness between 60 and 70 Shore D" seems to limit the hardness of the synthetic materials but no member found the background of the description which has been incorporated since Rev.1 (1990). Synthetic bearing materials are required to be approved type, so it is considered that safety of the materials can be ensured even with hardness exceeding 70 Shore D.

3. Source/derivation of the proposed IACS Resolution

None.

4. Summary of Changes intended for the revised Resolution:

The actual modified text is indicated as follows:

Table 3 ~~Maximum~~ Allowable surface pressure q_a

Bearing material	q_a [N/mm^2]
lignum vitae	2.5
white metal, oil lubricated	4.5
synthetic material with hardness ~~between 60 and 70~~ greater than 60 Shore D[1)]	5.5[2)]
steel[3)] and bronze and hot-pressed bronze-graphite materials	7.0

5. Points of discussions or possible discussions

An IACS member pointed out that the interpretation of the specification "synthetic material with hardness between 60 and 70 Shore D" in Table 3 is not clear, whether synthetic materials with hardness greater than 70 Shore D may be accepted or not.

Some members advised that synthetic materials with high hardness will be prone to cracking but this is not considered as a problem anymore for fibre reinforced synthetic materials since the mid 90'ies.

Considering the member's opinion and implementation, Hull Panel concluded that synthetic materials with hardness greater than 70 Shore D may be accepted.

Requirement S10.9.3.1

1. Scope and objectives

The scope of this revision is to make the application of rudder trunk requirements more appropriate.

2. Engineering background for technical basis and rationale

The rudder trunk requirements in 9.3.1 of UR S10 are based on 3.4.3 and 3.4.4, Ch.10 Sec.1 of CSR-BC. These CSR-BC requirements are applied only to a rudder trunk supporting rudder stock such as specified in Fig.7, Ch.10 Sec.1 of CSR-BC, which construction is same as Figure A2, Annex S10.3 of UR S10.

When the requirements were incorporated into UR S10 (Rev.4), the scope of application of the requirements were extended without technical justification to other rudder trunk configurations as specified in 9.3.1 of UR S10 that "This requirement applies to both trunk configurations (extending or not below stern frame)." (See below Figure 1 and Figure 2)

However, since the rudder trunk not extending below stern frame is not subject to considerable bending moment, the requirements in 9.3.1 of UR S10 are too strict for such rudder trunk configuration.

Taking into account above consideration, Hull Panel concluded that 9.3.1 of UR S10 should apply only to a rudder trunk configuration extending below stern frame.

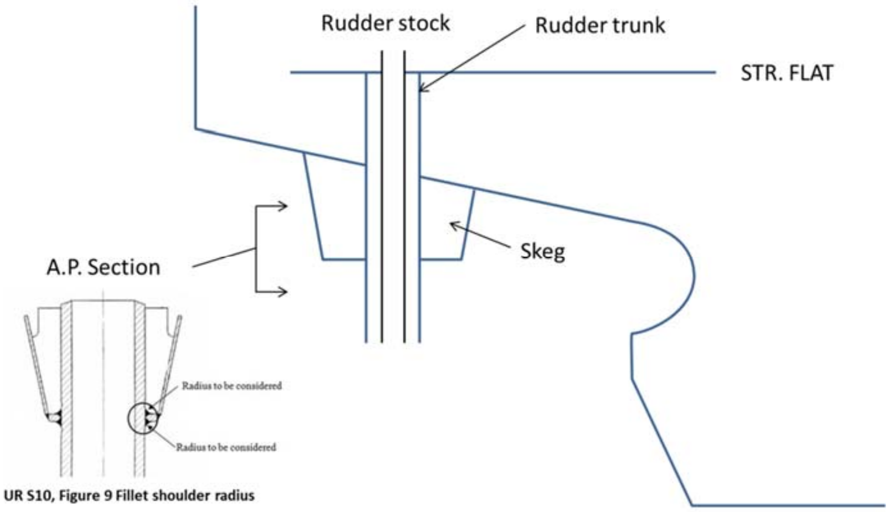

Figure 1: Rudder trunk <u>extending</u> below stern frame

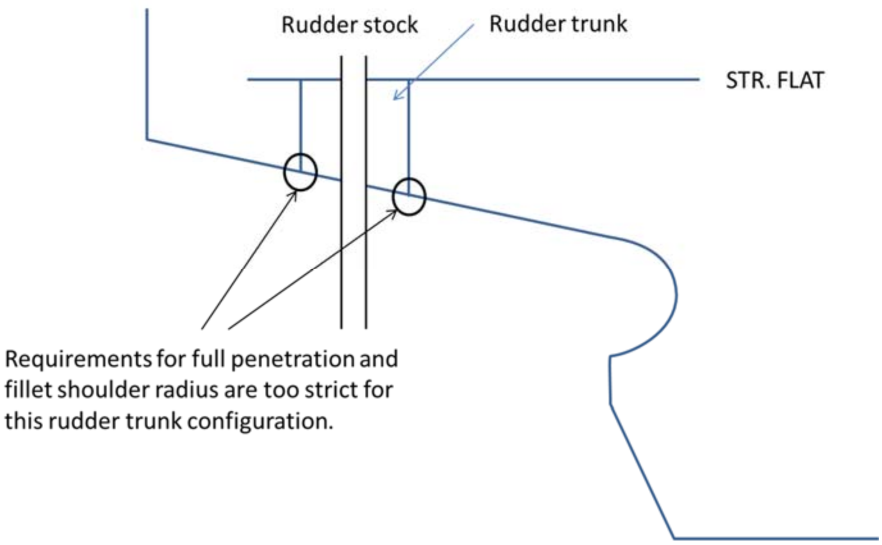

Figure 2: Rudder trunk <u>not extending</u> below stern frame

The radius for trunks with stresses above 40 N/mm^2 should be the same or higher than the radius for trunks with stress level below 40 N/mm^2. An error is corrected so that this is intention is obtained also for rudder stock diameter above 600mm.

3. Source / derivation of the proposed IACS Resolution

None

4. Summary of Changes intended for the revised Resolution:

The scope of application of 9.3.1 is modified to apply only to a rudder trunk configuration extending below stern frame as same as 9.3.2.

5. Points of discussions or possible discussions

None

6. Attachments, if any

Technical Background document for UR S10 Rev.7 (Feb 2023)

Requirements S10.1.2.3

1. Scope and objectives

Improvement of clarity of requirement S10.1.2.3 related to sealing arrangement.

2. Engineering background for technical basis and rationale

A manufacturer asked that if two separate seals can be considered as equivalent devices to two separate stuffing boxes. It is the manufacturer's opinion that considering the performance of the sealing device in recent years, two seal devices serve a function to have a sufficient redundancy.
In addition, in the first sentence of 1.2.3 a seal is accepted as equivalent to a stuffing box, while in the second sentence of 1.2.3 explicitly two separate stuffing boxes are required.
This question was discussed in Hull Panel and agreed. Furthermore, the meaning of "deepest waterline" was discussed, as during the design stage of the rudder a "deepest waterline" with respect to possible loading conditions might not be available. To clarify this issue, it was agreed to define the waterline at scantling draught as basis for rudder design and sealing arrangement.

3. Source / derivation of the proposed IACS Resolution

None

4. Summary of Changes intended for the revised Resolution

Modification of UR S10.1.2.3 as below:

1.2.3 In rudder trunks which are open to the sea, a seal or stuffing box is to be fitted above the deepest load waterline, to prevent water from entering the steering gear compartment and the lubricant from being washed away from the rudder carrier. If the top of the rudder trunk is below the ~~deepest~~ waterline at scantling draught (without trim), two separate watertight seals / stuffing boxes are to be provided.

Accordingly, the summer loadline draught *Td* to be considered for the scantlings of the rudder plating in UR S10.5.2 was replaced by the scantling draught T_{SC}.

5. Points of discussions or possible discussions

None

6. Attachments, if any

None

Requirements S10.1.4.3

1. Scope and objectives

Improvement of clarity of requirement S10.1.4.3 related to welding of rudder plating.

2. Engineering background for technical basis and rationale

Cracking in way of one-sided welding against steel backing bars have in some cases occurred in areas experiencing significant stresses from rudder bending, e.g. at connection weld between rudder side plating and closing plate as well as between heavy pieces and rudder plating. Hence it is proposed to make this requirement generally applicable for rudder side plating subjected to rudder bending, not only the connection between heavy pieces and plating.

Fitting steel backing strip by continuous weld at the bevelled edge instead of a separate fillet weld at the edge of the steel backing strip have two benefits:

a) By avoiding tack welding and/or separate weld on the edge of the steel backing bar, the fatigue performance will be improved, typically from a G-curve to a F-curve, ref. T.R. Gurney: Fatigue Design Rules for Welded Steel Joints. The Welding Institute Research Bulletin no. 177 (1976).
b) The initial weld between the steel backing bar and the plating will be a part of the full penetration weld.

3. Source / derivation of the proposed IACS Resolution

None

4. Summary of Changes intended for the revised Resolution

Modification of UR S10.1.4.3 as below, in addition new Figure 1 added and the following figures are re-numbered.

1.4.3 Welds <u>in the rudder side plating subjected to significant stresses from rudder bending and</u> welds between plates and heavy pieces (solid parts in forged or cast steel or very thick plating) are to be made as full penetration welds. In way of highly stressed areas e.g. cut-out of semi-spade rudder and upper part of spade rudder, cast or welding on ribs is to be arranged. Two sided full penetration welding is normally to be arranged. Where back welding is impossible welding is to be performed against ceramic backing bars or equivalent. Steel backing bars may be used and are to be <u>fitted with</u> continuous~~ly~~ weld~~ed~~ on one side to the ~~heavy piece~~ <u>bevelled edge, see Figure 1. The bevel angle is to be at least 15° for one sided welding.</u>

5. Points of discussions or possible discussions

Requirements S10.2.1.1

1. Scope and objectives

Clarify and align definition of astern speed.

2. Engineering background for technical basis and rationale

Machinery Panel amended UR M25 and found disparities between the requirement in UR M25 and the design astern speed as stated in UR S10.
HP reviewed the definition of the design astern speed in revised UR M25 and found that this definition is equivalent to the definition given in SOLAS II-1/3.15 which reads as follows:
"15 Maximum astern speed is the speed which it is estimated the ship can attain at the designed maximum astern power at the deepest sea-going draught."
HP decided to make reference to SOLAS but keep the current requirement as a minimum for rudder and steering gear design.

3. Source / derivation of the proposed IACS Resolution

N/A

4. Summary of Changes intended for the revised Resolution

Modification of definition of astern speed in UR S10.2.1.1 as below:

For the astern condition the maximum astern speed <u>as defined in SOLAS Regulation II-1/3.15</u> is to be used, however, in no case <u>taken</u> less than:

$$V_{astern} = 0.5\ V$$

5. Points of discussions or possible discussions

Requirements S10.4.2, S10.6.4.2 and Annex S10.2 and S10.3

1. Scope and objectives

Clarify of determination of bending moments and bearing forces was found necessary in the Annex S10.2 and S10.3. In addition, it was found necessary to consider a second case for loading of spade rudders with trunk extending inside the rudder. The additional case is covering partly submerged rudders, which may yield to increased bending moment.

2. Engineering background for technical basis and rationale

Spade rudder with trunk extending inside the rudder may have, due to the special arrangement of the bearings, higher bending moment and higher moment at the cone coupling in partly submerged condition compared to the fully submerged condition. Therefore, it is decided to consider the partly submerged condition for the scantlings of rudder stock and the cone coupling.

Comparisons were calculated for four examples as summarised in the below table, indicating that in some cases impact on scantlings might occur.

item		Ship A	Ship B	Ship C	Ship D
A (fully submerged) [m²]		69.1	40.3	38.8	50.2
A_2 (below middle of neck bearing) [%]		71 %	58 %	72 %	72 %
Moment at neck	Percentage of fully submerged condition	118 %	125 %	118 %	118 %
Torque	Percentage of fully submerged condition	71 %	58 %	72 %	72 %
Rudder stock diameter for torque [mm]		No change	No change	No change	No change
Rudder stock scantling combined loads (neck) [mm]		99.4%	100.3%	102%	100.7%
Minimum section modulus of rudder blade		72%	71%	50%	78%
Horizontal web (thickness) [mm]		74%	64%	74%	94%
Connection length of cone coupling (with key) [mm]	Due to increase of rudder stock diameter (neck)	97%	98%	102%	100.6%
Gudgeon diameter [mm]		73%	78%	91%	87%
Required push up length $\Delta\ell_1$ [mm]		91%	98%	90%	102.5%
Permissible push up length $\Delta\ell_2$ [mm]		104%	117%	87%	87%

3. Source / derivation of the proposed IACS Resolution

None

4. Summary of Changes intended for the revised Resolution

UR S10.4.2 the following sentence is added:

For a spade rudder with trunk extending inside the rudder, the rudder stock scantlings shall be checked against the two cases defined in Annex S10.3.

UR S10.6.4 the requirement for the determination of the push-up pressure, the following sentence is added:

For spade rudder with trunk extending inside the rudder, the coupling shall be checked against the two cases defined in Annex S10.3

In AnnexS10.3 Figure A2 is modified and renumbered as Fgure A2 a) and a figure A2 b) is added, showing moment and force distribution for a partly submerged spade rudder. The description for determination of Moments and forces is modified as below:

For a spade rudder with trunk extending inside the rudder, the strength shall be checked against the following two cases:

a) pressure applied on the entire rudder area
b) pressure applied only on rudder area below the middle of neck bearing.

~~For spade rudders with rudder trunks t~~The moments~~, in Nm,~~ and forces~~, in N,~~ for the two cases defined above may be determined according to Figure A2 a) and b), respectively.

Requirements S10.7.2.2

1. Scope and objectives

IACS Members have been contacted by industry partners in view of the requirements related to the push-up lengths in case of cone couplings mainly for pintles. The changes are made to clarify the requirements of the push-up pressure for pintles and to align with rudder stock requirements

2. Engineering background for technical basis and rationale

In Rev.6 in case of the pintle cone coupling the required push up pressure is to be calculated following UR S10.7.2.2 This formulation considers the required push up pressure related to the torsion that needs to be taken by the cone coupling.
In contrast to that, in case of the rudder stock, two formulations for the required pressure are given in UR S10.6.4.2. considering the torsion as well as the bending moment in the cone coupling. In addition to that a permissible push up pressure for the rudder stock is to be calculated by UR S10.6.4.2. to avoid damage to the gudgeon. However, a permissible pressure is not required to be calculated for the pintle connection. In UR S10.6.4.3 a minimum and maximum push-up length shall be calculated for the rudder stock connection based on the required and permissible push-up pressure respectively. Following the reference in UR S10 7.2.2 this would not be possible for the pintle connection as only a required push-up pressure is calculated.

In the TB information to Rev. 5 and Rev.6 there is no difference given between the design and calculation of cone coupling for rudder stock and pintle, however, the requirements in UR S10 for cone coupling of rudder stock and pintle differ.

The current p_{req} under UR S10 7.2.2 Rev.6 is obviously based on a torsion moment that will appear in case the pintle bearing will fail and steel-to-steel friction will occur with a friction factor similar to what is assumed for steel-to-steel surfaces e.g. in hatch cover supports (friction factor about 0.35 to 0.38).

A formulation calculating a p_{req} for the cone coupling under bending effect, similar to what is required for the rudder stock was established. For that purpose the bending moment $\boldsymbol{M_{bp}}$ to be considered needs to be defined. The proposal is to determine the bending moment by multiplying the pintle force $\boldsymbol{B}$ by the distance between the middle of the bearing and the top of the pintle cone $\boldsymbol{\ell_a}$.

The required push-up-pressure for calculation of the required push-up-length was defined by using the maximum of the calculated required push-up-pressures related to the torque and the bending at the cone connection.

Furthermore it was proposed to require a permissible push-up-pressure based on the dimensions and material of the gudgeon for the pintle and based on the bending moment as defined above (similar as for the rudder stock in UR S10 6.4.2)

The permissible push-up-length for the pintle-cone-coupling considering the above was then defined similar to $\Delta\ell 2$ in URS 10 6.4.3 for the rudder stock.

To check the expected impact, existing pintle designs were recalculated using the above procedure and the results were compared with target values for the push-up length provided by the manufacturer.

For 24 designs target values could be provided and the re-calculations showed the results given in the table below. Required push-up lengths following the procedure in Rev.6 and the new proposal, considering the bending moment are given and compared with the target value. If the required push-up length following the new proposal found still below the target value, the check is marked "ok", otherwise "not ok". The last column contains the permissible push-up length acc. to the new proposal.

No	Pintle diameter [mm]	Bearing force [kN]	Bending moment [kNm]	$\Delta\ell_1$ Rev.6 [mm]	$\Delta\ell_1$ Rev.7 [mm]	Target value [mm]	check	$\Delta\ell_2$ Rev.7 [mm]

24	540	2698	1066	0.484	3.98	4.50	ok	9.25

Based on the results the following conclusions were drawn.

a) The permissible push-up lengths in the last column are always well above the target values. It was therefore decided to not require assessment of the permissible push-up length in UR S10.

b) In general, the calculated required push-up length using the new proposal (considering the bending) are more inline with the target values. However, in case of dry fitting (target push-up values below 1mm as indicated by light blue background in the table) the calculated required push-up values are too high. It was decided to keep in case of dry fitting the required push-up length as defined in Rev.6.

c) In four cases (No. 2, 7, 8 and 18) the calculated required push-up lengths were significantly larger than the target values. In some of these cases unusual design (taper) was applied, some other reasons might be dry fitting with unusual design parameters or mistakes in the collected input data.

Finally, HP agreed on the changes as summarised in section 4 below.

3. Source / derivation of the proposed IACS Resolution

None

4. Summary of Changes intended for the revised Resolution

Modification of the requirements in UR S10.7.2.2 as below:

Quote:
The required push-up pressure for pintle in case of dry fitting, in N/mm², is to be determined by p_{req1} as given below.

The required push-up pressure for pintle in case of oil injection fitting, in N/mm², is to be determined by the maximum pressure of p_{req1} and p_{req2} as given below ~~following formula~~:

$$p_{req1} = 0.4 \frac{B d_0}{d_m^2 \ell} \text{[N/mm²]}$$

$$p_{req2} = \frac{6 M_{bp}}{\ell^2 d_m} 10^3 \qquad \text{[N/mm²]}$$

where:

B = Supporting force in the pintle, in N, e.g. B_1 as defined in figure A4 for semi-spade rudder.

d_0 = Pintle diameter, in mm, see Figure 9.

M_{bp} = bending moment in the pintle cone coupling to be determined by:

$$M_{bp} = B \ell_a \text{ [Nm]}$$

ℓ_a = length between middle of pintle-bearing and top of contact surface between cone coupling and pintle in m, see Figure 9)

The required push-up length, $\Delta\ell_1$, is to be calculated similarly as in S10.6.4.3, using the required push-up pressure as defined above, and properties for the pintle.
Unquote:

In addition, Figure 9 was newly introduced to indicate the length ℓ_a. The following figures in UR S10 have been re-numbered.

Requirements S10.8.1.1

1. Scope and objectives

Clarify the requirement to fit liners in way of bearings.

2. Engineering background for technical basis and rationale

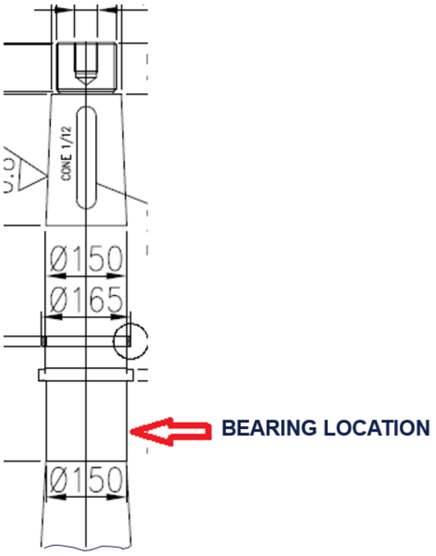
A member was approached by industry regarding the requirement UR S10.8.1.1 in which liners and bushes need to be fitted in way of bearings. Shipyards and ship repairers have indicated that replacement of worn-out liners is difficult especially in small diameter rudder stocks, i.e. the fitting of liners on rudder stocks with diameter below 200mm is found to have limited value, if any.
It is generally understood that the purpose of a liner is to facilitate replacement of the same (when worn out), instead of replacing the whole stock or repair if no liner is fitted.

I) There are several options available for repairing a worn-out rudder stock without liner, depending on the extent of damage and the resources available. Some of the common methods are:

a) Repairing by welding built up and then machining. This is done if the damage is not so severe, and the facilities are adequate and available.

b) Repairing by machining the rudder stock and providing the bush with a lower inner diameter to suit the machined stock. This is possible only if the provided diameter of the rudder stock in way of the bush is in excess to that required by Rules.

c) Replacing the rudder stock – This is done if the damage of the stock is beyond repair.
II) Shipyards and ship repairers find the above methods more convenient for smaller size rudder stocks and suggested to keep the liner's requirement mandatory only for larger diameter (above 200mm), which makes the above-mentioned repairs difficult.
III) In few cases the rudder stock geometry is complex as indicated in the figure below. The rudder stock needs to be tapered from bottom to top to insert the liner.



HP discussed this industry input and decided to modify the requirement as given in section 4 below.

3. Source / derivation of the proposed IACS Resolution

None

4. Summary of Changes intended for the revised Resolution

UR S10.8.1.1 has been modified as below:

Liners and bushes are to be fitted in way of bearings. <u>For rudder stocks and pintles having diameter less than 200 mm, liners in way of bushes may be provided optionally.</u> The minimum thickness of liners and bushes is to be equal to:
…

Requirements S10.9.3.1

1. Scope and objectives

Clarify the requirement in UR S10.9.3.1 regarding the fillet shoulder radius.

2. Engineering background for technical basis and rationale

One member drew the attention of the hull panel to the fact that the requirement for the fillet shoulder radius in UR S10.9.3.1 should be dependent from the material used for the trunk. Hull panel discussed and agreed to that proposal. In addition, it was made clear that this requirement is only applicable to trunks which are extending below the shell or the skeg as shown in figure 12 already.

3. Source / derivation of the proposed IACS Resolution

None

4. Summary of Changes intended for the revised Resolution

UR S10.9.3.1 was modified as below:

…
For rudder trunks extending below shell or skeg, ~~The~~ the fillet shoulder radius *r*, in mm, (see Figure ~~9~~ 12) is to be as large as practicable and to comply with the following formulae:

$r = 0.1 d_c \underline{/ k}$
…
k = material factor for the rudder trunk as given in S10.1.3.2 or S10.1.3.5 respectively.
…

UR S11A "Longitudinal Strength Standard for Container Ships"

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
New (June 2015)	02 June 2015	1 July 2016

- **New (June 2015)**

.1 Origin for Change:

☑ Action initiated to address UK MAIB recommendations following the MSC Napoli incident

.2 Main Reason for Change:

The main technical reason for the change is to clarify longitudinal strength requirements for container ships and to include recommendations made in the UK MAIB report on the MSC Napoli incident and recommendations made by the IACS EG/Containerships with respect to the safety of large container ships..

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

The original version was made through project work of a project team under the Hull Panel. The original version, drafted by the project team was reviewed and accepted by the Hull Panel.

.5 Other Resolutions Changes

UR S34

.6 Dates:

Original Proposal: 23 March 2015 Made by: PT56
Panel Approval: 14 May 2015 by Hull Panel
GPG Approval: 02 June 2015 (Ref: 8566_IGzo)

Part B. Technical Background

List of Technical Background (TB) documents of UR S11A:

Annex 1. **TB for New (June 2015)**

See separate TB document in Annex 1.

◄▼►

Technical Background (TB) document for UR S11A (New, June 2015)

1 Scope and objectives

Original version is made to clarify documentation of hull girder strength of large container ships and to incorporate recommendations made by the UK MAIB in their report on the investigation into the structural failure of the MSC Napoli.

2 Engineering background for technical basis and rationale

Evaluation of hull girder longitudinal strength for large containerships was investigated and revised based on the existing requirements of UR S11 and the recommendations from the UK MAIB investigations into the MSC Napoli incident. Furthermore the recommendations given by the IACS EG/Containerships and the outcome of the IACS work shop on Container ship safety held in October 2014 were taken into consideration.

A complete new version of the longitudinal strength requirements for Container ships was developed using direct non-linear load computations as a basis for the development of the load (vertical wave bending moment and shear forces) requirements and using the IACS Common Structural Rules for Bulk Carriers and Oil Tankers strength requirements (buckling of plates and stiffeners and ultimate hull girder capacity check) as a basis for the strength requirements of this UR. Consequence studies were carried out to investigate the impact of the new requirements to well-known and accepted designs. Detailed information is given in the attachments.

3 Source / derivation of the proposed IACS Resolution

The source of the information was obtained through the work of a project team supervised by the Hull Panel.

4 Summary of Changes intended for the revised Resolution

Original version of the UR.

5 Points of discussions or possible discussions

The original version was made through discussions of the draft version provided by the project team within the Hull Panel which involved mainly incorporating individual comments and accepting the consolidated text.

6 Attachments if any

Detailed technical background document is attached.

Detailed Technical Background for UR S11A (New, June 2015)

Longitudinal Strength Standard for Container Ships

TB S11A.1 General

UR S11A was developed to incorporate recommendations made by the UK MAIB in their report on the investigation into the structural failure of the MSC Napoli back in 2007. In addition the recommendations given by the IACS EG/Containerships and the outcome of the IACS work shop on Container ship safety held in October 2014 were taken into account.

The philosophy behind the new requirements follows as far as possible the idea of the IACS Common Structural Rules for Bulk Carriers and Oil Tankers (CSR). The loads were determined based on non-linear load computations of more than 120 ships and two loading conditions for each ship as described in more detail below. The strength assessment is based on stress checks for the yielding failure mode, a local check of the buckling failure mode following the prescriptive approach in CSR and the check of the global ultimate limit state in bending, also based on the CSR approach.

Net scantlings have to be taken into account when carrying out the strength assessment. The corrosion margins defined are based on the CSR-values for similar structural elements. In addition the selection of corrosion margins is supported by statistical analysis of measured data as described in more detail below.

The permissible stresses for the yield assessment are set to the same values as in CSR for the mid-ship region. A decrease of these stresses towards the ship ends is not defined, however the strength assessment according to the new requirements is limited for the region between 0.2L and 0.75 L. Areas outside this region have to be assessed according to the requirements of the individual society.

The decrease of the section modulus caused by the net-scantling approach (deduction of 50% of the corrosion margin) for Container ships is in general smaller than for Bulk Carriers of Tankers. While at the bottom area of Containerships the difference between the gross and net-50 section modulus is about 7%, the difference at the upper flange area is only about 4%, caused by the very thick plates within that area. However corrosion effects and corrosion rates obviously are ship-type dependent, therefore using the same permissible stress level and the same philosophy regarding the determination of net-scantlings should lead to a comparable level of safety in general.

Regarding the ultimate limit state a local (buckling assessment of longitudinal structural members) and a global check (ultimate hull girder strength) is introduced in the new requirement.

The local buckling check for the longitudinal strength members follows the prescriptive approach as implemented in the CSR. Due to the limitation of Container ships and the consideration of only the longitudinal normal hull girder stress induced by vertical bending moment and the shear stress induced by the vertical shear force, the formulations given in the CSR could be simplified as in detail described below.

The ultimate hull girder strength check follows the iterative-incremental approach as defined in the CSR. Only changes were made with respect to the partial safety factors as described in detail below. While it would be desirable to recalibrate these factors for other ship-types as

Bulk Carriers and Oil Tankers by means of Structural Reliability Analysis (SRA), the selection of the PSF for the new requirement was done by comparison of results obtained during a consequence assessment with well-known designs, considering the experience of class societies that carry out this checks for long time and taking into account information public available, like the report of NK with respect to the MOL Comfort accident.

Therefore the new requirement is based on a technical sound and transparent concept following basically the same philosophy as the CSR, establishing rationally based load formulations and applying general and harmonized methods for the strength assessments.

TB S11A.1.3 Corrosion margin and net thickness

Net thickness approach is consistent with CSR (reference is also made to technical background for CSR). Even in the existing UR S11 net thicknesses (a certain percentage of gross thickness deducted as corrosion margin) is implemented for the buckling check.

The net thickness approach affects the permissible stress level compared to UR S11, and is used in checks of buckling, yield, ultimate capacity and moment of inertia. The effect of the net thickness approach for an open cross section (container ship) differs from a closed cross section (tanker) with respect to the change of the section modulus in deck and bottom due to the corrosion margins (refer to Figure 1).

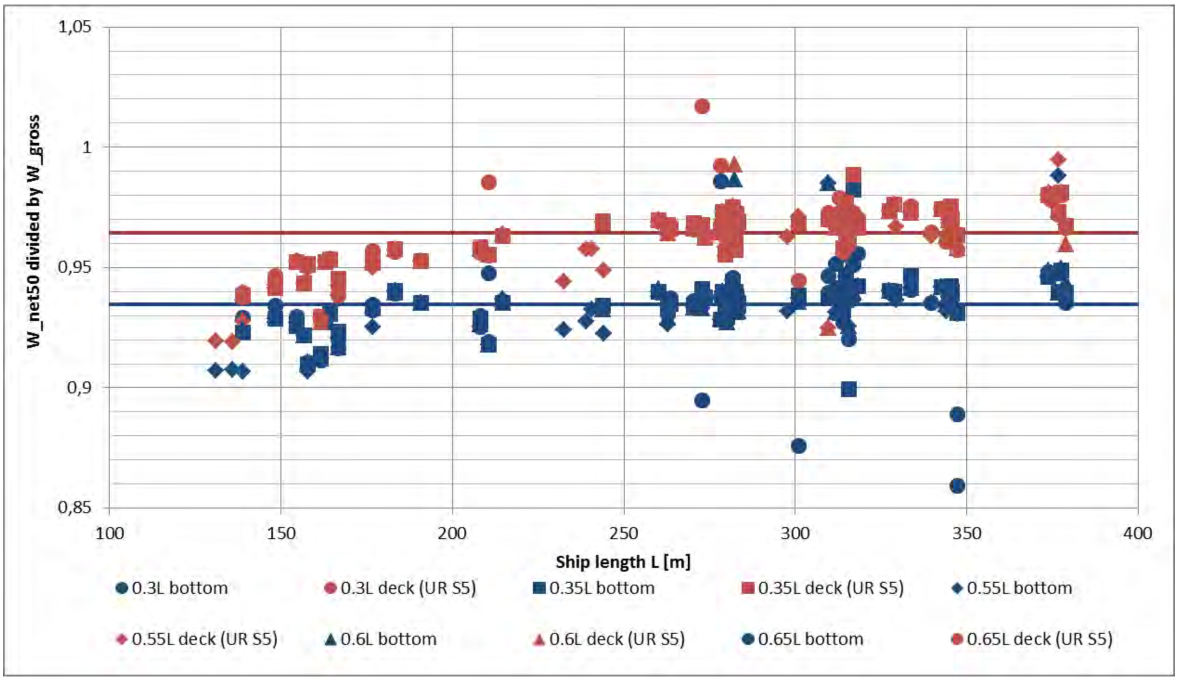

Figure 1: Relation between section modulus obtained by applying t_{net} and t_{gross} for 5 different sections of container ships at bottom level and at equivalent deck level according to UR S5.

In case of Tanker and Bulk carrier cross sections the difference between the section moduli obtained at gross scantlings and at net scantlings is of about 10%, while in case of Container ships the change from gross to net gives a change in section moduli of about 7% at bottom level and of about 3 to 4% at deck level, see Figure 1. However, because the corrosion effects are ship type dependent, the permissible stresses are set to the same values than in CSR.

The proposed corrosion margins are regarded as minimum values, and the individual class society may require higher corrosion margins, if statistical data of corrosion measured during operation is supporting this.

Detailed corrosion addition values

The corrosion addition for each of the two sides of a structural member as listed in Table 1 is simplified compared to CSR. In addition to the corrosions additions on each surface, a reserve thickness of 0.5mm should be added. The corrosion additions have been rounded to the nearest 0.5mm for simplification (to avoid rounding rule).

The total corrosion addition, t_c, in mm, for both sides of the structural member is obtained by the following formula:

$$t_c = (t_{c1} + t_{c2}) + t_{res}$$

With t_{res} the reserve thickness of 0.5mm as explained above.

The formulations below consider ships in general, and not everything is regarded relevant for Container ships.

Ballast water tank

t_c has been rounded down to nearest 0.5mm. Increased corrosion margin in 3m zone below deck and increased corrosion in way of heated surfaces are generally not followed up in ship in service evaluation and are removed for simplicity.

Tanks for cargo oil, liquid chemicals

The criteria are simplified compared to CSR and values rounded down considering these are ships not covered by CSR and typically less than 150m.

Cargo holds of dry bulk, container and general cargo holds

t_c reduced due to higher coating standard than what was used in the investigation for CSR. In addition the CSR corrosion additions are considered too large. t_c is increased in lower area due to mechanical wear and tear, and water/moisture.

Exposed to sea water

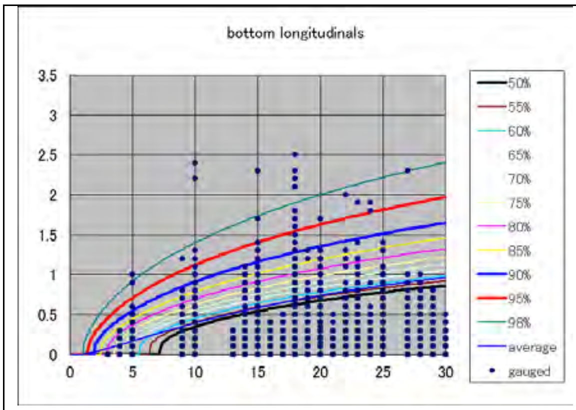
Addition between scantling draught and ballast draught is removed for simplicity and because 20% corrosion margin is typically used for ships in operation.

Table 1: corrosion addition for one side of structural member

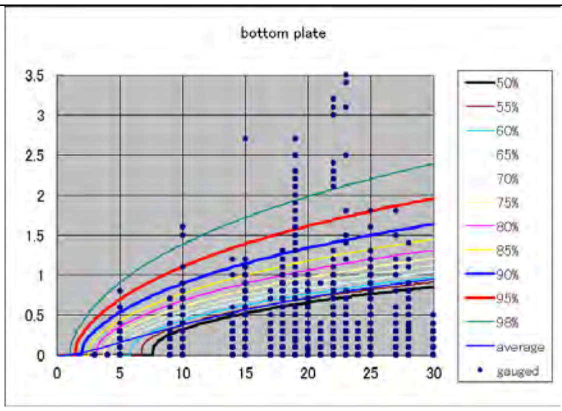
Compartment type	**One side corrosion addition t_{c1} or t_{c2} [mm]**
Exposed to sea water	1.0
Exposed to atmosphere	1.0

Ballast water tank	1.0
Void and dry spaces	0.5
Fresh water, fuel oil and lube oil tank	0.5
Accommodation spaces	0.0
Container holds	1.0
Compartment types not mentioned above	0.5

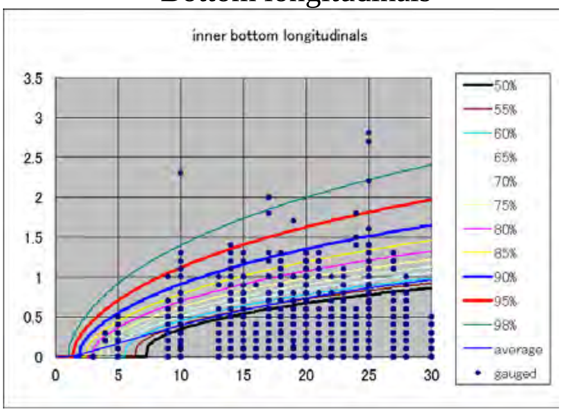
The values above are in addition supported by approximately 210,000 thickness measurement data sampled from 22 thickness measurements for Container ships with an age from 3 to 30 years. Corrosion behavior is estimated by the probabilistic theory and thickness measurement data of each structure member of Container ships. Evaluation results for each structure member are shown in Figure 2.



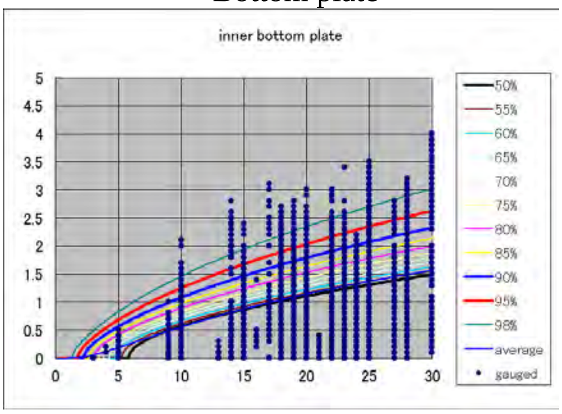
Bottom longitudinals



Bottom plate



Inner bottom longitudinals



Inner bottom plate

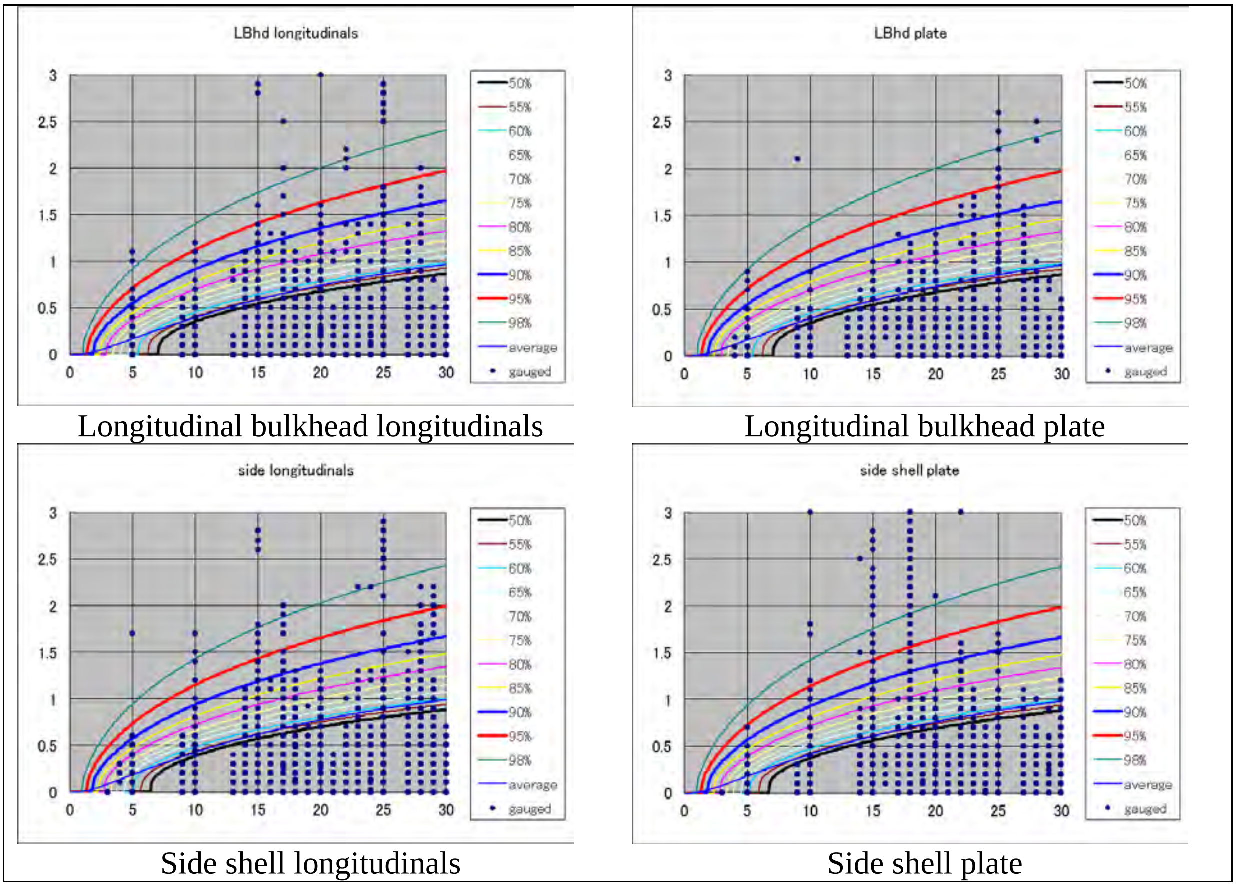


Figure 2: Evaluation results of measured data for structural members

The lines shown in the above figures represent expected values of thickness diminution corresponding to the ship's ages and the different levels of cumulative probabilities, and the dots in the above figures represent thickness measurement data.

Adopting the same approach for corrosion addition of CSR, the expected values at the cumulative probability of 90% for 25 years are used as corrosion additions for the measured structural members. They are summarized in Table 2.

Table 2: Summary of corrosion data

Structural member	Compartment type	Corrosion addition (mm)	Number of samples
Bottom longitudinal	BWT / BWT	1.51	35260
Bottom plate	BWT / Exposed to sea water	1.50	14640
Inner bottom longitudinal	BWT / BWT	1.51	35061
Inner bottom plate	BWT / Container cargo area	2.07	15540
LBhd longitudinal	BWT / BWT	1.52	36598
LBhd plate	BWT / Container cargo area	1.52	11787
Side longitudinal	BWT / BWT	1.54	43581
Side shell plate	BWT / Exposed to sea water	1.53	16309

In order to determine the corrosion additions for corrosive environments for each side one by one, the following steps have been carried out.

Since the bottom longitudinal, the inner bottom longitudinal, the LBhd longitudinal and the side longitudinal are exposed to the water ballast tank in both sides, the each corrosion addition of them (t_{bl}, t_{ibl}, t_{Ll} and t_{sl}) can be obtained respectively as follows:

$$2t_{bl}=1.51 \text{(bottom longitudinal)}$$

$$t_{bl}=0.755 \text{ (mm)}$$

$$2t_{ibl}=1.51 \text{(inner bottom longitudinal)}$$

$$t_{ibl}=0.755 \text{ (mm)}$$

$$2t_{Ll}=1.52 \text{(LBhd longitudinal)}$$

$$t\_Ll=0.76\ (mm)$$

$$2t\_sl=1.54(\text{side longitudinal})$$

$$t\_sl=0.77\ (mm)$$

The obtained four types of longitudinal corrosion additions are in good agreement, and can be appropriate values as the corrosion addition for water ballast tank. Thus, the corrosion addition for water ballast tank (t_ballast) has been determined from their weighted average values as follows:

$$t\_ballast=\frac{t\_bl\times35260+t\_ibl\times35061+t\_Ll\times36598+t\_sl\times43581}{35260+35061+36598+43581}$$

$$t\_ballast=0.76\ (mm)$$

The inner bottom plate and the LBhd plate are exposed to the water ballast tank in one side and container cargo area in the other side. We attempt to determine the corrosion additions for container cargo area from those of the inner bottom plate and the LBhd plate (t_ibp and t_Lp) as follows:

$$t\_ibp+t\_ballast=2.07(\text{inner bottom plate})$$

$$t\_ibp+0.76=2.07$$

$$t\_ibp=1.31\ (mm)$$

$$t\_Lp+t\_ballast=1.52(\text{LBhd plate})$$

$$t\_Lp+0.76=1.52$$

$$t\_Lp=0.76\ (mm)$$

The difference between the two corrosion additions obtained above seems even reasonable because the corrosion additions for bulk cargo hold and cargo tank are given different values for upper part and lower part in the CSR. Therefore, it is determined that the corrosion additions for lower part and upper part of container cargo area are set separate values based on the measured data as follows:

Corrosion addition for lower part of container cargo area: 1.30 (mm)

Corrosion addition for upper part of container cargo area: 0.75 (mm)

Keeping in mind, that the selected corrosion margins, see Table 1, are minimum values, the selected values are supported by the measured data as demonstrated above.

Application for strength assessments

Hull girder yield strength

UR S11A yield check is proposed to be carried out on net scantlings with 190/k N/mm² allowable bending stress, and 120/k N/mm² shear stress.

Local strength

Buckling capacity of longitudinal strength members should be calculated based on full corrosion addition, and hull girder stresses should be calculated based on half corrosion margin.

The corrosion addition factor is implemented to determine the net thickness to be applied for the strength assessment under consideration. The net thickness, t_{net}, for the plates, webs and flanges is obtained by subtracting the voluntary addition t_{vol_add} and the factored corrosion addition t_c from the as built thickness t_{as_built}, as follows:

$$t_{net} = t_{as\_built} - t_{vol\_add} - \alpha t_c$$

where α is a corrosion addition factor whose values are defined in Table 3.

Table 3: Values of corrosion addition factor

Structural requirement	**Property / analysis type**	α
Strength assessment(S11A.3)	Section properties	0.5
Buckling strength (S11A.4)	Section properties (stress determination)	0.5
	Buckling capacity	1.0
Hull girder ultimate strength (S11A.5)	Section properties	0.5
	Buckling / collapse capacity	0.5

TB S11A.2 Loads

TB S11A.2.2 Still water bending moments and shear forces

The requirements regarding the still water bending moments and shear forces were developed based on existing unified requirements. For the strength assessment according to the S11A it is important to combine the still water loads that envelope the vertical bending moment and shear forces in possible seagoing loading conditions with the envelope values for the wave loads.

Therefore the design loading conditions have to envelop the maximum and minimum still water bending moments and shear forces for the seagoing loading conditions defined in the Loading Manual and additional maximum and minimum still water bending moments and shear forces that are specified by the designer, if any (S11A.2.2.2).

This includes the in more detail described loading conditions of the current S11, including the requirements with respect to intermediate conditions of ballasting and deballasting, if applicable, as well as the requirements with respect to partially filled ballast tanks in ballast loading conditions, as required under S11.2.1.3 and S11.2.1.4.

Other particular mentioned loading conditions in the current S11.2.1.2 as

- Homogeneous loading conditions at maximum draught;
- Ballast conditions;
- Special loading conditions e.g., container or light load conditions at less than the maximum draught, non-homogeneous cargo conditions, deck cargo conditions, etc., where applicable

as well as additional loading conditions mentioned in Annex 1 of UR S1 as:

- Short voyage or harbour conditions, where applicable
- Docking condition afloat
- Loading and unloading transitory conditions, where applicable

are seen to be covered by the formulations in the new S11A. It has to be mentioned that for the checks in S11A only seagoing conditions are of relevance.

In principle all relevant seagoing loading conditions, including ballast conditions and ballast exchange conditions and intermediate conditions, if necessary should be included in the Loading Manual. Because a unified requirement for the loading conditions that has to be included in the Loading Manual already exists (UR S1), reference to that UR was made for the definition of the still water loads (S11A.2.2.2).

TB S11A.2.3 Vertical wave bending moments and shear forces

Ship database used for direct calculations

All the new formulations were derived by comparison with direct computations results. For this purpose a database of 124 ships was built, including slender ships and blunt ships for comparison. For each ship two different loading conditions were considered (full load / ballast, or maximum hogging / minimum hogging).

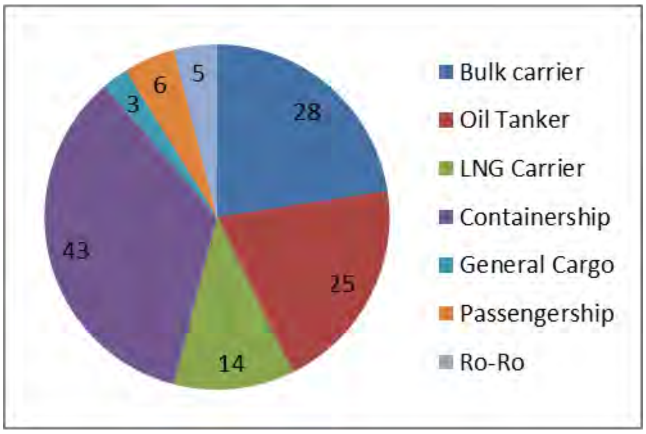

Figure 3: Distribution of ship types in the database

For each ship and each loading conditions the design hull girder loads have been computed at 21 sections along the ship (every 0.05 L), with the following assumptions

- Sea states described by the North Atlantic scatter diagram from IACS Rec. no. 34
- All headings with a step of 15 degrees and even probability distribution
- Ship speed equal to 5 knots (instead of 0 knots from IACS Rec. no. 34)
- Extreme response corresponding to one exceedance every 25 years (probability of exceedance of about 10^{-8})

The ships were characterized by their rule length L and by the following dimensionless parameters:

- B/L: Ratio beam over length
- T/L: Ratio draft over length
- C_B: Block coefficient
- C_W: Waterplane coefficient (waterplane area divided by B.L)
- Trim: static trim of the ship (not used in the formulations)
- LCG/L: longitudinal position of the center of gravity (not used in the formulations)
- kyy/L: dimensionless radius of gyration in pitch (not used in the formulations)
- GM/B: dimensionless vertical position of the center of gravity (not used in the formulations)
- f_{bow}: bow flare coefficient (used for the nonlinear sagging coefficient)

The block coefficient and the water plane coefficient depend on the draft of the loading condition.

The limitations in the application of the load formulations are directly derived from the range of parameters of the ship database. In the following figures, the plain dots are for the full load conditions, the hollow dots are for the ballast conditions. Whenever possible, all the formulations have been developed to be applicable to any type of ship, and any loading condition (draft), even if in the scope of S11A they are applied only to containerships at design draft. It was also found difficult to make a clear definition of slender and blunt ships based on the block coefficient and it was found unreasonable to end up with two different formulations for slender and blunt ships, which would have a step at a certain block coefficient. This would also make the formulation inconsistent with URS11 for other ship types.

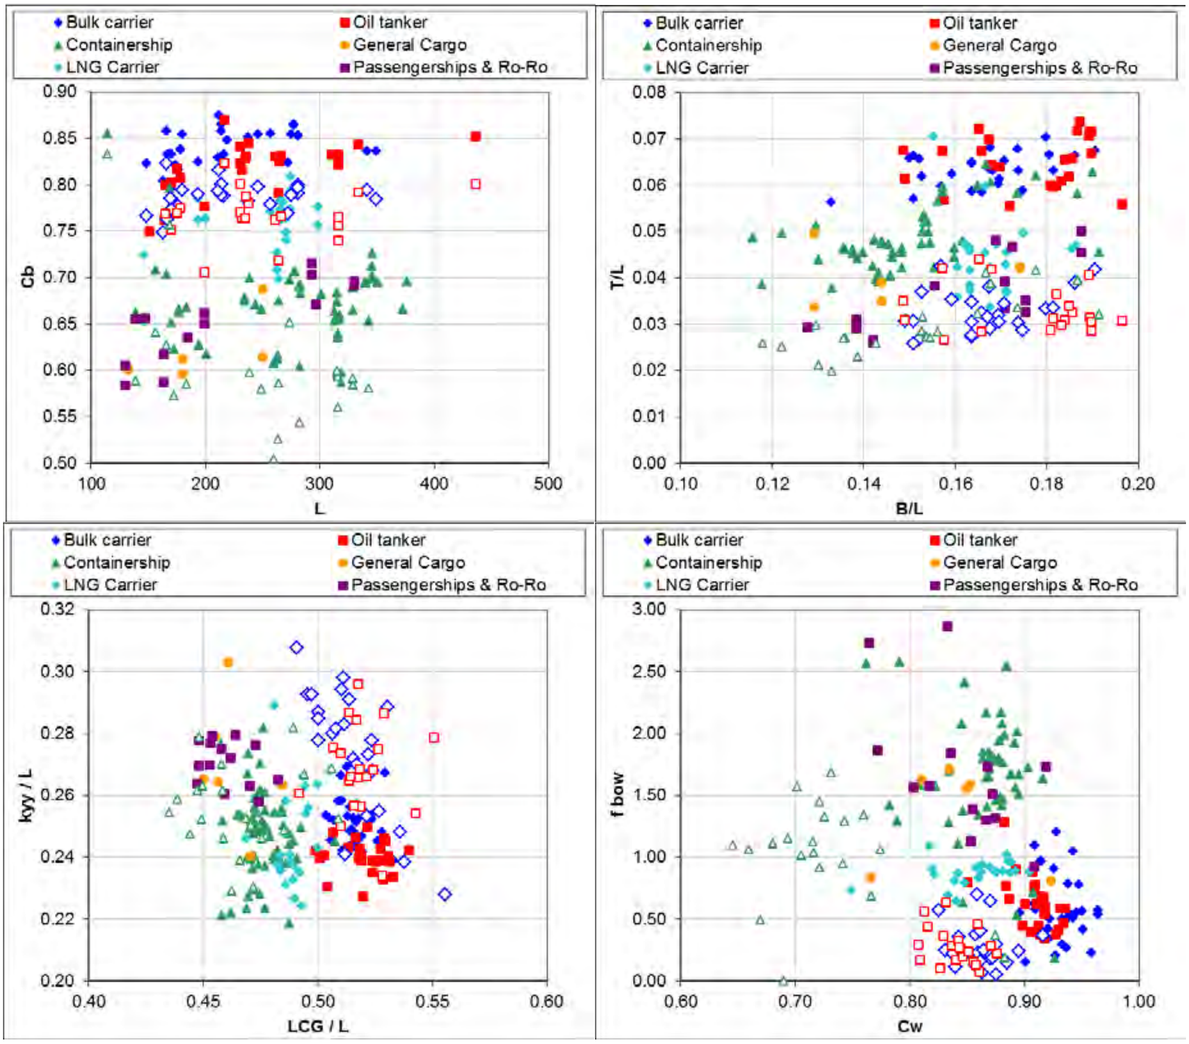

Figure 4: Main dimension parameters of the ships in the database

Comparison of the software from each class society

3 ships have been selected for a comparison of the results given by the different class society software. The main characteristics of these ships are given below.

Table 4: Main characteristics of ships used for comparison calculations between the societies

		L	B	Δ	LCG/L	Kyy/L	TM	GM	Cb	Cw
		m	m	t	-	-	m	m	-	-
LNG Tanker	Full	268.0	47.0	98610	0.505	0.260	11.00	4.05	0.69	0.80
Container	MaxBM	350.7	51.4	210374	0.489	0.261	16.62	0.65	0.68	0.88
Container	MinBM	350.7	51.4	210378	0.489	0.237	16.63	3.54	0.68	0.88
Bulk	Alternate	277.3	46.6	200751	0.544	0.267	17.67	9.61	0.86	0.93
Bulk	Homogenous	277.3	46.6	200750	0.538	0.252	17.65	5.76	0.86	0.93

The methodologies and tools used by each classification societies to compute the linear design loads are very similar. Hull girder loads RAOs are computed using 3D Boundary Element Method seakeeping software (with Rankine or Kelvin sources). The linear long-term analysis is performed using the IACS scatter diagram, and the linear long-term design loads corresponding to a 25 year return period are computed. The results from each class society are very consistent.

Table 5: Linear design loads (different colours indicate results of different societies)

	Vertical Bending Moment My / (M.L.g)	Vertical Shear Force Fz / (M.g)
Bulk Carrier Alternate		Bulk Carrier Homogeneous		Container Vessel MaxBM		Container Vessel MinBM		
LNG Tanker		
The methodologies and tools used by each classification societies to compute the non-linear design loads are very different.

Different types of seakeeping codes are used to compute the hull girder loads:

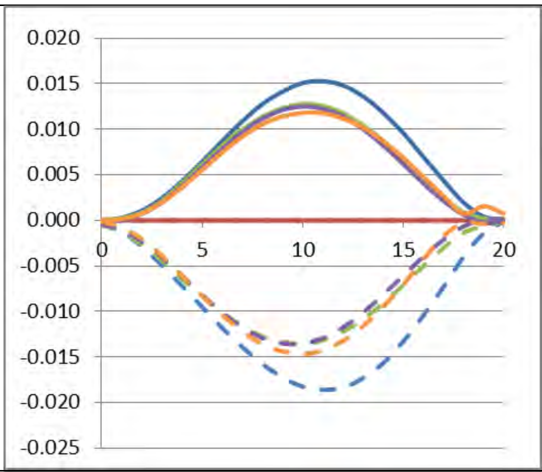
- Some codes are based on a simple pressure correction (pressure added above the mean free surface under the wave crest, and set to zero above the wave trough). The equilibrium is achieved either by adjusting the ship position, or by changing the acceleration.
- Some codes are time domain codes based on hydrostatic and Froude-Krylov pressure correction. Ship position and acceleration are computed at each time step.

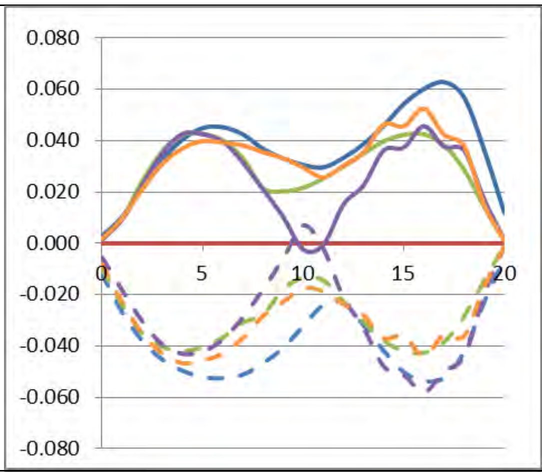
Different types of wave conditions are used: Regular Design Waves, or a Design Sea States of several hours from which short-term statistics are extracted.

The following non-linear envelopes are obtained for each ship. Even if the methods used by the different class societies represent state of the art methods, the differences in results are quite large.

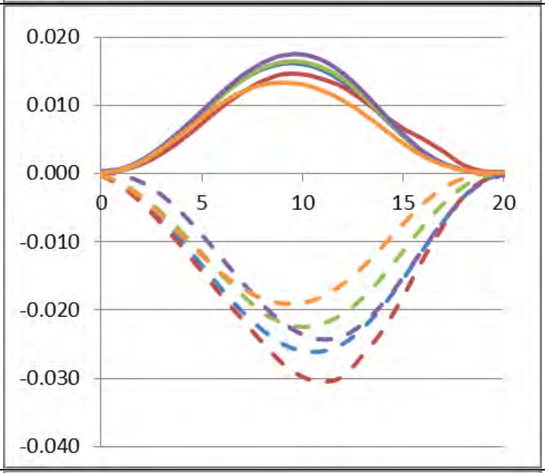
Table 6: Non-linear design loads (different colours indicate results of different societies)

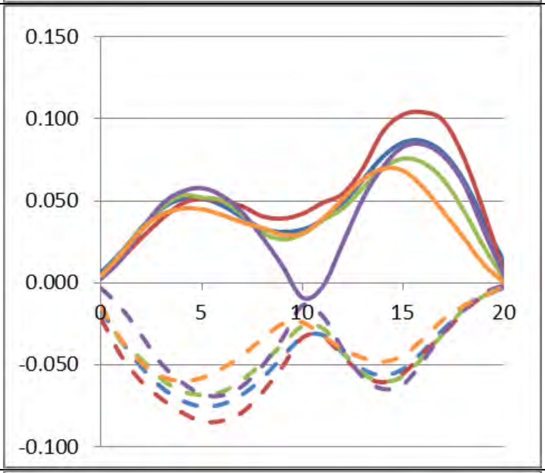
	Vertical Bending Moment My / (M.L.g)	Vertical Shear Force Fz / (M.g)
Bulk Carrier Alternate		
Bulk Carrier Homogeneous



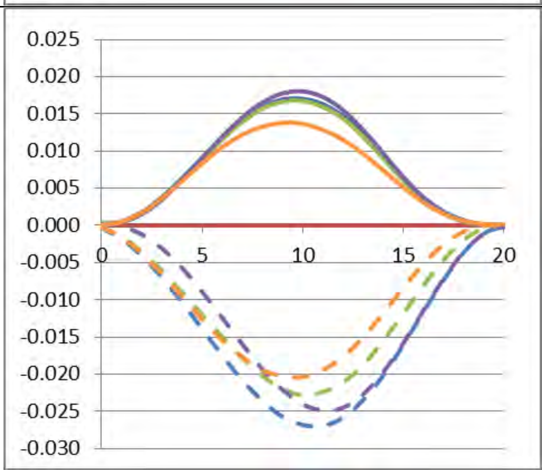


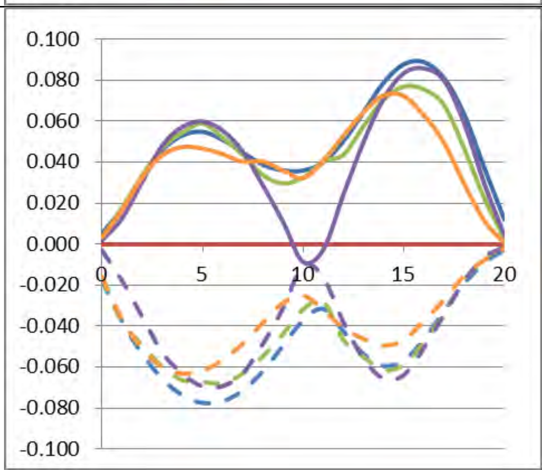
Container Vessel MaxBM



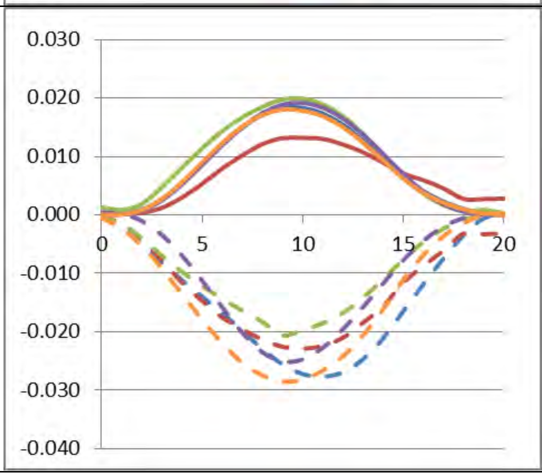


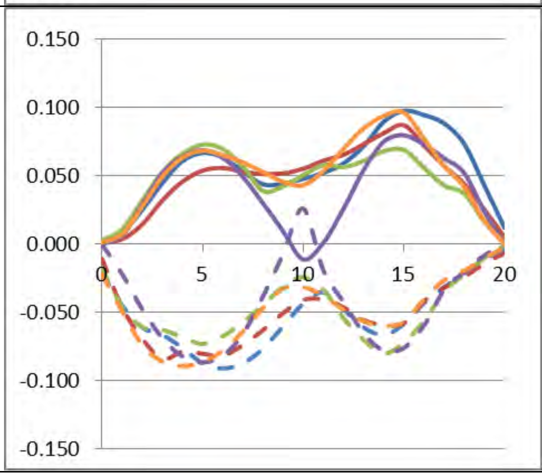
Container Vessel MinBM





LNG Tanker





Format of the rule formulations

The rule formulation for the hull girder loads is split in four parts:

- Scale factor
- Wave parameter
- Non-dimensional formulation
- Non-linear factor

This split was not explicit in the UR S11 formulation, but the same four terms can be easily identified. For example the formulation for the sagging moment can be rewritten as:

$$M_{Sag} = 0.11CL^2B(Cb+0.7) = L^3 \cdot C \cdot \left(0.19\frac{B}{L}Cb\right) \cdot \left(\frac{11}{19}\frac{Cb+0.7}{Cb}\right)$$

- Scale factor: L^3
- Wave parameter (representative for the scatter diagram used): C
- Non-dimensional formulation: $0.19\frac{B}{L}Cb$
- Non-linear factor: $\frac{11}{19}\frac{Cb+0.7}{Cb}$

The scale factor depends only on the dimension of the load. It is equal to L^3 for bending moment and to L^2 for shear force.

Linear seakeeping computations have been used to calibrate the linear part of the rule formulations (wave parameter and non-dimensional formulation). Non-linear computations have been used to calibrate the non-linear factors. The computations have been done for all the ships in the database, and the rule formulations have been fitted to cover all ship types, and all loading conditions.

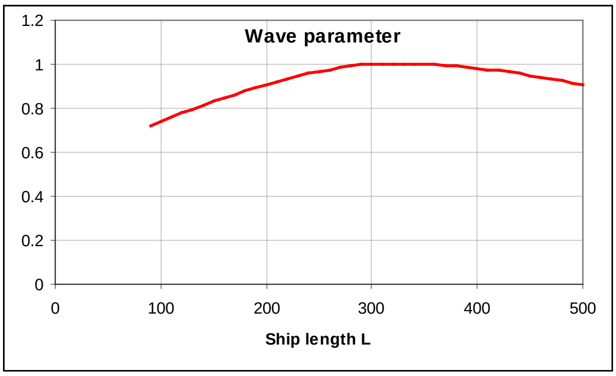
Wave parameter

The wave parameter C is given in S11 as:

$$C = 10.75 - \left(\frac{300-L}{100}\right)^{1.5} \qquad 90 \le L \le 300$$

$$C = 10.75 \qquad 300 \le L \le 350$$

$$C = 10.75 - \left(\frac{L-350}{150}\right)^{1.5} \qquad 350 \le L \le 500$$



It can be rewritten as:

$$C = 1 - 0.48\left(1 - \frac{L}{300}\right)^{1.5} \qquad 90 \le L \le 300$$

$$C = 1.0 \qquad 300 \le L \le 350$$

$$C = 1 - 0.33\left(\frac{L}{350} - 1\right)^{1.5} \qquad 350 \le L \le 500$$

Note that the constant 10.75 has been removed from the wave parameter and has to be included in the non-dimensional formulation.

If we have two ships of different length L1 and L2, but with the same hull form, then the block coefficient, the ratio B/L and all other non-dimensional coefficients are the same. The ratio between the design loads of ship 1 and 2 is:

$$\frac{VBM_1}{VBM_2} = \left(\frac{L_1}{L_2}\right)^3 \frac{C_1}{C_2}$$

For each ship of the database, some homothetic ships have been derived, ranging from L=90m to L=740m. Those virtual ships have been derived through a pure homothetic scaling of all dimensions; hence the non-dimensional parameters such as Cb, Cw or B/L have not been changed.

For all those homothetic ships, the long-term vertical bending moment at midship section is computed and then divided by L^3 to remove the scale effect. For each homothetic family, the length corresponding to the maximum of this ratio is determined and called the reference length (L_{ref}). The wave parameter for all the other lengths can then be computed as:

$$C = \frac{VBM / L^3}{VBM_{ref} / L_{ref}{}^3}$$

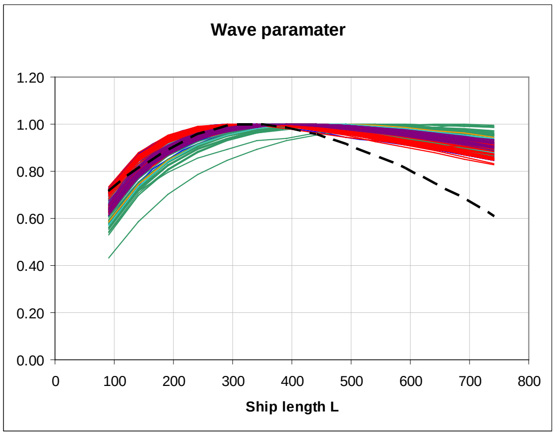
The procedure is done again using the long-term vertical shear force at 0.25L and at 0.75L. Note that for the shear force, the long-term value is divided by L^2. Three wave parameters are then defined: for VBM at 0.5L, VSF at 0.25L and VSF at 0.75L.

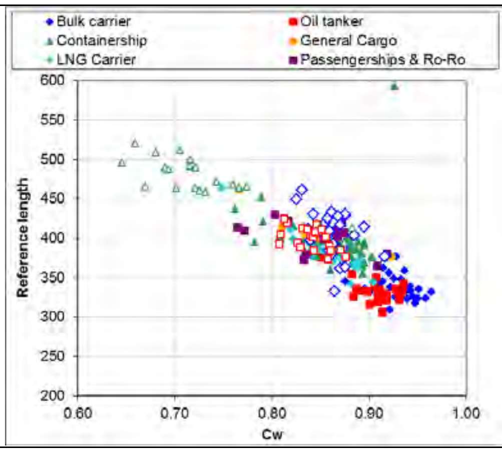
The results shown in the following figures show that:

- the wave parameters for bending moment and shear forces are nearly the same
- The reference length is ranging from 300m to more than 500m, and seems to depend on the ship type
- The current formulation for the wave parameter doesn't perform very well for the longest ships.
- The reference length is greater for containerships than for blunt ships

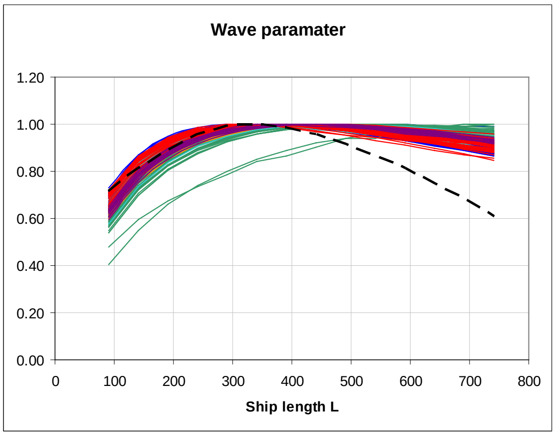
Table 7: Wave parameter and reference length

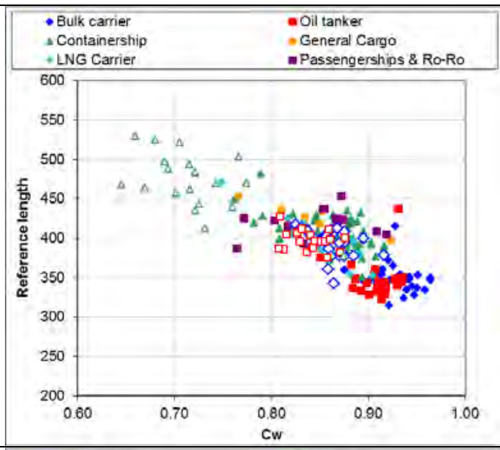
VBM at 0.5L



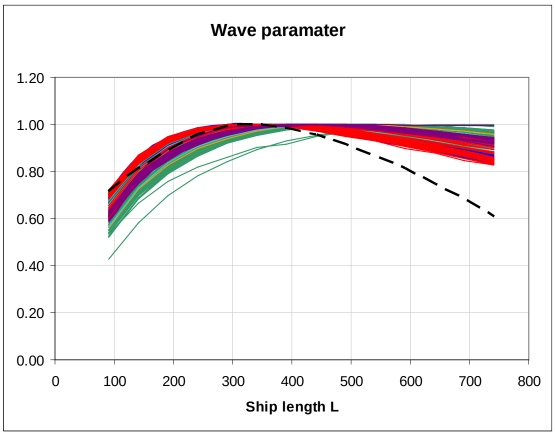


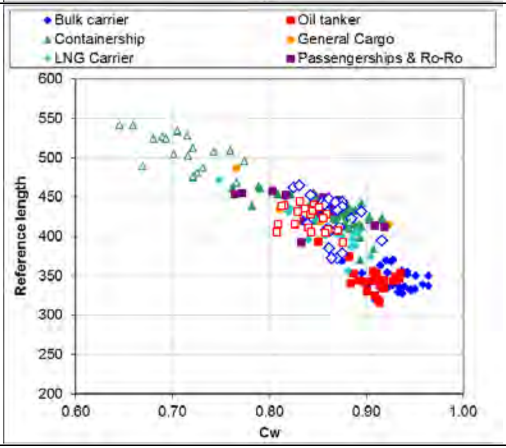
VSF at 0.25L





VSF at 0.75L





It is interesting to see that when the reference length L_{ref} is taken into account, it is possible to formulate a very accurate wave parameter. The following figures are showing the computed wave parameter plotted with respect to $\sqrt{L/L_{ref}}$, where L_{ref} is the computed reference length.

The black dotted line in these figures is the proposed formulation:

$$C = 1 - 1.50\left(1 - \sqrt{\frac{L}{L_{ref}}}\right)^{2.2} \quad \text{for } L \leq L_{ref}$$

$$C = 1 - 0.45\left(\sqrt{\frac{L}{L_{ref}}} - 1\right)^{1.7} \quad \text{for } L > L_{ref}$$

Table 8: Wave parameter function of (L/L_{ref})^0.5

VBM at 0.5L

VSF at 0.25L	VSF at 0.75L	
The following formulations are proposed for the reference length, which depends on the water plane coefficient C_W. Note that this coefficient is draft dependent.

$L_{ref} = 315\ C_W^{-1.3}$ for wave bending moment

$L_{ref} = 330\ C_W^{-1.3}$ for wave shear force

The following figures show the ratio between the computed wave parameter and the rule formulation. The comparison is better with the proposed formulation than it was with the S11 formulation.

Table 9: Ratio between the computed wave parameter and the proposed formulation

<table>
<tr><th></th><th>S11 formulation</th><th>New formulation (S11A)</th></tr>
<tr><td>VBM at 0.5L</td><td></td><td></td></tr>

<tr><td>VSF at 0.75L</td><td></td><td></td></tr>
</table>

The accuracy of the formulation is defined as the coefficient of variation (ratio between the standard deviation and the average) of the ratios between the computed wave parameter and the formulation. The accuracy of the new formulation is twice better than the S11 formulation.

$$\frac{STDEV\left(\frac{C_{Computed}}{C_{Rule}}\right)}{Average\left(\frac{C_{Computed}}{C_{Rule}}\right)}$$

Table 10: Accuracy of the S11 and S11A formulations for the wave parameter (entire database)

	VBM	VSF aft	VSF fore
UR S11 formulation	3.4%	3.4%	3.6%
UR S11A formulation	2.0%	2.3%	2.0%

UR S11A formulation	0.8%	1.1%	0.8%

Non-dimensional formulation

For each ship of the database the linear long-term vertical bending moment has been computed for every section. The maximum VBM over the ship length is taken (this maximum may not occur exactly at 0.5L). The wave coefficient has been computed for the midship section 0.5L only, but is supposed to be the same for all the midpart of the ship, hence for the location of the maximum. The adimensional part of the bending moment is computed by dividing the long-term VBM by the scale parameter L^3, and by the wave parameter.

For each ship of the database the linear long-term vertical shear force has been computed for every section. The maximum VSF over the aft part of the ship (x/L<0.5) and over the fore part of the ship (x/L>0.5) are taken (these maxima may not occur exactly at 0.25L and 0.75L). Two wave coefficients have been computed at 0.25L and 0.75L. They are supposed to be valid for the location of the aft maximum and the forward maximum respectively. Two non-dimensional vertical shear forces are computed by dividing the long-term VSF by the scale parameter L^2, and by the wave parameter, for the fore and aft parts.

The adimensional part of the vertical bending moment and the vertical shear forces (aft and fore) are compared with the current UR S11 formulation. For all the ships of the database the ratio between the computed wave value and the rule value is calculated:

- For blunt ships (bulk carriers, tankers and even LNG) the mean value of this ratio is about 1.17 for VBM and 1.60 for VSF: bending moment is slightly underestimated by the rules, whereas shear forces are largely underestimated.
- For slender ships (Containerships, General cargo, Passenger ships and Ro-Ro), the difference is much higher: 1.35 for VBM and 1.90 for VSF

The non-dimensional formulations have been derived to minimise the difference between the linear direct computation results and the formulation. However a compromise has always been chosen between a little more accurate formulation and a more simple formulation (with less coefficients). It is found that both for bending moment and shear force, the waterplane coefficient C_W and the ratio B/L are the most important parameters. The new formulations for the non-dimensional part are:

$1.5\ C_W\ \left(\frac{B}{L}\right)^{0.8}$ for wave bending moment

$5.2\ C_W\left(\frac{B}{L}\right)^{0.8}$	for wave shear force at aft location
$4.0\ C_W\left(\frac{B}{L}\right)^{0.8}$	for wave shear force at midship
$5.7\ C_W\left(\frac{B}{L}\right)^{0.8}$	for wave shear force at fore location

With the new formulation, the mean values of the ratios are equal to 1.0, and the scatters around the mean have been reduced. Again, the accuracy of the formulation has been improved.

Table 12: Accuracy of the S11 and S11A formulations for the non-dimensional part (entire database)

	VBM	VSF aft	VSF fore
UR S11 formulation	11.7%	12.5%	13.5%
UR S11A formulation	7.1%	6.4%	8.9%

UR S11A formulation	5.2%	3.3%	6.0%

Table 14: Ratio between the computed value and the rule formulation

	S11 formulation	New formulation (S11A)
VBM		VSF fore		

Because the use of the waterplane coefficient C_W is new, it has been suggested to propose an approximation, to be used in case this coefficient is not available in the drawings. This approximation is based on the block coefficient, and is valid only for design draft or full load draft. It should not be used for a ballast draft.

$$C_W = C_B + 0.09 \qquad \text{for} \quad C_B > 0.73$$
$$C_W = 0.7C_B + 0.4 \qquad \text{for} \quad C_B < 0.73$$

For containerships, only the second part of the formulation is to be used, as the block coefficient is always below 0.73. The following figure shows the strong correlation between the block coefficient and the water-plane coefficient that justify the previous approximation:

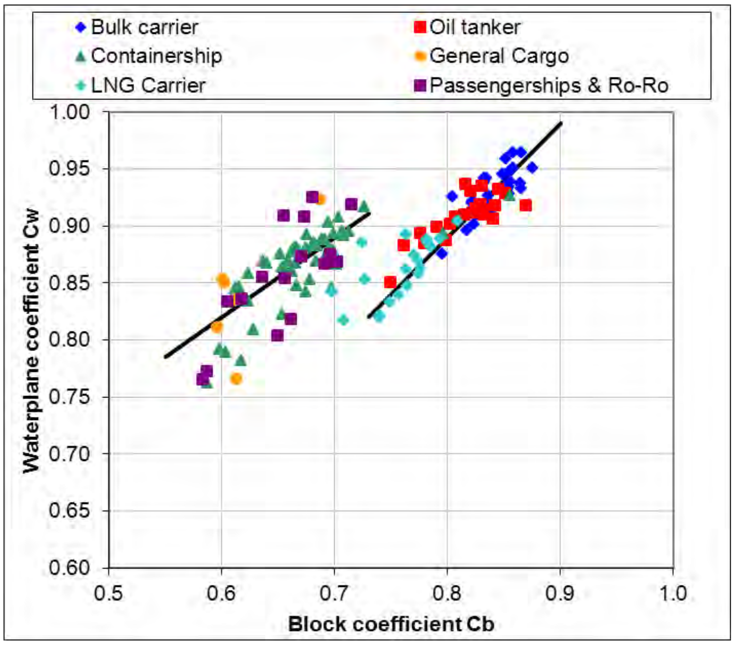

Figure 5: Correlation between the waterplane coefficient and the block coefficient

This formulation has been validated with the 157 ships in full load condition from the common database

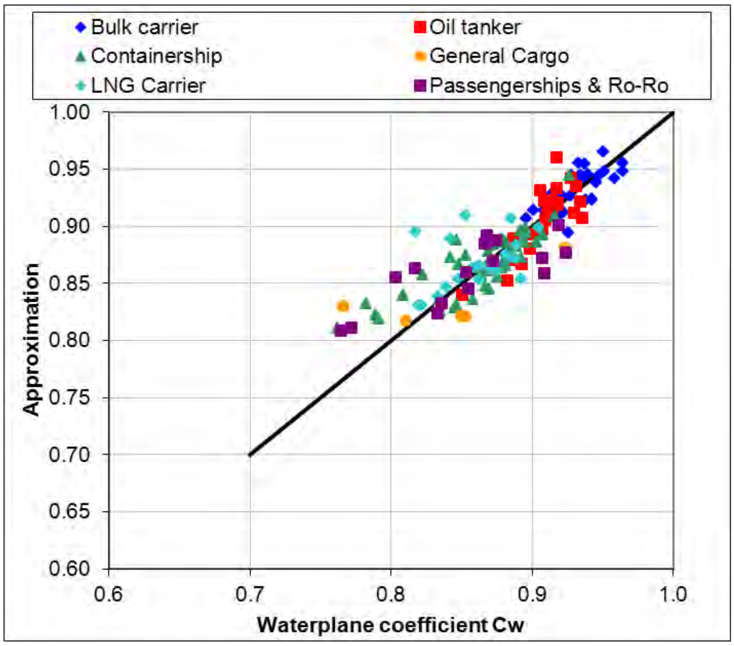

Figure 6: Comparison of the approximation and the exact water-plane coefficient

Non-linear factors

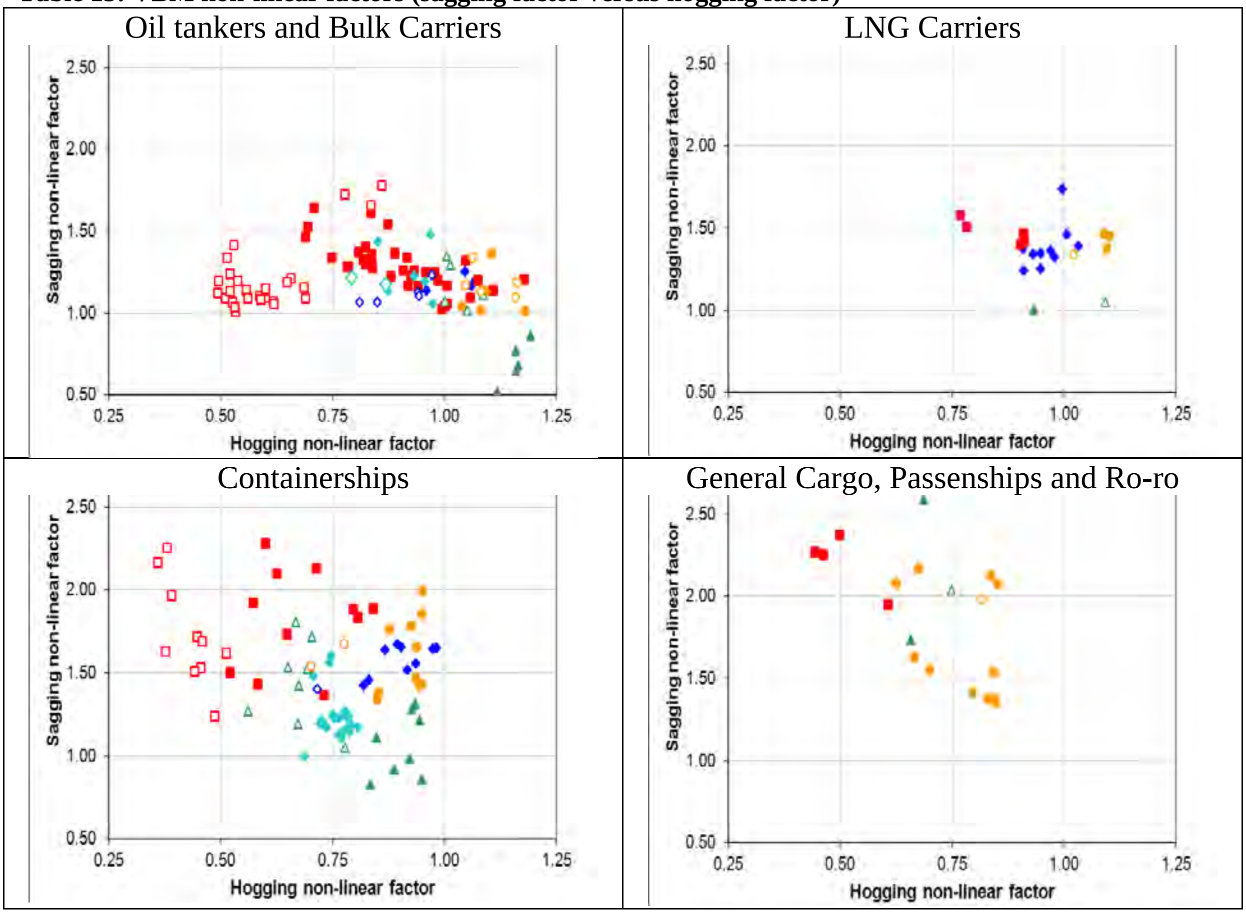
The non-linear coefficients have been computed using non-linear seakeeping software and methods described above. For each ship of the database the non-linear envelope corresponding to the long-term vertical bending moment and shear forces have been computed for every section.

For each ship, 6 characteristic values are taken:

- The maximum vertical bending moment along the ship (hogging)
- The minimum vertical bending moment along the ship (sagging)
- The maximum vertical shear force in the aft part (hogging)
- The minimum vertical shear force in the aft part (sagging)
- The maximum vertical shear force in the fore part (sagging)
- The minimum vertical shear force in the fore part (hogging)

The non-linear factors are computed by dividing the non-linear values by the corresponding linear values. The following graphs are showing the non-linear factors for the vertical bending moment in hogging and sagging.

Table 15: VBM non-linear factors (sagging factor versus hogging factor)



Despite a large discrepancy between the different Class Society results, some formulations have been fitted to the results. A bow flare factor has been introduced to characterize the geometry of the hull shape above the waterline in the bow region. This bow flare coefficient is used in the sagging non-linear coefficient.

$$f_{Bow} = \frac{A_{DK} - A_{WL}}{0.2\ L\ z_f}$$

A_{DK} is the deck area in front of 0.8L. It includes the forecastle deck if there is one.
A_{WL} is the waterline area in front of 0.8L.
z_f is the vertical distance from the waterline to the deck (or forecastle deck).

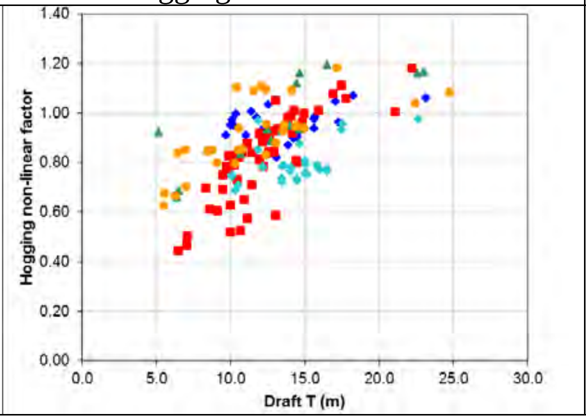
The new formulations for the non-linear factors for vertical bending moment are:

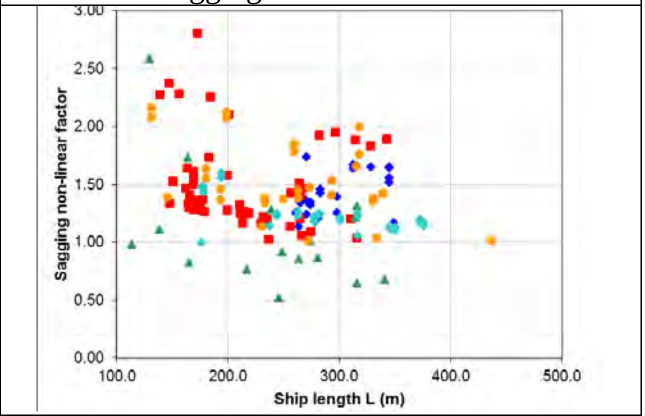
$$f_{NL-Hog} = Min\left(0.3\frac{C_B}{C_W}\sqrt{T}, 1.1\right)$$

$$f_{NL-Sag} = Max\left(4.5\frac{1+0.2f_{Bow}}{C_W\sqrt{C_B}L^{0.3}}, 1.0\right)$$

The C_W has been introduced on purpose, to cancel the effect of the C_W in the linear formulation. It was discussed that in general C_W has a big variation due to the stern shape and the selected waterline level, hence a designer will be able to reduce the wave VBM by adjusting the hull form shape locally to reduce the C_W whilst maintaining the displacement and most other resistance performance. This coefficient is however very correlated to the linear results, and is used in the proposed formulation. Introducing the C_W again in the non-linear factors will cancel the effect on the total VBM, while keeping a good comparison between the linear formulations and the linear calculations.

The non-linear coefficients are not dimensionless. Computations results have shown that the amount of non-linearity depends on the ship shape (C_W, C_B, f_{Bow}), but also on the ship size. For smaller ships, the design sea states are much more steep and severe relatively to the ship size, than they are for the longer ships. Hence the non-linear effects are more important for smaller ships: lower hogging non-linear factor and higher sagging non-linear factor.

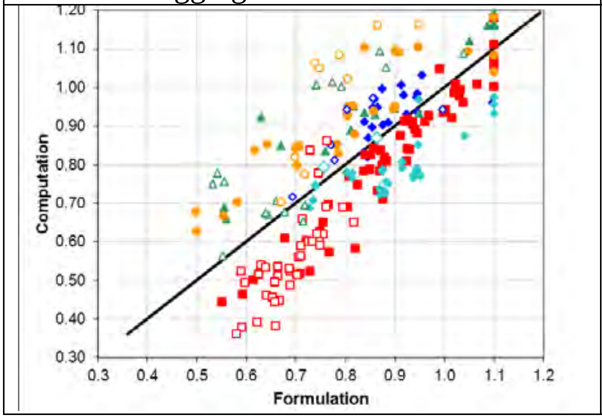
Hogging non-linear factor	Sagging non-linear factor
	




VBM non-linear factors with respect to ship size (draft or length)

The following figures show the comparison between the computed non-linear coefficient and the proposed formulations. For each Class Society (represented by one colour), the correlation between the computations and the rule formulation is very clear. The general scatter comes from the difference between the Class Society tools and methods. The rule formulations have been fitted to the average of the results.

Table 16: VBM non-linear factors: computations versus rule formulation

Hogging non-linear factor	Sagging non-linear factor
	


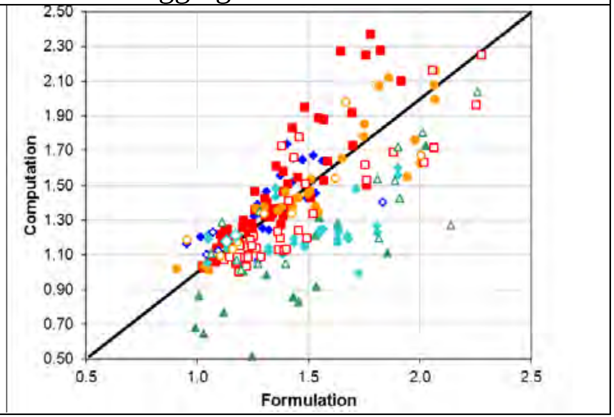


Table 17: VBM non-linear factors: computations versus rule formulation (Containerships in full load only)

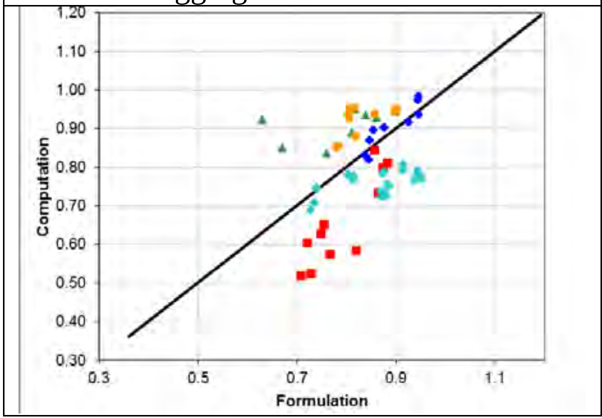
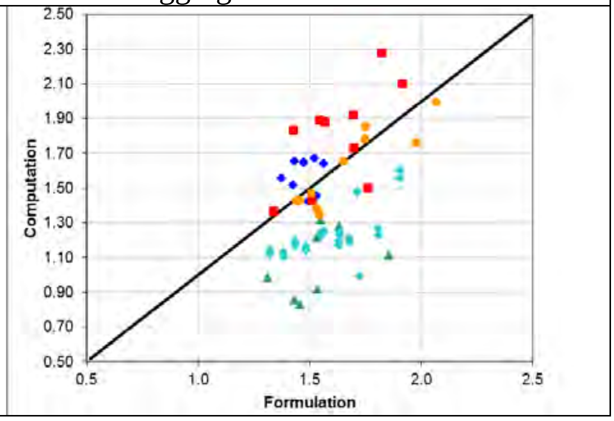
Hogging non-linear factor	Sagging non-linear factor
	


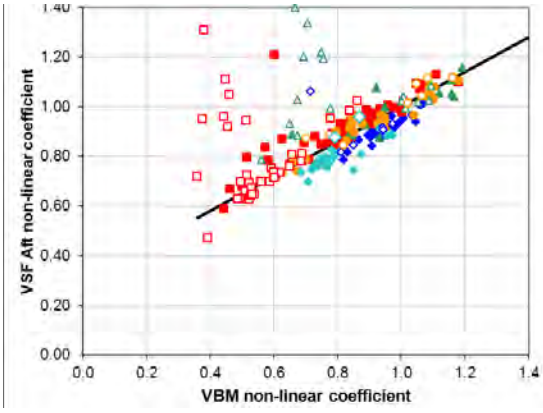


For vertical shear forces the computations show a very strong correlation with the non-linear factors from the vertical bending moment, as shown in the following figures. Hence the rule formulations are based on the same factors f_{NL-Hog} and f_{NL-Sag}.

Table 18: Correlation between the shear forces non-linear factors and the bending moment non-linear factors

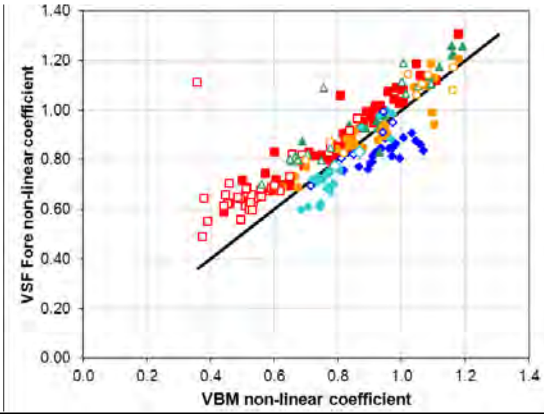
Aft part in hogging

$$0.3 + 0.7 f_{NL-Hog}$$



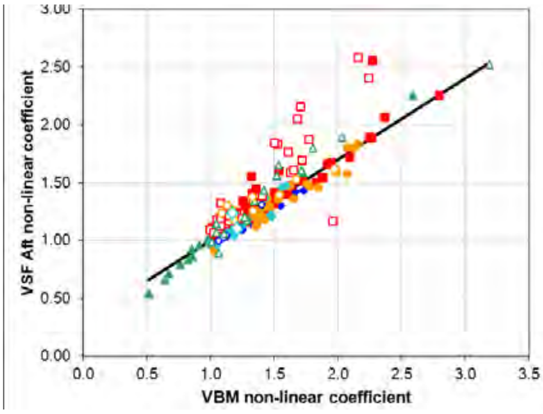
Fore part in hogging

$$f_{NL-Hog}$$



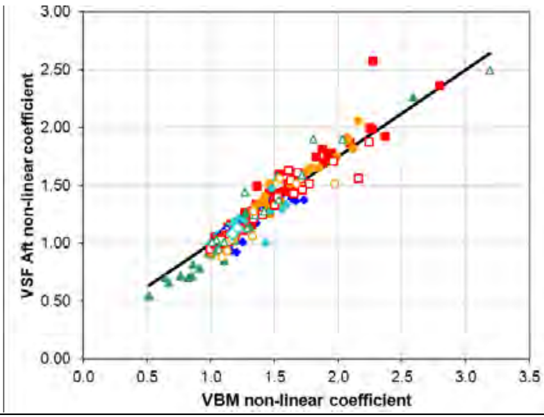
Aft part in sagging

$$0.3 + 0.7 f_{NL-Sag}$$



Fore part in sagging

$$0.25 + 0.75 f_{NL-Sag}$$



The accuracy of these new formulations is compared to the accuracy of the S11 non linear factors (assumed to be 1.0 in hogging):

Table 19: Accuracy of the S11 and S11A formulations for the non-dimensional part (entire database)

	Hogging			Sagging		
	VBM	VSF aft	VSF fore	VBM	VSF aft	VSF fore
UR S11 formulation	23.2%	14.8%	19.1%	19.0%	18.3%	18.0%
UR S11A formulation	16.7%	14.6%	14.7%	14.3%	14.5%	14.0%

Table 20: Accuracy of the S11 and S11A formulations for the non-dimensional part (containership in full load only)

	Hogging			Sagging		
	VBM	VSF aft	VSF fore	VBM	VSF aft	VSF fore
UR S11 formulation	14.4%	10.3%	11.9%	21.7%	20.9%	21.6%
UR S11A formulation	12.8%	12.1%	11.5%	19.7%	18.0%	19.3%

The accuracy have been improved slightly, but it is clear that the accuracy in the nonlinear factor governs the uncertainty compared to the non-dimensional factor and the wave parameter.

Routing factor

The comparison of the new formulations with the current S11 formulations shows an increase of all the loads, even for the blunt ships (Oil Tankers and Bulk Carriers). It has been decided to introduce a calibration coefficient, called routing factor, to lower the design loads. This coefficient has been calibrated to $f_R = 0.85$, so that the hogging vertical bending moment is not changed for the blunt ships (small increase for ships longer than 200m, and small decrease for ships smaller than 200m).

For the Container ships in full load condition, the hogging vertical bending moment is decreased for ships smaller than 300m. The hogging shear force however is still increased by 20% to 60%.

Table 21: Ratio between the new formulation and the S11 formulation (Hogging)

	Without routing factor	With routing factor 0.85
VBM		VSF fore		VSF aft		
Concerning the sagging case, despite this routing factor, the vertical bending moment is increased by 40% to 90% for the Container ships, and the vertical shear forces are increased by 70% to 130%.

Table 22: Ratio between the new formulation and the S11 formulation (Sagging)

<table>
<tr><th></th><th>Without routing factor</th><th>With routing factor 0.85</th></tr>
<tr><td>VBM</td><td></td><td></td></tr>
<tr><td>VSF fore</td><td></td><td></td></tr>
<tr><td>VSF aft</td><td></td><td></td></tr>
</table>

This routing factor is a pure empirical factor. There is no strong justification except a partial tunning with the S11 loads. However it could be qualitatively explained by the operating conditions: it corresponds to a decrease of 15% of the highest significant wave heights in the North Atlantic scatter diagram that might be explained by weather avoidance capabilities, considering the increased accuracy of weather forecast.

Distribution function

The distribution functions for vertical bending moment and vertical shear forces have been fitted directly to non-linear results for containerships. These functions are specific to containerships because, contrary to what has been done for the previous loads formulations where all the ship from the database have been taken into account, only the containerships have been used to fit the distribution function. The comparison between the computations and the proposed formulation is given in the following figures:

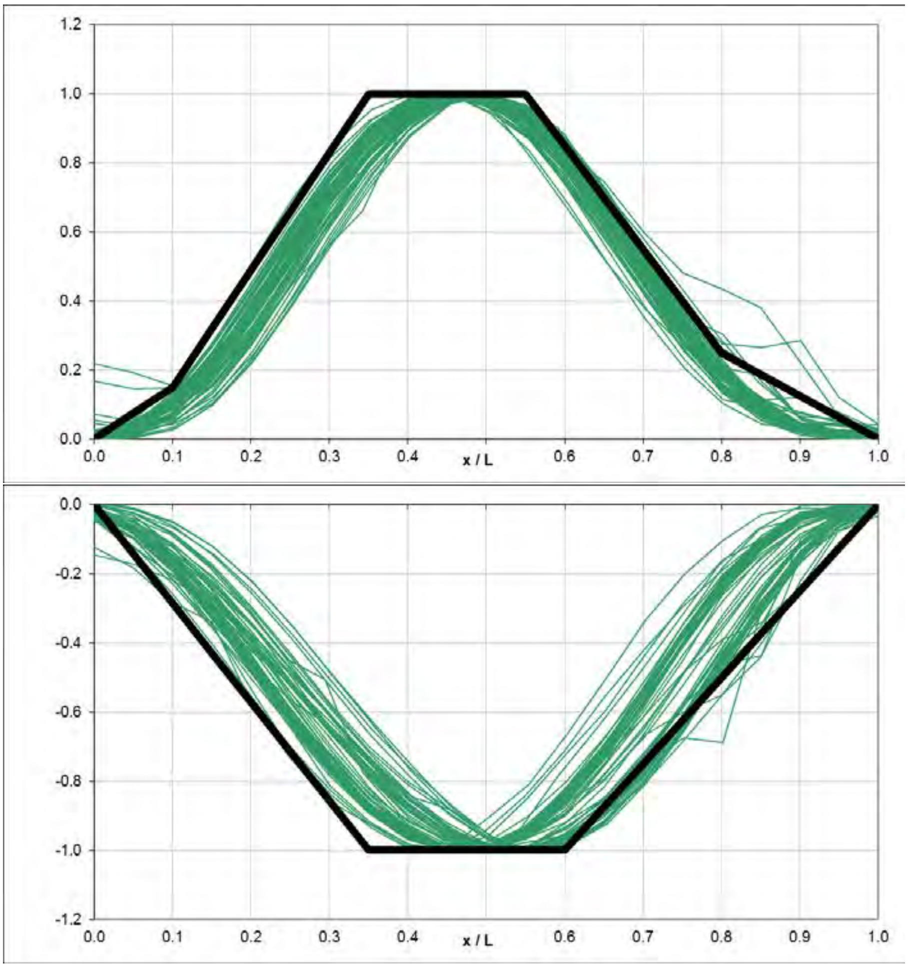

Figure 7: Vertical Bending Moment Distribution Function (hogging upper plot and sagging lower plot)

The following figures show the distribution functions for the vertical shear forces. The forward half and the aft half of the ships are presented separately as the results have been made dimensionless with the Fore shear force and Aft shear force respectively.

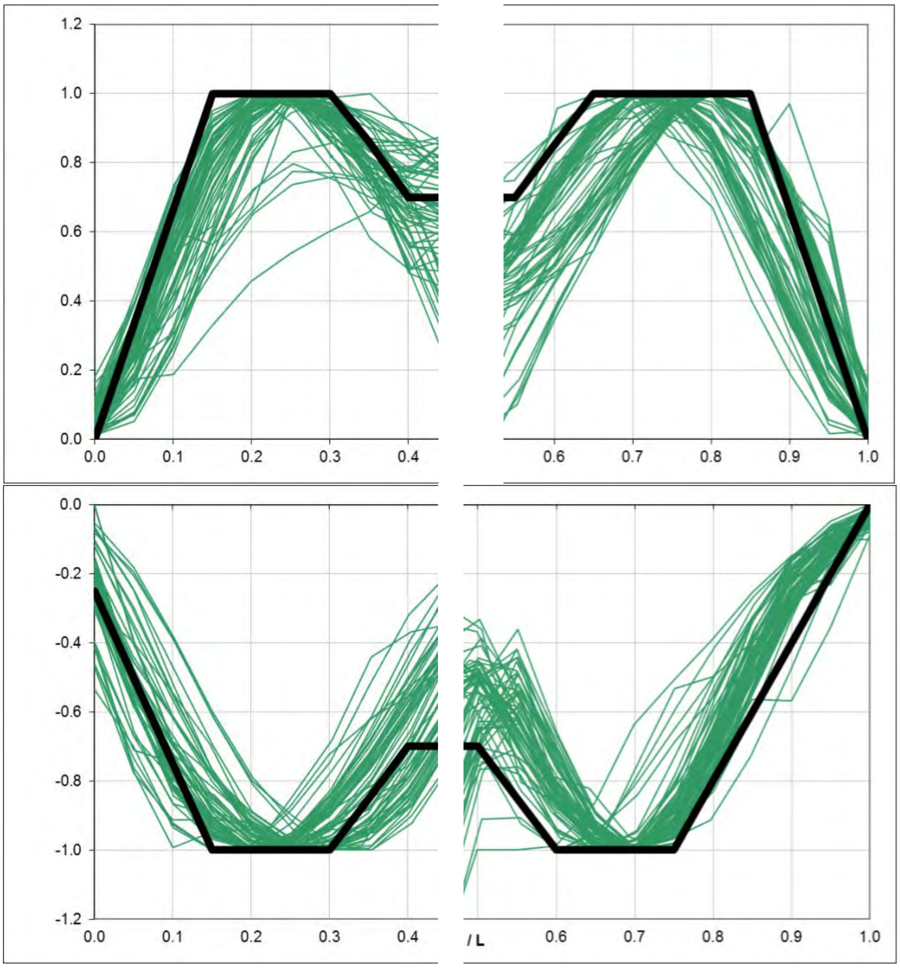

Figure 8: Vertical Shear Force Distribution Function

Final formulation

All the new formulations for vertical bending moment and shear forces are summarized here:

Wave parameter

$$C = 1 - 1.50\left(1 - \sqrt{\frac{L}{L_{ref}}}\right)^{2.2} \quad \text{for } L \leq L_{ref}$$

$$C = 1 - 0.45\left(\sqrt{\frac{L}{L_{ref}}} - 1\right)^{1.7} \quad \text{for } L > L_{ref}$$

$$L_{ref} = 315\, C_W^{-1.3}$$

Vertical bending moment

$$M_{W-Hog} = +1.5\, f_R\, L^3\, C\, C_W\left(\frac{B}{L}\right)^{0.8} f_{NL-Hog}$$

$$M_{W-Sag} = -1.5\, f_R\, L^3\, C\, C_W\left(\frac{B}{L}\right)^{0.8} f_{NL-Sag}$$

$f_{NL-Hog} = 0.3\frac{C_B}{C_W}\sqrt{T}$, not to be taken greater than 1.1

$f_{NL-Sag} = 4.5\frac{1+0.2f_{Bow}}{C_W\sqrt{C_B}L^{0.3}}$, not to be taken less than 1.0

$$f_{Bow} = \frac{A_{DK} - A_{WL}}{0.2\, L\, z_f}$$

A_{DK} is the deck area in front of 0.8L. It includes the forecastle deck if there is one.
A_{WL} is the waterline area in front of 0.8L.
z_f is the vertical distance from the waterline to the deck (or forecastle deck).

$$f_R = 0.85$$

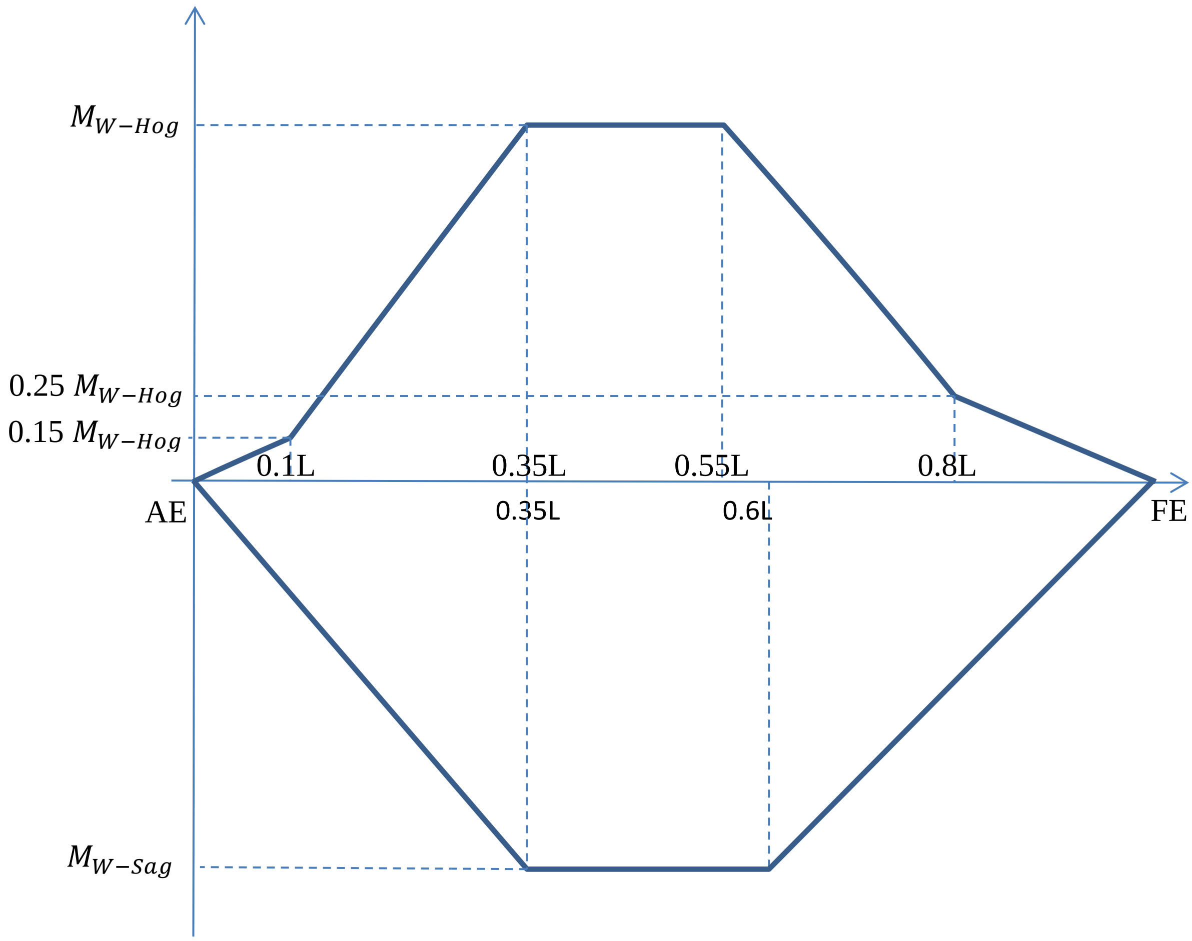

Figure 9: Distribution of the vertical wave bending moment

The comparison of the final formulations is done on the following figures. The linear and non-linear long-term bending moment distribution has been made non-dimensional by dividing by the rule bending moment amidship. The comparison is done only on containerships in full load. The routing coefficient 0.85 is used in S11A formulations, which explains that in average the computations are higher than the rules.

Table 23: Comparison of rule formulation and computations (containership in full load only)

	S11	S11A
Linear			The comparison is done with respect to the hogging bending moment	
Hogging		Sagging		
Vertical shear force

$L_{ref} = 330\ C_W^{-1.3}$ for wave shear force

$$Fw_{Hog}^{Aft} = +5.2\ f_R\ L^2\ C\ C_W\ \left(\frac{B}{L}\right)^{0.8}\left(0.3 + 0.7 f_{NL-Hog}\right)$$

$$Fw_{Hog}^{Fore} = -5.7\ f_R\ L^2\ C\ C_W\ \left(\frac{B}{L}\right)^{0.8}\ f_{NL-Hog}$$

$$Fw_{Sag}^{Aft} = -5.2\ f_R\ L^2\ C\ C_W\ \left(\frac{B}{L}\right)^{0.8}\left(0.3 + 0.7 f_{NL-Sag}\right)$$

$$Fw_{Sag}^{Fore} = +5.7\ f_R\ L^2\ C\ C_W\ \left(\frac{B}{L}\right)^{0.8}\left(0.25 + 0.75 f_{NL-Sag}\right)$$

$$Fw^{Mid} = +4.0\ f_R\ L^2\ C\ C_W\ \left(\frac{B}{L}\right)^{0.8}$$

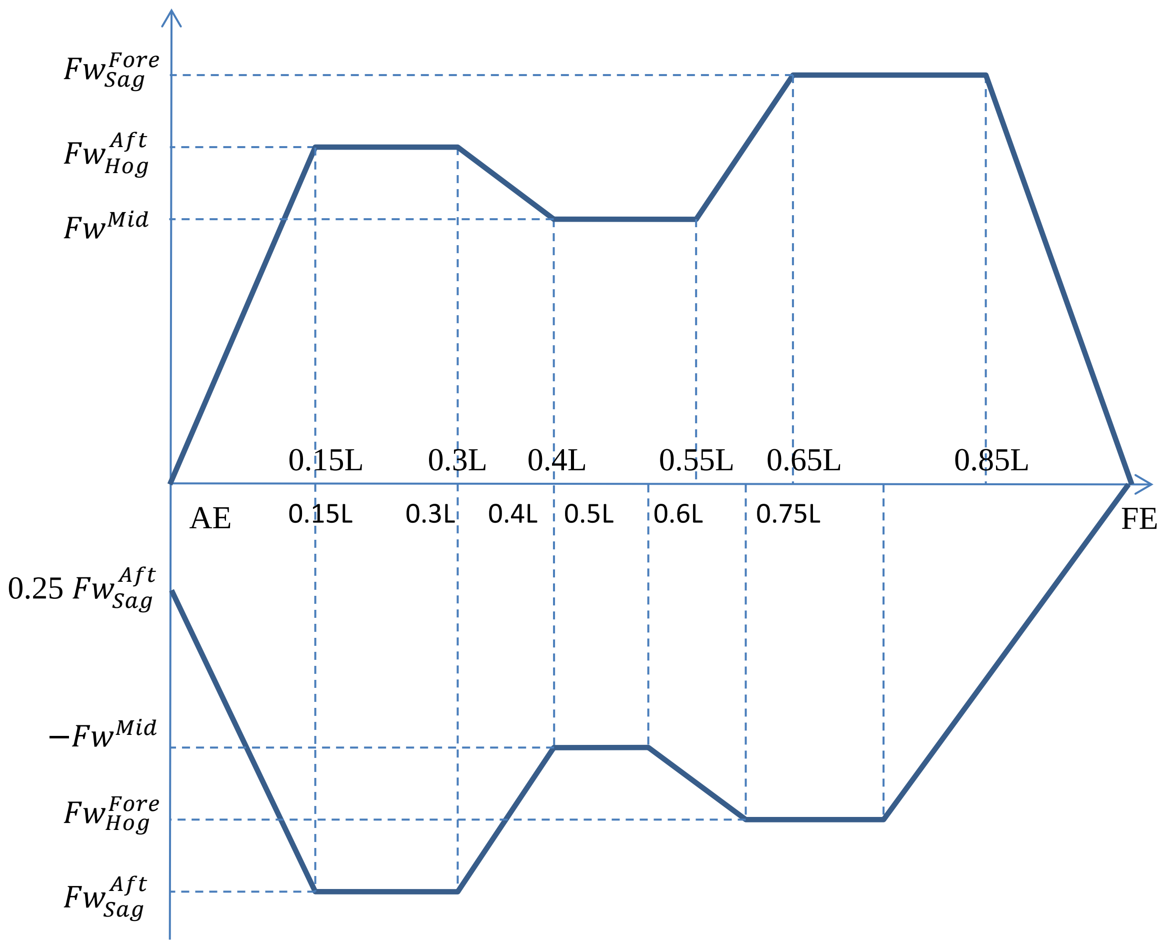

Figure 10: Distribution of the vertical wave shear force

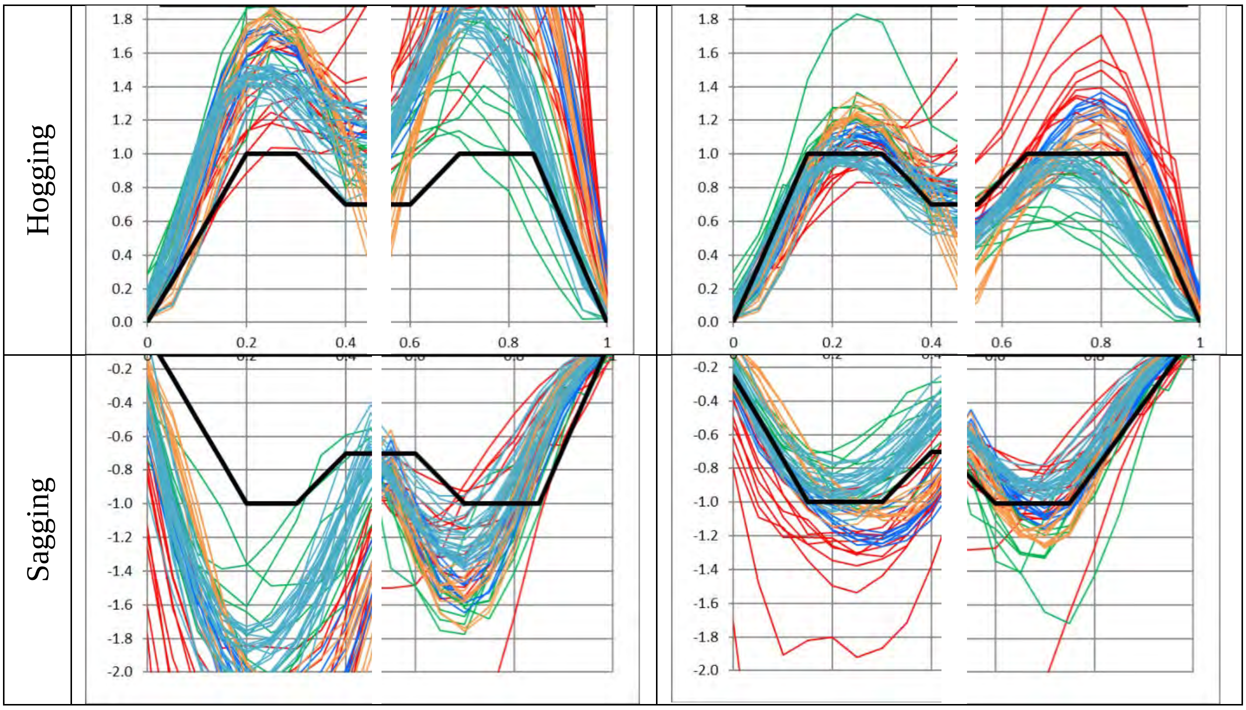
The comparison of the final formulations is done on the following figures. The linear and non-linear long-term shear force distribution has been made non-dimensional by dividing by the rule shear force in the fore part and in the aft part separately. The comparison is done only on containerships in full load. The routing coefficient 0.85 is used in S11A formulations, which explains that in average the computations are higher than the rules.

Table 24: Comaprison of rule formulation and computations (containership in full load only)

	S11	S11A
Linear	 The comparison is done with respect to the hogging shear force	



TB S11A.3 Strength Assessment

TB S11A.3.2 Stiffness criterion

The S11 bending strength assessment specifies a minimum moment of inertia of the midship section:

$$I_{Min} = 3CL^3B(C_B + 0.7) \quad (cm^4)$$

No technical background has been found to explain the meaning of this criterion, and hence how it should be updated due to the change in the bending moment formulations. A tentative interpretation is done and a new formulation is proposed. It is found that the minimum inertia criterion is equivalent to a maximum curvature radius.

In 1965 this minimum moment of inertia did not exist in the Bureau Veritas rules, but there was a criterion on the depth of the hull:

- For standard steel ships, the depth is to be greater than L/16 : $D > \frac{L}{16}$
- A ship made with higher tensile (HT) steel should not have a higher deflection than a corresponding ship in standard steel for which $D = \frac{L}{16}$

Hence the criteria was on the deflection (or curvature) of a ship with the characteristics D=L/16.

Looking at the relation between the moment of inertia, the section modulus and the distance from the neutral axis, we can write:

$$I = Z_{Deck}\,(z_{Deck} - z_{Neutral}) = Z_{Bottom}\,(z_{Neutral} - z_{Bottom})$$

The minimum distance from the neutral axis to the deck or to the bottom is equal to D/2. Moreover a minimum section modulus is specified in UR S7 and in UR S11. Hence, we can write:

$$I > Z_{min}\frac{D}{2} > Z_{min}\frac{L}{32} \approx Z_{min}\,0.03L$$

The formulation given in UR S7 (with material factor k=1) is (in SI units):

$$Z_{min} = CL^2B(C_B + 0.7)10^{-6}$$

From this we can compute the corresponding minimum moment of inertia, and we find the expression given in S11 with material factor k=1.

$$I > 3CL^3B(C_B + 0.7)10^{-8}$$

The deflection of the hull girder submitted to a given bending moment M can be characterized by its radius of curvature $R = \frac{E\,I}{M}$, E being the Young modulus of steel. If we consider the sagging bending moment from S11, the corresponding minimum radius of curvature is:

$$R = \frac{E\,I}{|M_{Sag}|} > 56.2\,L$$

Conclusion 1: The S11 formulation for the minimum moment of inertia is consistent with the S7 formulation of the minimum section modulus and the initial BV criterion $\mathrm{D} > \frac{\mathrm{L}}{16}$. It corresponds to a maximum deflection of the hull girder due to the wave sagging bending moment, characterized by a minimum radius of curvature equal to 56.2 L. The deflection due to the total bending moment is however not a constant as it depends on the amount of still water bending moment.

However the S11 gives another formulation of the minimum section modulus, depending on the total bending moment (still water + wave):

$$Z > \frac{|M_S + M_W|}{175} 10^{-6}$$

From this expression we can compute the corresponding minimum moment of inertia:

$$\mathrm{I} > 17.1\,L\,|M_S + M_W| 10^{-11}$$

This formulation is different from the actual S11 minimum moment of inertia, but is more consistent as it takes into account the S11 minimum section modulus and the total applied bending moment. The radius of curvature at the midship section can be computed from the inertia and the total applied bending moment (still water + wave):

$$R = \frac{E\,I}{|M_S + M_W|} > 35.3\,L$$

Conclusion 2: This reformulation of the minimum moment of inertia is corresponding to a minimum radius of curvature at the midship section for the total bending moment (still water + wave). This formulation applies to all HT steels as the maximum authorized deflection should not depend on the steel type.

To take into account the net scantling approach a reduction of the permissible radius of curvature is proposed.

$$R = \frac{E\,I}{|M_S + M_W|} > 32\,L$$

Amother way to present this criteria is to propose a minimum net moment of inertia:

$\mathrm{I} > 1.55\mathrm{L}|\mathrm{M_S} + \mathrm{M_W}|\ 10^{-7}$ [m4]

This equation is directly derived from the previous one using $E = 2.06\ 10^5\ N/mm^2$
This criterion is now used in the S11A.3.2

TB S11A.3.3 Yield strength assessment

In the current S11, the yielding strength assessment is divided in a bending strength (section modulus, moment of inertia) and a shearing strength (minimum thickness). It is proposed here to have a unified approach with two load combinations, and to express the criteria in term of Von-Mises stress.

In the S11 the bending stress criterion is a minimum section modulus. Corrosion is not taken into account.

$$Z > \frac{|M_S + M_W|}{175/k}$$

In the CSR the bending strength criterion is formulated with a maximum allowed normal bending stress. The computations are done using the net-scantling approach as defined in CSR.

$$\frac{|M_S + M_W|}{Z} < 190/k$$

For the shearing strength a minimum thickness of the structural members carrying most of the shear force (shell and effective longitudinal bulkheads) is specified in S11. Corrosion is not taken into account. For ships without effective longitudinal bulkheads, the formulation is:

$$t > \frac{0.5|F_S + F_W|}{110/k}\frac{S}{l}$$

For ships with two effective longitudinal bulkheads the formulation is different but the principle is the same.

For the shearing strength the CSR formulation is a maximum allowed shear force based on a shear flow calculation of the cross section under consideration and applying the net-scantling approach of CSR.

$$|F_S + F_W| < Q_R = \min_i \left(\frac{120/k}{q_{vi}/t_i}\right)$$

Due to the net scantling approach the allowable stress in CSR was increased from 175/k to 190/k for the bending check, and from 110/k to 120/k for the shear stress.

In the proposed formulation two load combinations are considered, see S11A3.3.2 and S11A.3.3.3:

- 100% bending and 0% shear. This load combination corresponds to the actual bending strength assessment
- 100% shear and 0% bending. This load combination corresponds to the actual shearing strength assessment

The reason for splitting the two checks is that the deck and bottom (horizontal material) is considered to carry the bending moment, while the side and inner side (vertical material) is considered to carry the shear force, when the hull girder is considered as a beam.

The resulting Von-Mises stress (S11A.3.3.1) is computed by the hull girder stress determined according to S11A.2.5:

$$\sigma_{HG} = \frac{\gamma_S\, M_S + \gamma_W M_W}{I_{net}}(z - z_n)10^{-3}$$

$$\tau_{HG} = \frac{\gamma_S F_S + \gamma_W F_W}{t_{net}/q_v}$$

$$\sigma_{eq} = \sqrt{\sigma_x^2 + 3\tau^2}$$

where for the bending strength assessment:
$\sigma_x = \sigma_{HG}$
$\tau = 0$

and for the shear strength assessment:
$\sigma_x = 0$
$\tau = \tau_{HG}$

The yielding criterion is expressed in terms of permissible stress, including partial safety factors. It makes more sense to compare the stress to the specified minimum yield stress R_{eH} , including some partial safety factors, than to a value definded as 190/k (the intention with the former stress criterion is to leave some stress to other load components than the vertical hull girder loads considered). That is why the partial safety factor γ_1 has been introduced.

$$\sigma_{VM} < \frac{R_{eH}}{\gamma_1\, \gamma_2}$$

- R_{eH}: specified minimum yield stress
- γ_1: partial safety factor for high tensile steels $\gamma_1 = k\frac{R_{eH}}{235}$

Specified minimum yield stress R_{eH}	235	315	355	390	390	460
K	1.00	0.78	0.72	0.68	0.66	0.62
γ_1	1.00	1.05	1.09	1.13	1.10	1.21

- γ_2: partial safety factor to take into account the other loads that are neglected
  - for pure bending case: $\gamma_2 = 1.24$
  - for pure shear case: $\gamma_2 = 1.13$

This approach is consistent with the yielding check applied to the FE Analysis in CSR, where a Von-Mises stress is computed for each load case (Equivalent Design Wave), and compared to the R_{eH} with appropriate safety factors.

TB S11A.4 Buckling strength

General

The buckling strength assessment of the new UR S11A is based on the prescriptive buckling requirements developed for the IACS Common Structural Rules for Bulk Carriers and Oil Tankers (refer to the CSR Pt1, Ch08, Sec03). Background information to the general approach is therefore given in the technical background documentation of the CSR, available via the IACS web-site.

Changes compared to CSR formulation

The changes compared to the CSR formulations are caused by the following to issues:

- The UR S11A is applicable for container ships only.
- The new UR S11A provides only longitudinal hull girder stresses caused by vertical bending moment and shear stresses caused by vertical shear forces.
- The structural components checked by the buckling assessment according to UR S11A are basically plates, stiffeners and stiffened panels. Struts, Pillars and transverse primary members etc. are not in scope of UR S11A.

Based on the list above the requirements developed for the CSR were simplified as follows:

Allowable Utilisation Factor (UR S11A.4.2)

Because only plates, stiffeners and stiffened panels under seagoing conditions are checked according to the UR S11A requirements, the allowable buckling utilisation factor η_{all} is set to 1.0 according to IACS CSR Pt.1, Ch08, Sec01, Table 1. Therefore the buckling acceptance criterion was generalised and simplified to:

$\eta_{act} \leq 1$

Where η_{act} is the maximum buckling utilisation factor as calculated according to the UR S11A requirements.

Interaction formulaes (plate limit state) (UR S11A, Annex 2, [2.1.1] and [2.2])

Because UR S11A is applicable for container ships only the partial safety factor S as defined in IACS CSR Pt.1, Ch08, Sec05 can be set to 1.0 and is therefore deleted from the interaction equations in the UR S11A. Furthermore only the normal stress in longitudinal direction of the ship hull and the shear stresses are defined according to UR S11A. This yields to a constant coefficient e_0 according to IACS CSR Pt.1, Ch08, Sec05 Table1 of $2/\beta_p^{0.25}$. Therefore the interaction equation for plates can be simplified for longitudinal and transverse stiffening arrangement as follows:

a) Longitudinal stiffening arrangement:

$$\left(\frac{\gamma_C \sigma_x}{\sigma_{cx}}\right)^{2/\beta_p^{0.25}} + \left(\frac{\gamma_C |\tau|}{\tau_c}\right)^{2/\beta_p^{0.25}} = 1$$

b) Transverse stiffening arrangement:

$$\left(\frac{\gamma_C \sigma_y}{\sigma_{cy}}\right)^{2/\beta_p^{0.25}} + \left(\frac{\gamma_C |\tau|}{\tau_c}\right)^{2/\beta_p^{0.25}} = 1$$

Even for curved plate panels only axial stresses can be considered following the UR S11A requirements. Therefore the buckling cases in IACS CSR Pt1, Ch08, Sec05, Table 4 can be reduced to two cases and the interaction formulae is simplified to:

$$\left(\frac{\gamma_c \sigma_{ax}}{C_{ax} R_{eH\_P}}\right)^{1.25} + \left(\frac{\gamma_c \tau \sqrt{3}}{C_\tau R_{eH_P}}\right)^2 = 1.0$$

Ultimate critical buckling stresses (UR S11A, Annex 2, [2.1.3])

The determination of the ultimate critical buckling stresses is defined in IACS CSR Pt.1, Ch08, Sec05 [2.2.3]. The reduction factors C_x, C_y and C_τ as defined in IACS CSR Pt.1, Ch08, Sec05, table 3, have to be calculated considering the factor c_1, which is dependent from the stress state and the method of buckling assessment (method A and B) in the IACS CSR. Considering the scope of S11A factor c_1 will become in any case:

$$c_1 = \left(1 - \frac{1}{\alpha}\right) \geq 0$$

This value is directly included in UR S11 A, Annex 2, Table 2 for the buckling case 2.

Correction factors F_{trans} and F_{long} (UR S11A, Annex 2, [2.1.4])

The correction factor F_{trans} is to be set in general to 1.0. Other values are only provided for structures in Bulk Carriers, refer to IACS CSR Pt1, Ch08, Sec05 [2.2.5], which is not in scope of UR S11A. Therefore the factor F_{trans} was deleted.

The correction factor F_{long} as defined in IACS CSR Pt1, Ch08, Sec05, table 2 was simplified in order to not consider U-type profiles on hatch covers, which is not in scope of UR S11A.

Lateral load P (UR S11A, Annex 2 [4.4.3])

Due to the fact that IACS has no common procedure to calculate lateral pressures on plate panels for other than CSR ships, the definition of the lateral load P (IACS CSR Pt.1, Ch08, Sec05 [2.3.4] as necessary for the determination of the buckling capacity of stiffeners was discussed within the PT.

In theory the pressure P affects the bending stress σ_b as given in the stiffener limit state formulation:

$$\frac{\gamma_c \sigma_a + \sigma_b + \sigma_w}{R_{eH}} = 1$$

σ_b is calculated as follows:

$$\sigma_b = \frac{M_0 + M_1}{Z} 10^{-3}$$

Where the lateral load P is only affecting M_1 by

$$M_1 = C_i \frac{|P| s \ell^2}{24} 10^{-3} \quad \text{for continuous stiffener}$$

While M_0 is the moment caused by the longitudinal (hull girder) stress and the deformation w of the stiffener. Therefore the influence of the lateral load P is relative small, if the stiffener under consideration is subject to high hull girder stresses as it is normally the case in the midship area. In these areas M_1 becomes relative small compared to M_0 and even the component σ_a, the axial stress component dominates the buckling behaviour. In areas with small hull girder stresses (fore- and aft part of the hull structure) the influence of the lateral load P is of greater importance.

An investigation considering the influence of the lateral load P on the buckling utilisation was carried out for the midship area for two ships (a Bulk Carrier and an Oil Tanker) and gave the results illustrated in the figure below.

The calculations were carried out following the CSR procedure considering the static and dynamic pressures according to CSR, setting the lateral load P to zero and considering only the static pressure. The buckling utilisation for P equal to zero and P equal to the static pressure was compared to the buckling utilisation factor according to CSR (x-axis on the figure below). As shown in most cases the difference in the buckling utilisation is very small, if the static pressure is considered (red), however increased, if the lateral load is set to zero (blue).

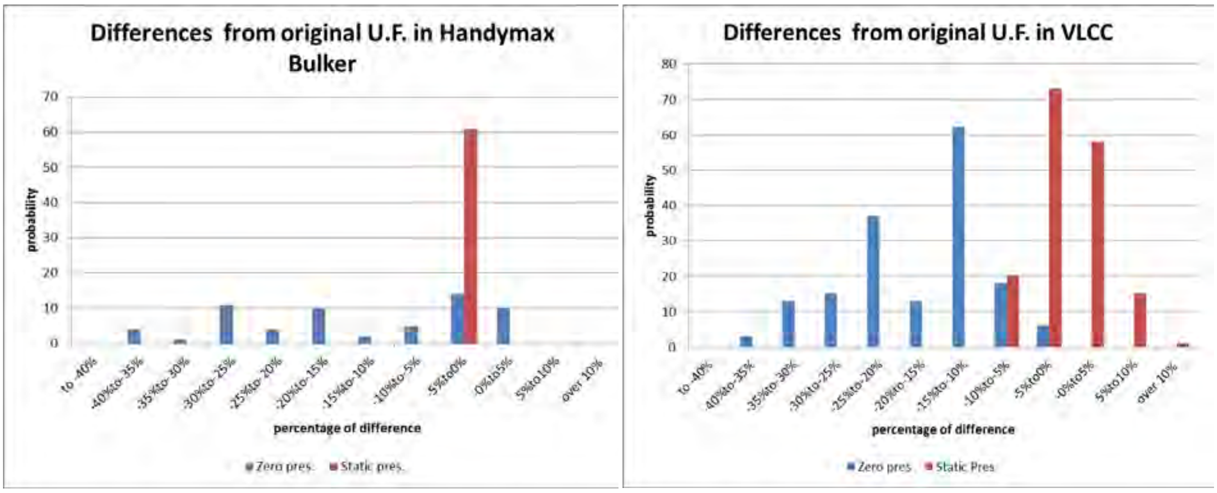


Figure 11: Probability of differences in buckling utilisation of stiffeners in midship area (Bulk Carrier left, Oil Tanker right)

It was therefore decided to use the static pressures within the consequence assessments carried out by the PT. The formulation in the requirement was changed to use the maximum static pressure only. While this will result in slightly uncertain results, the results will be the same independent from the classification society. The differences in terms of buckling utilisation in comparison to results determined by using the total pressure will be small, at least in the mid-ship part. Furthermore it has to be noted that for larger Container ships Cargo-Hold Analyses by means of Finite element method is required (refer to UR S34) and that also for these calculations buckling checks are required including consideration of other load components.

TB S11A.5 Ultimate Hull girder strength assessment

General

The ultimate hull girder strength assessment refers to the collapse capacity check, i.e. the cross section should not break in two. Even though it may be regarded as obvious that this should be a requirement, such assessment have for many class societies been taken care of implicitly by requiring that the individual panel should not fail. The collapse requirement refers to that the whole cross section should not fail, but it does not mean that the individual panel will not fail. Therefore the collapse capacity and the buckling check should be regarded as complimentary checks on two levels with different acceptance criteria; a local check and a global check. It is absolutely not acceptable that the cross section fails, but it is less critical if only a single panel fail. A panel failing in theory may imply that the panel is actually not failing in practise, i.e. no damage is observed, because the loads may be redistributed to surrounding elements. The latter is also a justification to require a collapse capacity check, since lack of observed damage may imply a false safety margin. The redistribution from some panels to others is partly included in the incremental-iterative method. If one element fails another has to take a higher load.

The two buckling checks as described above should ideally be based on the same common methodology, i.e. the same local buckling model. It is however inconvenient to have iteration on the local model and then also a second iteration in the global model. The buckling model may therefore differ in the local and global buckling, which also is the case in IACS CSR for Bulk Carrier and Oil Tanker (CSR). The proposal for the ultimate capacity check is to use the theory according to CSR (with reference to the CSR). Further background of the method may be found in TB for CSR.

The ultimate capacity shear check from CSR-H has been excluded and regarded as a secondary check. Documentation of damage experience due to global shear failure of container vessels have not been identified.

The introduction of the collapse assessment is considered as a substantial improvement for URS 11A, although several IACS class societies have already such requirements.

The ultimate hull girder capacity check formulation

The collapse check formulation is written as

$$\gamma_S M_S + \gamma_W M_W \leq \frac{M_U}{\gamma_M \gamma_{DB}}$$

Where

M_s = Permissible still water bending moment
M_w = Vertical wave bending moment
γ_S = Partial safety factor for the still water bending moment
γ_W = Partial safety factor for the vertical wave bending moment
M_U = Vertical hull girder ultimate bending capacity
γ_M = Partial safety factor for the vertical hull girder ultimate bending capacity, covering material, geometric and strength prediction uncertainties
γ_{DB} = Partial safety factor for the vertical hull girder ultimate bending capacity, covering the effect of double bottom bending

The partial safety factors should ideally be calibrated based on structural reliability analysis combining wave loading and strength with probability density functions for parameters related to significant variation and uncertainty. The objective would then be to find partial safety factors that together give an acceptable low probability of failure. This has been the basis for some of the factors used in CSR, and some of these factors have therefore been assumed to have been representative also for container vessels.

Still water overloading case

The check can in principle be done based on a high partial safety factor for the still water load, γ_S=1.2, and with a reduced safety factor for the wave bending, γ_W =0.7, to represent a static overloading case. This is regarded as a relevant scenario. This check was however been found to not be governing for any of the vessels in the consequence assessment, so this check have been omitted. The static overloading case should thereby be regarded as implicit in the dynamic overloading case.

Whipping

Whipping has been considered as relevant for the ultimate capacity check. The class society procedures differ considerably. A common approach and the magnitude, i.e. the importance, have not been agreed on. It will depend on the ship design, trade, size, powering, seamanship and even the financial crisis with slow steaming. Whipping is included as a requirement in the functional requirements for Post-Panamax container vessels, but is left to the individual class society to consider.

Partial safety factor for wave loading

From CSR the partial safety factor for the wave bending moment has been selected as γ_W =1.2. Several of the class societies already use this factor and it seems to have been an accepted factor also for container ships.

Partial safety factor for still water loading
From CSR the partial safety factor for the still water loading has been set to γ_S=1.0. The same factor has been considered relevant for container ships.

Partial safety factor for the material effect
The partial safety factor for the material effect γ_M should include uncertainties related to material, geometrical imperfections e.g. due to welding, and the method used to estimate the collapse strength. An important material property is the yield strength. The minimum specified yield strength is to be used, and the real yield strength may be higher. The collapse strength is based on half the corrosion addition deducted. This is regarded conservative for the global stress level. The geometrical imperfections should not exceed the accepted level of fabrication tolerances required by the class societies and IACS Rec. 47. These imperfections should already be included in the buckling model. Exceedance of the fabrication tolerances, e.g. the deformation at the mid span of the stiffener or flange, will normally not be significant, as the big change of local buckling capacity happens from a zero to a small imperfection. All of these supports that a material factor of γ_M = 1.0 should be sufficient. However, the method for collapse capacity may introduce uncertainties. The different class societies use γ_M varying between 1.0 to 1.1. In the "Investigation Report on Structural Safety of Large Container Ships" a comparison is shown between the ultimate hull girder strength calculated by using 3-hold non-linear finite element calculations and the method used in IACS CSR, see Figure 12 . As shown for most of the Containerships investigated here the difference is between 15 % and 20%. However one has to note that in this case the non-linear FE calculations already consider the double bottom bending effect, which should be taken out, if we discuss the difference between the calculation methods only. Considering this, a factor γ_M of about 1.05 seems to be reasonable and in addition it demonstrates that it is important to choose the PSF γ_M consistently with the approach used for the estimation of the collapse strength. There should be mentioned that there are also uncertainties in the estimates of the various methods due to definition of collapse and implementation, but the results supports that a higher γ_M than 1.0 should be used when the CSR method is used. The Figure 12 also suggests that the combined factor of γ_M and γ_{DB} should be in the order of 1.2 (vessel A is not representative and is related to MOL Comfort).

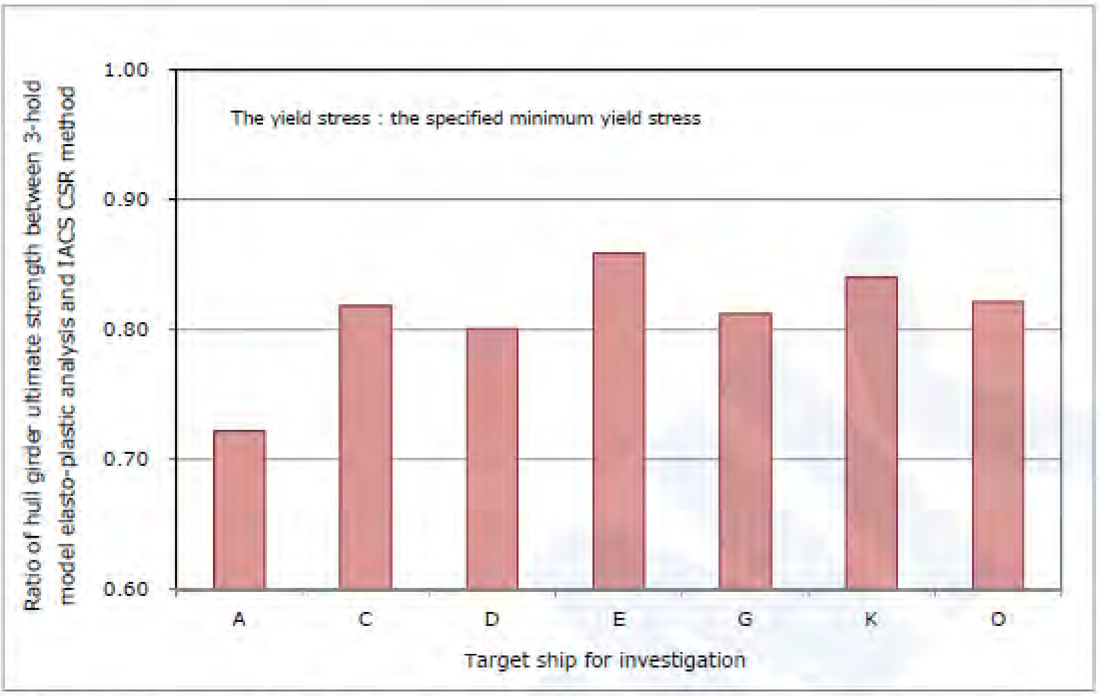

Figure 12: Ratio of hull girder ultimate strength calculated by 3-hold non-linear finite element analysis and IACS CSR method, taken from the "Investigation Report on Structural Safety of Large Container Ships" issued by the Investigative Panel on Large Container Ship Safety of ClassNK in September 2014

Plus sign between the still water and wave bending moment

It should be noted that the plus sign between the still water and wave bending moment implies a hidden safety margin, since the still water loading when fully utilized does not always occur simultaneously with the extreme wave loading. Studies on the implicit safety margin in relation to container ships have not been identified , and the magnitude of the hidden safety margin may vary with ship size and trade. However, as an illustration, the probability distribution of the still water bending moment for one container ship on two different trades is given in Figure 13. The probability of exceeding the permissible maximum hogging moment is about 4% on Asia-Europe trade and closer to 0% in North Pacific. It is thereby low likelihood of exceeding the maximum permissible hogging moment at the same time as exceeding the rule wave bending moment (for this particular ship). The probability of simultaneously occurrence decays for increasing design life time and for a 25 year return period it may therefore be relevant with a partial safety factor of less than 1.0. For other vessel types like tankers and bulk carriers or FPSO's the hidden safety margin may be significant. The relevant combination factor (understood as the partial safety factor) for the still water bending moment was estimated to 0.70 in sagging and 0.60 in hogging for a return period of 100 years for a FPSO in North Sea (Huang, W. and Moan, T., Combination of global still-water and wave load effects for reliability based design of floating production, storage and offloading (FPSO) vessels, *Applied Ocean Research* 27, 2005, pp.127-141). For Container ships these two results suggest that a partial safety factor of less than 1.0 could be relevant, but it is set to 1.0 to be conservative.

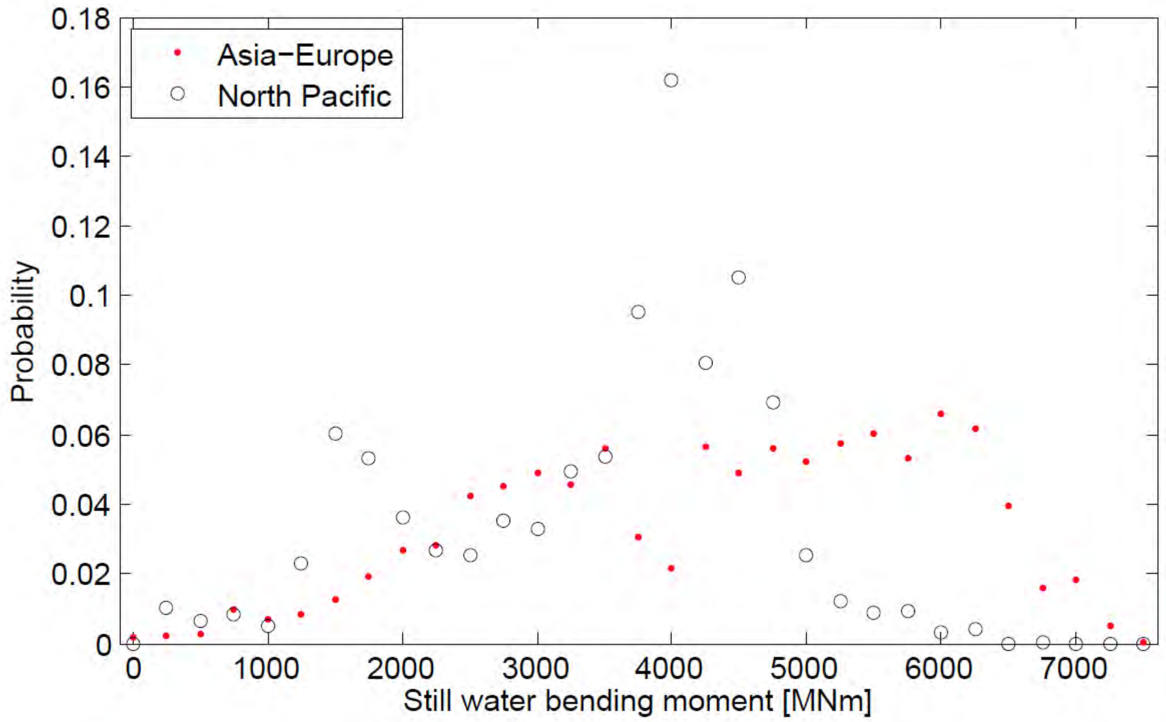

Figure 13: Probability distribution of still water bending moment from full scale measurements of a 8600TEU Post-Panamax container ship in two different trades (ref. Storhaug, G. and Kahl, A., Hyel2015, paper in progress). Permissible still water bending moment is 6700MNm.

Double bottom effect

The partial safety factor for the double bottom needs to be included. Although several of the class societies already has accounted for such factors, the MOL Comfort assessment and report from NK has publically demonstrated values that are in line with what some of the class societies have already been using. These values are also in fair agreement with what has been used in CSR (γ_{DB} = 1.1 except 1.25 for empty cargo holds in alternate loading). It should be noted however that these factors are ship type and design dependent. For container ships the double bottom effect in container cargo holds, does not act exactly as for bulk holds or oil cargo tanks on tankers and bulk carriers. The partial safety factor γ_{DB} varies from 1.0 to 1.2 between the class societies in hogging. The NK report seems to demonstrate a factor of 1.2 for several Post-Panamax ships although it is slightly unclear if this is actually also representative for FE prediction with and without lateral loading depending on the accuracy of the simplified model. There are uncertainties in the double bottom factor, because even nonlinear FE analysis with “standard” approach does not handle this correctly, hence the factors from “standard” nonlinear FE analysis may be regarded as somewhat conservative. For UR S11A the following is proposed

γ_{DB} = 1.15 for hogging

γ_{DB} = 1.0 for sagging (the double bottom in tension)

Combining the double bottom factor with the material factor, this is in line with **Figure 12**.

Principle of ultimate capacity calculation

Regarding the ultimate bending capacity of the hull girder an iterative calculation method based on the well-known Smith-Method is included in the CSR. The ultimate bending capacity of the hull girder cross section under consideration is defined as the maximum moment of the moment-curvature curve for that cross section. The method determining this curve is given in Annex 3 of S11A and described in detail in technical background documents of CSR.

TB S11A.6 Additional requirements for large container ships

Following the Recommendations of IACS EG/Containerships the project team developing the new S11A requirements was tasked to include explicitly additional requirements for large Container ships in a format of functional requirements.

The additional requirements are limited in their application to ships with a breadth B greater than the old Panamax breadth of 32.26 m.

As one of the most important effects related to the hull girder strength of Container ships, the influence of the double hull bending, including the influence of the transverse stresses (bi-axial stress state) was identified following the MOL Comfort accident. To avoid similar accidents the effect of the local loads as well as additional hull girder loads are to be taken into account for yielding and buckling assessment of large Container ships (S11A.6.2)

The assessment of the whipping effect in terms of hull girder strength and structural integrity is currently still a matter of research. Therefore IACS is at this point in time not able to define a harmonized process that accounts for whipping in the longitudinal strength checks. Because the effect is obviously of importance it was decided to include the requirement S11A.6.3 to take into considerations the whipping contribution to the vertical wave bending moment for the hull girder ultimate strength assessment for large Container ships.

Overview of results of Consequence Assessment

General

A consequence assessment was carried out by using a number of ships of the database that was already used for the load computations.

The intention was to investigate the differences of the new proposed requirements compared to the current S11 and to estimate the design impact.

Therefore for the selected ships at 5 locations along the length of the ship (0.3, 0.35, 0.55, 0.6 and 0.65L) the vertical bending moments and shear forces were calculated and the required strength checks were carried out according to the existing S11 and the new proposed S11A requirements. In cases of new requirements in the S11A like the ultimate hull girder strength check, or in case where reservations exist, the checks for the current requirements were carried out according to the requirements of the society.

The results of the investigations are summarised in the following subsections.

Loads

The formulations for vertical wave bending moments and shear forces were changed for the new S11A. In the following comparisons between the loads calculated according to the formulations of the current S11 and the new proposed S11A are shown and discussed.

	a) Hogging	b) Sagging

Figure 14: Comparison of the wave bending moments new S11A requirement versus existing S11 requirement for a) hogging and b) sagging

As shown in Figure 14 in case of hogging the new requirement will give higher wave bending moments for larger ships while the wave bending moments for smaller ships are smaller compared with the existing S11 formulation. In case of sagging the new formulation will always result in larger wave bending moments compared with the current requirement.

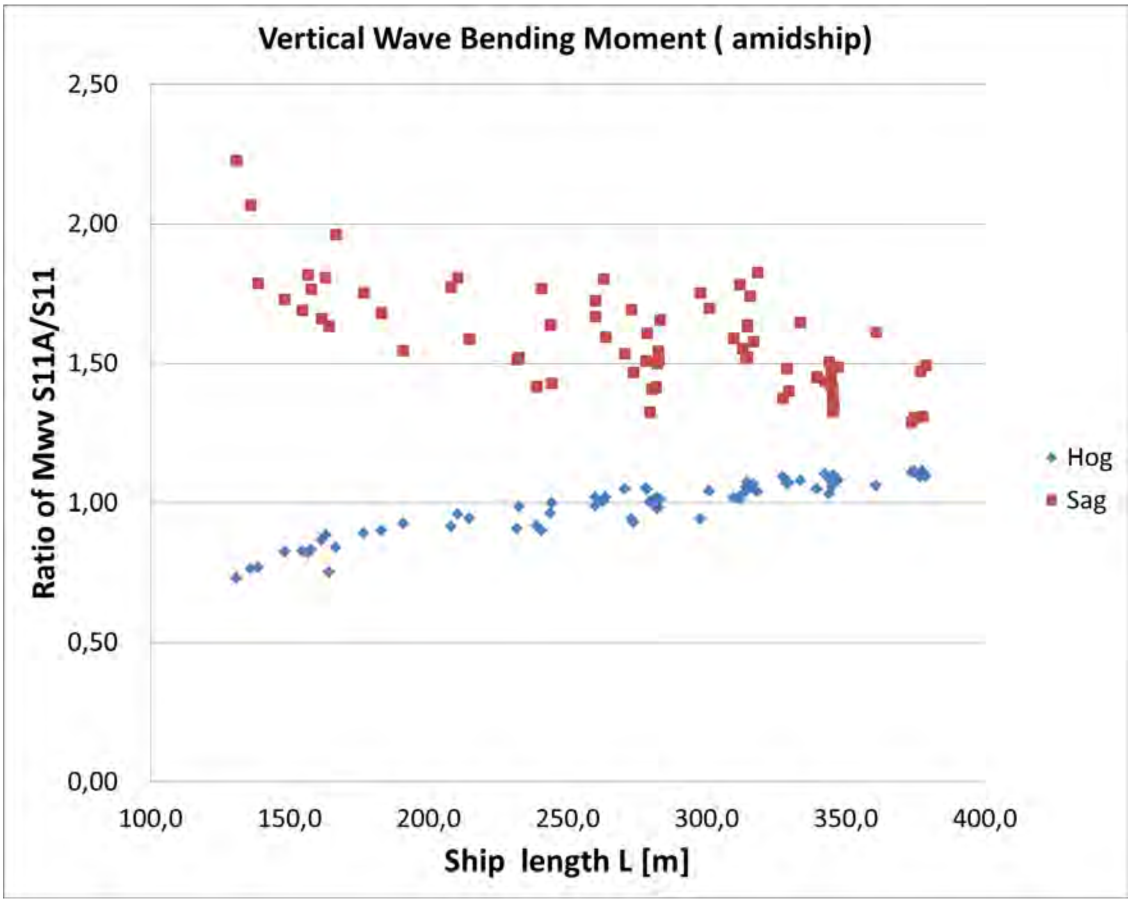

Figure 15: Ratio of new S11A to existing S11 requirement versus ship length L

Plotting the ratio of the wave bending moment according to the new S11A divided by the existing S11 formulation versus the ship length shows clearly that for smaller ships the hogging moment decreases, while the sagging moment increases. The reason here is obviously that the nonlinear effects are more important for smaller ships than for longer ships. This is also supported by the results obtained by the non-linear load computations. For smaller ships and the used wave scatter diagram the design sea states are much more steep and severe relatively to the ship size, than they are for the longer ships. The new proposed formulation of the vertical wave shear forces yields to significantly higher forces compared to the formulation in the current S11, as shown in Figure 16. The new formulation solves the since long time known problem of the inconsistency of the wave bending moment formulation of the current S11 at one hand and the shear force formulation at the other. Therefore the increase of the shear forces compared to the current formulation is partly caused by the elimination of this inconsistency.

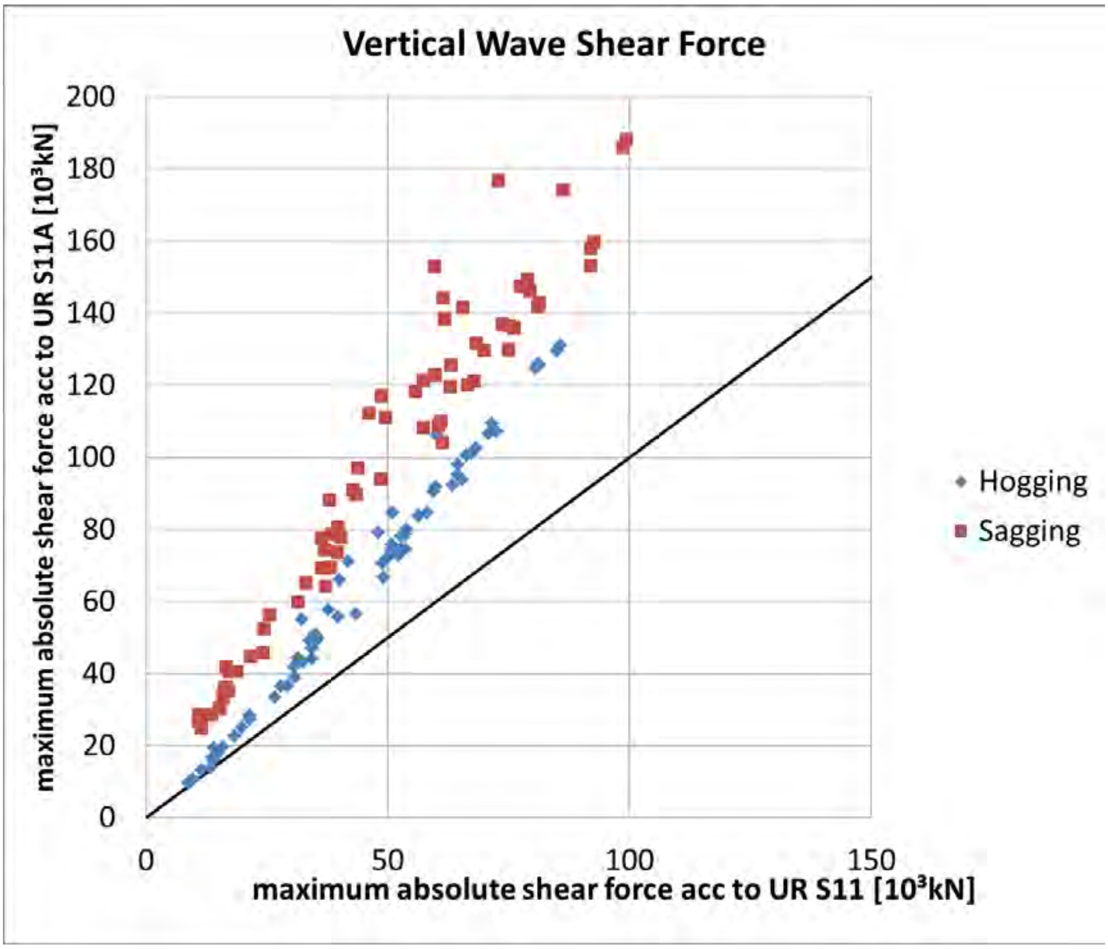

Figure 16: maximum absolute shear force obtained using the new proposed S11A formulation versus the maximum absolute shear force obtained using the current S11 formulation

Yield Assessment

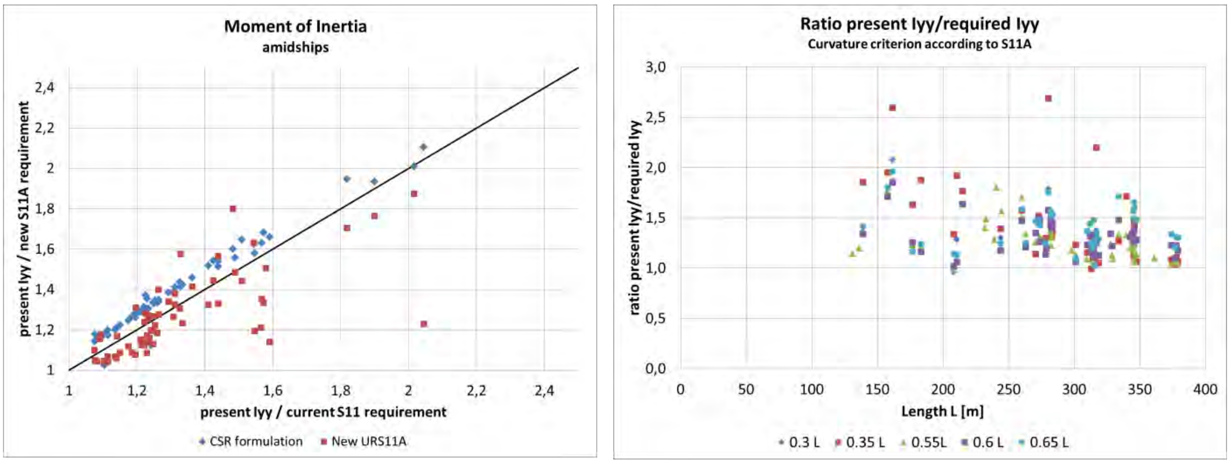

Figure 17: Comparison of required moment of inertia, left comparison with current S11 requirement (red, new formulation of S11A, blue formulation of CSR), right comparison of the new requirement of S11A with existing moment of inertia of the ship cross sections.

Figure 18 shows the results of a comparison of the new required moment of inertia compared with the existing requirements of S11 and CSR (left) and the existing moment of inertia calculated for the different cross sections of the ships in the database. As can be seen, the new requirement introduces a wider scatter of the required values, which is caused by the consideration of the load (total vertical bending moment). However the right side of the figure illustrates that almost all cross sections of the existing Container Ships that were checked in the CA, fulfil the new requirement.

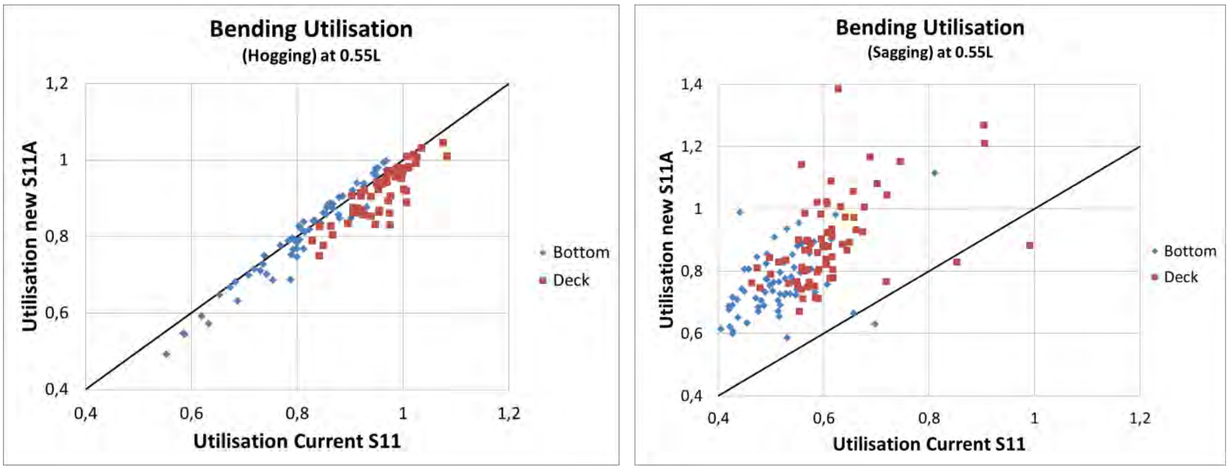

Figure 18: Utilisation factor of bending strength comparison between the new requirement in S11A with the requirement in the existing S11 at 0.55L, left hogging condition, right sagging condition

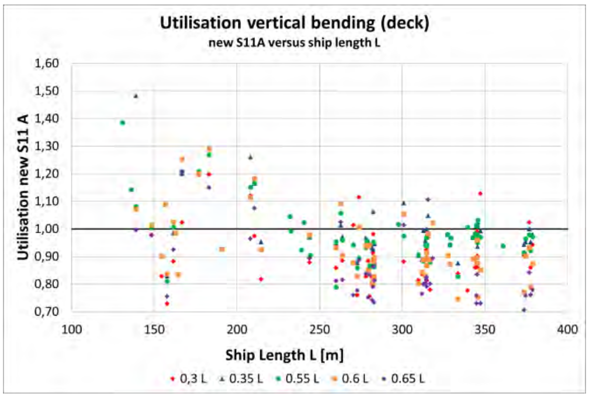
Figure 18 shows the results for the utilization factors for bending strength calculated for cross sections near mid-ship (0.55L) left in hogging condition and right in sagging. Blue rhombs indicate results obtained at bottom, while red squares indicate results obtained at equivalent deck level according to UR S5. At left hand side of the figure it can be clearly seen that the utilization in hogging conditions at deck level is in general equal or lower compared with the current S11, while the results at bottom are in some cases above the current S11 requirement. The reason here is mainly the difference of the change of the section modulus at bottom and deck level caused by the implementation of the net-scantling approach as described above. In case of sagging, at right hand side of Figure 18, the results are almost above the current S11 requirement, mainly caused by the significant increase of the wave bending moment in sagging.



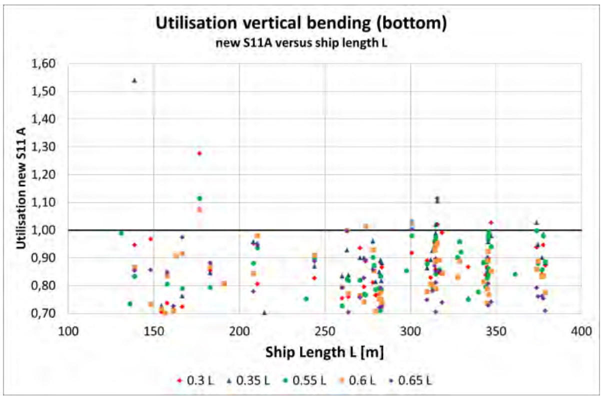


Figure 19: Utilisation factor of bending strength according to the new S11A requirement versus the Ship length L, left results obtained at equivalent deck level (UR S5), right results obtained at bottom

Figure 19 shows the utilization factors for bending according to the new S11A requirement versus the ship length L. At left hand side the results obtained at equivalent deck level are shown, at right hand side the results at bottom. As can be seen most of the cross sections fulfill the requirements, however at deck level more cross sections fails the check than at bottom level. Furthermore it can be observed that higher deviations are found for smaller ships compared to the larger ones. There are basically two reasons for this effect. One is the trend to higher non-linear load factors as already described above for smaller ships, the second is in case of sagging the relative high uncertainty with respect to the still water values.

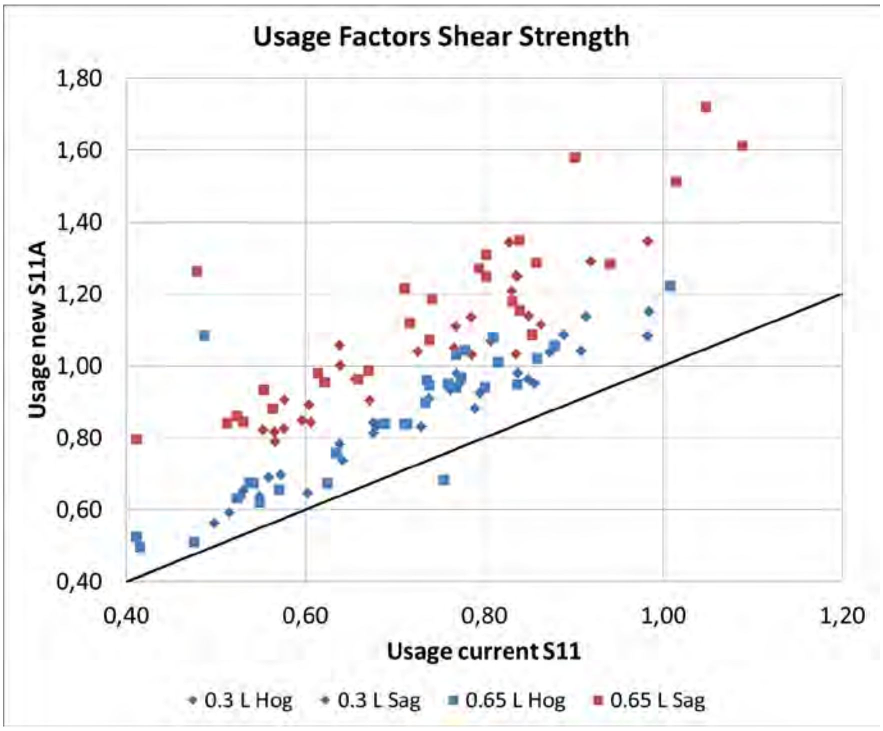

Figure 20: Usage factors for shear strength at cross sections 0.3L and 0.65L compared with the current S11 requirement

Figure 20: shows the usage factors for the shear assessment obtained according to the new S11A requirements versus the old S11 requirement. As can be seen the usage in case of shear is almost significantly increased compared to the old requirements, which is especially true for the sagging condition (red points in the graph). Furthermore it is shown that a large number of cross sections do not fulfill the new requirements. This is also observed from Figure 21, where the usage factors calculated according to the new S11A are plotted versus the ship length.

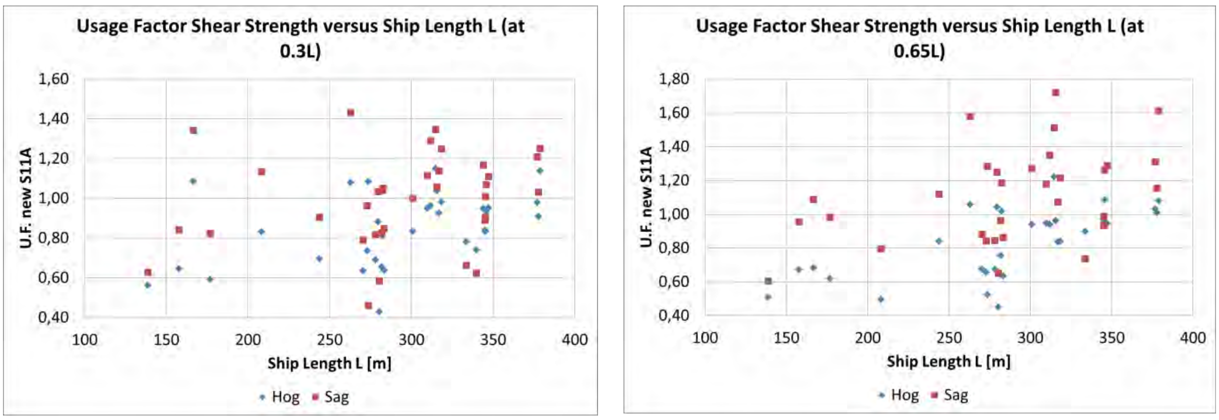

Figure 21: Usage Factors for shear strength versus the ship length L, left cross sections at 0.3L, right cross sections at 0.65 L

There are mainly three reasons for the high deviation of the results compared to the current S11 requirements. At first the existing in-consistency between the vertical wave bending moment and the vertical wave shear force, which tends to obtain too low shear forces following the current S11 approach is removed in the new S11A. In addition the wave loads, especially in case of sagging have increased significantly, which is the reason that in sagging condition the utilization is higher than in hogging, see Figure 20. The third reason is the high uncertainty that we have with respect to the still water loads in sagging condition for the ships in the data base. Even the still water sagging values given in the loading manuals seems to be based on sometimes “unrealistic” load case assumptions. Therefore the significance of the CA results with respect to the bending and shear utilization in sagging condition is somehow limited.

Buckling assessment

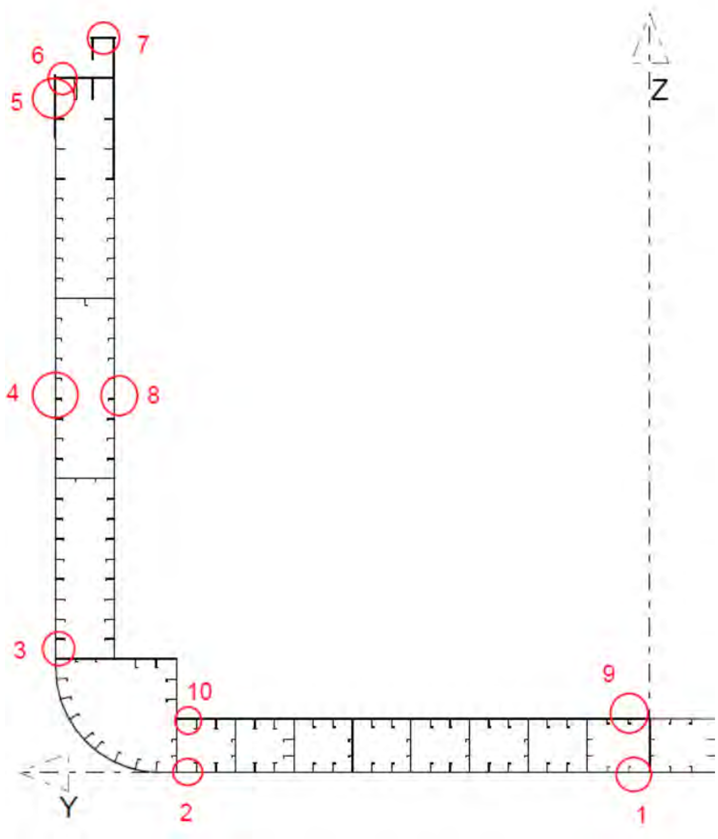

Figure 22: Positions of the 10 evaluation points fort he buckling assessments

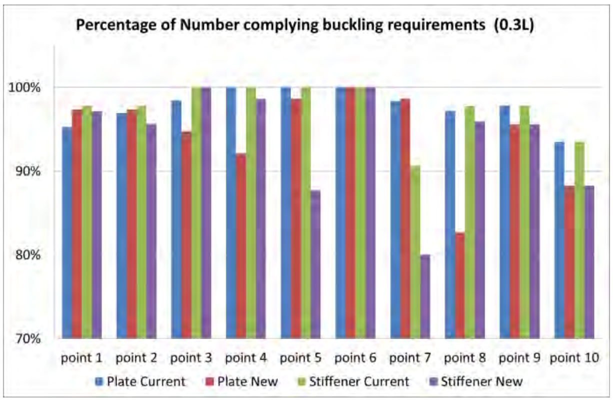
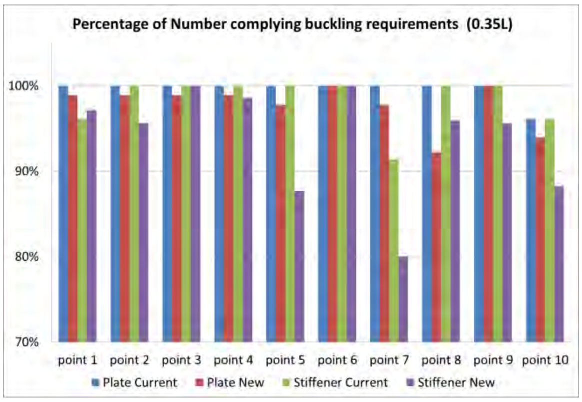
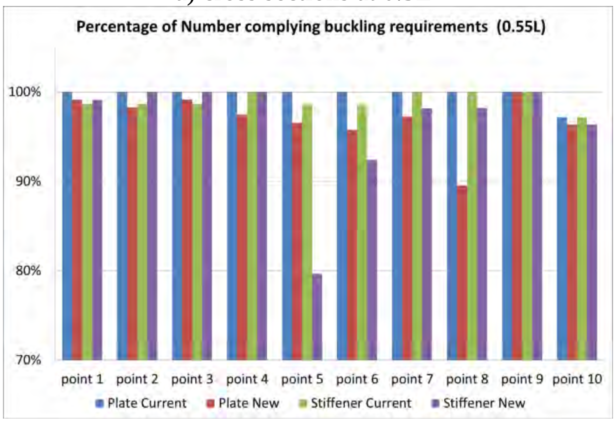
The buckling assessment following the new proposed requirements in S11A was carried out for the five cross sections as used for the yield strength assessment and the 10 elements as shown in Figure 22. The checks were carried out for the plating as well as for the stiffeners, if applicable. For comparison buckling assessment following the current S11 requirements or the requirements of the class society (in case of reservations against the buckling requirement in S11) were carried out. The results obtained are summarised in Figure 23, for each cross section and each evaluation point.



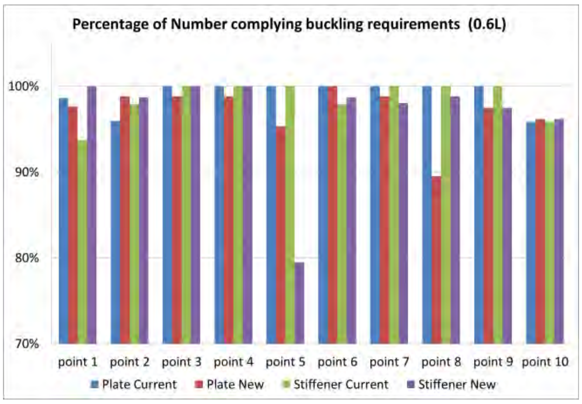
a) cross sections at 0.3L



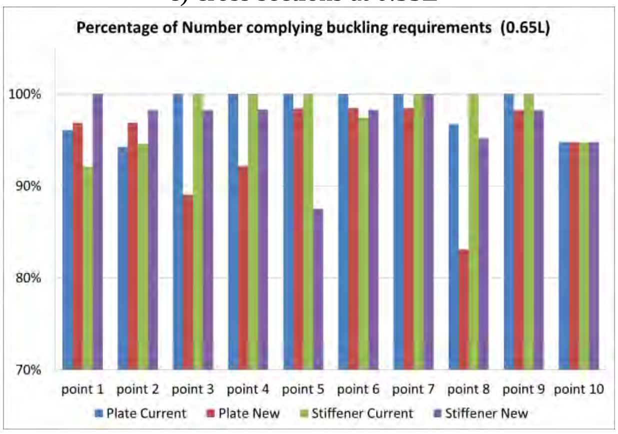
b) cross sections at 0.35L



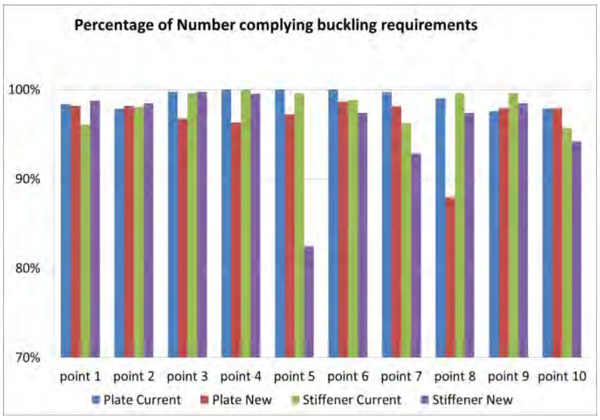
c) cross sections at 0.55L



d) cross sections at 0.6L



e) cross sections at 0.65L



f) summary of all cross sections

Figure 23: Results of the buckling assessments, a) to e) for cross sections at 0.3, 0.35, 0.55, 0.6 and 0.65L respectively, f) summary considering all buckling results

The blue columns in Figure 23 indicate the number of plate elements that fulfill the buckling requirements according to the existing rules, the red column indicates the number of plate elements that pass the buckling check following the approach in S11A. Similar the green columns indicate the results for the stiffener check following the existing rules and the purple column indicates the results for the stiffeners following the S11A. As shown in Figure 23 most of the elements pass the buckling checks. However some areas with larger deviations from the existing situation can be identified. Especially the plate elements at evaluation points 3, 4 and 8 as well as the stiffener at evaluation point 5 shows some deficiencies with respect to the S11A requirements. The reason for the plate elements is mainly related to the significantly increased shear stresses, which yields to the high utilization not only in case of buckling but also in case of shear yield checks as already described above. This is supported by the observation that the deficiencies for these evaluation points and the plate elements are found especially at the cross sections at 0.3L and 0.65L, see Figure 23 a) and e), while at mid ship section (Figure 23 c)) much more elements fulfill the requirement. Furthermore the stiffener in the shear plate is found in some cases insufficient (evaluation point 5). This obviously is true for all the checked cross sections and could be caused by the significantly increased sagging wave bending moments.

Also here it should be noted that in some cases the still water values in case of sagging are uncertain and can influence the results obtained in the buckling check.

Ultimate Hull Girder Strength

Ultimate hull girder strength was assessed during the CA following the S11A approach as well as applying existing approaches of the class societies for comparison. The checks were carried out at the cross sections used for the yield and buckling checks as described above. The partial safety factor for the double bottom effect was kept constant irrespective of changes in the double bottom structure at the forward ore afterward cross sections.

Results obtained following the approach in S11A compared with results following existing class requirements are shown in Figure 24. As can be shown, the S11A requirement is obviously a bit stricter than the existing requirements of the class societies. Furthermore most of the checked cross sections pass the check. The obvious increased usage by applying the S11A requirements is mostly caused by the increased wave bending loads, especially in case of sagging (red points in Figure 24).

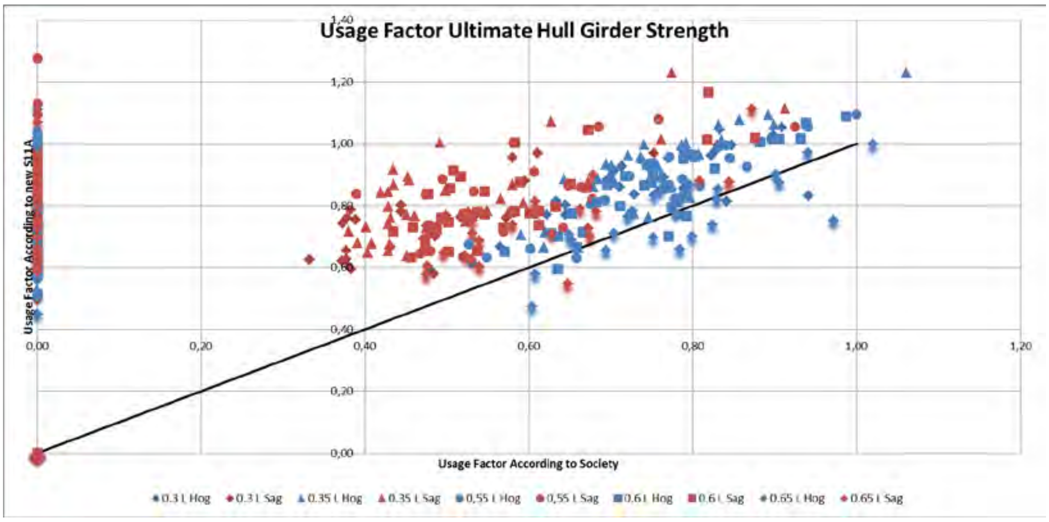


Figure 24: Comparison of the usage factor for ultimate hull girder strength of the S11A requirement to existing class requirements

Figure 25 shows the utilisation for the ultimate strength check versus the ship length. At left hand side the results obtained for hogging condition and at left hand side the results for the sagging condition are shown. It can be seen clearly that in hogging some larger ships do not pass the ultimate strength check, while in hogging only two larger and a few smaller ships fails. In sagging case it is expected that probably not correct still water bending moments cause the failure of the check. In hogging case obviously a few larger ships are required to be strengthened.

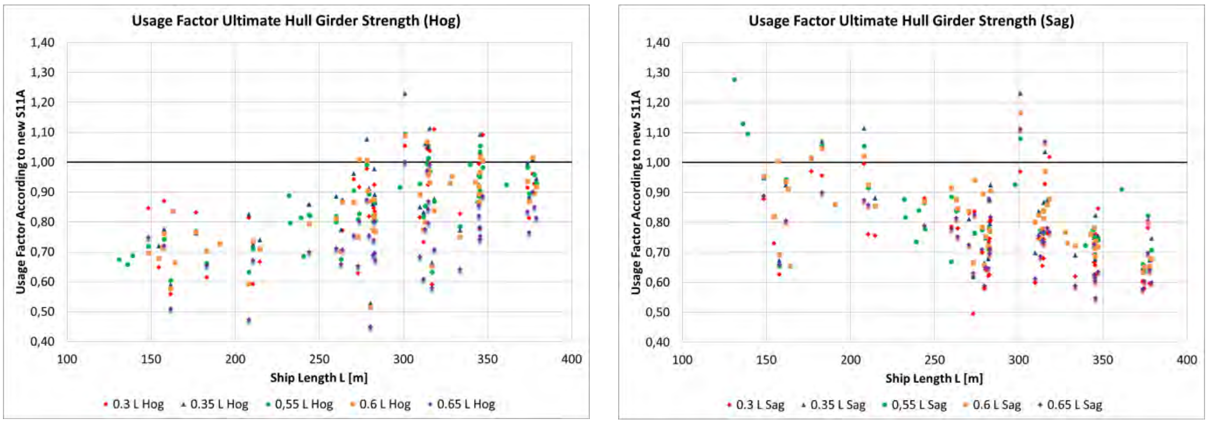

Figure 25: Usage factor for ultimate hull girder strength versus the ship length L, left hogging condition, right sagging condition

However it has to be kept in mind that a possible reduction of the partial safety factor for the double bottom effect was not considered in the checks, even in cases were the structure of the double bottom changes or the breadth of the double bottom decreases in comparison to the midship part. Consideration of the variability of the partial safety factor for the double bottom effect will reduce remarkably the number of cross sections at the forward and aft part of the ships that do not pass the check.

☑ Based on IACS Requirement *(Common Structural Rules for Bulk Carriers and Double Hull Oil Tankers)*

.2 Main Reason for Change:

Following the introduction of the IACS Common Structural Rules for Bulk Carriers and Double Hull Oil Tankers, Hull Panel were tasked to review all the UR S files to consider whether or not they are applicable to ships covered by the CSR.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None.

.4 History of Decisions Made:

After review it was decided that for CSR bulk carriers the requirements of UR S12 are superseded by those of the Common Structural Rules and therefore do not apply.

UR S12 is not applicable for CSR oil tankers.

.5 Other Resolutions Changes

All UR S files, except UR S8, S9, S15, S16, S19, S22, S23, S30 and S31.

.6 Dates:

Original proposal: *2007, made by Hull Panel Task 50*
Panel submission to GPG: *19 April 2010*
GPG Approval: *24 May 2010 (Ref. 10051_IGd)*

Note: *There are no separate Technical Background (TB) documents for the original resolution (1992), Rev.1 (1997), Rev.2.1 (1997), Rev.4 (July 2004) and Rev.5 (May 2010).*

UR S13 “Strength of bottom forward in oil tankers”

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Corr.1 (May 2014)	13 May 2014	-
Rev.2 (May 2010)	24 May 2010	-
Rev.1 (1993)	2 December 1993	1 July 1994
NEW (1993)	*No record*	-

- **Corr.1 (May 2014)**

.1 Origin for Change:

☑ Suggestion by an IACS Member

.2 Main Reason for Change:

UR S13 currently refers to Regulation 13 of MARPOL 73/78 Annex I however the structure of MARPOL Annex I has been substantially revised since UR S13 was first introduced and Regulation 13 no longer refers to segregated ballast tanks. Instead, Regulation 18 should be referenced.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None.

.4 History of Decisions Made:

A Hull Panel Member noted that UR S13 still referenced Regulation 13 instead of Regulation 18.

.5 Other Resolutions Changes

None

.6 Dates:

Original proposal: 14 April 2014
Panel submission to GPG: 29 April 2014
GPG Approval: 13 May 2014 (Ref: 14068_IGb)

- ## Rev.2 (May 2010)

.1 Origin for Change:

☑ Based on IACS Requirement *(Common Structural Rules for Bulk Carriers and Double Hull Oil Tankers)*

.2 Main Reason for Change:

Following the introduction of the IACS Common Structural Rules for Bulk Carriers and Double Hull Oil Tankers, Hull Panel were tasked to review all the UR S files to consider whether or not they are applicable to ships covered by the CSR.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None.

.4 History of Decisions Made:

After review it was decided that for CSR oil tankers the requirements of UR S13 are superseded by those of the Common Structural Rules and therefore do not apply.

UR S13 is not applicable for CSR bulk carriers.

UR S14 "Testing Procedures of Watertight Compartments"

Summary

Changes were made to clarify application of UR S14 especially for smaller ships / non-SOLAS ships. For that purpose, Part B was modified, and new Part C was added. Test pressure head for ships under Part C was newly developed.

Part A. Revision History

- ### Rev.7 (Dec 2022)

.1 Origin for Change:

☑ Suggested by IACS member

.2 Main Reason for Change:

UR S14 provides tank testing requirements which were in part developed to address the SOLAS tank testing requirements however since IACS URs are applicable to seagoing ships over 100 GT in size, UR S14 is also applicable to small non-SOLAS ships and yachts. As a result of this, LR placed a reservation against UR S14 with respect to the application to LR's Special Service Craft Rules on the basis that the testing regime is too onerous. Therefore, it was decided to revise UR S14 to include an appropriate tank testing regime for small ships.

.3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None.

.4 History of Decisions Made:

A project team was set up to investigate appropriate tank testing requirements for small ships where aspects such as overflow arrangements, materials other than steel, the practical application of the existing requirements and the relationship between design pressure and test pressure were considered. The existing Part B is now only applicable to SOLAS exempt/equivalent ships, and a new Part C has been added which is applicable to non-SOLAS ships.

See Part B Annex 3 for a detailed technical background.

Existing paragraph Part B 2.5 (2.6 in Rev. 7) has been amended to clarify that the relaxations for sister ships are applicable to both lead ships which were tested in accordance with Part A and lead ships which have been tested in accordance with Part B Paragraph 2.3. The previous reference to Table 1 has been removed.

Part B Section 2.5.2 of UR S14 rev. 6 requires that structural testing be carried out for at least one tank of each type among all tanks of each sister vessel. One topic of discussion within the Hull Panel was whether for sister ships in Parts B and C there should be a requirement that one tank of each type be structurally tested given that this requirement means that there may not be much relaxation for sister ships. This is because the requirement to structurally test one tank of each type of structural similarity applies to the lead ship. It was decided to only require one tank to be structurally tested for a sister ship subject to Part C (Part B kept as before) since the purpose of the structural test is to confirm the design. As this will already have been done for the lead ship, it is only necessary to test the workmanship on sister ships which is done by means of a leak test. This relaxation does not apply to tanks carrying pollutants however rather than require every such tank to be structurally tested, on a sister ship one tank of each type need only be structurally tested.

The relaxations for sister ships have also been extended to cover spaces such as chain lockers.

The Hull Panel also decided to make other minor amendments as follows:

- Fuel oil overflow tanks not intended to hold fuel have been added to Part A, Table 1.
- A reference to Recommendation 47 or a recognised fabrication standard has been removed in line with changes made to other URs.
- Part B, Section 2.6 was amended to clarify that the lead ship is to be structurally tested in accordance with either Part A or Part B, Section 2.3.
- A definition of the overflow has been included; this is any physical means of preventing overflow.
- The requirement to test tanks based on the pressure relief valve setting has been replaced with a requirement to test tanks based on the design vapour pressure. This is to align with the requirements of the CSR BC & OT.
- The requirement to consider an appropriate additional head for chemical cargo tanks where the density is greater than 1 has been revised to refer to Section 4.4.1 where there is a description of how to test such tanks. Section 4.4.1 has also been amended to clarify the test pressure for such tanks which shall not exceed the maximum design internal pressure in the top of tank.
- In Annex 1/Part A/Table 1/Note 6 in UR S14, MSC/Circ.1176 has been replaced by MSC.1/Circ.1572/Rev.1

.5 Other Resolutions Changes

None

6 Any hinderance to MASS, including any other new technologies:

None

.6 Dates:

Original proposal	: 09 November 2018	(Ref: 18193_PHa)
Submission to GPG	: 08 December 2022	(Ref: PH18018_IHcb)
GPG Approval	: 28 December 2022	(Ref: 18193_IGr)

- ## Rev.6 (Aug 2016)

.1 Origin for Change:

☑ Based on IMO Regulation SOLAS II-1/11

.2 Main Reason for Change:

The CSR BC & OT refers to UR S14 which is considered by the IMO to be a lesser standard than the SOLAS tank testing requirements. In order to resolve this issue, it was proposed that UR S14 be amended to comply with SOLAS II-1/11.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None.

.4 History of Decisions Made:

Various options for satisfying the SOLAS requirements were discussed and it was agreed that SOLAS ships (including CSR BC & OT) should comply with SOLAS II-1/11. Hence, it was concluded that UR S14 should be amended to comply with SOLAS so that the tank testing requirements of Chapter II-1/11 are applicable to all SOLAS ships. However, it was noted that the requirements of UR S14 apply to both SOLAS and non-SOLAS vessels and that Flag Administrations may issue either exemptions against Chapter II-1/11 or state that UR S14 Rev 5 tank testing requirements are equivalent to SOLAS chapter II-1/11. Hence, it was decided that UR S14 should be split into two Parts; Part A giving requirements for SOLAS ships and Part B giving requirements for non-SOLAS ships and ships which have been given exemption/equivalency by their Flag. The decision was also made to require documentary evidence of the owner's agreement to seek exemption/equivalency as well as evidence that the Flag Administration has granted exemption/equivalency.

In addition, the Survey Panel requested that some amendments be made to the air test procedures and the requirements for NDT; these have been included.

There was some discussion about the SOLAS requirements concerning the following:

- Structural testing of Fore Peak, double bottom and side skin voids.
- Use of stagger testing
- Definition of watertight sub-division

<u>Structural testing of Fore Peak, double bottom and side skin voids.</u>

UR S14 does not require a structural test for these spaces and this was queried by one Member who advised that:

"Structural test is required for the watertight boundaries of spaces even other than tanks in accordance with SOLAS II-1/11.2."

However, Regulation 11.1 states that "Testing watertight spaces not intended to hold liquids and cargo holds intended to hold ballast by filling them with water is not compulsory." Although Regulation 11.2 does state that the forepeak, double bottom (including duct keels) and inner skins are to be tested with a head of water, when Regulation 11.1 is taken into account it is clear that the spaces mentioned in Regulation 11.2 are assumed to be spaces intended to carry liquid and not void spaces; the purpose of Regulation 11.2 is to specify the test pressure for these spaces.

It was, therefore, decided to retain the existing text in UR S14.

Use of stagger testing

UR S14 allows stagger testing to be used however one Member advised that there had been issues with certain Flags regarding the implementation of this procedure.

Upon closer examination of SOLAS it was found that there is no requirement in SOLAS that tanks have to be tested from both sides; just that the boundaries have to be tested for both tightness and structural strength. In addition, the stagger testing is a miniumum level of testing and has to cover both tension and compression cases.

It was, therefore, decided to retain the existing text in UR S14.

<u>Definition of watertight sub-division</u>

There was some debate about the definition of watertight sub-division. SOLAS II-1/11.3 requires tanks which are intended to hold liquids, and which form part of watertight sub-division of the ship, shall be tested for tightness and strucutural strength… In Rev. 6 of UR S14, watertight sub-division has been defined as follows:

"Watertight subdivision means the main transverse and longitudinal subdivisions of the ship required to satisfy the subdivision requirements of SOLAS Chapter II-1"

The watertight sub-division can be related to the damage stability requirements contained in SOLAS as it is understood that when the damage stability is being assessed, various spaces on the ship are assumed to be flooded but that this flooding is limited by longitudinal and transverse sub-division. If the boundary of the tank is not required to satisfy the watertight subdivison requirements (and hence damage stability) then it does not need to be tested. An example would be small engine room tanks.

.5 Other Resolutions Changes

None

.6 Dates:

Original proposal: 11178dIGad 15 June 2016
Panel submission to GPG: 19 August 2016 (Ref: 11178dPHI)
GPG Approval: 19 September 2016 (Ref: 11178dIGzc)

- **Rev.5 (Jan 2015)**

.1 Origin for Change:

☑ Request by the GPG.

.2 Main Reason for Change:

To align UR S14 with the Guidelines submitted to the Correspondence Group on Testing of Watertight Compartments which was established at SDC 1. These are based on the guidelines submitted to SDC 1 (SDC 1/INF.13). Also to remove the relaxations and reintroduce the structural tests for Tankers and Combination Carriers, based on Industry feedback and the discussion at GPG74.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None.

.4 History of Decisions Made:

At GPG74 (April 2013), the GPG noted the Industry feedback received during the IMO DE56 and DE57 sessions and requested that the relaxations for Tankers and Combination Carriers be removed from the Guidelines that were submitted to DE57, which, in effect, reintroduces the structural tests for Tankers and Combination Carriers. In addition, it was agreed to update UR S14 to align with the DE57 Guidelines (all changes made between MSC86 and DE57 submissions). It is noted that the UR S14 (Rev 4) was previously updated to align with the MSC86 version which was introduced in IACS paper MSC 86/23/13, 25 Feb 2009 and gained widespread agreement among flag states at that time.

The relationship between Rev. 4 and Rev. 5 to the various submissions to IMO MSC and DE is shown in the following table:

IACS	IMO
UR S14, Rev. 4, Aug 2012	MSC 86/23/13, 25 Feb 2009
–	DE 56/INF.11, 9 Dec 2011
–	DE 57/INF.6, 8 Jan 2013
UR S14, Rev. 5, Jan 2015	Same as the updated version of SDC 1/INF.13 submitted to the CG established at SDC 1

A summary of changes made between UR S14 Rev. 4 and Rev. 5 is as follows:

- Updating the definitions for the test types.
- Clarifying the "Testing Schedule for New Construction or Major Structural Conversion".
- Clarifying the "Test Methods".
- Specifying additional requirements for "Hydrostatic or hydropneumatic tightness test".
- Updating Table 1 "Test Requirements for Tanks and Boundaries" and specifying requirements for additional "Tanks or boundaries to be tested".
- Combined Rev 4, Table 1, Notes 7 and 8 and clarified that for watertight bulkheads (item 11.1) the alternative testing methods may only be applicable where a hose test is not practicable. For items 12, 16 and 17 of Table 1 the alternative to the hose test may be made at the discretion of who performs the test.
- Updating the requirements for Liquefied gas carriers, in Para 2.2 and Table 2.
- Updating the notes for Table 3.
- Reintroduce the structural tests for Tankers and Combination Carriers.

Following SDC 1, the guidelines were further revised and submitted to the IMO SDC Correspondence Group on Testing of Watertight Compartments. A summary of the changes is as follows:

- Enhancement of the conditions for confirming structural adequacy while afloat.
- Inclusion of requirements for fore and aft peak spaces with equipment.
- Note 9 covering a structural test waiver.
- Testing to be carried out to the satisfaction of the Administration instead of the Class Society.

.5 Other Resolutions Changes

None

.6 Dates:

Original proposal: GPG74 FUA 3, 11 April 2013
Panel submission to GPG: 07 November 2014 by Hull Panel
GPG Approval: 15 January 2015 (Ref: 11178dIGo)

- **Rev.4 (August 2012)**

.1 Origin for Change:

☑ Request by Hull Panel and the GPG.

.2 Main Reason for Change:

To place the testing updates made in the IACS "PROCEDURES FOR TESTING TANKS AND TIGHT BOUNDARIES" (the PROCEDURES) into a new update of UR S14.

The following is a roadmap showing changes made to arrive at Rev. 4.

Roadmap for the Rev. 4 of UR S 14

Section in UR S14 (Rev. 3, May 2010)		Location in UR S14 (Rev. 4, Aug 2012)
14.1.1	Shop primer and final coating	4.5 – Application of Coating
	Structural test	3.1 – Structural test
	Hydropneumatic testing	3.1 – Leak test, 3.2 – Definition, Hydropneumatic test
	Leak testing	3.1 – Leak test
	Hose testing	3.2 – Definition, Hose test
14.1.2	Application - Test conditions	2.1 – Application
	Purpose	1 – General
	Stage of construction at which to test and general testing requirements	4.1 – General test procedure
	Not applicable to CSR BC/OT	(Statement no longer valid)
14.2.1	Structural testing and coating	4.5 – Application of coating, Table 3
14.2.2	Leak testing air pressure	4.4.4 – 4.4.6 (Tank air test, compressed air fillet weld test, and vacuum box test)
	Indicating Liquid	3.2 – Definition - Air test, Compressed air fillet weld test, and vacuum box test
	Test pressure verification (U-tube and gauge)	4.4.4 – U-tube, Master gauge
	Leak testing and coating	4.5 – Application of coating, Table 3
	Other recognized methods	4.4.9 – Other Test
14.2.3	Hose Testing (pressure, nozzle and distance)	4.4.3 – Hose test (pressure, nozzle and distance)
14.2.4	Hydropneumatic	4.4.2 – Hydropneumatic test
14.2.5	Other Testing Methods	4.4.9 –Other Test
14.3	General Testing Requirements	4.1 – General test procedure, Table 1
14.4	Additional Requirements for special type vessels/tanks	Table 2 (although no text as in 14.4)
Table 1	General Testing Requirements	Table 1 – General Testing Requirements
Table 2	Additional testing requirements for spaces within the cargo area of certain types of ships – LNG Carriers	(Direct reference to URs G1 and G2 not made)

Section in UR S14 (Rev. 3, May 2010)		Location in UR S14 (Rev. 4, Aug 2012)
	Additional testing requirements for spaces within the cargo area of certain types of ships – Other vessel types	Table 2 – Additional Test Requirements for Special Service Ship/Tanks
N/A		2.3 – Testing of structures not listed in Table 1 or 2
N/A		4.2.1 – Type and time of test
N/A		4.2.2 – Number of Structural Tests
N/A		4.3 – Leak Test Procedures
N/A		4.4.1 – Hydrostatic Test
N/A		4.4.3 – Hose test practicability
N/A		4.4.7 – Ultrasonic Test
N/A		4.4.8 – Penetration Test
N/A		4.6 – Safe Access to Joints
Based Sec. 14.2.1 and 14.2.2		Table 3 – Application of Leak Test, Coating and Provisions for Safe Access for Type of Welded Joints

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None.

.4 History of Decisions Made:

The Hull Panel created the PROCEDURES based on Rev. 3 of the UR S14 and then IACS (with the Cook Islands and the Marshall Islands) submitted the PROCEDURES to IMO MSC86 meeting held in May/June 2009 (Ref. Paper MSC 86/23/13, dated 25 February 2009).

The reason for developing the PROCEDURES was to document well established and proven practices used for testing the integrity of watertight compartments intended to contain liquids which are at variance to certain degrees with both the previous requirements of SOLAS (which addressed the testing of subdivision boundaries for watertightness) and the new requirements contained in resolution MSC.194(80) that entered into force on 1 January 2009, which include additional requirements for testing the structural strength of tanks intended to contain liquids. The PROCEDURES were developed to remove variances which will impact all ships to which the requirements of SOLAS chapter II-1 apply.

With the Rev. 4 update, the requirements of UR S14 are confirmed to be applicable to ships to which the Common Structural Rules apply, reversing the application note previously in Rev. 3.

.5 Other Resolutions Changes

None

.6 Dates:

Original proposal: *GPG72 FUA 5*
Panel submission to GPG: *10 July 2012 (By Hull Panel)*
GPG Approval: *20 August 2012 (Ref. 11178aIGc)*

- **Rev.3 (May 2010)**

.1 Origin for Change:

☑ Based on IACS Requirement *(Common Structural Rules for Bulk Carriers and Double Hull Oil Tankers)*

.2 Main Reason for Change:

Following the introduction of the IACS Common Structural Rules for Bulk Carriers and Double Hull Oil Tankers, Hull Panel were tasked to review all the UR S files to consider whether or not they are applicable to ships covered by the CSR.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None.

.4 History of Decisions Made:

After review it was decided that for CSR ships the requirements of UR S14 are superseded by those of the Common Structural Rules and therefore do not apply.

.5 Other Resolutions Changes

All UR S files, except UR S8, S9, S15, S16, S19, S22, S23, S30 and S31.

.6 Dates:

Original proposal: *2007, made by Hull Panel Task 50*

Part B. Technical Background

List of Technical Background (TB) documents for UR S14:

Annex 1. **TB for Rev.1 (Feb 2001)**

See separate TB document in Annex 1.

Annex 2. **TB for Rev.2 (May 2001)**

See separate TB document in Annex 2.

Annex 3. **TB for Rev.7 (Dec 2022)**

See separate TB document in Annex 3.

Note: *There are no separate Technical Background (TB) documents for the original resolution (1996), Rev.3 (May 2010), Rev.4 (Aug 2012), Rev.5 (Jan 2015) and Rev.6 (Aug 2016).*

Technical Background (TB) document for UR S14 (Rev.1 Feb 2001)

The attached change is proposed in order to eliminate the one Member's reservation on UR S14 – Testing Procedures of Watertight Compartments. It was considered by ABS that application of the requirements of S14.1.2 should not extend to pressure tanks and small gravity tanks. To accommodate this, WP/S agreed that the wording 'tanks, including independent tanks' should be replaced by 'gravity tanks including independent tanks of $5m^3$ or more in capacity' as shown on the attached.

The change was agreed unanimously and no unresolved issues remain.

Submitted by WP/S Chairman on 9 January 2001

Technical Background (TB) document for UR S14 (Rev.2 May 2001)

a) Objective/Scope

Further to adoption of Rev.1 (February 2001) to eliminate a Member's reservation on S14.1.2, there was a need to remove the ambiguity of the changes made in Rev.1, thereby achieving uniform implementation in practice.

b) Source of Proposed Requirements

One Member provided an editorial improvement to S14.1.2.

c) Points of Discussion

- On Member further proposed that all types of gravity tanks under 5 m^3 (small integral gravity tanks inclusive) should be exempted from S14. No discussion was pursued by GPG. However, ABS pointed out that SOLAS II-1/Reg.14.4 requires hydrotesting of double bottom testing and II-1/14.5 requires tanks forming part of subdivision bulkheads to be likewise tested.

- This revision was limited to achieve the clarity of S14.1.2.

- After exchange of alternative wordings for the first bullet of S14.1.2, the following wording was finally agreed by GPG: S 14.1.2 -*"gravity tanks, excluding independent tanks of less than 5 m^3 in capacity."*

Remark: When incorporating the revisions of UR S14 into their Rules, Member Societies are to ignore Rev.1 (Feb 2001).

Technical Background (TB) document for UR S14 (Rev.7 Dec 2022)

1 Aims

UR S14 Rev. 6 'Testing Procedures of Watertight Compartments' provides tank testing requirements which were in part developed to address the SOLAS tank testing requirements however UR S14 Rev. 6 is also applicable to small non-SOLAS ships and yachts. Hence, it was decided to investigate the applicability of the SOLAS requirements as well the appropriateness of the tank testing requirements given in UR S14 Rev. 6 to small ships.

2 Applicability of UR S14 Rev. 6

According to Vol 1 IACS General Procedures Part A;

Generally, and unless stated otherwise, IACS's scope of interest and activity is with respect to vessels of over 100 GT of whatever type, self-propelled or not, restricted or unrestricted service; except for "inland waterway" vessels, military vessels, and other government ships operated for non-commercial purposes.

Hence, UR S14 Rev. 6 is applicable to all passenger ships and cargo ships over 100 GT (except IWW and Great Lakes) including work boats, yachts, high speed craft, barges, pontoons, fishing vessels and domestic ferries and irrespective of the material of construction.

3 Review of Statutory requirements

3.1 Applicability of SOLAS

The applicability of the SOLAS tank testing requirements are as follows;

- All passenger ships engaged on international voyages (carries more than 12 passengers)
- Cargo ships greater than or equal to 500 GT engaged on international voyages

SOLAS does not apply to;

- Ships of war and troopships
- Cargo ships of less than 500 GT
- Ships not propelled by mechanical means
- Wooden ships of primitive build
- Pleasure yachts not engaged in trade
- Fishing vessels

The SOLAS tank testing requirements are given in Pat B-2, Regulation 11;

1 Testing watertight spaces not intended to hold liquids and cargo holds intended to hold ballast by filling them with water is not compulsory. When testing by filling with water is not carried out, a hose test shall be carried out where practicable. This test shall be carried out in the most advanced stage of the fitting out of the ship. Where a hose test is not practicable because of possible damage to machinery, electrical equipment insulation or outfitting items, it may be replaced by a careful visual examination of welded connections, supported where deemed necessary by means such as a dye penetrant test or an ultrasonic leak test or an equivalent test. In any case a thorough inspection of the watertight bulkheads shall be carried out.

2 The forepeak, double bottom (including duct keels) and inner skins shall be tested with water to a head corresponding to the requirements of regulation 10.1. (Head of water up to the bulkhead deck of passenger ships and the freeboard deck of cargo ships.)

3 Tanks which are intended to hold liquids, and which form part of the watertight subdivision of the ship, shall be tested for tightness and structural strength with water to a head corresponding to its design pressure. The water head is in no case to be less than the top of the air pipes or to a level of 2.4 m above the top of the tank, whichever is the greater.

4 The tests referred to in paragraphs 2 and 3 are for the purpose of ensuring that the subdivision structural arrangements are watertight and are not to be regarded as a test of the fitness of any compartment for the storage of oil fuel or for other special purposes for which a test of a superior character may be required depending on the height to which the liquid has access in the tank or its connections.

3.2 Background to the SOLAS requirements

The requirement to test tanks originally introduced into the 1914 draft SOLAS Convention (which was not ratified due to the outbreak of World War I) and the requirements were as follows;

Double bottoms, deep tanks and all compartments intended to hold liquids shall be tested with water at least to a head eight feet above the top of the tank or to the load waterline, whichever is greater.

Unfortunately, in the Minutes of Proceedings there is no background provided as to why 8 ft was selected as a suitable margin for the structural testing. However, at the time the British Board of Trade were investigating the strength of bulkheads and had authorised the construction of experimental watertight bulkheads with the aim of 'providing a proper margin of resistance'. These experiments are described in 'Strength of Watertight Bulkheads' by J. Foster (read at the spring meeting of the 57th session of the Institution of Naval Architects, 1916).

It seems that for the majority of bulkheads, the maximum deflection recorded before the bulkheads started experiencing plastic deformation was at around 8ft of additional head above the top of the bulkhead. Some bulkheads started failing earlier and the paper discusses changes made to the bulkhead (bracket design etc.) to improve the performance. Although not explicitly stated it is clear that the British Board of Trade decided that 8ft was a suitable margin; partly because it was largely achievable for existing bulkhead designs but also because 8ft was the standard height of a tween deck. It should be noted that the smallest bulkhead tested had a height of 13.75 ft which is approximately 4.2 metres and this bulkhead was one of the ones requiring reinforcement. The smallest height bulkhead where 8ft did not cause damage was 17 ft which is approximately 5.2 metres. Hence, it can be concluded that very small ships were not considered when the standard was set.

This is relevant for the 1914 draft SOLAS convention because the committee drafting the convention was led by Sir Archibald Denny who was British and there is mention of the British Board of Trade submitting a report on the strength of bulkheads to the committee. It had already been decided that it was too complicated to mandate bulkhead scantlings in the SOLAS convention and to rely on Class requirements but a test to 'an appropriate head' had been proposed. It seems likely that the British pushed for the test head to be 8 ft in order to guarantee their proposed 'margin of resistance'.

it is interesting to note that the 1929 SOLAS Convention states the following;

Tanks which are intended to hold liquids, and which form part of the subdivision of the ship, shall be tested for tightness with water to a head up to the deepest subdivision waterline or to a head corresponding to two-thirds of the depth from the top of keel to the margin line in way of the tanks, whichever is the greater; provided that in no case shall the test head be less than 3 feet above the top of the tank.

When viewed in the light of the extensive damage cases arising from World War I, one explanation could be that the reduced margin was informed by real world data. It is possible that the original intention of the SOLAS requirements was to ensure the survival of the watertight subdivision in the event of flooding and that might be why the margin of safety was reduced to 3 ft above the top of the tank rather than 8 ft. This is borne out by the 1948 SOLAS Convention which retained the above requirement and went on to state that;

The tests referred to in paragraphs (d) and (e) are for the purpose of ensuring that the subdivision structural arrangements are watertight and not to be regarded as a test of fitness of any compartment for the storage of oil fuel or for other special purposes for which a test of a superior character may be required depending on the height to which the liquid has access in the tank or its connections.

The above requirements were retained in both the 1960 SOLAS Convention and the 1974 SOLAS Convention. The current requirements were introduced in MSC 216(82) in 2006; the technical background for the 2.4 metres is given in SLF 44-3-4 where it is stated that IACS UR S14 was used as the basis for the 2.4 metres and the following is noted;

It is to be noted that the proposed margin of 2.4 m might be too stringent in the case of smaller ships and will need further discussion.

However, it appears that no further discussions took place on the appropriateness of the above requirements and they were accepted on the basis of being class requirements and to a higher standard than SOLAS. The technical background for the original version of UR S14 is not available however prior to 1996 some class societies were using 2.4 metres (or similar) in their Ship Rules although not in their other Rule sets. It is important to note that the application of this test pressure to small ships would have been based on a set of assumptions concerning required safety margins and it is possible that an individual class society might have been accounting for the size of tank elsewhere in their rules when deriving the scantlings of bulkheads.

3.3 Other statutory requirements

A review of other statutory requirements was carried out to determine what their tank testing requirements are, and these are as follows;

The Passenger Yacht Code (PYC)

Applies to yachts carrying between 12 and 36 passengers; the tank testing requirements are given in Part III, Regulation 4.13;

(1) Testing of watertight spaces not intended to hold by filling them with water is not compulsory but where such testing is not carried out-

- *(a) a hose test shall be carried out where practicable;*
- *(b) this test shall be carried out in the most advanced stage of the fitting out of the ship;*
- *(c) where a hose test is not practicable because of possible damage to machinery, electrical equipment insulation or outfitting items, it may be replaced by a careful visual examination of welded connections, supported where deemed necessary by means such as a dye penetrant test or an ultrasonic leak test or an equivalent test; and*
- *(d) in any case a thorough inspection of the watertight bulkheads shall be carried out.*

(2) *The forepeak, double bottom (including duct keels) and inner skins shall be tested with water to a head corresponding to the requirements of section 4.12(1).* (head of water up to the bulkhead deck)

(3) *Tanks which are intended to hold liquids, and which form part of the watertight subdivision of the ship, shall be tested for tightness and structural strength with water to a head corresponding to its design pressure and the water head is in no case to be less than the top of the air pipes or to a level of 2.4 metres above the top of the tank, whichever is the greater.*

Essentially, the requirements are the same as SOLAS.

The Large Commercial Yacht Code (LY3)

Applies to yachts greater than 24 metres which are in commercial use for sport or pleasure, carry no cargo and no more than 12 passengers. The requirements for watertight bulkheads refer out to Class requirements however yachts subject to LY3 which are greater than 500 GT are also subject to SOLAS.

High Speed Craft Code, 2000

Applies to high speed craft engaged in international voyages and;

- Passenger craft which do not proceed in the course of their voyage more than four hours at 90% of maximum speed from a place of refuge; and

- Cargo craft of 500 gross tonnage and upwards which do not proceed in the course of their voyage more than eight hours at 90% of maximum speed from a place of refuge when fully laden.

The HSC Code does not contain any explicit requirements for tank testing however given that it is general principle that for aspects which are not covered by IMO Codes, reference is to be made to the relevant IMO Conventions, then the SOLAS requirements are applicable to vessels which are subject to the HSC Code.

MGN 280 – Small Vessels in Commercial Use for Sport or Pleasure, workboats and Pilot Boats – UK

Applies to UK vessels up to 24 metres Load Line length which are engaged at sea in activities on a commercial basis, which carry cargo and/or not more than 12 passengers, or provide a service in which neither cargo nor passengers are carried, or are UK pilot boats of whatever size.

There are no explicit tank testing requirements however;

The design of hull structure and construction should provide strength and service life for the safe operation of a vessel, at its service draught and maximum service speed, to withstand the sea and weather conditions likely to be encountered in the intended area of operation.

Guidelines for Survey of Fishing Vessels 15 m Length Overall and Over – Ireland

Applies to fishing vessels which are over 15 metres in length, and which are not classed.

Part B, Section 1.1 stipulates;

Boundaries of double bottom, deep, ballast, peak and other tanks are to be tested with a head of liquid to the top of air pipes, except that fuel oil and lube oil tanks may be tested to the highest point that liquid will rise under service condition. Tank testing of fuel oil, lube oil *and fresh water tanks may be specially considered based on satisfactory external examination of the tank boundaries.*

Large Fishing Vessel Inspection Regulations – Canada

Applies to fishing vessels greater than 24.4 metres or 150 GT that are not sailing ships.

The tank testing requirements are given in Regulation 18;

Before a steel fishing vessel is launched, the compartments within the main hull shall, before the cementing is commenced, be subjected to hose or pressure tests as follows:

(a) double bottoms that are not to be used for the carrying of oil shall be tested to a head of water equal to the maximum head that can be experienced in service;

(b) deep tanks and peak tanks used for carrying water, and deep tanks and double bottom tanks arranged for carrying oil fuel shall be tested to a head of water equal to the maximum head to which the tanks can be subjected in service, but not less than 2.44 m above the crown of the tanks where the moulded depth to the strength deck exceeds 4.88 m, and 915 mm where the moulded depth does not exceed 3.05 m; intermediate heads may be obtained by interpolation between 4.88 and 3.05 m;

(c) peak bulkheads that do not form the boundaries of tanks shall be tested by filling the peaks with water to the level of the load water line;

(d) watertight bulkheads, including recesses and watertight flats, watertight tunnels, weatherdecks and waterways, shall be hose tested; the pressure of water in the hose shall not be less than 207 kPa;

(e) watertight doors shall be tried under working conditions and hose tested; the pressure in the hose shall not be less than 207 kPa.

Construction and Outfit Standards – Fishing Vessels of less than 15 metres – UK

Applies to commercial fishing vessels of less than 15 metres length overall

The tank testing requirements are given in Part 1, Section 1.7

Freshwater, ballast, oil fuel, and other tanks, void spaces and collision bulkheads should be either water or air pressure tested at the discretion of MCA or the Fishing Vessel Certifying Authority.

Where water tested, the head in integral tanks is to be not less than 2.4m above the tank top or to the overflow point whichever is the greater.

Where tested by air pressure, the test pressure is to be no greater than 0.2kg/cm2 (2.85 psi).

Fish stowage tanks and vivier tanks are to be tested by filling with water to overflow level.

Japan Craft Inspection Organisation

Applies to all craft less than 24 metres; tanks are to be tested either hydrostatically to the top of the overflow or with an air test to 0.025 MPa.

ISO 21487 – Small Craft – Permanently Installed Petrol and Diesel Fuel Tanks

Applies to craft less than 24 metres.

Petrol fuel tanks are to be leakage tested in accordance with 7.2.1. (Pressure of 20 kPa)

Petrol fuel tanks shall be pressure tested in accordance with 7.3. Metallic tanks may as an alternative be pressure tested in accordance with 7.2.2 using a pressure which is the higher of the following;

- *30 kPa; or*
- *1.5 times the highest hydrostatic pressure to which the tank may be subjected in service (maximum fill-up height above the tank top) plus 10 kPa*

Division 242 Recreational Vessels with a Hull Length of 24 m or more and of Gross Tonnage of less than 3000 – France

There are no explicit tank testing requirements however the requirements for bulkheads refer out an approved body in Article 242-3.04;

Sealed bulkheads shall meet the requirements of this Article. Their positions shall ensure that
the vessel remains sufficiently buoyant to meet damage stability requirements, where appropriate.

Their resistance, watertightness and the openings and gangways installed therein shall meet the requirements of an approved body.

Other Flag Requirements

Although many Flags have requirements for small vessels, most of these refer out to Class requirements for tank construction and testing and do not have their own explicit requirements.

3.4 Relevance of Small Boat Requirements

To determine the relevance of the national and international standards it is necessary to relate the lower limit of UR S14 (100 GT) to the lower limit used by the national and international standards which are primarily length based. The tonnage certificates (both ITC 69 and Certificate of Measurement) issued by Lloyd’s Register’s Southampton Office between 2015 and March 2021 were analysed and the Gross Tonnage (up to 700 GT) was plotted against length. As can be seen from Figure 1, the least ship length for a Gross Tonnage greater than 100 GT is approximately 12 metres. Hence, all of the small boat standards identified in the standards review will be taken into account when developing appropriate tank testing requirements.

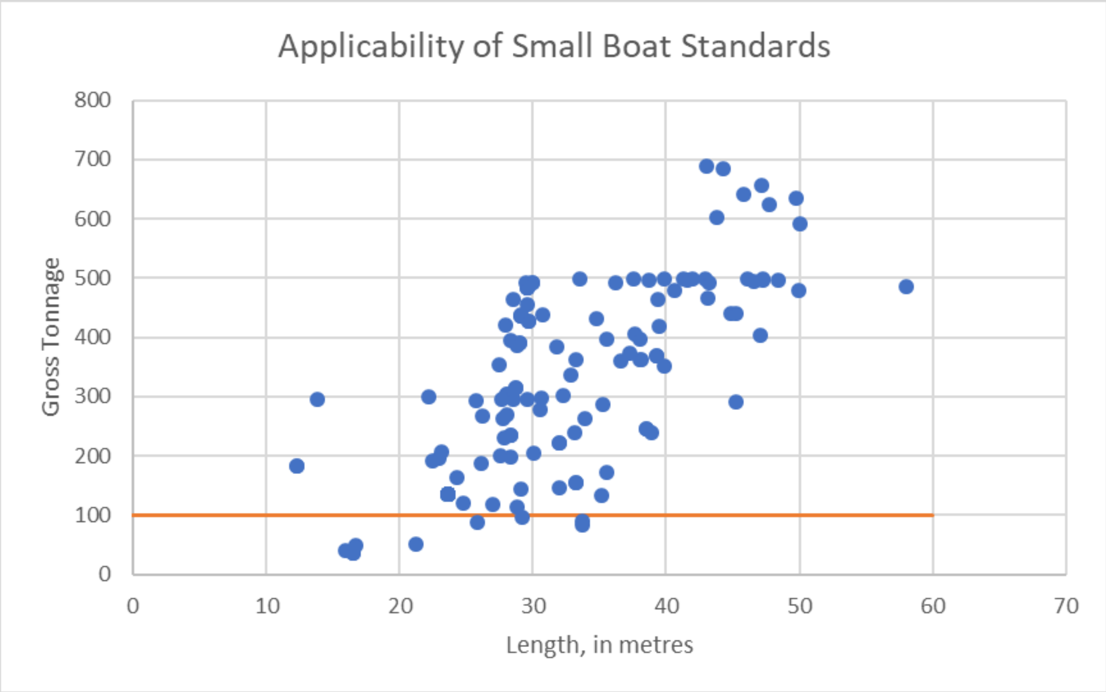

Figure 1

3.5 Conclusion

A review of the various standards shows that the various ship types can be categorised as follows;

- International cargo ships > 500 GT
- International cargo ships <= 500 GT
- Domestic cargo ships > 100 GT
- International passenger ships > 100 GT
- Domestic passenger ships > 100 GT
- Fishing vessels > 100 GT
- International passenger yachts > 100 GT
- Domestic passenger yachts > 100 GT
- International commercial yachts > 500 GT
- International commercial yachts <= 500 GT
- Domestic commercial yachts > 100 GT
- Pleasure yachts > 100 GT
- International cargo HSC > 500 GT
- International cargo HSC <= 500 GT
- Domestic cargo HSC > 100 GT
- International passenger HSC > 100 GT
- Domestic passenger HSC > 100 GT
- Barges and pontoons > 100 GT
- Domestic workboats > 100 GT

All of these vessel types are covered by UR S14 (for GT > 100) however it should be noted that SOLAS only applies to the following vessels;

- International cargo ships > 500 GT
- International passenger ships
- International passenger yachts
- International commercial yachts > 500 GT

- International cargo HSC > 500 GT
- International passenger HSC

In practical terms there is no difference between a ship engaged on an international voyage and one engaged on a domestic voyage when it comes to the strength of the bulkhead; the reason the SOLAS requirements are limited to ships engaged on international voyages is due to the IMO having no jurisdiction over domestic vessels. Furthermore, ships engaged on international voyages are no more likely to experience a flooding event than domestic vessels (indeed it could be argued that the reverse is true as the likelihood of grounding or collision increases for ships close to the coastline/port).

From a 'strength of bulkhead point of view there is no difference between a cargo ship and a passenger ship and hence there is no real justification for having different tank testing requirements for a cargo ship ≤ 500 GT than for a domestic passenger ship less than 500 GT. Therefore, the question is not so much about how strong the bulkhead should be but what is the acceptable risk to the ship in the event of the bulkhead failing

It is clear that for small cargo ships the IMO is prepared to accept a greater degree of risk which they are not prepared to accept for small passenger ships engaged on international voyages. Furthermore, since no flags have introduced mandatory tank testing requirements for large domestic passenger ships let alone small passenger ships it must be concluded that the main driver for there being tank testing requirements for all passenger ships engaged on international voyages is the combination of passengers and the international voyage. Passengers on ships in international waters are less likely to be rescued quickly in the event of a casualty and hence the risk to life is higher. Hence, there is no reason to impose stricter requirements for domestic passenger ships than for cargo ships.

4. Investigation into test pressure

4.1 Air pipe and overflow arrangements

When determining the test head, IACS UR S14 refers to the height of the overflow whereas SOLAS refers to the height of the air pipe. This difference is critical as Class Rules treat overflows and air pipes differently; essentially an overflow is fitted where the height of the air pipe exceeds the pressure head to which the tank has been designed. Hence the height of the overflow can be lower than the height of the air pipe; especially for double bottom tanks where an overflow tank can be used. It also important to note that the overflow is not necessarily an overflow pipe. In fact, the overflow is any device used to prevent the overfilling of a tank and can be an airpipe, overflow pipe, intermediate tank or high-level alarm.

In many classification rules, the height of the overflow is used as the basis for the design head, but when a tank has an overflow pipe and an air pipe, as in Figures 2 and 3 which give an example of a typical overflow pipe and air pipe arrangement, it is not clear which should be used for the basis of the test pressure. Therefore, consideration needs to be given to determining the highest point to which the liquid will rise in service. For example, for cargo tanks which could have a vent and an overflow pipe, the presence of high-level alarms and cargo filling procedures means that overfilling the tank is not likely to occur. The governing criteria for these tanks is hence the requirement to test to 2.4 metres above the top of the tank.

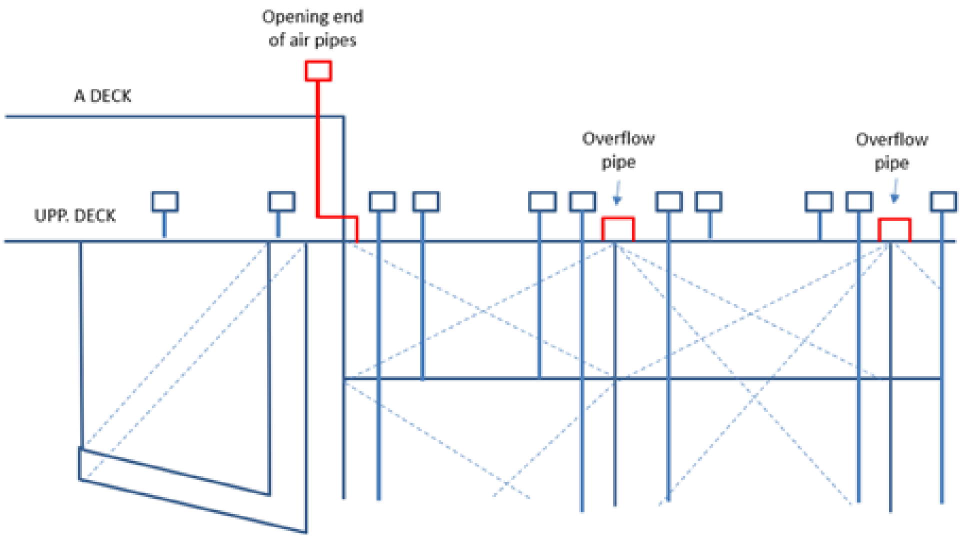

Figure 2

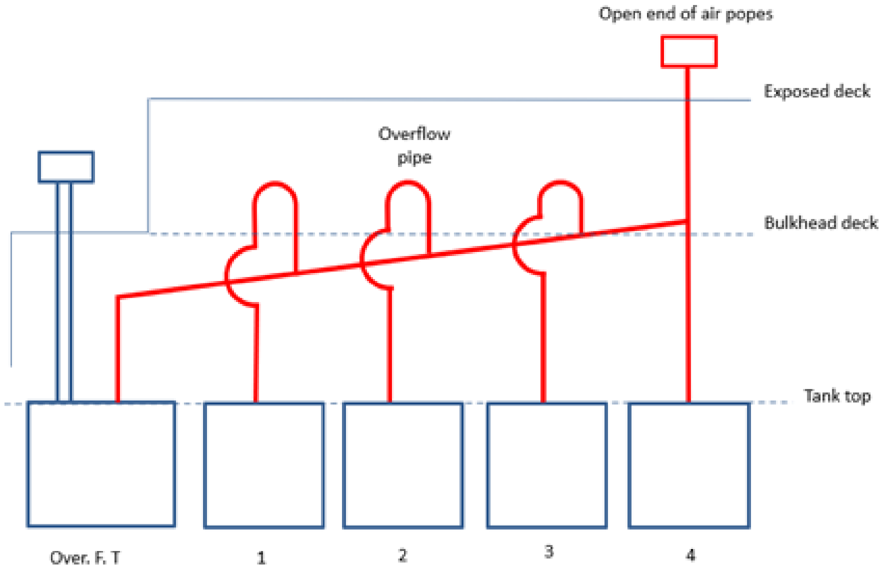

Figure 3

As an alternative to the standard overflow arrangement, it is also possible to use an intermediate tank to reduce the design loads for double bottom tanks, see Figure 4 below.

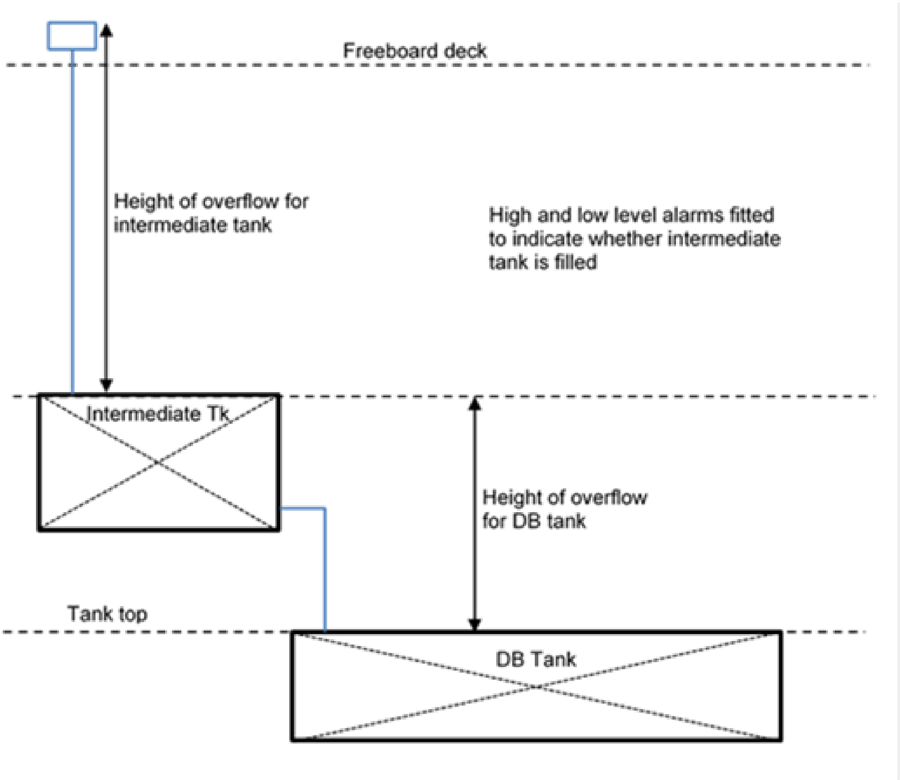

Figure 4

The design pressure for the double bottom tank is based on the distance to the top of the intermediate tank and the design pressure for the intermediate tank is be based on the height of the air pipe. In this case the "overflow pipe" referred to in UR S14 is not the line connected to the double bottom tank but the opening of the line leading onto the freeboard deck, which is the reference point for the test head. This case is rare and is less relevant for small ships which are unlikely to have this arrangement.

In cases where the height of the air pipe or overflow above the crown of the tank is less than 2.4m, UR S14 and SOLAS require a hydrostatic test with a minimum test pressure of 2.4m. The concern here is that for small ships with small tanks, the test pressure is significantly larger in relation to the anticipated in-service loads and hence design pressure than it is for large ships. This is primarily relevant for wing tanks and cargo tanks as for double bottom and small engine room tanks, the height of the overflow will normally exceed 2.4 metres.

It is concluded that difference between the design pressure and the test pressure is only an issue for small ships in the case of wing tanks and cargo tanks where the crown of the tank corresponds to the bulkhead deck and therefore the overflow pipe is less than 2.4m. This arrangement will be used for the investigation into the relationship between test pressure and design pressure.

4.2 Design pressure v test pressure

The relationship between the test pressure and the design pressure was investigated to determine the appropriate minimum test pressure for small tanks.

It is the responsibility of the class society to ensure that the design pressure and associated stress level used to obtain bulkhead scantlings is such that the tank will not fail subjected to the test pressure. However, the means by which this is achieved varies. Some class societies consider the test pressure as a separate load case with its own allowable stress factor. Other class societies relate the design pressure to the test pressure and some do not consider the test pressure at all and instead use a lower stress factor (inverse of safety margin) for the design pressure in order to achieve a safety margin which will cover tank testing. This variation in approach can be seen in Figure 6.

In order to determine the depth of ship (a more useful measure for the purposes of tank test pressures than ship length) which generally corresponds to 500 GT, the gross tonnages reviewed in Section 3.4 were re-analysed. As Figure 5 shows, the majority of ships with a gross tonnage less than 500 GT also have a depth less than 6 metres. Therefore, the range of depths considered will be limited on this basis.

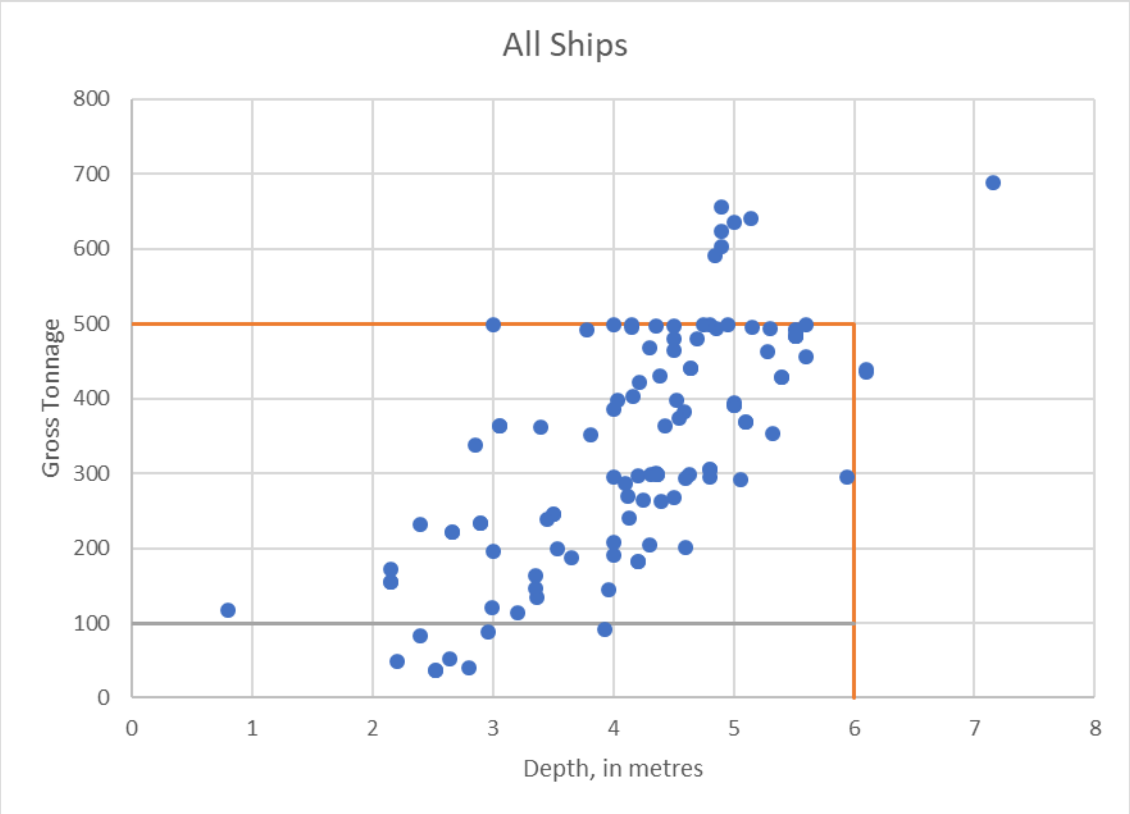

Figure 5

The plate thicknesses required by each IACS Member for ships with a depth up to 6 metres (small ships) were calculated based on both the design pressure and the required test pressure; the height of the tank was assumed to be the same as the depth of the ship. The resulting plate thicknesses were then used to reverse engineer the CSR plating formula.

The CSR plate formula is as follows:

$$t = 0.0158\alpha_p b\sqrt{\frac{|P|}{\chi C_a R_{eH}}}$$

Rearranging for C_a (stress factor) gives:

$$C_a = \frac{|P|(0.0158\alpha_p b)^2}{\chi R_{eH} t^2}$$

By calculating the required plate thickness for a given design pressure it is possible to first obtain the stress factor associated with the design pressure and then the stress factor associated with the test pressure. For Class Societies where the test pressure is not directly considered when calculating the required plate thickness, the plate thickness associated with the design pressure was used for both the design and test cases.

The ratio of the test case stress factor to the design case stress factor was then calculated and plotted. Note that although a simpler method to obtain the utilisation ratio would have been to just divide the test pressure by the design pressure this would not have accounted for the approach where the test pressure has its own stress factor.

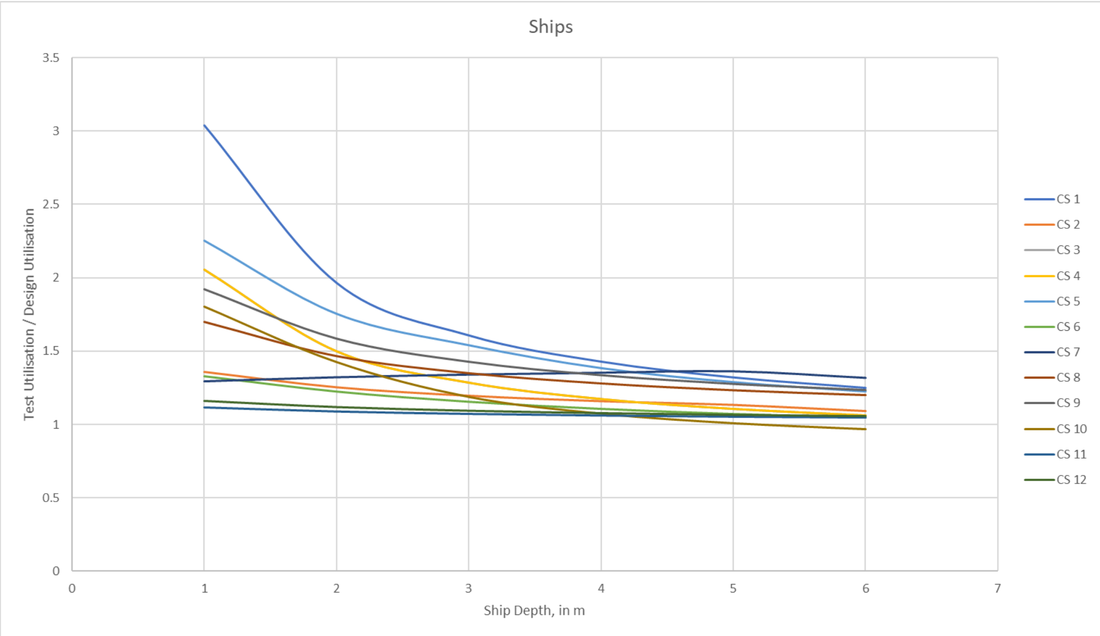

Figure 6

As Figure 6 shows the utilisation ratio generally increases as the ship depth reduces (although in most cases the stress does not exceed yield). This is because the smaller tanks the test pressure is much greater in comparison to the design pressure. Even where a higher stress factor is used in association with the test pressure, a slight increase in the utilisation ratio can be seen (e.g. CS 12) where the utilisation at 1 metre is 1.06 and at 6 metres is 1.16). This suggests that in order to account for tank testing, Class Societies have had to increase bulkhead scantlings generally and for small tanks in particular.

The question then becomes whether it is reasonable to firstly base all tank scantlings on the stress factor required for a small tank to not exceed yield and secondly to require a higher level of safety for small tanks than for large tanks. Ultimately, it does not make sense for a work boat to be required to have a higher safety level than an oil tanker or passenger ship and hence it seems reasonable to set the test pressure such that the increase in stress is similar to that seen for ships where the SOLAS test pressure is applicable. To determine what this test pressure should be, the average utilisation ratio across all IACS members was calculated for a 6-metre depth ship (the smallest size ship to which SOLAS is generally applicable). This utilisation ratio was calculated to be 1.14; i.e. for a ship with a depth of 6 metres, the acceptable increase in stress in the plate is 14%. This compares well to the CSR where the utilisation ratio is 1.11 (the CSR uses the same allowable stress for the tank testing load case as for the static load case).

4.3 Proposed test pressure

It is proposed to use a minimum test pressure head which is linked to the depth of the ship where for ships where depth is less than 6 metres, the minimum test pressure head will be calculated as follows in order to achieve a target utilisation of around 1.1;

$$Test\ pressure = 0.3D + 0.76$$

or 2.4 metres whichever is lesser.

This results in the following test heads;

Depth of Ship	Min test head
6 metres	2.4 metres
5 metres	2.26 metres
4 metres	1.96 metres
3 metres	1.66 metres
2 metres	1.36 metres
1 metres	1.06 metres

Note that in no case can the test pressure be less than the minimum airpipe height of 0.76 metres.

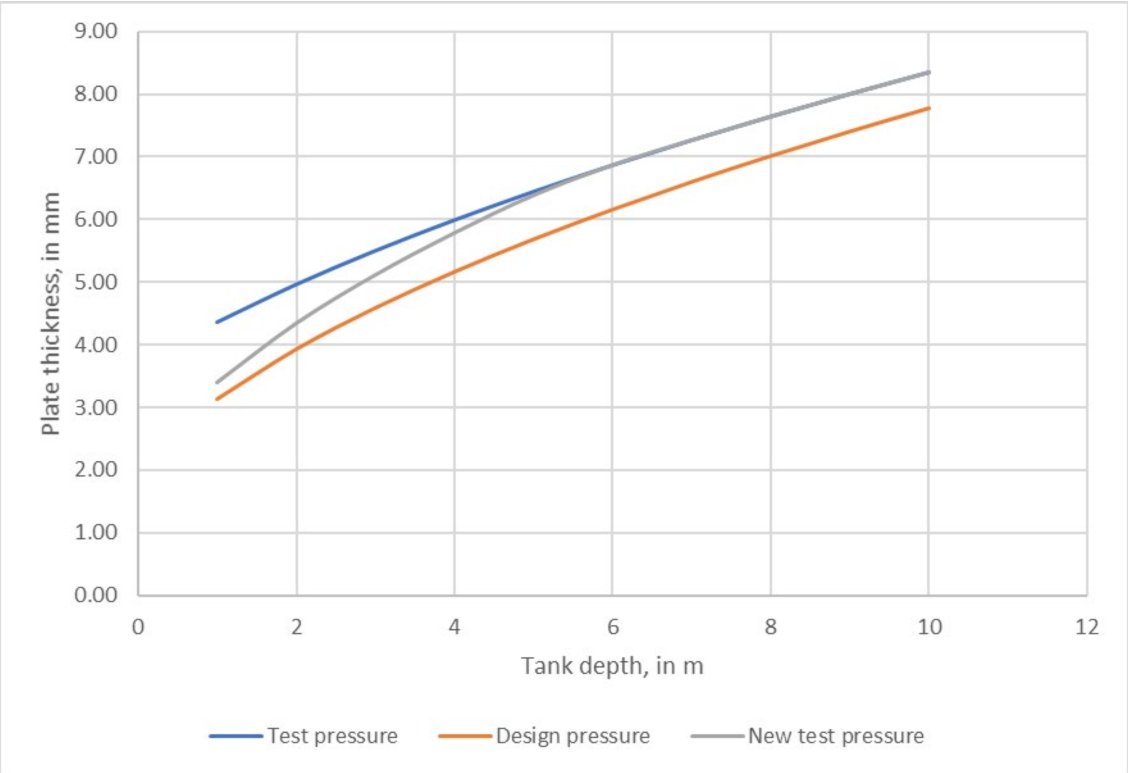

Figure 7

To confirm the resulting stress levels, the net plate thicknesses required by the CSR BC & OT for transverse bulkheads were calculated for a spacing of 650 mm, an aspect ratio of 1 and $C_{a\text{-}max} = 0.8$.

D (m)	Design p (kN/m^2)	Design t (mm)	Test p (kN/m^2)	Test t (mm)	Ratio	New test p (kN/m^2)	New test t (mm)	Ratio
10	107.6	7.77	124	8.34	1.07	124	8.34	1.07
9	97.6	7.40	114	8.00	1.08	114	8.00	1.08
8	87.6	7.01	104	7.64	1.09	104	7.64	1.09
7	77.6	6.60	94	7.26	1.10	94	7.26	1.10
6	67.6	6.16	84	6.86	1.11	84	6.86	1.11
5	57.6	5.68	74	6.44	1.13	72.6	6.38	1.12
4	47.6	5.17	64	5.99	1.16	59.6	5.78	1.11
3	37.6	4.59	54	5.50	1.20	46.6	5.11	1.11
2	27.6	3.94	44	4.97	1.26	33.6	4.34	1.10
1	17.6	3.14	34	4.37	1.39	20.6	3.40	1.08

This results in a utilisation ratio of 1.12 for a 5 metre tank depth and 1.08 for a 1 metre tank depth. The corresponding reduction in plate thickness is largely insignificant for the 4 and 5 metre tank depths but is 0.5 mm for the 3 metre tank depth and 1 mm for the 1 metre tank depth (after rounding).

5 Review of survey practices

As part of the investigation into whether the tank testing requirements given in UR S14 Rev. 6 are appropriate for small ships, information was obtained from each IACS member concerning the following:

- Practical limitations of tank testing
- Types of tests conducted
- Failures due to overloading
- Failures due to tank material
- Smallest tank size tested

When the failures due to tank testing were investigated it was found that the failure rate during structural tank testing was less than 5%. A couple of cases concerned the failure of the equipment, e.g. the pressure gauge failed and so the applied test pressure was greater than required. Other examples relate to the tank testing not being carried out correctly however, the majority of failures appear to be because the bulkheads were too weak.

For the majority of ships, the new construction tank testing requirements given in UR S14 are satisfactory however for smaller tanks (and hence small ships), in practice the surveyors are waiving the structural test and relying on the leak test only. It is therefore proposed to introduce a lower limit for the size of tank which needs to be structurally tested of a volume of 2m^3.

For composites, issues were reported relating to the test procedures however due to the wide variation in composites and construction methods, it would be very difficult to include a prescriptive requirement which covers all composite tanks. Instead, a statement will be included in UR S14 that test procedures need to be discussed and agreed with the composite manufacturer in order to achieve equivalency to the test required for steel tanks.

UR S17 "Longitudinal Strength of Hull Girder in Flooded Condition for Non-CSR Bulk Carriers"

Summary

Clarification that this UR S17 is applicable to self-unloading bulk carrier only if the unloading system maintains the watertightness during seagoing operations.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev.10 (Mar 2019)	04 March 2019	1 July 2020
Rev.9 (Apr 2014)	17 April 2014	1 July 2006
Rev.8 (May 2010)	24 May 2010	1 July 2006
Corr.1 (Oct 2009)	15 October 2009	-
Rev.7 (Feb 2006)	1 February 2006	1 July 2006
Rev.6 (July 2004)	5 July 2004	-
Rev.5 (June 2003)	20 June 2003	1 July 2003

NEW (1997)	8 September 1997	1 July 1998

- **Rev.10 (Mar 2019)**

1 Origin for Change:

☒ Request by GPG 15139_IGh dated 18/9/2016

2 Main Reason for Change:

The applicability of ESP to the self-unloading bulk carriers (SUBC) leads to the GPG request to identify the UR S which are NOT applicable to SUBC.

The Hull Panel decided to insist on the fact that the flooding conditions considered in the UR S17 and 18 are relevant for each cargo hold if the unloading system watertighness is maintained during the seagoing conditions.

3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

4 History of Decisions Made:

Discussion at the HP meeting in 2016

Analysis by Hull Panel Chair
Discussion and decision by the Hull Panel in 2018

5 Other Resolutions Changes:

Within this study for SUBC application: UR S18, 21A and 30.

6 Any hinderance to MASS, including any other new technologies:

None

7 Dates:

Original Proposal:	14 June 2018	Made by:	Hull Panel
Panel Approval:	11 December 2018		
GPG Approval:	04 March 2019 (Ref. 15139_IGl)		

- **Rev.9 (Apr 2014)**

.1 Origin for Change:

☑ Suggestion by IACS member

.2 Main Reason for Change:

To clarify the scope of application of UR S17, S18 and S20.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None.

.4 History of Decisions Made:

It was decided not to assign implementation dates for versions Corr.1 (Oct 2009), Rev.8 (May 2010) and Rev.9 (April 2014) because these revisions/corrections are retrospectively applicable from 1 July 2006 i.e. the assigned date of implementation of Rev.7 (Feb 2006).

.5 Other Resolutions Changes

UR S18 and UR S20

.6 Dates:

Original proposal: 19 Feb 2014, made by Hull Panel Chair
Panel submission to GPG: 01 Apr 2014
GPG Approval: 17 April 2014 (14044_IGb)

- **Rev.8 (May 2010)**

.1 Origin for Change:

☑ Based on IACS Requirement *(Common Structural Rules for Bulk Carriers and Double Hull Oil Tankers)*

.2 Main Reason for Change:

Following the introduction of the IACS Common Structural Rules for Bulk Carriers and Double Hull Oil Tankers, Hull Panel were tasked to review all the UR S files to consider whether or not they are applicable to ships covered by the CSR.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None.

.4 History of Decisions Made:

After review it was decided that for CSR bulk carriers the requirements of UR S17 are superseded by those of the Common Structural Rules and therefore do not apply.

UR S17 is not applicable for CSR oil tankers.

.5 Other Resolutions Changes

All UR S files, except UR S8, S9, S15, S16, S19, S22, S23, S30 and S31.

.6 Dates:

Original proposal: *2007, made by Hull Panel Task 50*
Panel submission to GPG: *19 April 2010*
GPG Approval: *24 May 2010 (Ref. 10051_IGd)*

- **Corr.1 (Oct 2009)**

.1 Origin for Change:

☑ Suggestion by IACS member

.2 Main Reason for Change:

In January 2006, GPG did not reach consensus on a single uniform application date for the revisions of URs S17, S18 and S20, but did agree, by 2/3 majority, to an application statement reading *"Revision [x] of this UR is to be applied by IACS Societies to ships contracted for construction from a date commencing not later than 1 July 2006"* that was intended to mean that the revised URs S17, S18 and S20 were to be applied by IACS Societies to ships contracted for construction on or after a date dd/mm/2006 (to be chosen by each Society) that had to be not later than 1 July 2006.

However, the application statement, as it was written, was not clear because it could be understood that the revised URs were applicable to ships contracted for construction before 1 July 2006 only and not on or after 1 July 2006.

In order to make the application statement clearer and user-friendly, in October 2009 - when the circumstances that brought to the adoption of that peculiar wording were no longer valid - GPG agreed to change it to read: *"Revision [x] of this UR is to be applied by IACS Societies to ships contracted for construction on or after 1 July 2006"*.

.3 History of Decisions Made:

Technical Background to changes proposed in respect of UR's S1A, Annex 2 to S1A, S12, S17, S18, S19, S20 and S22

The objective of the proposal is to reflect the IMO interpretation of 'single side skin construction' in the above mentioned Unified Requirements for bulk carriers. The Working Party on Strength discussions were unable to yield unanimous agreement and the following matters remain unresolved:

- The titles for UR's S17, S18, S19, S20 and S22 include the wording 'single side skin'. It was generally considered that this wording should now be deleted as the text clearly defines the scope of application and refers additionally to arrangements with double side skin construction. The GL Member does not support this view on the basis that the expression 'single side skin' appears in the text of SOLAS Chapter XII. In view of this difference, the wording 'single side skin' has been enclosed in square brackets pending further consideration by GPG.

- In order to clarify how the breadth of the side shell should be measured, the phrase 'between topside tank and hopper tank' has been used in S17.1(ii) and (iii), S18.1(ii) and (iii), S19.1(ii), S20.1(ii) and (iii), and S22(ii). This was not supported by the ABS member who considers that the IMO definition of single side skin construction does not necessarily refer only to the location between topside and hopper tanks. Also this was not supported by the CRS Member who considers that MSC 89(71), which identifies that measurements are to be made perpendicular to the side shell, provides sufficient guidance**.** For these reasons, the text has been enclosed in square brackets pending further consideration by GPG.

In addition to the above, two other issues have been raised as follows:

- The ABS Member has requested that the following be considered in respect of the deletion of reference to damage stability requirements from paragraph S17.1 of URS17. It is noted that the reference was originally included in order to cover a six months difference in implementation timetables between SOLAS and IACS. Although both implementation dates have now passed and the need for this provision is limited, there could still be cases where it is relevant due to a change of Class from a non-IACS Society to an IACS Society. It is, therefore, proposed that the present clause in URS17 be replaced by an alternative clause within a unified requirement more specifically related to stability requirements. Support for this proposal has been indicated by PRS, DNV, KR, RINA, CRS and LR.

- The GL Member has requested that consideration be given to amending URS20 and URS22 such that these requirements are only applicable when corrugated bulkheads are fitted. This matter has not received support from the other WP/S Members and is considered to be outside the scope of the present Task.

Submitted by WP/S Chair on 31 May 2000
(Note: For GPG action, refer to GPG Chair's message 0064dIGa, 31/7/00)

UR S17 (Rev. 5, June 2003)

Technical background

The new revision specifies more in detail which loading conditions are to be considered in UR S17, among those required in UR S1 and S1A. Intermediate loading conditions encountered during ballast water e[...]be considered in UR S17, as they are very transient conditions, and [...]n the normal and not extreme conditions.

For clarification, a note is added t[...]nentation date of [1 July 2003] stating that such bulk carriers cont[...]2003] are to comply with the applicable version of S17.

The second paragraph of S17.1 is relocated to S17.2.1 "Floodable holds".

The first sentence of the fourth paragraph of S17.3 is relocated to S17.2.2 "(Floodable conditions) Loads". The second sentence of the fourth paragraph of S17.3 is combined with the third paragraph (with "intermediate" deleted).

The last paragraph of S17.1 is deleted as this is not applicable to bulk carriers defined in S17 (Rev.5). SOLAS itself takes care of damage stability.

S17.2 is divided into S17.2.1 and S17.2.2 each with a title appropriate to the contents.

In the definition of fsfc in S17.4, "alternate loading condition" is changed to "loading conditions with empty hold(s)" to agree with S25.

<u>Note by the IACS Permanent Secretariat</u>

Council (C 47, 10-12 June 2003) decided that the implementation date of S11(Rev.3) and S17(Rev.5) should be aligned with that of UR S25 – 1 July 2003. NK will implement UR S25 from 1 January 2004. In the interim period between 1 July 2003 and 1 January 2004 NK will recommend that Owners/Builders stipulate in their contract compliance with URs S11 Rev.3 and S17 Rev.5 when UR S25 is applied.

Adopted on 20 June 2003

Technical Background

UR S17(Rev.7), UR S18(Rev.7) and UR S20(Rev.4)

(February 2006)

1. Objective

These revisions are proposed to extend the application of URs S17, S18 and S20 to bulk carriers of double side skin construction.

2. Background

The Maritime Safety Committee in the IMO, at its 76th session (MSC 76), agreed that new ships of 150 m in length and upwards, which would be of double-side-skin construction, should also comply with all the structural strength provisions of regulation XII/5 of SOLAS requiring that the ship shall have sufficient strength to withstand flooding of any one cargo hold. DE Sub-Committee, at its 47th session (DE 47), prepared a final draft text for amendments to SOLAS XII mainly by removing the words which refer to single-side skin construction from this regulation after having discussed about hold flooding scenarios. The agreed hold flooding scenario or assumption was a hypothetical one in which only a cargo hold would be flooded to the water level outside the ship in that flooded condition without flooding the double side skin spaces. Finally the amendments of SOLAS XII were approved at MSC 78 and adopted at MSC 79.

IACS UR S17, S18 and S20 have been referred to in SOLAS 1997 Conference Resolution 3, Recommendation on compliance with SOLAS regulation XII/5. Therefore GPG decided to revise these URs in line with the above-mentioned IMO decision on 10 Jan 2003 and tasked WP/S to effect the revision. Hull Panel took over the task after the reorganization of IACS in 2005.

3. Amendment

Hull Panel prepared a draft revision.

In the application of these three URs, the exemption of cargo holds of double side skin construction was deleted or explicit inclusion of double side skin construction was described. The definition of bulk carrier is referred not to the new definition of the SOLAS XII but to the definition in UR Z11.2.2.

4. Additional Note

4.1 S17.4 Strength Assessment.

The requirements regarding the shear stress in the rev 6 were relative to the side shell only of a single side skin vessel. These requirements are to be applied to the side shell and the inner

hull in case of a double side skin bulk carrier. These requirements refer to the corresponding requirements of URS11.4 (Rev 4 in force today) in which the formulations are given for ships with and without longitudinal bulkheads. Moreover the door is open in UR S11.4.1 to the possible use of a method of direct stress calculation.

4.2 S18.6 'Corrosion addition and steel renewal' and 'S20.3 Shear Capacity of the double bottom'

Attention is drawn on the fact that it will be necessary to update UR S18 and S20 after the entry into force of the JBP Rules. The corresponding corrosion additions and criteria for steel renewal will be changed.

5. Source/ derivation of proposed requirement

Hull Panel

6. Decision by voting

N.A.

26 October 2005

Prepared by Hull Panel

Notes:

2248eIGj, 8 Jan 2006: GPG concluded that the following be added to the TB.

> *"GPG unanimously approved the amended URs and TB. After several rounds of correspondence, GPG did not reach concensus on a single uniform application date for these revisions but did agree, by 2/3 majority, to an application statement to the effect that these revisions of these URs are to be applied by IACS Societies to ships contracted for construction from a date commencing not later than 1 July 2006. GPG Chairman also encouraged all Members to endeavor to apply the requirements of the amended URs in conjunction with their approval of double hull bulk carriers subject to amended SOLAS XII/5.2 by one means or another."*

* * *

Technical Background Document for UR S17 (Rev. 9, Apr 2014)

1. Objective/Scope

The objective of this revision is to clarify the scope of application of IACS UR S17, S18, and S20.

2. Source of Proposed Requirements

- IACS UI SC207
- SOLAS XII/5.1 & 5.2

3. Technical Basis and Rationale

IACS UR S18 and S20 only apply to conventional bulk carriers with cargoes having a density of 1.0 t/m^3. Ore Carriers, combination carriers, box-type bulk carriers and hybrid bulk carriers are excluded and the URs do not apply to CSR bulk carriers.

IACS UR S17 applies mostly to conventional bulk carriers as well as hybrid bulk carriers and box-type bulk carriers. Ore carriers and combination carriers are excluded and the UR does not apply to CSR bulk carriers.

However UI SC207 states that;

"Regardless of the date of contract for construction, or the cargo hold cross section configuration, of ships which shall comply with SOLAS XII/5.2, such ships are to comply with IACS Unified Requirements (UR) S17 (rev.7), S18 (rev.7) for corrugated transverse bulkheads, where fitted, and S20 (rev.4), if they do not comply with the IACS CSR for Bulk Carriers."

This means that UR S17, S18 and S20 are applicable to all of the bulk carrier types covered by SOLAS XII/5.2 with the exception of CSR bulk carriers. This includes conventional bulk carriers, ore carriers, combination carriers, box-type bulk carriers, hybrid bulk carriers and other bulk carrier types.

4. Summary of Changes

The scope of application of UR S17, S18 and S20 has been revised to incorporate the requirements of SOLAS Chapter XII, Sections 5.1 & 5.2. The exclusion of CSR bulk carriers is retained.

5. Points of Discussion

See above sections.

6. Attachments, if any

None

UR S18 "Evaluation of Scantlings of Corrugated Transverse Watertight Bulkheads in Non-CSR Bulk Carriers Considering Hold Flooding"

Summary

Clarification that this UR S18 is applicable to self-unloading bulk carrier only if the unloading system maintains the watertightness during seagoing operations.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev.10 (Mar 2019)	04 March 2019	1 July 2020
Rev.9 (Apr 2014)	17 April 2014	1 July 2006
Rev.8 (May 2010)	24 May 2010	1 July 2006
Corr.1 (Oct 2009)	15 October 2009	-
Rev.7 (Feb 2006)	1 February 2006	1 July 2006

NEW (1997)	8 September 1997	1 July 1998

Notes:
1. *The change made in Rev.1.1 was not properly reflected in the clean version in the Blue Book CD-ROM and so Corr.1 of the clean version was issued on 26 February 1999.*
2. *There were editorial errors in the first version of Rev.1 circulated and so a corrected version was circulated on 28 November 1997.*

- **Rev.10 (Mar 2019)**

1 Origin for Change:

☒ Request by GPG 15139_IGh dated 18/9/2016

2 Main Reason for Change:

The applicability of ESP to the self-unloading bulk carriers (SUBC) leads to the GPG request to identify the UR S which are NOT applicable to SUBC.

The Hull Panel decided to insist on the fact that the flooding conditions considered in the UR S17 and 18 are relevant for each cargo hold if the unloading system watertighness is maintained during the seagoing conditions.

3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

7 Dates:

Original Proposal:	14 June 2018	Made by:	Hull Panel
Panel Approval:	11 December 2018		
GPG Approval:	04 March 2019 (Ref. 15139_IGl)		

- **Rev.9 (Apr 2014)**

.1 Origin for Change:

☑ Suggestion by IACS member

.2 Main Reason for Change:

To clarify the scope of application of UR S17, S18 and S20.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None.

.4 History of Decisions Made:

It was decided not to assign implementation dates for versions Corr.1 (Oct 2009), Rev.8 (May 2010) and Rev.9 (Mar 2014) because these revisions/corrections are retrospectively applicable from 1 July 2006 i.e. the assigned date of implementation of Rev.7 (Feb 2006).

.5 Other Resolutions Changes

UR S17 and UR S20

.6 Dates:

Original proposal: 19 Feb 2014, made by Hull Panel Chair
Panel submission to GPG: 01 Apr 2014
GPG Approval: 17 April 2014 (Ref: 14044_IGb)

- **Rev.8 (May 2010)**

.1 Origin for Change:

☑ Based on IACS Requirement *(Common Structural Rules for Bulk Carriers and Double Hull Oil Tankers)*

.2 Main Reason for Change:

Following the introduction of the IACS Common Structural Rules for Bulk Carriers and Double Hull Oil Tankers, Hull Panel were tasked to review all the UR S files to consider whether or not they are applicable to ships covered by the CSR.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None.

.4 History of Decisions Made:

After review it was decided that for CSR bulk carriers the requirements of UR S18 are superseded by those of the Common Structural Rules and therefore do not apply.

UR S18 is not applicable for CSR oil tankers.

.5 Other Resolutions Changes

All UR S files, except UR S8, S9, S15, S16, S19, S22, S23, S30 and S31.

.6 Dates:

Original proposal: *2007, made by Hull Panel Task 50*
Panel submission to GPG: *19 April 2010*
GPG Approval: *24 May 2010 (Ref. 10051_IGd)*

- **Corr.1 (Oct 2009)**

.1 Origin for Change:

☑ Suggestion by IACS member

.2 Main Reason for Change:

In January 2006, GPG did not reach consensus on a single uniform application date for the revisions of URs S17, S18 and S20, but did agree, by 2/3 majority, to an application statement reading *"Revision [x] of this UR is to be applied by IACS Societies to ships contracted for construction from a date commencing not later than 1 July 2006"* that was intended to mean that the revised URs S17, S18 and S20 were to be applied by IACS Societies to ships contracted for construction on or after a date dd/mm/2006 (to be chosen by each Society) that had to be not later than 1 July 2006.

However, the application statement, as it was written, was not clear because it could be understood that the revised URs were applicable to ships contracted for construction before 1 July 2006 only and not on or after 1 July 2006.

In order to make the application statement clearer and user-friendly, in October 2009 - when the circumstances that brought to the adoption of that peculiar wording were no longer valid - GPG agreed to change it to read: *"Revision [x] of this UR is to be applied by IACS Societies to ships contracted for construction on or after 1 July 2006"*.

.3 History of Decisions Made:

See .2 above.

.4 Other Resolutions Changes

URs S17 and S20

Note:
There are no separate Technical Background (TB) documents for the original resolution (1997), Rev.1 (1997), Rev.1.1 (March 1998)/Corr.1, Rev.6 (July 2004), Corr.1 (Oct 2009), Rev.8 (May 2010) and Rev.10 (Mar 2019).

Technical Background to changes proposed in respect of UR's S1A, Annex 2 to S1A, S12, S17, S18, S19, S20 and S22

The objective of the proposal is to reflect the IMO interpretation of 'single side skin construction' in the above mentioned Unified Requirements for bulk carriers. The Working Party on Strength discussions were unable to yield unanimous agreement and the following matters remain unresolved:

- The titles for UR's S17, S18, S19, S20 and S22 include the wording 'single side skin'. It was generally considered that this wording should now be deleted as the text clearly defines the scope of application and refers additionally to arrangements with double side skin construction. The GL Member does not support this view on the basis that the expression 'single side skin' appears in the text of SOLAS Chapter XII. In view of this difference, the wording 'single side skin' has been enclosed in square brackets pending further consideration by GPG.

- In order to clarify how the breadth of the side shell should be measured, the phrase 'between topside tank and hopper tank' has been used in S17.1(ii) and (iii), S18.1(ii) and (iii), S19.1(ii), S20.1(ii) and (iii), and S22(ii). This was not supported by the ABS member who considers that the IMO definition of single side skin construction does not necessarily refer only to the location between topside and hopper tanks. Also this was not supported by the CRS Member who considers that MSC 89(71), which identifies that measurements are to be made perpendicular to the side shell, provides sufficient guidance. For these reasons, the text has been enclosed in square brackets pending further consideration by GPG.

In addition to the above, two other issues have been raised as follows:

- The ABS Member has requested that the following be considered in respect of the deletion of reference to damage stability requirements from paragraph S17.1 of URS17. It is noted that the reference was originally included in order to cover a six months difference in implementation timetables between SOLAS and IACS. Although both implementation dates have now passed and the need for this provision is limited, there could still be cases where it is relevant due to a change of Class from a non-IACS Society to an IACS Society. It is, therefore, proposed that the present clause in URS17 be replaced by an alternative clause within a unified requirement more specifically related to stability requirements. Support for this proposal has been indicated by PRS, DNV, KR, RINA, CRS and LR.

- The GL Member has requested that consideration be given to amending URS20 and URS22 such that these requirements are only applicable when corrugated bulkheads are fitted. This matter has not received support from the other WP/S Members and is considered to be outside the scope of the present Task.

Submitted by WP/S Chair on 31 May 2000
(Note: For GPG action, refer to GPG Chair's message 0064dIGa, 31/7/00)

Technical Background to changes proposed in respect of UR S18.4.1(a) (Rev. 3, 2001)

The attached change is proposed in response to a problem raised by a shipbuilder and reported by DNV in respect of the distance requirement from the edge of the stool top plate to the surface of the corrugation flange, as given in S18.4.1(a). The need for a distance of this magnitude was questioned, particularly for cases where the lower stool top plate is inclined, as this detail could encourage accumulation of dirt and moisture leading to excessive corrosion at the bulkhead to stool interface.

The matter was debated by WP/S and it was concluded that the specified distance could be reduced to alleviate the above problem while maintaining a sufficient distance to form a satisfactory weld and avoid lamella tearing of the stool top plate.

The change was agreed unanimously and no unresolved issues remain.

Submitted by WP/S Chairman on 9 January 2001

Technical Background to changes proposed with respect to UR S18.4.1(a) & S18.4.1(c)

The attached changes are proposed to achieve greater uniformity in practice among IACS members with respect to the welding requirements at the lower end of vertically corrugated bulkheads. These changes affect: (a) connections between the corrugations and the stool top plate or inner bottom plating; (b) connections between the stool side plating and the stool top and inner bottom plating; and (c) connections between the floors and the inner bottom plating in-way-of transverse corrugated bulkheads. In the proposal, the text has been modified to remove the non-specific phrase “generally to be connected to…. by full penetration welds” and to replace it with more specific requirements for each of the above mentioned locations.

Submitted by WP/S Chairman on 28 August 2001.

Technical Background
S18.4.1 in Rev. 5 of UR S18

The objective of the attached proposal is to avoid any misinterpretation of the lower stool requirement for ships less than 190 m in length. As presently written, the requirement could be interpreted that for ships less than 190 m in length a stool not complying with the requirements in S18.4.1 itself is allowed and its presence taken into account when defining the corrugation spans according to Figure 2 of UR S18. This is not the intention of the requirements.

With the occasion, the specifications of “bottom” and “top” stool have been unified to “lower” and “upper” as used in other parts of UR S18.

***

Technical Background

UR S17(Rev.7), UR S18(Rev.7) and UR S20(Rev.4)

(February 2006)

1. Objective

These revisions are proposed to extend the application of URs S17, S18 and S20 to bulk carriers of double side skin construction.

2. Background

The Maritime Safety Committee in the IMO, at its 76th session (MSC 76), agreed that new ships of 150 m in length and upwards, which would be of double-side-skin construction, should also comply with all the structural strength provisions of regulation XII/5 of SOLAS requiring that the ship shall have sufficient strength to withstand flooding of any one cargo hold. DE Sub-Committee, at its 47th session (DE 47), prepared a final draft text for amendments to SOLAS XII mainly by removing the words which refer to single-side skin construction from this regulation after having discussed about hold flooding scenarios. The agreed hold flooding scenario or assumption was a hypothetical one in which only a cargo hold would be flooded to the water level outside the ship in that flooded condition without flooding the double side skin spaces. Finally the amendments of SOLAS XII were approved at MSC 78 and adopted at MSC 79.

IACS UR S17, S18 and S20 have been referred to in SOLAS 1997 Conference Resolution 3, Recommendation on compliance with SOLAS regulation XII/5. Therefore GPG decided to revise these URs in line with the above-mentioned IMO decision on 10 Jan 2003 and tasked WP/S to effect the revision. Hull Panel took over the task after the reorganization of IACS in 2005.

3. Amendment

Hull Panel prepared a draft revision.

In the application of these three URs, the exemption of cargo holds of double side skin construction was deleted or explicit inclusion of double side skin construction was described. The definition of bulk carrier is referred not to the new definition of the SOLAS XII but to the definition in UR Z11.2.2.

4. Additional Note

4.1 S17.4 Strength Assessment.

The requirements regarding the shear stress in the rev 6 were relative to the side shell only of a single side skin vessel. These requirements are to be applied to the side shell and the inner

hull in case of a double side skin bulk carrier. These requirements refer to the corresponding requirements of URS11.4 (Rev 4 in force today) in which the formulations are given for ships with and without longitudinal bulkheads. Moreover the door is open in UR S11.4.1 to the possible use of a method of direct stress calculation.

4.2 S18.6 'Corrosion addition and steel renewal' and 'S20.3 Shear Capacity of the double bottom'

Attention is drawn on the fact that it will be necessary to update UR S18 and S20 after the entry into force of the JBP Rules. The corresponding corrosion additions and criteria for steel renewal will be changed.

5. Source/ derivation of proposed requirement

Technical Background Document UR S18 (Rev. 9, Apr 2014)

1. Objective/Scope

The objective of this revision is to clarify the scope of application of IACS UR S17, S18, and S20.

2. Source of Proposed Requirements

- IACS UI SC207
- SOLAS XII/5.1 & 5.2

3. Technical Basis and Rationale

IACS UR S18 and S20 only apply to conventional bulk carriers with cargoes having a density of 1.0 t/m^3. Ore Carriers, combination carriers, box-type bulk carriers and hybrid bulk carriers are excluded and the URs do not apply to CSR bulk carriers.

IACS UR S17 applies mostly to conventional bulk carriers as well as hybrid bulk carriers and box-type bulk carriers. Ore carriers and combination carriers are excluded and the UR does not apply to CSR bulk carriers.

However UI SC207 states that;

"Regardless of the date of contract for construction, or the cargo hold cross section configuration, of ships which shall comply with SOLAS XII/5.2, such ships are to comply with IACS Unified Requirements (UR) S17 (rev.7), S18 (rev.7) for corrugated transverse bulkheads, where fitted, and S20 (rev.4), if they do not comply with the IACS CSR for Bulk Carriers."

This means that UR S17, S18 and S20 are applicable to all of the bulk carrier types covered by SOLAS XII/5.2 with the exception of CSR bulk carriers. This includes conventional bulk carriers, ore carriers, combination carriers, box-type bulk carriers, hybrid bulk carriers and other bulk carrier types.

4. Summary of Changes

The scope of application of UR S17, S18 and S20 has been revised to incorporate the requirements of SOLAS Chapter XII, Sections 5.1 & 5.2. The exclusion of CSR bulk carriers is retained.

5. Points of Discussion

See above.

6. Attachments, if any

None.

Technical Background to changes proposed in respect of UR's S1A, Annex 2 to S1A, S12, S17, S18, S19, S20 and S22

The objective of the proposal is to reflect the IMO interpretation of 'single side skin construction' in the above mentioned Unified Requirements for bulk carriers. The Working Party on Strength discussions were unable to yield unanimous agreement and the following matters remain unresolved:

- The titles for UR's S17, S18, S19, S20 and S22 include the wording 'single side skin'. It was generally considered that this wording should now be deleted as the text clearly defines the scope of application and refers additionally to arrangements with double side skin construction. The GL Member does not support this view on the basis that the expression 'single side skin' appears in the text of SOLAS Chapter XII. In view of this difference, the wording 'single side skin' has been enclosed in square brackets pending further consideration by GPG.

- In order to clarify how the breadth of the side shell should be measured, the phrase 'between topside tank and hopper tank' has been used in S17.1(ii) and (iii), S18.1(ii) and (iii), S19.1(ii), S20.1(ii) and (iii), and S22(ii). This was not supported by the ABS member who considers that the IMO definition of single side skin construction does not necessarily refer only to the location between topside and hopper tanks. Also this was not supported by the CRS Member who considers that MSC 89(71), which identifies that measurements are to be made perpendicular to the side shell, provides sufficient guidance. For these reasons, the text has been enclosed in square brackets pending further consideration by GPG.

In addition to the above, two other issues have been raised as follows:

- The ABS Member has requested that the following be considered in respect of the deletion of reference to damage stability requirements from paragraph S17.1 of URS17. It is noted that the reference was originally included in order to cover a six months difference in implementation timetables between SOLAS and IACS. Although both implementation dates have now passed and the need for this provision is limited, there could still be cases where it is relevant due to a change of Class from a non-IACS Society to an IACS Society. It is, therefore, proposed that the present clause in URS17 be replaced by an alternative clause within a unified requirement more specifically related to stability requirements. Support for this proposal has been indicated by PRS, DNV, KR, RINA, CRS and LR.

- The GL Member has requested that consideration be given to amending URS20 and URS22 such that these requirements are only applicable when corrugated bulkheads are fitted. This matter has not received support from the other WP/S Members and is considered to be outside the scope of the present Task.

UR S20 "Evaluation of Allowable Hold Loading for Non-CSR Bulk Carriers Considering Hold Flooding"

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev.6 (Apr 2014)	17 April 2014	1 July 2006
Rev.5 (May 2010)	24 May 2010	1 July 2006
Corr.1 (Oct 2009)	15 October 2009	-
Rev.4 (Feb 2006)	1 February 2006	1 July 2006
Rev.3 (July 2004)	5 July 2004	-
Rev.2 (Sept 2000)	7 September 2000	1 July 2001
Rev.1 (1997)	4 November 1997	-
NEW (1997)	8 September 1997	1 July 1998

- **Rev.6 (Apr 2014)**

.1 Origin for Change:

☑ Suggestion by IACS member

.2 Main Reason for Change:

To clarify the scope of application of UR S17, S18 and S20.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None.

.4 History of Decisions Made:

It was decided not to assign implementation dates for versions Corr.1 (Oct 2009), Rev.5 (May 2010) and Rev.6 (Apr 2014) because these revisions/corrections are retrospectively applicable from 1 July 2006 i.e. the assigned date of implementation of Rev.4 (Feb 2006).

.5 Other Resolutions Changes

UR S17 and UR S18

.6 Dates:

Original proposal: 19 Feb 2014, made by Hull Panel Chair
Panel submission to GPG: 01 Apr 2014
GPG Approval: 17 April 2014 (Ref: 14044_IGb)

- ## Rev.5 (May 2010)

.1 Origin for Change:

☑ Based on IACS Requirement *(Common Structural Rules for Bulk Carriers and Double Hull Oil Tankers)*

.2 Main Reason for Change:

Following the introduction of the IACS Common Structural Rules for Bulk Carriers and Double Hull Oil Tankers, Hull Panel were tasked to review all the UR S files to consider whether or not they are applicable to ships covered by the CSR.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None.

.4 History of Decisions Made:

After review it was decided that for CSR bulk carriers the requirements of UR S20 are superseded by those of the Common Structural Rules and therefore do not apply.

UR S20 is not applicable for CSR oil tankers.

.5 Other Resolutions Changes

All UR S files, except UR S8, S9, S15, S16, S19, S22, S23, S30 and S31.

.6 Dates:

Original proposal: *2007, made by Hull Panel Task 50*
Panel submission to GPG: *19 April 2010*
GPG Approval: *24 May 2010 (Ref. 10051_IGd)*

- ## Corr.1 (Oct 2009)

.1 Origin for Change:

☑ Suggestion by IACS member

.2 Main Reason for Change:

In January 2006, GPG did not reach consensus on a single uniform application date for the revisions of URs S17, S18 and S20, but did agree, by 2/3 majority, to an application statement reading *"Revision [x] of this UR is to be applied by IACS Societies to ships contracted for construction from a date commencing not later than 1 July 2006"* that was intended to mean that the revised URs S17, S18 and S20 were to be applied by IACS Societies to ships contracted for construction on or after a date dd/mm/2006 (to be chosen by each Society) that had to be not later than 1 July 2006.

However, the application statement, as it was written, was not clear because it could be understood that the revised URs were applicable to ships contracted for construction before 1 July 2006 only and not on or after 1 July 2006.

In order to make the application statement clearer and user-friendly, in October 2009 - when the circumstances that brought to the adoption of that peculiar wording were no longer valid - GPG agreed to change it to read: *"Revision [x] of this UR is to be applied by IACS Societies to ships contracted for construction on or after 1 July 2006"*.

.3 History of Decisions Made:

See .2 above.

.4 Other Resolutions Changes

URs S17 and S18

Note: *There are no separate Technical Background (TB) documents for the original resolution (1997), Rev.1 (1997), Rev.3 (July 2004), Corr.1 (Oct 2009) and Rev.5 (May 2010).*

Technical Background to changes proposed in respect of UR's S1A, Annex 2 to S1A, S12, S17, S18, S19, S20 and S22

The objective of the proposal is to reflect the IMO interpretation of 'single side skin construction' in the above mentioned Unified Requirements for bulk carriers. The Working Party on Strength discussions were unable to yield unanimous agreement and the following matters remain unresolved:

- The titles for UR's S17, S18, S19, S20 and S22 include the wording 'single side skin'. It was generally considered that this wording should now be deleted as the text clearly defines the scope of application and refers additionally to arrangements with double side skin construction. The GL Member does not support this view on the basis that the expression 'single side skin' appears in the text of SOLAS Chapter XII. In view of this difference, the wording 'single side skin' has been enclosed in square brackets pending further consideration by GPG.

- In order to clarify how the breadth of the side shell should be measured, the phrase 'between topside tank and hopper tank' has been used in S17.1(ii) and (iii), S18.1(ii) and (iii), S19.1(ii), S20.1(ii) and (iii), and S22(ii). This was not supported by the ABS member who considers that the IMO definition of single side skin construction does not necessarily refer only to the location between topside and hopper tanks. Also this was not supported by the CRS Member who considers that MSC 89(71), which identifies that measurements are to be made perpendicular to the side shell, provides sufficient guidance. For these reasons, the text has been enclosed in square brackets pending further consideration by GPG.

In addition to the above, two other issues have been raised as follows:

- The ABS Member has requested that the following be considered in respect of the deletion of reference to damage stability requirements from paragraph S17.1 of URS17. It is noted that the reference was originally included in order to cover a six months difference in implementation timetables between SOLAS and IACS. Although both implementation dates have now passed and the need for this provision is limited, there could still be cases where it is relevant due to a change of Class from a non-IACS Society to an IACS Society. It is, therefore, proposed that the present clause in URS17 be replaced by an alternative clause within a unified requirement more specifically related to stability requirements. Support for this proposal has been indicated by PRS, DNV, KR, RINA, CRS and LR.

- The GL Member has requested that consideration be given to amending URS20 and URS22 such that these requirements are only applicable when corrugated bulkheads are fitted. This matter has not received support from the other WP/S Members and is considered to be outside the scope of the present Task.

Submitted by WP/S Chair on 31 May 2000
(Note: For GPG action, refer to GPG Chair's message 0064dIGa, 31/7/00)

Technical Background

UR S17(Rev.7), UR S18(Rev.7) and UR S20(Rev.4)

(February 2006)

1. Objective

These revisions are proposed to extend the application of URs S17, S18 and S20 to bulk carriers of double side skin construction.

2. Background

The Maritime Safety Committee in the IMO, at its 76th session (MSC 76), agreed that new ships of 150 m in length and upwards, which would be of double-side-skin construction, should also comply with all the structural strength provisions of regulation XII/5 of SOLAS requiring that the ship shall have sufficient strength to withstand flooding of any one cargo hold. DE Sub-Committee, at its 47th session (DE 47), prepared a final draft text for amendments to SOLAS XII mainly by removing the words which refer to single-side skin construction from this regulation after having discussed about hold flooding scenarios. The agreed hold flooding scenario or assumption was a hypothetical one in which only a cargo hold would be flooded to the water level outside the ship in that flooded condition without flooding the double side skin spaces. Finally the amendments of SOLAS XII were approved at MSC 78 and adopted at MSC 79.

IACS UR S17, S18 and S20 have been referred to in SOLAS 1997 Conference Resolution 3, Recommendation on compliance with SOLAS regulation XII/5. Therefore GPG decided to revise these URs in line with the above-mentioned IMO decision on 10 Jan 2003 and tasked WP/S to effect the revision. Hull Panel took over the task after the reorganization of IACS in 2005.

3. Amendment

Hull Panel prepared a draft revision.

In the application of these three URs, the exemption of cargo holds of double side skin construction was deleted or explicit inclusion of double side skin construction was described. The definition of bulk carrier is referred not to the new definition of the SOLAS XII but to the definition in UR Z11.2.2.

4. Additional Note

4.1 S17.4 Strength Assessment.

The requirements regarding the shear stress in the rev 6 were relative to the side shell only of a single side skin vessel. These requirements are to be applied to the side shell and the inner

hull in case of a double side skin bulk carrier. These requirements refer to the corresponding requirements of URS11.4 (Rev 4 in force today) in which the formulations are given for ships with and without longitudinal bulkheads. Moreover the door is open in UR S11.4.1 to the possible use of a method of direct stress calculation.

4.2 S18.6 'Corrosion addition and steel renewal' and 'S20.3 Shear Capacity of the double bottom'

Attention is drawn on the fact that it will be necessary to update UR S18 and S20 after the entry into force of the JBP Rules. The corresponding corrosion additions and criteria for steel renewal will be changed.

5. Source/ derivation of proposed requirement

Hull Panel

6. Decision by voting

N.A.

Prepared by Hull Panel

Notes:

2248eIGj, 8 Jan 2006: GPG concluded that the following be added to the TB.

> *"GPG unanimously approved the amended URs and TB. After several rounds of correspondence, GPG did not reach concensus on a single uniform application date for these revisions but did agree, by 2/3 majority, to an application statement to the effect that these revisions of these URs are to be applied by IACS Societies to ships contracted for construction from a date commencing not later than 1 July 2006. GPG Chairman also encouraged all Members to endeavor to apply the requirements of the amended URs in conjunction with their approval of double hull bulk carriers subject to amended SOLAS XII/5.2 by one means or another."*

* * *

Technical Background Document UR S20 (Rev. 6, Apr 2014)

1. Objective/Scope

The objective of this revision is to clarify the scope of application of IACS UR S17, S18, and S20.

2. Source of Proposed Requirements

- IACS UI SC207
- SOLAS XII/5.1 & 5.2

3. Technical Basis and Rationale

IACS UR S18 and S20 only apply to conventional bulk carriers with cargoes having a density of 1.0 t/m^3. Ore Carriers, combination carriers, box-type bulk carriers and hybrid bulk carriers are excluded and the URs do not apply to CSR bulk carriers.

IACS UR S17 applies mostly to conventional bulk carriers as well as hybrid bulk carriers and box-type bulk carriers. Ore carriers and combination carriers are excluded and the UR does not apply to CSR bulk carriers.

However UI SC207 states that;

"Regardless of the date of contract for construction, or the cargo hold cross section configuration, of ships which shall comply with SOLAS XII/5.2, such ships are to comply with IACS Unified Requirements (UR) S17 (rev.7), S18 (rev.7) for corrugated transverse bulkheads, where fitted, and S20 (rev.4), if they do not comply with the IACS CSR for Bulk Carriers."

This means that UR S17, S18 and S20 are applicable to all of the bulk carrier types covered by SOLAS XII/5.2 with the exception of CSR bulk carriers. This includes conventional bulk carriers, ore carriers, combination carriers, box-type bulk carriers, hybrid bulk carriers and other bulk carrier types.

4. Summary of Changes

The scope of application of UR S17, S18 and S20 has been revised to incorporate the requirements of SOLAS Chapter XII, Sections 5.1 & 5.2. The exclusion of CSR bulk carriers is retained.

5. Points of Discussion

See above.

6. Attachments, if any

UR S21 "Evaluation of Scantlings of Hatch Covers and Hatch Coamings and Closing Arrangements of Cargo Holds of Ships"

Summary

The buckling requirements in UR S21 are improved based on latest CSR buckling requirements. Then UR S21 and S21A are harmonized and combined as a single UR S21 Rev.6. And UR S21A is deleted since 1 July 2024.

Part A. Revision History

Version No.	Approval date	Implementation date when applicable

NEW (1997)	*No record*	-

- **Rev.6 (Jan 2023)**

1 Origin of Change:

☑ Suggestion by IACS member

2 Main Reason for Change:

(1) Improvement of the buckling requirements

Different buckling assessment methods, have been included in the relevant UR-Ss, such as UR S11, S11A, S21 and S21A. With the development of the harmonized buckling method in the Common Structural Rules for Bulk Carriers and Oil Tankers (CSR), it's considered necessary to also harmonise the buckling methods among all the different UR-Ss based on the CSR buckling methodology.

For the introduction of the new buckling methodology, it's to be carried out as part of the comprehensive work package on the harmonisation of buckling requirements in different IACS Resolutions, with a newly proposed UR S35-Buckling as a common unified buckling toolbox and simultaneous amendments to the Relevant UR-S including UR S11, S11A, S21 and S21A.

For UR S21 specifically, this harmonization will introduce the latest IACS buckling method for the buckling check of hatch covers of related ship types.

(2) Harmonisation and combination of UR S21 and S21A

After improvement of the buckling requirements in UR S21 and S21A respectively, it’s decided by Hull Panel at the 37th meeting (Sept 2022) to further harmonize and combine UR S21 and S21A as a single UR S21. After this combination, UR S21A is deleted.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

The Hull Panel at the 23rd meeting (Sept 2015) considered for the first time the need for harmonising the different IACS Resolutions. A comment received from shipyards is that the IACS approaches regarding buckling requirements were different in the UR S11, S11A, S21, S21A and CSR.

The decision to revise UR S21 is an outcome of the work of IACS GPG Meeting 83. Therefore, a Project Team PT PH43 was ad hoc nominated by the Hull Panel and tasked for the harmonization of buckling requirements in the UR-Ss, as well as for making improvements in the formulation itself.

Hull Panel at the 37th meeting (Sept 2022) decided to further harmonize and combine UR S21 and S21A as a single UR S21.

.5 Other Resolutions Changes

- The requirements in UR S21A are harmonized with corresponding requirements in S21, which are then included in UR S21 Rev.6.

- UR S21A is deleted since 1 July 2024. The revised UR S21 is cross-referenced in UR S35.

.6 Any hindrance to MASS, including any other new technologies:

None

.7 Dates:

Original proposal	: 14 September 2017	(Made by: An IACS member)
Panel Approval	: 22 December 2022	(Ref: PH17036b)
GPG Approval	: 26 January 2023	(Ref: 18058aIGc)

- **Rev.5 (May 2010)**

.1 Origin for Change:

☑ Based on IACS Requirement *(Common Structural Rules for Bulk Carriers and Double Hull Oil Tankers)*

.2 Main Reason for Change:

Following the introduction of the IACS Common Structural Rules for Bulk Carriers and Double Hull Oil Tankers, Hull Panel were tasked to review all the UR S files to consider whether or not they are applicable to ships covered by the CSR.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None.

.4 History of Decisions Made:

After review it was decided that for CSR bulk carriers the requirements of UR S21 are superseded by those of the Common Structural Rules and therefore do not apply.

UR S21 is not applicable for CSR oil tankers.

.5 Other Resolutions Changes

IACS WP/S - Task 70
Revision 3 of UR S21
April 2003

UR S21 Rev. 3 Technical background

Background

Following the hearings of the Re-Opened Formal Investigation into the loss of the m.v. Derbyshire, held in the U.K., the Court recommended that UR S21 should be re-appraised in the light of the latest sea-keeping model tests, and that this new standard be made applicable both to new ships and retrospectively to existing vessels. Later, in March 2002, IACS announced a series of eight initiatives to improve the safety of bulk carriers. UR S21 Rev. 2 was firstly developed by AHG/EBC, working in association with members of WP/S to address the application of measure number 6 to new ships. In addition to the green sea load model, this Revision incorporates changes to the strength formulation for hatch covers, strength standards for the design of hatch coamings, and for the securing of hatch covers to resist horizontal green sea loads.

At its 46 Meeting in December 2002, the Council assigned a new task to the WP/S, to amend UR S21 Rev.2 as submitted to MSC 76) to incorporate loads, allowable stress (0,8 yielding) and deflection criteria as adopted in the revisions to Load Line Convention adopted by IMO at MSC 76. S21(Rev.3) has been so developed.

The new WP/S task was then labelled as Task 70.

Application

Hatch cover secondary stiffeners are required to be continuous in order to have the necessary buckling strength against the compressive loads induced by the bending of primary supporting members.

Hatch coaming secondary stiffeners are required to be continuous in order to be able to sustain the plastic bending moment distribution assumed for these elements.

Hatch cover primary supporting members are required to be continuous to ensure their load carrying capacity and an adequate transmission of forces when grillage effects are taken into account. For similar reason, a maximum spacing of the primary supporting members parallel to the direction of secondary stiffeners is included.

Hatch cover load model

According to the decisions taken by IACS after MSC 76, as reflected in the Task 70 Form A, the load model adopted in Rev. 2 of UR S21 is the one adopted by IMO in Regulation 16-1 of the revised Load Line Convention.

The value formula reported in Regulation 16-1 of the revised LLC for ships less than 24 m in length is not included since it is not applicable to the bulk carriers to which UR S21 applies. However, the relevant values are used to interpolate the pressure values for ship's length less than 100 m.

Hatch cover strength criteria

Following the assumptions stated in the 1988 LL Protocol, the hatch covers are assumed to behave in the elastic domain under the assigned loads. Consequently, the allowable stresses are:

- 0,8 and 0,46 times the minimum upper yield stress for normal and shear stresses, respectively,
- 0,8 times the critical buckling stress for normal compression and shear stresses.

The stress response of the hatch cover primary supporting members is generally to be determined through a grillage or a Finite Element calculation, beam models are adopted only for hatch covers that are not designed as a grillage of longitudinal and transverse primary supporting members. Prescriptive requirements for the hatch cover top plate thickness and secondary stiffener section modulus are given.

Based on the elastic approach used for the strength criteria of secondary stiffeners and plating, the effective width of the primary supporting members is equal to the spacing of primary supporting members, to be taken not greater than 0,165 times the member side span, on each side of it.

However, since the formula for the secondary stiffener required section modulus does not account for the stresses induced by the bending of primary supporting members, the attached plate flange area of the primary supporting members is to be calculated without any contribution from the secondary stiffener area.

In the S21 requirement for minimum plate thickness, the coefficient 15,8 used in the expression applies for plates under pressure with clamped edges that are free to pull in and with plastic hinges at the edges and at mid-span. An additional factor of 1,5 is introduced to account for co-existing compressive membrane stress in the hatch cover top plate as well as the possibility that the lateral pressure loading may locally exceed the UR S21 value. Considering the combined effects of the local plate bending stress and the flange stress of primary supporting members, the 1,5 factor is increased linearly to 1,90 for the attached plate flange of primary stiffening members stressed above 80% of the allowable stress limit. The 1,90 factor gives a plate flange thickness consistent with hatch cover designs that have been assessed with respect to their lateral load capacity by non-linear FE analysis.

The requirements for hatch cover plate thickness include a buckling check of the compression stress induced by the bending of primary supporting members either parallel or perpendicular to the secondary stiffeners. The formulae adopted for these buckling checks are taken from UR S11.

For secondary stiffeners, the elastic section modulus is derived from the elastic bending moment at the fixed end. Only the lateral pressure is considered, while the second order bending moment caused by the combined effect of stiffener deflection (by the lateral pressure load) and the membrane stress in the plate (from the bending of the primary supporting member) is disregarded.

In order to ensure the elastic behaviour of the hatch cover structures, it is required that buckling checks are carried out for secondary stiffeners parallel to primary supporting members, subjected to the compression stresses induced in the top plate flange by the bending of primary supporting members. The formulae adopted for these buckling checks are taken from UR S11.

For flat bar secondary stiffeners, a limit on the web depth to net thickness ratio is introduced, based on typical Society criteria, to prevent their local buckling.

The breadth of the primary supporting member flanges is to be at least 40% of their depth, in association with a laterally unsupported span not greater than 3,0 m, in order to avoid tripping.

The critical buckling stress check for the web panel of the primary supporting members is based on the formula valid for simply supported plate. The criteria adopted for calculating the actual shear stress to be compared with the critical buckling stress are the following.

- Primary supporting members parallel to the direction of secondary stiffeners do not directly support such stiffeners, which are the load carrying elements. Therefore, the shear is uniform in each panel bounded by the crossing with other primary supporting members, the face plate (or the bottom cover plate) and the cover plate. In this case, the web panels bounded by the above elements, subjected to uniform shear stresses, are to be considered in the buckling check.

- Primary supporting members perpendicular to the direction of secondary stiffeners are subjected to an almost linearly varying shear force distribution, induced by the vertical loads transmitted through the secondary stiffeners. In this case, the buckling check is to be carried out for an assumed square panel with sides equal to the primary supporting member web height. This assumption is based on the 45° orientation of the principal compressive stresses in the web subjected mainly to shear (at least in the vicinity of the neutral axis), which allows square panels to be idealised in which the shear stress may be assumed to be uniform.

A deflection limit and closing requirements between hatch cover panels are included with the intention of ensuring weathertightness of the hatch cover under extreme green sea loads. The limit of 0,0056 l (where l is the greatest span of the primary supporting members) included in the revised Load Line Convention is assumed.

Hatch coamings – Load and strength criteria

The values for the pressure p_{coam} were provided by the IACS AHG/WD-SL study on the assessment of UR S21 based on the MARIN model test results.

The pressure of 290 kN/m^2 on the No. 1 forward transverse hatch coaming is the upper bound of the measured longitudinal loads appropriate to a 20-year North Atlantic storm excluding flooding.

The pressure of 220 kN/m^2 on the other coamings is the upper bound obtained for transverse loads on side coamings.

The pressure reduction from 290 kN/m^2 to 220 kN/m^2, due to the protection provided to the forward transverse hatch coaming by a forecastle complying with UR S28, is also derived from the IACS study based on the MARIN model test results. Although these tests were carried out on models not fitted with a forecastle, the effect of the forecastle protection on the No. 1 forward hatch coaming was estimated to be equivalent to the protection given by the No. 1 hatch cover to the No. 2 forward hatch coaming.

It is to be noted that the pressures on hatches aft of 0,25 L from the forward perpendicular have not been exhaustively investigated during the MARIN tests. However, the following considerations are to be taken into account.

- The investigations carried out by the AHG/WD-SL have shown that the maximum transverse pressures on transverse hatch coamings occur in beam sea conditions. In these conditions, it is deemed that the pressures on transverse hatch coamings are largely the same for all hatches, irrespective of their location along the ship's length.

- The maximum longitudinal pressures, acting on the front hatch covers, are surely lower for aft hatches, with respect to No. 2 hatches, due to the protection offered by the forward hatches.

- For practical design purposes, the horizontal forces are conservatively assumed to be the same for hatch No. 2 and for hatches aft of hatch No.2.

In the formula for the local net plate thickness, the coefficient 14,9 appropriate for plates not subjected to in-plane stresses is adopted. Considering the low probability of load occurrence a plastic approach is adopted for secondary stiffeners, although, for consistency with the hatch cover formulation, an allowable stress rather than a yield stress limit is used. A safety factor equal to 1,15 is then included in the formulae to arrive at an overall safety margin of 1,2 with respect to the development of plastic hinges.

As a plastic bending moment distribution is specified for secondary stiffener, the required elastic section modulus is evaluated by introducing the term c_p, which is the ratio of the plastic section modulus to the elastic section modulus. Again a safety factor of 1,15 is incorporated to establish an overall margin of 1,2 against yield.

Formulae for the thickness and elastic minimum section modulus of the coaming stays were derived for the elastic shear force and bending moment appropriate to a cantilever under a uniformly distributed pressure. For stays of non-cantilever design the same allowable stress limits apply, but prescriptive scantlings have not been formulated.

Securing devices

The criteria of Recommendation No. 14 are explicitly required to be complied with.

Stoppers

No credit is given for the friction forces between the covers and the coamings. The stoppers are to be dimensioned against longitudinal and transverse forces arising from a pressure of 175 kN/m^2.

For the hatch coaming of hatch No.1, a pressure equal to 230 kN/m^2 is to be considered, unless a forecastle is fitted in accordance with UR S28. In this case, a value of 175 kN/m^2 may be considered.

Compared with the pressures on the hatch coamings, these values take into consideration the local reduction of pressure that occurs at the upper edge of the vertical boundary created by the coaming and hatch cover side or end plate.

Corrosion addition and steel renewal criteria

The corrosion addition of 1,5 mm for the hatch coaming and coaming stays is based on the results of the NK report "Corrosion Analysis for Bulk Carriers and Determination of Corrosion Margin (Part 3)" of January 2002, prepared in relation to WP/S Task No. 22.

Steel renewal criteria are defined consistently with the corrosion addition values.

Remarks made by some Member Societies

1. GL has repeated its reservation on the adopted buckling check formulae, also placed on the previous Rev. 2 of UR S21, which reflects the GL reservation on UR S11.

2. LR has accepted the present revision of UR S21 on a majority basis, but they supported a different approach in which the strength criteria were the same as those adopted in the previous Rev. 2 prepared by the AHG/EBC, with the permissible stresses changed from 0,95 to 0,8 times the yielding stress.

   In the LR's view, when Regulation 16-1 states that "the product of the maximum stress determined in accordance with the above loads and the factor 1,25 shall not exceed the critical buckling strength in compression", it does not say how the critical buckling strength is to be calculated. According to LR, the criteria of Regulation 16-1 are fulfilled by changing the allowable stresses in the expressions of the previous Rev. 2 of UR S21, which should therefore be retained for this purpose.

   The other Members, however, did not agree on this interpretation of Regulation 16-1 and were in favour of explicit buckling stress checks.

Note by the Permanent Secretariat:

- GPG decided to expand the scope of application to bulk carriers, ore carriers and combination carriers as defined in UR Z11. See the title and S21.1.

- Adopted on 7 April 2003 (2248gICa). An information paper on the revision of S21(Rev.3, April 2003) was submitted to IMO MSC 77(May 2003).

Technical Background document for UR S21 Rev.6 (Jan 2023)

1. Scope and objectives

For this revision of UR S21, it's mainly about two aspects. The first is to adopt a new buckling methodology for hatch cover analysis, which is based on CSR -- Common Structural Rules for Bulk Carriers and Oil Tankers. The second is to further harmonize and combine UR S21 and S21A as a single UR S21. After this combination, UR S21A is deleted.

Regarding the first aspect, on the improvement of the buckling requirements, the major revision is made to Section S21.3.6 "Buckling Strength". As two directly related items, Section S21.3.1 "Yield Strength" and Section S21.3.2 "Stress Calculation Model" are also improved based on corresponding requirements in CSR.

For the introduction of the new buckling methodology, it's been carried out as part of the comprehensive work package on the harmonisation of buckling requirements in different IACS Resolutions, with a newly proposed UR S35-Buckling as a common unified buckling toolbox and simultaneous amendments to the Relevant UR-S including UR S11, S11A, S21 and S21A.

For the application of UR S35-Buckling to specific ship types or structural members requiring buckling assessment, definition of loading conditions, standard corrosion deductions, hull girder stresses, stress combinations, safety factors should be given in the individual UR-Ss; based on these definitions as input parameters, wherever applicable it links to UR S35-Buckling for buckling assessment with respect to slenderness requirements, prescriptive buckling requirements and buckling requirements for direct strength analysis. With this framework of general rule organization and a standardized interface of reference to the same UR S35-Buckling for buckling assessment in all relevant UR-S (S11, S11A, S21, S21A, etc.), the goal of Harmonisation of Buckling Requirements in IACS Resolutions is achieved. Specifically, in this revision of UR S21 definition of load model, net scantlings, stress calculation methods, safety factors are given in S21.3.6 to be used as input parameters for buckling check, while a link to UR S35-Buckling is also given referring to the common unified slenderness requirements and the direct strength analysis (DSA) buckling assessment requirements.

Regarding the second aspect, on the harmonisation and combination of UR S21 and S21A, all the requirements in UR S21A are harmonized with corresponding parts in S21, which are then included in UR S21 Rev.6.

2. Engineering background for technical basis and rationale

(1) Improvement of the buckling requirements

It is mainly to introduce the CSR buckling methodology into this UR under the broader perspective of Harmonisation of Buckling Requirements in IACS Resolutions, for which this UR is taken as part of the Relevant UR-S. Therefore, the TB for this harmonisation can be taken as a whole for the common part, and this part is mainly included in the TB of the new UR S35-Buckling. For details, refer to the Part B, Annex 1 of the HF+TB for the new UR S35-Buckling.

For simplicity and avoiding repetition, therefore only the part specific to this UR S is included in this text. For this revision of UR S21, it's considered that there is only one technical point to be noted, i.e. the safety factor defined in S21.3.6.3.4 and the allowable buckling utilization factors defined in S21.3.6.3.5 are to follow the corresponding CSR requirements. Specifically, the allowable buckling utilization factors definitions in CSR Pt2, Ch1, Sec 5, Table 3 are followed as defined below.

Allowable buckling utilisation factors

Structural component	Subject to	η_{all}, Allowable buckling utilisation factor
Plates and stiffeners Web of PSM	External pressure, as defined in S21.2	0.80
	Other loads (cargo loads, etc.)	0.90 for static+dynamic load case 0.72 for static load case

where the value of η_{all} =0.8 corresponding to vertical weather design load is the same as in previous revision of UR S21(rev. 5), and is also taken to substitute the generally equivalent safety factor S=1.25 in previous revision of UR S21A (Corr.2 Mar 2019). The value of h_{all}=0.9 for other static+dynamic load case is taken to substitute the generally equivalent safety factor S=1.1 in previous revision of UR S21A (Corr.2 Mar 2019). In addition, an additional value of h_{all}=0.72 for other static load case is introduced considering the same value already defined in CSR with well accepted technical background. Therefore, actually no additional TB besides that for corresponding CSR requirement is considered necessary.

(2) Harmonisation and combination of UR S21 and S21A

After improvement of the buckling requirements in UR S21 and S21A respectively, all the requirements in UR S21A are harmonized with corresponding parts in S21 as far as possible, which are then included in UR S21 Rev.6. These requirements apply to all ships except CSR bulk carriers, and are for all cargo hatch covers and coamings on exposed decks. However, parts of the requirements are for some specific ship types as categorized below:

- Type-A ships, including all ships except bulk carriers, self-unloading bulk carriers, ore carriers and combination carriers, as defined in UR Z11.

- Type-B ships, including all bulk carriers, self-unloading bulk carriers, ore carriers and combination carriers, as defined in UR Z11.

Generally, it's decided that the harmonized UR S21 Rev.6 is to generally follow the rule text organization framework of UR S21A. For this harmonisation, firstly all major structural strength requirements with possible scantling impacts are compared. Specifically, the formulae related to the following aspects are compared:

- Hatch cover local strength on plating and stiffeners

- PSM and edge girders

- Hatch coaming plating, stiffeners, coaming stays and securing devices

Based on the comparison, it shows that generally all scantling requirements in UR S21 and S21A can be harmonized except for the following items due to some identified reasons.
First, due to different horizontal weather design load in UR S21A, 2.2 and UR S21.4.1, the following items need to be listed as dependent on either Type-A or Type-B ships:

- S21A, 5.1: Local net plate thickness of coamings
- S21A, 5.2: Net scantling of stiffeners of coamings
- S21A, 5.3.1: Coaming stay section modulus and web thickness
- S21A, 7.1 Corrosion addition for hatch covers and hatch coamings

Second, there are some requirements included in UR S21A but not in UR S21. Some of them are harmonized based on calculation of typical designs showing no apparent scantling impact, such as the hatch cover stiffener shear area requirement in S21A, 3.3. However, based on calculations of typical designs, it shows that due to apparent scantling impact the following requirements are only for Type-A ships:

- S21A, 3.4.2: Edge girders (skirt plate) thickness requirement
- S21A, 5.2: Requirement to gross thickness of coaming plate with sniped stiffeners.
- S21A, 6.2.2: Hatch cover supports with tabled permissible nominal surface pressure.

In addition, there are some detailed requirements in UR S21 but not in UR S21A, which are kept only for Type-B ships as below:

- S21A, 5.3.1: Size of welding at the lower end of coaming stays
- S21A, 6.2.3: Some specific requirements on hatch cover stoppers.

With the above harmonisation and classification of all requirements in UR S21 and S21A, besides the already identified consequences caused by buckling rule improvement and some other harmonized requirements, it’s considered that no apparent scantling impact is to be observed based on the further harmonisation and combination of UR S21 and S21A as a single UR S21 Rev.6.

In addition, as far as possible the symbols used in CSR 2022 are followed in the revised UR S21, which makes it easier for either rule application by Industry or future further rule harmonisation within IACS.

2.4 Consequence Assessment

Regarding the first aspect, on the improvement of the buckling requirements, two CA (Consequence Assessment) reports are prepared based on the calculation of 2 typical hatch covers using this revised UR S21 and the previous revision (rev. 5) respectively. Based on the reports, it indicates that some design improvements might need to be introduced to meet the buckling requirements in this revision of UR S21 especially for relatively big size hatch covers. However, this is same as required in CSR, which had been proved more reasonable from both theoretical analysis and practical design points of view.

The two CA reports are attached as listed below:

(1) PTPH43_WPA_CA Rep_UR_S21_Rev.6_TB Annex 2_BC110k_HC1.docx

(2) PTPH43_WPA_CA Rep_UR_S21_Rev.6_TB Annex 2_BC325k_HC1.docx

Regarding the second aspect, on the harmonisation and combination of UR S21 and S21A, it's considered that no apparent scantling impact is to be observed due to the further harmonisation and combination of UR S21 and S21A as a single UR S21 Rev.6. Specifically, for the hatch cover stiffener shear area requirement in S21A, 3.3, it's a requirement originally included in UR S21A but not in UR S21, after harmonisation it applies to both Type-A and Type-B ships in UR S21 Rev.6. For consequence assessment, some calculations are carried out regarding typical hatch cover stiffeners compliant with UR S21 originally designed without considering this net shear area requirement. Based on the calculation, it shows that the net section modulus requirement is always a far more governing factor than net shear area requirement. Therefore, for typical hatch cover designs no scantling impact is expected to be caused by this rule harmonisation.

3. Source/derivation of the proposed IACS Resolution

For this revision of UR S21 which is mainly to adopt a new buckling methodology for hatch cover analysis, it's to be applied in conjunction with the new UR S35-Buckling as a general unified buckling toolbox. The revised buckling requirements in both Resolutions are in general based on CSR Pt 1, Ch 8, Sec 5 and App 1. Background information to the general approach is therefore same as the corresponding parts in the technical background documentation of CSR, available via the IACS web-site.

4. Summary of Changes intended for the revised Resolution:

Regarding the first aspect, on the improvement of the buckling requirements, referring to the previous revision of UR S21(rev. 5), the major revision is made to Section S21.3.6 "Buckling Strength". As two directly related items, Section S21.3.1 "Yield Strength" and Section S21.3.2 "Stress Calculation Model" are also improved based on corresponding requirements in CSR.

Referring to the previous revision of UR S21A (Corr.2 Mar 2019), the major revision is made to Section 3.6 "Buckling strength of hatch cover structures". As two directly related items, Section 3.5 "Strength calculations" and Section 3.1.1 "Yield strength" are also improved based on corresponding requirements in CSR.
For both UR S21 and S21A, some editorial or minor revisions corresponding to the revision of the buckling requirements are introduced.

For details, a modified text indicating changes in red and with underlining for new additions and strike through for deletions is attached.

(1) Specifically, from UR S21(rev. 5) to UR S21(rev. 6), for the sub-items of UR S21(rev. 6), Section 3.6 "Buckling Strength", the rule revisions can be summarized as below:

- S21, 3.6.1 General

Technical background is not considered necessary.

- S21, 3.6.2 Slenderness requirements

The slenderness requirement on stiffeners applicable for hatch covers is newly introduced from CSR.

- S21, 3.6.3 Buckling requirements

S21, 3.6.3.1 Application
Technical background is not considered necessary.

S21, 3.6.3.2 Panel types and assessment methods
This is newly introduced from CSR.

S21, 3.6.3.3 Applied stresses and pressure
The level of applied stresses on hatch cover plate structures are not intended to be modified by present text changes.

It has to be highlighted that, even with unchanged stresses, the longitudinal stress and the transversal stress, respect to orientation of stiffeners and the shear stress are no more checked for buckling assessment in isolation as was up to previous revision, but they shall be checked in a combined manner, as relevant, into interaction equations. It is also now explicitly covered the bi-axial compressive case that, up to the prior revision, was left to each Classification Society's judgement.

Moreover, according to the general procedure in UR S-Buckling, also the case with one stress component in compression and the other component in tension shall also be assessed.

In the stiffener buckling check, the additional contribution of lateral pressure will also be accounted for.

S21, 3.6.3.4 Safety factors
Technical background is not considered necessary.

S21, 3.6.3.5 Buckling acceptance criteria
This is newly introduced from CSR, which uses the same definition of allowable buckling utilisation factors for a hatch cover subject to different loading conditions.

(2) Specifically, from UR S21A (Corr.2 Mar 2019) to UR S21(rev. 6), for the sub-items of UR S21(rev. 6), Section 3.6 "Buckling Strength", the rule revisions can be summarized as below:

- S21, 3.6.1 General

Technical background is not considered necessary.

- S21, 3.6.2 Slenderness requirements

The slenderness requirement on stiffeners applicable for hatch covers is newly introduced from CSR.

- S21, 3.6.3 Buckling requirements

S21, 3.6.3.1 Application
Technical background is not considered necessary.

S21, 3.6.3.2 Panel types and assessment methods
This is newly introduced from CSR.

S21, 3.6.3.3 Applied stresses and pressure
Technical background is not considered necessary.

S21, 3.6.3.4 Safety factors
The explanation given in the above Section 2 of this document on the technical point of allowable buckling utilisation factors applies.

S21, 3.6.3.5 Buckling acceptance criteria

This is newly introduced from CSR, which uses the same definition of allowable buckling utilisation factors for a hatch cover subject to different loading conditions.

Regarding the second aspect, on the harmonisation and combination of UR S21 and S21A, generally the harmonized UR S21 Rev.6 is revised based on UR S21A (Corr.2 Mar 2019) after improving the buckling requirements.

In the harmonized and combined UR S21 Rev.6, besides the majority part following UR S21A (Corr.2 Mar 2019) and the buckling improvement, firstly the following items are listed as dependent on either Type-A or Type-B ships:

- S21, 5.1: Local net plate thickness of coamings
- S21, 5.2: Net scantling of stiffeners of coamings
- S21, 5.3.1: Coaming stay section modulus and web thickness
- S21, 7.1 Corrosion addition for hatch covers and hatch coamings

Secondly, the hatch cover stiffener shear area requirement in S21, 3.3 is harmonized, while the following requirements are only for Type-A ships:

- S21, 3.4.2: Edge girders (skirt plate) thickness requirement
- S21, 5.2: Requirement to gross thickness of coaming plate with sniped stiffeners.
- S21, 6.2.2: Hatch cover supports with tabled permissible nominal surface pressure.

Thirdly, the following requirements are only for Type-B ships:

- S21, 5.3.1: Size of welding at the lower end of coaming stays
- S21, 6.2.3: Some specific requirements on hatch cover stoppers.

In addition, as far as possible the symbols used in CSR 2022 is followed in the harmonized and combined UR S21 Rev.6.

5. Points of discussions or possible discussions

This Rev.6 of UR S21 was made through discussions of the draft version provided by the project team within the Hull Panel, which mainly involved incorporating individual comments on specific technical points, updates based on corresponding CSR improvements and accepting the consolidated text.

Major points of discussions and conclusions during the development of this revision have been the following:

No.	Section	Points of discussion and conclusions
1.	S21.3.1 and S21A, 3.1.1	The same yield strength assessment requirements are adopted from CSR 2022, which corresponds to using FE analysis method as the single prescribed method for hatch cover direct strength analysis.
2.	S21.3.2.2 and S21A, 3.5	The same General requirements for FE modelling and analysis as in CSR 2022 is adopted here, which generally also complies with UR S21A requirements. Note that the FE modelling and analysis of hatch covers fitted with U-type stiffeners is also adapted from CSR 2022.
3.	S21.3.6.3.3 and S21A, 3.6.3.3	In the previous version of UR S21 and S21A, the stresses for hatch cover direct strength buckling check may be determined by either grillage analysis or FEM. However, based on joint investigation of Societies and ship yards, it's determined that only FEM is to be kept in the rule for hatch cover direct strength analysis. For details, refer to the TB corresponding to the new UR S35-Buckling. Based on this decision, harmonization is achieved among UR S21, S21A and CSR to take FEM as the single prescribed method for hatch cover direct strength analysis.

6. Attachments if any

Two CA reports are attached as:

(1) PTPH43_WPA_CA Rep_UR_S21_Rev.6_TB Annex 2_BC110k_HC1.docx

(2) PTPH43_WPA_CA Rep_UR_S21_Rev.6_TB Annex 2_BC325k_HC1.docx

URS21A "Evaluation of Scantlings of Hatch Covers and Hatch Coamings and Closing Arrangements of Cargo Holds of Ships"

Summary

The requirements in UR S21A are harmonized with S21, which are then included in UR S21 Rev.6, UR S21A is deleted on the implementation of UR S21 Rev.6

1 Origin for Change:

☑ Suggestion by IACS member

.2 Main Reason for Change:

(1) Improvement of the buckling requirements

Different buckling assessment methods, each of which are then the latest available methods, have been included in the relevant UR-Ss, such as UR S11, S11A, S21 and S21A. With the development of the harmonized buckling method in the Common Structural Rules for Bulk Carriers and Oil Tankers(CSR), it's considered necessary to also harmonise the buckling methods among all the different UR-Ss based on the CSR buckling methodology.

For the introduction of the new buckling methodology, it's to be carried out as part of the comprehensive work package on the harmonisation of buckling requirements in different IACS Resolutions, with a newly proposed UR S35-Buckling as a common unified buckling toolbox and simultaneous amendments to the Relevant UR-S including UR S11, S11A, S21 and S21A.

For UR S21A specifically, this harmonization will introduce the latest IACS buckling method for the buckling check of hatch covers of related ship types.

(2) Harmonisation and combination of UR S21 and S21A

After improvement of the buckling requirements in UR S21 and S21A respectively, it's decided by Hull Panel at the 37th meeting (Sept 2022) to further harmonize and combine UR S21 and S21A as a single UR S21. After this combination, UR S21A is deleted.

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None

4 History of Decisions Made:

The Hull Panel at the 23rd meeting (Sept 2015) considered for the first time the need for harmonising the different IACS Resolutions. The shipyards complained that the IACS approaches regarding buckling requirements were different in the UR S11, S11A, S21, S21A and CSR.

The decision to revise UR S21A is an outcome of the work of IACS GPG Meeting 83. Therefore, a Project Team PT PH43 was ad hoc nominated by the Hull Panel and tasked for the harmonization of buckling requirements in the UR-Ss, as well as for making improvements in the formulation itself.

Hull Panel at the 37th meeting (Sept 2022) decided to further harmonize and combine UR S21 and S21A as a single UR S21.

5 Other Resolutions Changes:

The requirements in UR S21A are harmonized with corresponding requirements in S21, which are then included in UR S21 Rev.6.

6 Any hinderance to MASS, including any other new technologies:

None

7 Dates:

Original proposal	: April 2015	Made by: IACS PT56
Panel Approval	: 21 December 2022	(Ref: PH17036b)
GPG Approval	: 27 January 2023	(Ref: 18058bIGb)

Note: For this deletion, no TB document is available. However, on the harmonisation and its combination with UR S21, the TB is available in the TB for UR S21 Rev.6.

- **Corr.2 (Mar 2019)**

1 Origin for Change:

☒ Request by GPG 15139_IGh dated 18/9/2016

2 Main Reason for Change:

The applicability of ESP to the self-unloading bulk carriers (SUBC) leads to the GPG request to identify the UR S which are NOT applicable to SUBC.

The UR S21 is not applicable to bulk carriers as mentioned in 1.1. Therefore this corrigenda clarifies the UR is neither applicable to SUBC. This clarification has been added for removing any ambiguity in the application scope.

4 History of Decisions Made:

Discussion at the HP meeting in 2016
Analysis by Hull Panel Chair
Discussion and decision by the Hull Panel in 2018

5 Other Resolutions Changes:

Within this study for SUBC application: UR S17, 18 and 30.

6 Any hinderance to MASS, including any other new technologies:

None

7 Dates:

Original Proposal:	14 June 2018	Made by: Hull Panel
Panel Approval:	11 December 2018	
GPG Approval:	04 March 2019 (Ref. 15139_IGl)	

- **Corr.1 (Feb 2018)**

.1 Origin for Change:

☑ Requested by non-IACS entity

.2 Main Reasons for Change:

Many materials with lower friction coefficient are applied for hatch cover supports, not only one plastic material.

.3 List of non-IACS Member Classification Societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

A hatch cover manufacturer addressed questions to IACS related to the UR S21A permissible nominal surface pressure including the meaning of the different support materials provided in table 9. The Hull Panel developed the answer to Industry questions including necessary clarifications.

Please refer to the TB section (Annex 4) for the details of the correction.

.5 Other Resolutions Changes

None

.6 Dates:

Original proposal: December 2017 Made by: Hull Panel
Panel Approval: 26 January 2018 (Ref: PH17029)
GPG Approval: 19 February 2018 (Ref. 17179_IGf)

- **Rev.1 (May 2015)**

.1 Origin for Change:

☑ Request by non-IACS entity

.2 Main Reasons for Change:

Comments were received from industry in 2011 and the Hull Panel decided that further work was needed to clarify the requirements. Rule amendments include modifications of definition and application as well as clarification of the approach to partial loading of containers on hatches.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

UR S21A was issued in May 2011, with a minor correction in Oct 2011. In late 2011, an IACS Member received comments/questions on UR S21A from Cargotec during the Member's rules amendment process. In 2012, the Hull Panel developed unified IACS response to the comments, but noted that further work would be needed. At the 18th Hull Panel Meeting (Mar. 2013), the Hull Panel agreed to establish PT PH31/2013 to study the issues surrounding UR S21A. In addition, a small study was performed by PT PH31 which compared various partial loading conditions for a hatch cover on which a stack of containers is partially supported by an outboard stanchion.

A recommendation on fixing or harmonizing UR S21A was submitted to IACS Hull Panel on 28 Feb. 2014. After 20th Hull Panel meeting (Mar. 2014), the Hull Panel requested PT PH31/2013 to revise UR S21A according to the proposed recommendation.

At first, minor amendments were made to the document and submitted to Hull Panel for review. Then, feedback from Hull Panel was considered for further revision of the document.

Please refer to the rule text and TB section for the details of the amendments.

.5 Other Resolutions Changes

None

.6 Dates:

Original proposal: Mar 2015 Made by: PT PH31/2013
Panel Approval: 29 Mar 2015 by: Hull Panel
GPG Approval: 26 May 2015 (Ref: 13173_IGf)

- **Corr.1 (Oct 2011)**

.1 Origin for Change:

☑ Suggestion by an IACS member

.2 Main Reasons for Change:

Error in the equation of design load on freeboard deck for ships with less freeboard than type B according to ICLL in Table 1.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

A Hull Panel member located a possible error in the equation of design load on freeboard deck for ships with less freeboard than type B according to ICLL in Table 1. Hull Panel confirmed the error by comparing the equation with that in CSR-BC and requested for a correction.

Please refer to the TB section for the details of the correction.

.5 Other Resolutions Changes

None

.6 Dates:

Original proposal: *August 2011 Made by: Hull Panel*
Panel Approval: 24 *August 2011 by: Hull Panel*
GPG Approval: *21October 2011 (Ref. 11078_IGe)*

- **New (May 2011)**

.1 Origin for Change:

☑ Other (In order to specify strength criteria for hatch covers on ship types other than bulk carriers, ore carriers and combination carriers, to demonstrate compliance of hatch covers with ILLC 66 Regulation 16)

.2 Main Reasons for Change:

Regulation 16 of the International Load Line Convention (ILLC) 1966 specifies loads on hatch covers that are to be applied to all types of ships. UR S21, Rev. 5 gives strength criteria for hatch covers on bulk carriers, ore carriers and combination carriers as defined in UR Z11. Currently no requirement exists for hatch covers on ship types other than the aforementioned.

This UR is intended to cover that gap by enumerating strength requirements for hatch covers on ship types other than bulk carriers, ore carriers and combination carriers as defined in UR Z11.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

Action to create task decided at 2nd Hull Panel meeting. Task No. 14 was assigned by the Hull Panel to this undertaking. A dedicated project team was created to execute this task.

Form A was approved by GPG on 5 August 2005.Preliminary versions of the proposed UR and technical background documents were circulated among the Hull Panel members for review.

Final version approved at the 14th Hull Panel meeting in February 2011.

.5 Other Resolutions Changes

None

.6 Dates:

Original proposal: *December 2010 Made by: Hull Panel*
Panel Approval: *February 2011by: Hull Panel*
GPG Approval: *23May 2011 (Ref. 11078_IGc)*

Part B. Technical Background

List of Technical Background (TB) documents for UR S21A:

Annex 1. **TB for New (May 2011)**

See separate TB document in Annex 1.

Annex 2. **TB for Corr.1 (Oct 2011)**

Note: *There are no separate Technical Background (TB) documents for Corr.2 (Mar 2019) and Del (Jan 2023)*

Technical Background for UR S21A New, May 2011

1. Scope and objectives

To define strength criteria for hatch covers on ship types other than bulk carriers, ore carriers and combination carriers as defined in UR Z11.

2. Engineering background for technical basis and rationale

Reg. 16 of the ICLL 1966 specifies hatch cover loads for all ship types. While a UR (S21) pertaining hatch cover strength exists for bulk carriers, ore carriers and combination carriers, as defined in URZ11, there are no criteria for other ship types. This UR is intended to fill that gap.

3. Source/derivation of the proposed IACS Resolution

The source of the information was obtained through work performed by a dedicated project team and additional input from the Hull Panel.

4. Summary of Changes intended for the revised Resolution:

Not applicable

5. Points of discussions or possible discussions

The UR was developed by the project team (PT) for Task No. 14. Discussions on the draft documents prepared by the PT were reviewed and discussed within the Hull Panel at Panel meetings and via email correspondence.

6. Attachments if any

Detailed technical background document is attached.

Technical Background for UR S21A

Evaluation of Scantlings of Hatch Covers and Hatch Coamings and Closing Arrangements of Cargo Holds of Ships

Technical Background for UR S21a “Evaluation of Scantlings of Hatch Covers and Hatch Coamings and Closing Arrangements of Cargo Holds of Ships”

TB S21a.1 Introduction

UR S21a was developed to supplement UR 21 and applies to all ships except bulk carriers, ore carriers and combination carriers, as defined in UR Z11.

TB S21a.2 Application and definitions (UR S21a.1)

TB S21a.2.1 Definitions – Positions (UR S21a.1.2.2)

The defined positions for hatch covers upon exposed decks are as given by the International Convention on Load Lines (ICLL), 1966 as amended by the 1988 protocol, as amended in 2003, Regulation 13.

TB S21a.2.2 Material (UR S21a.1.3)

The structural integrity of hatch covers is important for the survivability of ships. As a consequence a material class I according to UR S6 (Use of steel grades for various hull members - ships of 90 m in length and above) is to be applied for hatch covers.

TB S21a.2.3 General requirements (UR S21a.1.4)

Hatch cover primary supporting members are required to be continuous to provide sufficient load carrying capacity and an adequate transmission of forces when grillage effects are taken into account.

For similar reason, a maximum spacing of the primary supporting members parallel to the direction of secondary stiffeners is included. It shall not exceed 1/3 of the span of primary supporting members. A ratio of spacing/length limited to 1/3 guarantees a relatively high ratio of effective breadth/spacing. When strength calculation is carried out by FE analysis using plane stress or shell elements, this requirement can be waived because shear lag effects are implicitly considered by this assessment method as long as the mesh density is sufficiently fine.

Hatch cover secondary stiffeners are required to be continuous in order to have the necessary buckling strength against the compressive loads induced by the bending of primary supporting members.

Hatch coaming secondary stiffeners are required to be continuous in order to be able to sustain the bending moment distribution assumed for these elements.

TB S21a.3 Hatch cover and coaming load model (UR S21a.2)

TB S21a.3.1 Vertical weather design load (UR S21a.2.1)

The vertical weather design loads adopted in UR S21a are identical with the loads given by ICLL in Regulation 16 (2), (3), and (4) except for exposed superstructure decks of ships with a length L > 100 m located at least one superstructure standard height above the lowest Position 2 deck. For these decks a reduced design load of 2.1 t/m^2 is required as given by UI LL 70.

The provision that, under the given conditions, the design load for hatch covers on the actual freeboard deck may be as required for a superstructure deck originates from UI LL 70 and is based on an assumed freeboard deck as defined in IACS UI LL64.

The height of the hatch coaming above deck less 600 mm may be considered for the definition of the assumed freeboard deck with respect to the determination of the vertical weather design load on hatch covers.

TB S21a.3.2 Horizontal weather design load (UR S21a.2.2)

As the load model adopted by S21 is very much specific to bulk carries and does not consider the height of a structure above the load line of the assessed ship, the project team decided to adopt the horizontal weather design load from UR S3 (Strength of end bulkheads of superstructures and deckhouses) except for the definition of factor f and c_L. Factor f is a wave coefficient and was adopted from UR S11 (Longitudinal strength standard). For ships of less than 90 m in length factor f was newly defined as it is not given by UR S11. Factor c_L is less than one for ships of less than 90 m in length and reduces the effect of wave coefficient f.

TB S21a.3.3 Calculation of container loads (UR S21a.2.4)

Formulas for the support forces A_z, B_z and B_y acting on the hatch cover are based on the assumption that the full vertical static and dynamic acceleration $g \cdot (1+a_v)$ is acting in combination with an acceleration of $0,5 \cdot g$ in transverse direction . The dynamic acceleration factor a_v depends on the position of the considered hatch cover in longitudinal direction. The typical distribution of a_v over the ship length is shown in Fig. 1. The transverse acceleration of $0,5 \cdot g$ corresponds to a static heel of 30°.

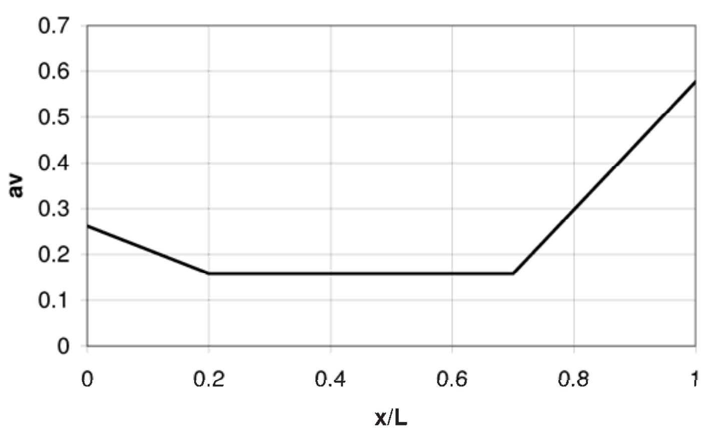

Fig. 1 Distribution of factor a_v

In case of container stacks secured to lashing bridges or carried in cell guides the forces acting on the hatch cover may be specially considered. Fig. 2 gives an example for container secured to the hatch cover (a) and secured to a lashing bridge (b). In the latter case the forces due to the ship's roll motion are transmitted partially to the lashing bridge so that the formulas for the forces acting on the hatch cover given by UR S21a.2.3 may not be applicable. However, as the torsional stiffness of container stacks is limited, support forces at corners of 20' container stacks away from lashing bridge or cell guides, respectively, may not be influenced considerably. These support forces at half length of the hatch cover are definitive for the structural design of the cover. Thus, A_z, B_z and B_y acting on the hatch cover at those stack corners may be assumed according to the given formulae in a conservative manner.

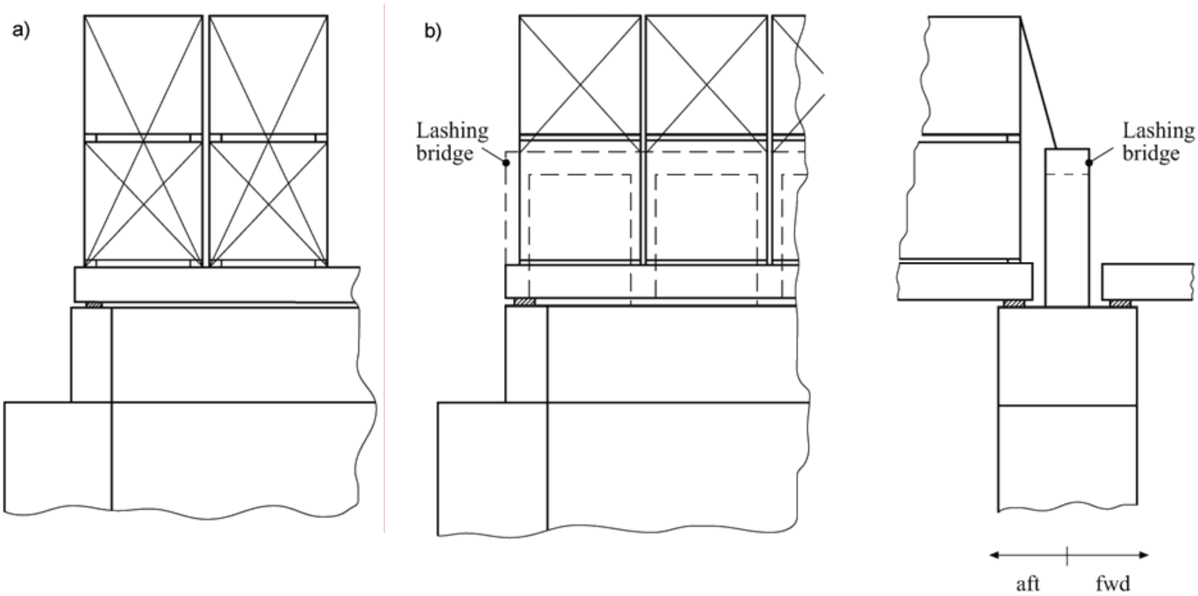

Fig. 2 Container secured to the hatch cover (a) and to a lashing bridge (b)

As an alternative to the given container loads, UR S21a allows applying container loads based on accelerations calculated by an individual acceleration analysis for the used lashing system. The individual acceleration analysis shall be carried out by the individual classification society.

This alternative assessment method allows designing hatch covers more individually with respect to the applied lashing system and according to the acceleration calculation of the individual class society. However, a load model independent from the lashing system provides more flexibility to the owner in choosing different lashing systems or modifying the lashing system without to be limited by the hatch cover design.

TB S21a.3.3.1 Load cases with partial loading (UR S21a.2.4.1)

Point loads and container loads acting on the hatch cover are also to be considered for partial non homogeneous loading which may occur in practice, e.g. where specified container stack places are empty.

UR S21a gives a simplified approach for assessing the partial loading of container hatch covers where the hatch cover is loaded without the outermost stacks, as can be seen in Fig. 3. It may be necessary to also consider partial load cases where more or different container stacks are left empty.

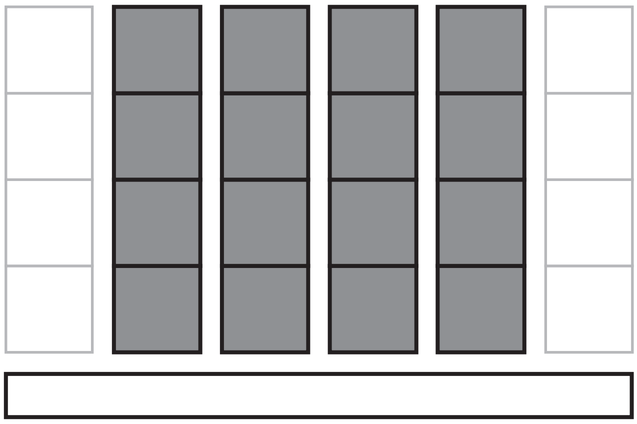

Fig. 3 Partial loading of a container hatch cover

The need for these considerations arise from the occurrence of increased loads due to the unbalanced vertical support forces at the supports of container stacks next to the empty stack places caused by the ship's roll motion.

Fig. 4 schematically illustrates resulting shear force distributions in a transverse primary supporting member of a hatch cover loaded with 20' containers. Distributions are shown for the hatch cover fully loaded and for the partial load case shown in Fig. 3 with horizontal acceleration acting. As can be seen, for the partial container load case in some areas increased shear forces occur.

For further illustration, Fig. 5 shows the equivalent stress distributions of a hatch cover loaded with stacks of 20' container and exposed to vertical and horizontal accelerations. On the left hand side, the hatch cover is fully loaded and on the right hand side the stress distribution is shown for a partial load case similar to the one shown in Fig. 3. It can be seen that increased stresses occur in the center transverse primary supporting members.

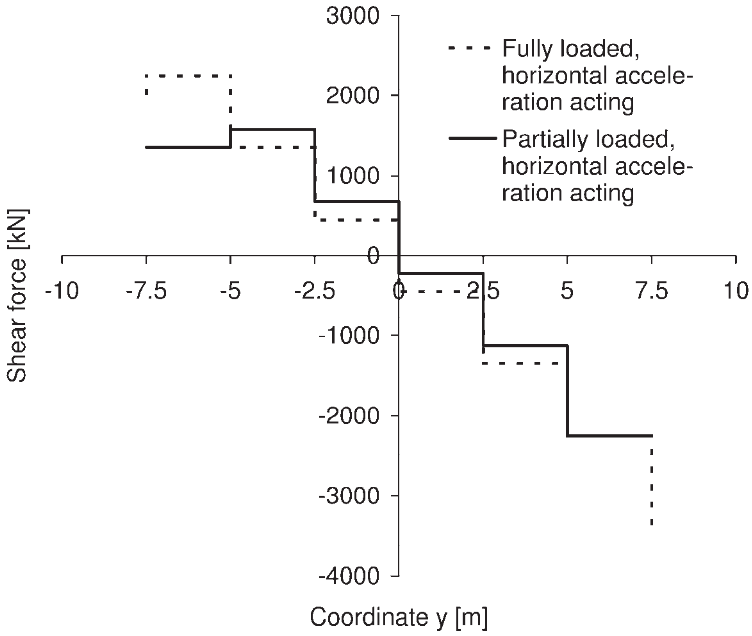

Fig. 4 Shear forces acting in a transverse primary supporting member of a hatch cover due to different load cases

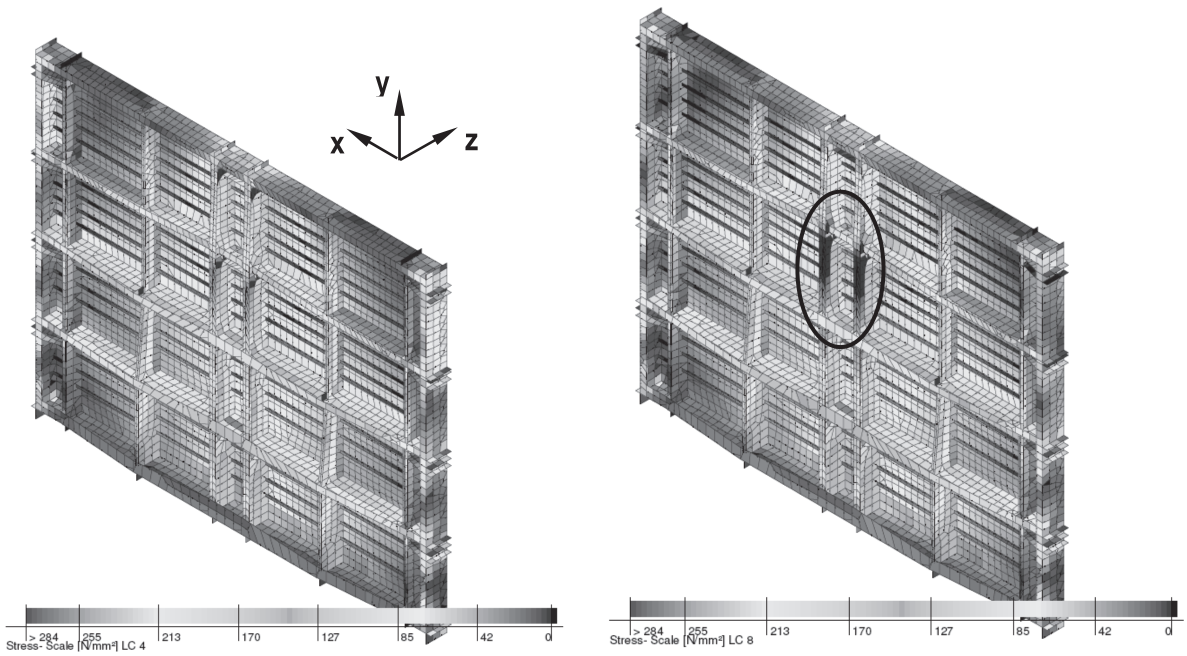

Fig. 5 Stress distribution in a hatch cover, fully loaded (left) and with partial loading (right)

TB S21a.4 Hatch cover strength criteria (UR S21a.3)

TB S21a.4.1 Permissible stresses and deflections - Stresses (UR S21a.3.1.1)

The equivalent stress according to v. Mises is to be assessed. In general, the permissible equivalent stress is 80% of the minimum yield point of the material as required by ICLL Regulation 16 (5).

When loads other than the vertical weather design load are assessed using FEM with plane stress or shell elements the permissible equivalent stress is 90% of the minimum yield point of the material. This is reasonable because due to Poisson effects FEM may calculate increased stresses compared to a grillage analysis. Furthermore, this is justified by the use of FEM as a more sophisticated assessment tool. However, the increased permissible stress is only to be applied for loads other than the vertical weather design load to not contradict ICLL regulations.

TB S21a.4.2 Permissible stresses and deflections - Deflection (UR S21a.3.1.2)

The deflection limit as given by ICLL Regulation 16 (5) is included for the vertical weather design load case.

Where hatch covers are arranged for carrying containers and mixed stowage is allowed, i.e., a 40'-container stowed on top of two 20'-containers, particular attention should be paid to the deflections of hatch covers. Fig. 6 gives an example for a mixed stowage situation and the resulting hatch cover and container stack deflection.

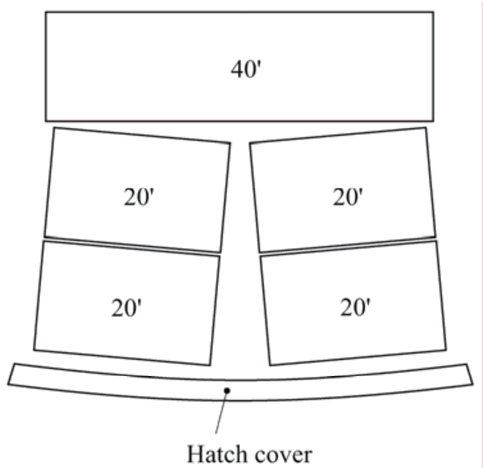

Fig. 6 Example for mixed stowage and resulting hatch cover and container stack deflection

TB S21a.4.3 Local net plate thickness (UR S21a.3.2)

The requirement for the minimum net plate thickness of hatch cover top plating subjected to the vertical weather design load and distributed cargo loads is the same as used in UR S21.

The coefficient 15,8 used in the expression applies for plates under pressure with clamped edges that are free to pull in and with plastic hinges at the edges and at mid-span.

An additional factor $F_P \geq 1{,}5$ is introduced to account for co-existing compressive membrane stress in the hatch cover top plate as well as the possibility that the lateral pressure loading may locally exceed the assumed value. Factor F_P is increased linearly to 1,90 for the attached plate flange of primary supporting members stressed above 80% of the allowable stress limit.

The normal stress of the hatch cover plating may be determined in a distance equal to the stiffener spacing s from webs of adjacent primary supporting members perpendicular to secondary stiffeners and in a distance equal to half of the stiffener spacing s from the web of an adjacent primary supporting member parallel to secondary stiffeners. This accounts for the shear lag effect leading to reduced membrane stresses at the assessed locations. As an example, Fig. 7 shows locations for determination of σ_x and σ_y for the plate field marked in grey. The greater of both stresses is to be taken for the normal stress of the hatch cover plating in the requirement for the local net plate thickness. At assessment point 1 an intermediate stress σ_x over the plate breadth s is determined which is reasonable for the assumed three-hinge-collapse failure mode. The assessment of σ_y at point 2, located in a distance equal to the stiffener spacing from the web of the adjacent primary supporting member, accounts for reduced local bending stresses close to the short edge of the plate field.

$$\sigma = \max\,[\sigma_{x1}(y=s/2);\ \sigma_{y2}(x=s)]$$

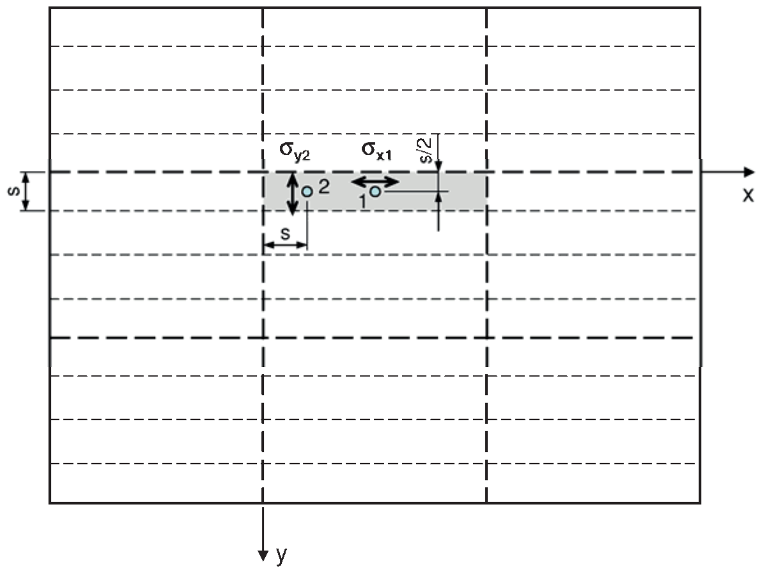

Fig. 7 Determination of normal stress of hatch cover plating

TB S21a.4.4 Net scantling of secondary stiffeners (UR S21a.3.3)

For secondary stiffeners, the minimum elastic section modulus is derived from the elastic bending moment at the fixed end under consideration of the permissible stress as required by ICLL Regulation 16 (5). Only the lateral pressure is considered, while the second order bending moment caused by the combined effect of stiffener deflection (by the lateral pressure load) and the membrane stress in the plate (from the bending of the primary supporting member) is disregarded.

If secondary stiffeners parallel to primary supporting members are regarded for calculating the cross sectional properties of these primary supporting members, it is to be verified that the combined stress of those stiffeners induced by the bending of primary supporting members and lateral pressures does not exceed the permissible stresses.

For hatch cover stiffeners under compression sufficient safety against lateral and torsional buckling is to be verified.

For flat bar secondary stiffeners, a limit on the web depth to net thickness ratio is introduced to prevent their local buckling. This requirement is adopted from UR S21.

TB S21a.4.5 Net scantling of primary supporting members - Primary supporting members (UR S21a.3.4.1)

For all components of primary supporting members sufficient safety against buckling must be verified. For biaxial compressed flange plates this is to be verified within the effective widths. For illustration, Fig. 8 shows a crossing of two primary supporting members with their effective widths. The area where a buckling proof must be carried out for biaxial compression is marked in grey. The buckling proof for parts of the hatch cover plating located in this area is to be done as a combined proof for cases 1 and 2 according to Tab. 5 of UR S21a.

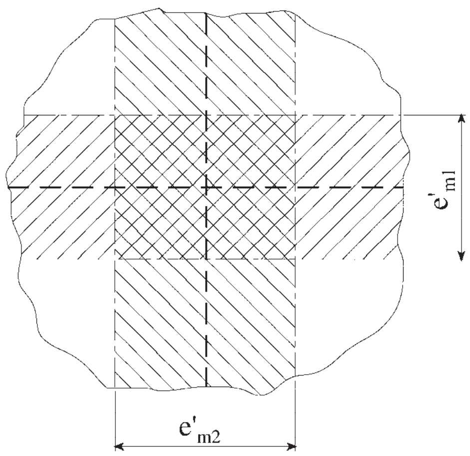

Fig. 8 Crossing of two primary supporting members and their effective widths

TB S21a.4.6 Edge girders (Skirt plates) (UR S21a.3.4.2)

For edge girders the same requirement for minimum net plate thickness is adopted as for the hatch cover top plating except for minimum thickness values that do not depend on the pressure load.

Furthermore, a stiffness requirement for edge girders similar to the requirement as given by IACS Rec. 14 is incorporated to maintain an adequate sealing pressure between securing devices.

TB S21a.4.7 Strength calculations (UR S21a.3.5)

Strength calculation for hatch covers may be carried out by either, using beam theory, grillage analysis or FEM. However, simple beam models shall be adopted only for hatch covers that are not designed as a grillage of longitudinal and transverse primary supporting members. In other cases a grillage analysis using beam elements or an FEM analysis using plane stress or shell elements is appropriate.

TB S21a.4.7.1 Strength calculations - Effective cross-sectional properties for calculation by beam theory or grillage analysis (UR S21a.3.5.1)

When determining cross-sectional properties of a primary supporting member, cross sectional areas of secondary stiffeners parallel to the primary supporting member under consideration and within the effective breadth can be included. In this case it is to be verified that the combined stress of those stiffeners induced by the bending of primary supporting members and lateral pressures does not exceed the permissible stresses.

Special calculations may be required for determining the effective breadth of one-sided or non-symmetrical flanges. This can be done by special engineering formulas or, if available, according to the individual class society's rules. In more complex cases an FEM calculation is recommended.

The cross-sectional area of flange plates under compression may be reduced by buckling of the plating. Flange plates with secondary stiffeners perpendicular to the web of primary supporting members are in particular prone to buckling failure. Thus, the effective width is to be considered for the determination of cross-sectional properties of such primary supporting members for grillage analysis or beam theory calculations. However, the effective width of plating is not to be taken greater than the value obtained for the effective breadth.

TB S21a.4.8 Buckling strength of hatch cover structures (UR S21a.3.6)

For further information regarding the buckling strength criteria refer to the technical background documents of Common Structural Rules for Bulk Carrier (CSR/BC), Chapter 6 – Hull Scantlings, Section 3 – Buckling & Ultimate Strength of Ordinary Stiffeners and Stiffened Panels.

Safety factors for the buckling strength assessment are based on the net scantling approach. To be in compliance with ICLL Regulation 16 (5) the safety factor for assessing the hatch cover when subjected to the vertical weather design load is to be taken equal to1,25. For loads other than the vertical weather design load, a safety factor equal to 1,1 is to be applied. This is justified by the more sophisticated buckling strength approach compared to the approach in UR S21. The chosen safety factor of 1,1 matches that of CSR/BC to be used with this kind of buckling strength approach.

The given correction factors F_1 for boundary conditions at the longitudinal stiffeners correspond to the values given by CSR/BC.

TB S21a.4.8.1 Buckling strength of hatch cover structures - Proof of partial and total fields of hatch covers - Lateral buckling of secondary stiffeners (UR S21a.3.6.3.3)

The factor c_s accounts for the boundary conditions of transverse secondary stiffeners. It is to be 1,0 for simply supported and 2,0 for partially constraint stiffeners. Fig. 9 gives examples for the factor c_s. For a stiffener, the supports of which are equally spaced, a factor $c_s = 1,0$ is to be chosen (a). If a stiffener spacing changes from a wide spacing to a much more narrow spacing, a partial constraint exists and $c_s = 2,0$ is to be chosen (b). Also when brackets are fitted at the supports of the stiffener, it is to be assumed as partially constraint.

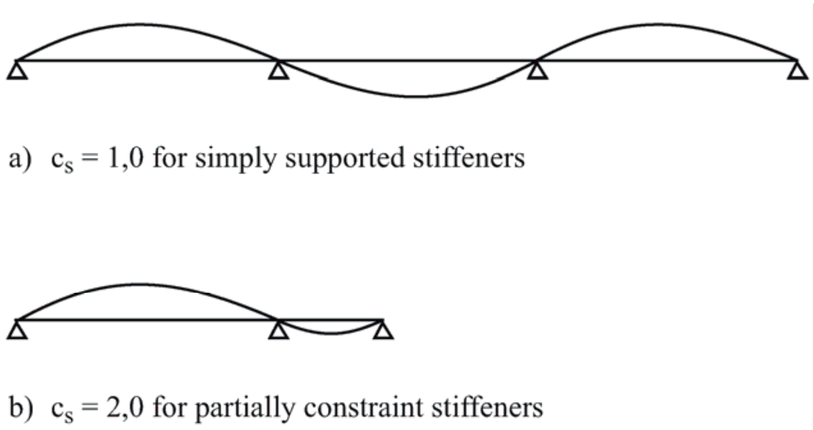

Fig. 9 Examples for the factor c_s accounting for the boundary conditions of transverse secondary stiffeners

TB S21a.5 Details of hatch covers (UR S21a.4)

TB S21a.5.1 Container foundations on hatch covers (UR S21a.4.1)

UR S21a requires designing substructures of container foundations for cargo and container loads applying the given permissible stresses.

Substructures are required to effectively distribute the localized support forces at the container stack corners. An example for container foundations and their substructures is given in Fig. 10. The figure shows a section through a primary supporting member with supporting structural elements like brackets beneath two container foundations. The detail drawing shows a typical container foundation more closely.

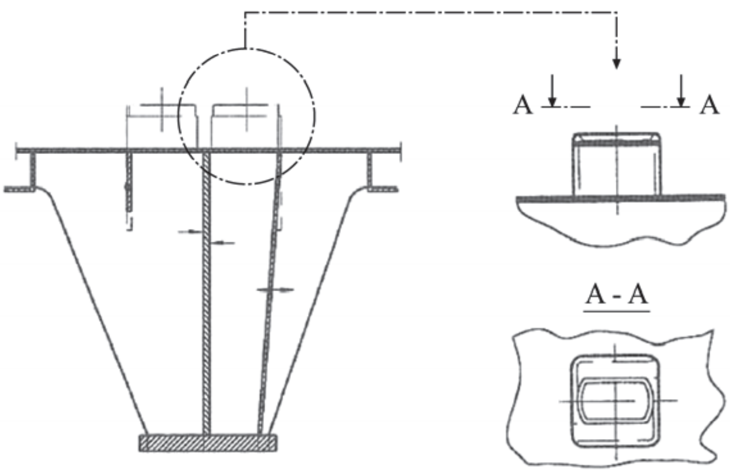

Fig. 10 Example for container foundations and their substructures

TB S21a.5.2 Weather tightness (UR S21a.4.2)

Further to the requirements as given by UR S21a the contents of IACS Rec. 14 are to be observed.

TB S21a.5.2.1 Weather tightness - Dispensation of weather tight gaskets (UR S21a.4.2.2)

For hatch covers of cargo holds solely for the transport of containers, the fitting of weather tight gaskets may be dispensed with upon request by the owners and subject to compliance with the given conditions that correspond to UI LL64.

Among others, it is to be complied with the condition that the exposed deck on which the hatch covers are located is situated above a depth H(x). H(x) is measured from the base line. The definition of H(x) is illustrated by Fig. 11 for a position forward of x/L = 0,75.

Further to the requirements as given by UR S21a, Chapter 3 of IMO MSC/Circ. 1087 is to be referred to concerning the stowage and segregation of containers containing dangerous goods.

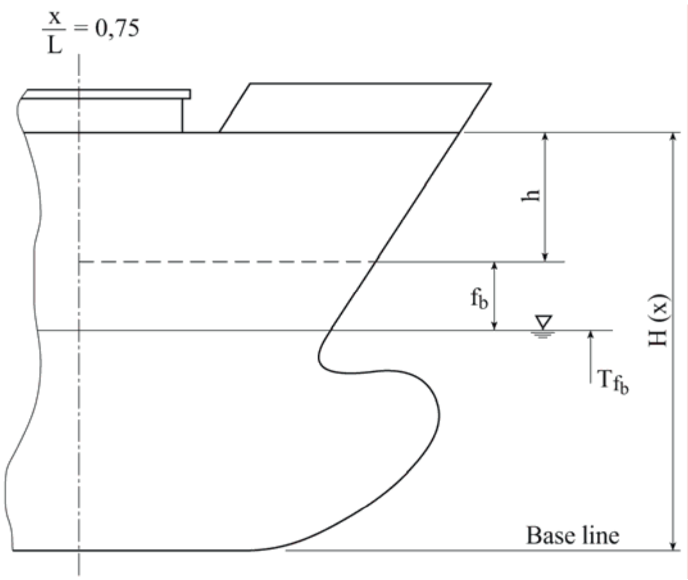

Fig. 11 Definition of H(x)

TB S21a.6 Hatch coaming strength criteria (UR S21a.5)

TB S21a.6.1 Local net plate thickness of coamings (UR S21a.5.1)

The horizontal weather design load model was adopted from UR S3. Thus, the prescriptive local net plate thickness of hatch coamings corresponds to that given in UR S3. The plate thickness required by UR S3 was assumed as a net plate thickness for UR S21a. Additionally, a minimum net plate thickness depending on the ship length was added which is not given by UR S3. Longitudinal strength aspects are to be observed as the given plate thickness formula merely covers local pressure loads.

TB S21a.6.2 Net scantlings of secondary stiffeners of coamings (UR S21a.5.3)

Similar to the prescriptive local net plate thickness, the prescriptive net scantlings for secondary stiffeners of hatch coamings correspond to those given in UR S3. Again, the stiffener section modulus required by UR S3 was assumed as a net section modulus for UR S21a. In addition, a minimum net cross sectional area of secondary stiffeners is required. The latter is based on the elastic shear force of a continuous beam under a uniformly distributed load.

TB S21a.6.3 Coaming stays (UR S21a.5.3)

Coaming stays in general are to be designed for the loads transmitted through them and permissible stresses as defined for hatch cover structures.

For stays of coamings with a height of less than 1,6 m and subjected to the horizontal design weather load, a prescriptive minimum section modulus and web thickness of the stay at the root point are given equal to the requirements of UR S21. Formulae were derived for the elastic shear force and bending moment appropriate to a cantilever under a uniformly distributed pressure. For coaming stays having a height of 1,6 m or more, prescriptive scantlings have not been formulated as a cantilever design can not be assumed.

TB S21a.7 Closing arrangements (UR S21a.6)

TB S21a.7.1 Securing devices - Cross-sectional area of the securing devices (UR S21a.6.1.4)

The requirements, UR S21a gives for the minimum cross-sectional area of securing devices used to maintain an adequate sealing pressure, correspond to the requirement as given by IACS Rec. 14.

For small hatch covers where the packing line pressure needs to be maintained by securing devices, typically rod type securing devices are used. For this type of securing device the given minimum cross-sectional area is applicable.

For large hatch covers securing devices may not be necessary to maintain packing line pressure as the covers are heavy enough. Securing devices then may be needed only as anti-lifting devices. These often exhibit designs which can not be sufficiently assessed only by a required cross-sectional area. They are to be designed according to the requirements for anti-lifting devices (UR S21a.6.1.5).

Where securing devices of special design are used to maintain the packing line pressure and in which significant bending or shear stresses occur, these may be designed as anti-lifting devices. As load the packing line pressure multiplied by the spacing between securing devices is to be applied.

TB S21a.8 Corrosion addition and steel renewal (UR S21a.8)

The requirements for corrosion additions of hatch cover structures are consistent with UI LL70. The requirements for corrosion additions of hatch coamings are consistent with UR S21.

The requirements for steel renewal of hatch cover structures are consistent with the requirements as given by UR S21. Steel renewal requirements for hatch coamings are to be according to the individual class society’s rules.

Technical Background for UR S21A Corr.1, Oct 2011

1. Scope and objectives

To correct the error in the equation of design load on freeboard deck for ships with less freeboard than type B according to ICLL in Table 1.

2. Engineering background for technical basis and rationale

See attachment 1& 2.

3. Source/derivation of the proposed IACS Resolution

See attachment 1& 2.

4. Summary of Changes intended for the revised Resolution:

See attachment 1& 2.

5. Points of discussions or possible discussions

None.

Technical Background for UR S21A

Evaluation of Scantlings of Hatch Covers and Hatch Coamings and Closing Arrangements of Cargo Holds of Ships

TB S21a.1 Introduction

UR S21a was developed to supplement UR 21 and applies to all ships except bulk carriers, ore carriers and combination carriers, as defined in UR Z11.

TB S21a.2 Application and definitions (UR S21a.1)

TB S21a.2.1 Definitions – Positions (UR S21a.1.2.2)

The defined positions for hatch covers upon exposed decks are as given by the International Convention on Load Lines (ICLL), 1966 as amended by the 1988 protocol, as amended in 2003, Regulation 13.

TB S21a.2.2 Material (UR S21a.1.3)

The structural integrity of hatch covers is important for the survivability of ships. As a consequence a material class I according to UR S6 (Use of steel grades for various hull members - ships of 90 m in length and above) is to be applied for top plate, bottom plate and primary supporting members.

TB S21a.2.3 General requirements (UR S21a.1.4)

Hatch cover primary supporting members are required to be continuous to ensure their load carrying capacity and an adequate transmission of forces when grillage effects are taken into account.

For similar reason, a maximum spacing of the primary supporting members parallel to the direction of secondary stiffeners is included. It shall not exceed 1/3 of the span of primary supporting members. A ratio of spacing/length limited to 1/3 guarantees a relatively high ratio of effective breadth/spacing. When strength calculation is carried out by FE analysis using plane stress or shell elements, this requirement can be waived because shear lag effects are implicitly considered by this assessment method as long as the mesh density is sufficiently fine.

Hatch cover secondary stiffeners are required to be continuous in order to have the necessary buckling strength against the compressive loads induced by the bending of primary supporting members.

Hatch coaming secondary stiffeners are required to be continuous in order to be able to sustain the bending moment distribution assumed for these elements.

TB S21a.2.4 Net scantling approach (UR S21a.1.5)

Hatch cover strength has to be calculated using grillage analysis or FEM. Grillage analysis means analysis of grillage structures using beam elements. FEM means finite element analysis using shell elements, plane stress elements and beam elements, where beam elements may be used to idealize flanges of primary supporting members and secondary stiffeners.

TB S21a.3 Hatch cover and coaming load model (UR S21a.2)

TB S21a.3.1 Vertical weather design load (UR S21a.2.1)

The vertical weather design loads adopted in UR S21a are identical with the loads given by ICLL in Regulation 16 (2), (3), and (4) except for exposed superstructure decks of ships with a length L > 100 m located at least one superstructure standard height above the lowest Position 2 deck. For these decks a reduced design load of 2.1 t/m^2 is required as given by UI LL 70.

The provision that, under the given conditions, the design load for hatch covers on the actual freeboard deck may be as required for a superstructure deck originates from UI LL 70 and is based on an assumed freeboard deck as defined in IACS UI LL64.

The height of the hatch coaming above deck less 600 mm may be considered for the definition of the assumed freeboard deck with respect to the determination of the vertical weather design load on hatch covers.

TB S21a.3.2 Horizontal weather design load (UR S21a.2.2)

As the load model adopted by S21 is very much specific to bulk carries and does not consider the height of a structure above the load line of the assessed ship, the project team decided to adopt the horizontal weather design load from UR S3 (Strength of end bulkheads of superstructures and deckhouses) except for the definition of factor f and c_L. Factor f is a wave coefficient and was adopted from UR S11 (Longitudinal strength standard). For ships of less than 90 m in length factor f was newly defined as it is not given by UR S11. Factor c_L is less than one for ships of less than 90 m in length and reduces the effect of wave coefficient f.

The horizontal weather design load needs not to be included in the direct calculation of skirt plates of the hatch cover. It is considered that the horizontal weather design load has no impact on scantlings of the primary supporting members except for the thickness of skirt plates, which is determined by formulae defined in 3.4.2.

TB S21a.3.3 Calculation of container loads (UR S21a.2.4)

Formulas for the support forces A_z, B_z and B_y acting on the hatch cover are based on the assumption that the full vertical static and dynamic acceleration $g \cdot (1+a_v)$ is acting in combination with an acceleration of $0,5 \cdot g$ in transverse direction . The dynamic acceleration factor a_v depends on the position of the considered hatch cover in longitudinal direction. The typical distribution of a_v over the ship length is shown in Fig. 1. The transverse acceleration of $0,5 \cdot g$ corresponds to a static heel of 30°.

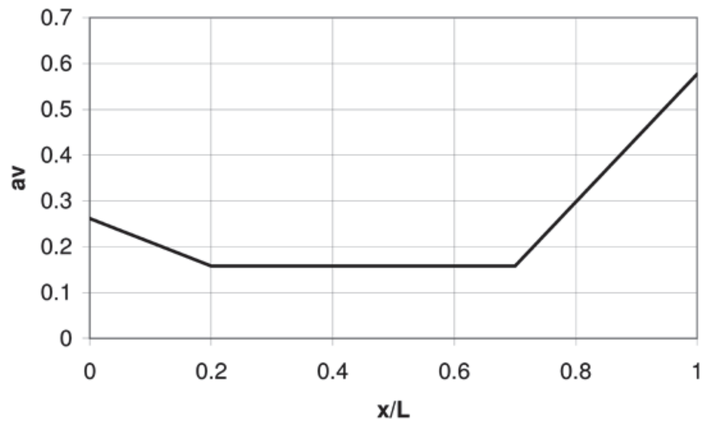

Fig. 1 Distribution of factor a_v

The designed height of centre of gravity (COG) of container stacks is defined as weighted mean value of the stack, where the COG of each tier is assumed to be located at the centre of each container. In terms of the position of the COG of each container, it is noted that classes may use different assumptions in container lashing calculations, e.g., at the centre of each container or one third of the height of each container. While the position at the centre of each container is adopted for the safer assumption in this UR, it should be also noted that the impact on the FE analysis due to the difference would be minimal, as can be seen from Fig. 2 and 3.

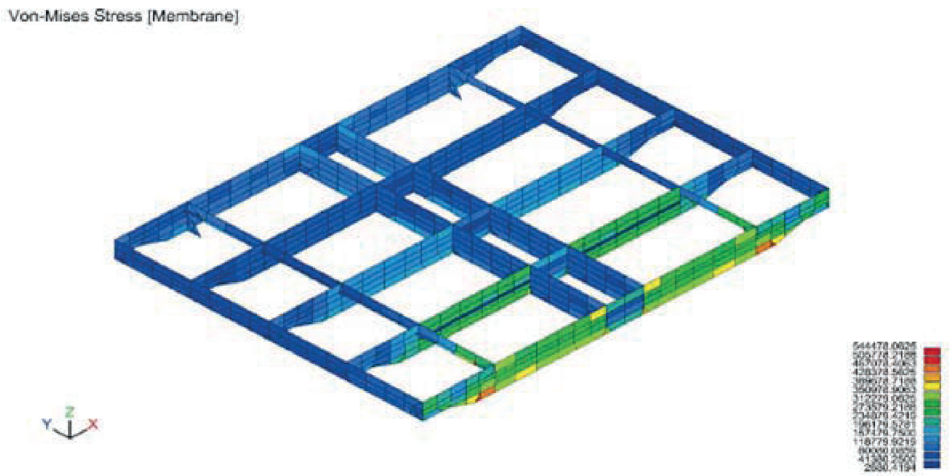

Fig. 2 Stress distribution with COG at the centre of each container

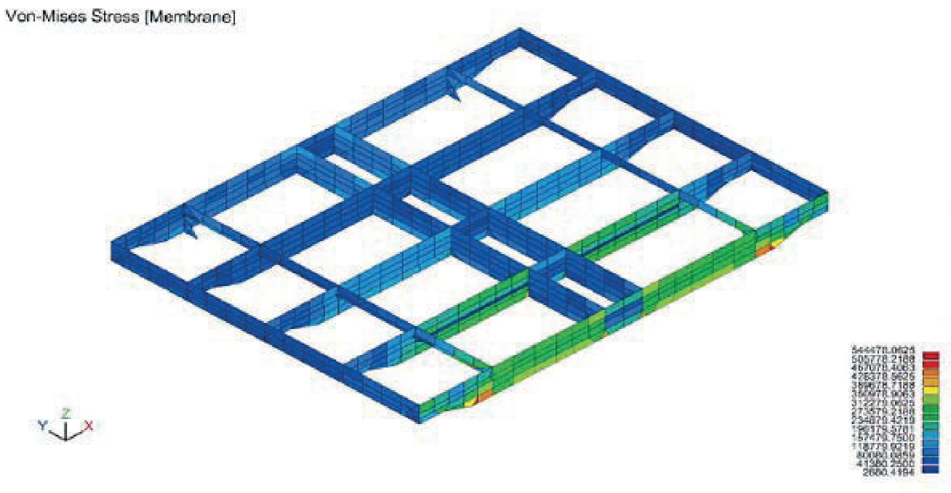

Fig. 3 Stress distribution with COG at one third of the height of each container

In case of container stacks secured to lashing bridges or carried in cell guides the forces acting on the hatch cover may be specially considered. Fig.4 gives an example for container secured to the hatch cover (a) and secured to a lashing bridge (b). In the latter case the forces due to the ship's roll motion are transmitted partially to the lashing bridge so that the formulas for the forces acting on the hatch cover given by UR S21a.2.3 may not be applicable. However, as the torsional stiffness of container stacks is limited, support forces at corners of 20' container stacks away from lashing bridge or cell guides, respectively, may not be influenced considerably. These support forces at half length of the hatch cover are definitive for the structural design of the cover. Thus, A_z, B_z and B_y acting on the hatch cover at those stack corners may be assumed according to the given formulae in a conservative manner.

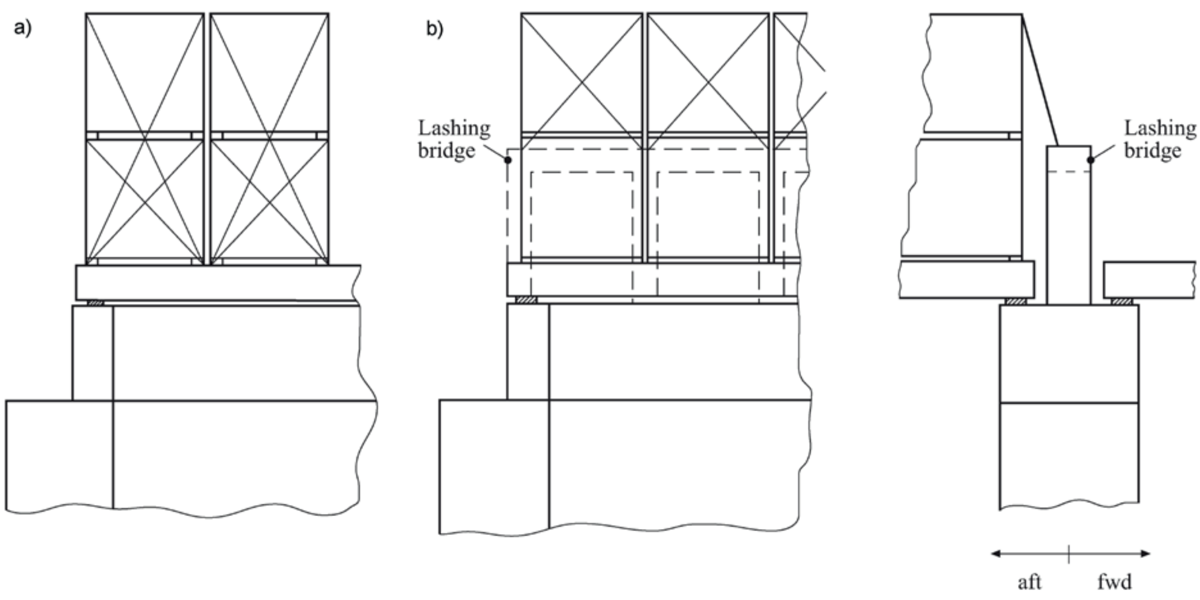

Fig. 4 Container secured to the hatch cover (a) and to a lashing bridge (b)

In general, the height of the center of gravity of the stack, h_m, needs to be taken above hatch cover top for the determination of the foot point forces A_Z and B_Z. However, when strength of the hatch cover structure is assessed by grillage analysis the height of the center of gravity of the stack is required to be taken above the hatch cover supports and the horizontal foot point forces B_Y do not need to be considered. The reason for this is that the grillage model will typically be idealized at the neutral axes of the primary supporting members of the hatch cover which do not coincide with the hatch cover top, where the foot point forces act. Thus, the foot point forces are typically applied to the grillage model in locations that do not match the real locations at which the foot point forces act. This is compensated by taking the height of the center of gravity of the stack above the hatch cover supports, which are typically located closer to the neutral axes of the primary supporting members than to hatch cover top. In cases, where the hatch cover supports are located below the neutral axes of the primary supporting members of the hatch cover, this procedure is conservative. The horizontal foot point forces B_Y will not have an effect on the bending stresses in the primary supporting members as they act in the idealization plane of the grillage model and, thus, can be omitted.

The approval of the hatch cover is made for the foot point loads as given by the drawings. It should be noted that these foot point loads are not to be exceeded in any loading condition of the vessel.

TB S21a.3.3.1 Load cases with partial loading (UR S21a.2.4.1)

Point loads and container loads acting on the hatch cover are also to be considered for partial non homogeneous loading which may occur in practice, e.g. where specified container stack places are empty.

UR S21a gives a simplified approach for assessing the partial loading of container hatch covers where the hatch cover is loaded without the outermost stacks. It may be necessary to also consider partial load cases where more or different container stacks are left empty.

The need for these considerations arise from the occurrence of increased loads due to the unbalanced vertical support forces at the supports of container stacks next to the empty stack places caused by the ship’s roll motion.

Fig. 5 schematically illustrates resulting shear force distributions in a transverse primary supporting member of a hatch cover loaded with 20' containers. Distributions are shown for the hatch cover fully loaded and for the partial load case shown in the upper part of Fig. 5 with horizontal acceleration acting. As can be seen, for the partial container load case in some areas increased shear forces occur.

For further illustration, Fig. 6 shows the equivalent stress distributions of a hatch cover loaded with stacks of 20’ container and exposed to vertical and horizontal accelerations. On the left hand side, the hatch cover is fully loaded and on the right hand side the stress distribution is shown for a partial load case similar to the one shown in Fig. 5. It can be seen that increased stresses occur in the center transverse primary supporting members.

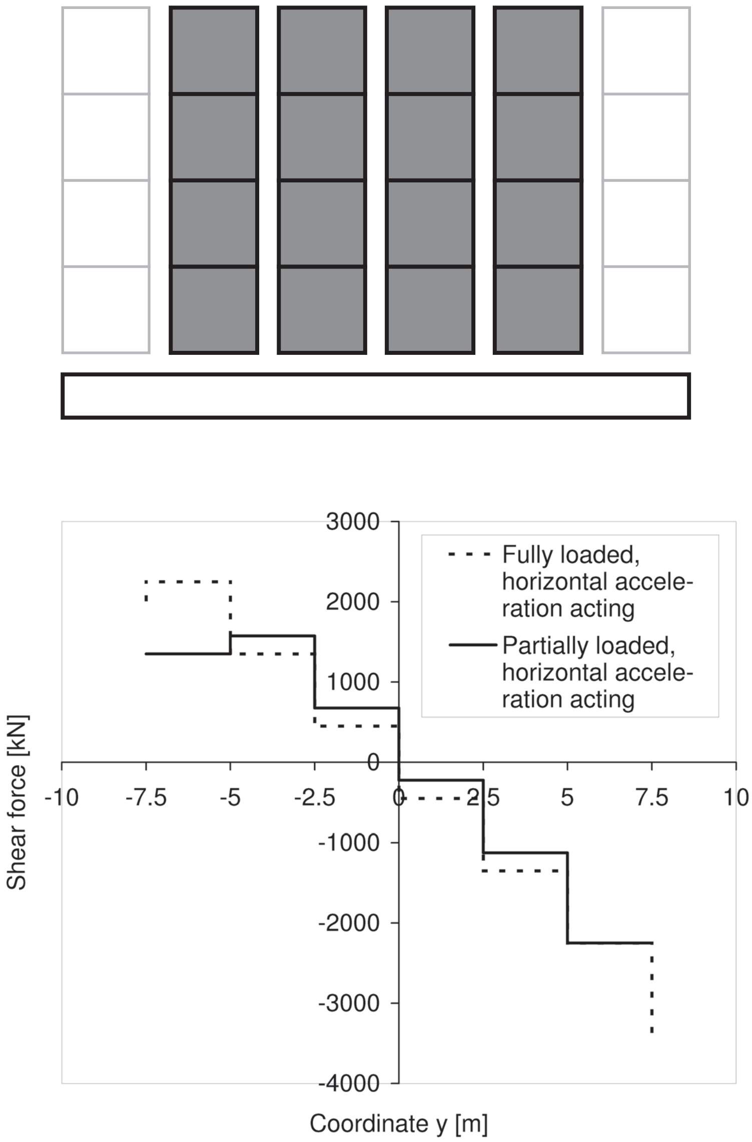

Fig. 5 Shear forces acting in a transverse primary supporting member of a hatch cover due to different load cases

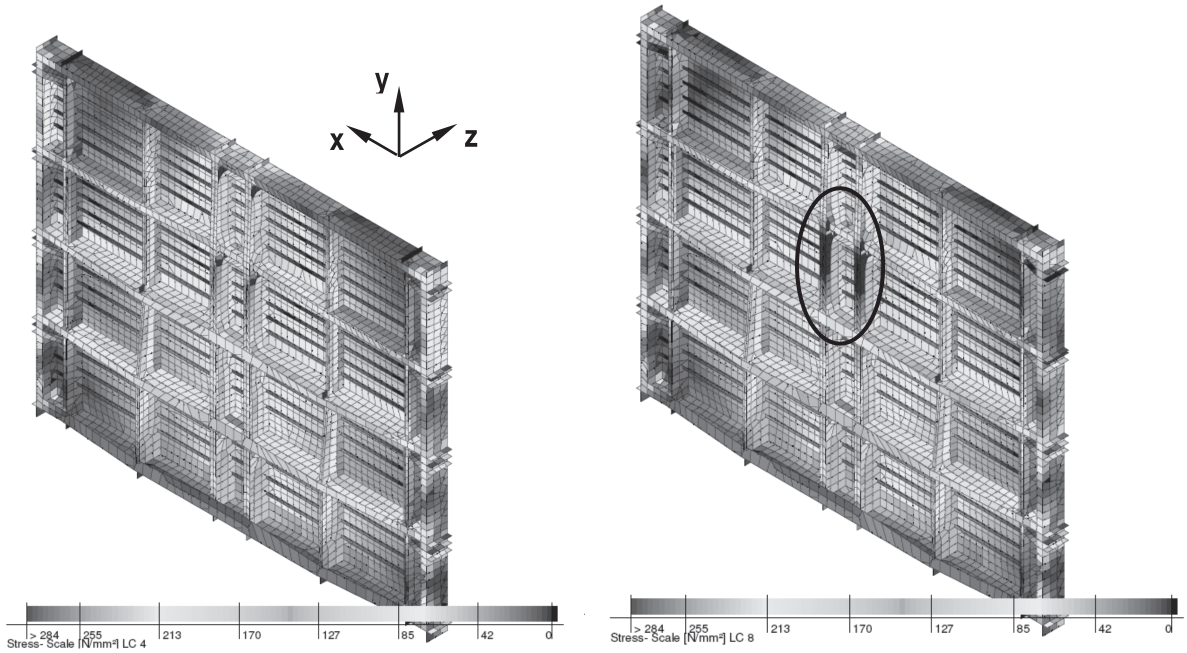

Fig. 6 Stress distribution in a hatch cover, fully loaded (left) and with partial loading (right)

TB S21a.4 Hatch cover strength criteria (UR S21a.3)

TB S21a.4.1 Permissible stresses and deflections - Stresses (UR S21a.3.1.1)

The equivalent stress according to v. Mises is to be assessed. In general, the permissible equivalent stress is 80% of the minimum yield point of the material as required by ICLL Regulation 16 (5).

When loads other than the vertical weather design load are assessed using FEM the permissible equivalent stress is 90% of the minimum yield point of the material. This is reasonable because due to Poisson effects FEM may calculate increased stresses compared to a grillage analysis. Furthermore, this is justified by the use of FEM as a more sophisticated assessment tool. However, the increased permissible stress is only to be applied for loads other than the vertical weather design load to not contradict ICLL regulations.

Attention should be paid to stress concentration due to structural discontinuities, e.g,

- knuckle points of face plates of primary supporting members, where the web height is changing
- connections between face plates of longitudinal and transverse primary supporting members, the web heights of which are the same.

The classification society may require further verifications of stress concentrations.

TB S21a.4.2 Permissible stresses and deflections - Deflection (UR S21a.3.1.2)

The deflection limit as given by ICLL Regulation 16 (5) is included for the vertical weather design load case.

Where hatch covers are arranged for carrying containers and mixed stowage is allowed, i.e., a 40'-container stowed on top of two 20'-containers, particular attention should be paid to the deflections of hatch covers. Fig. 7 gives an example for a mixed stowage situation and the resulting hatch cover and container stack deflection.

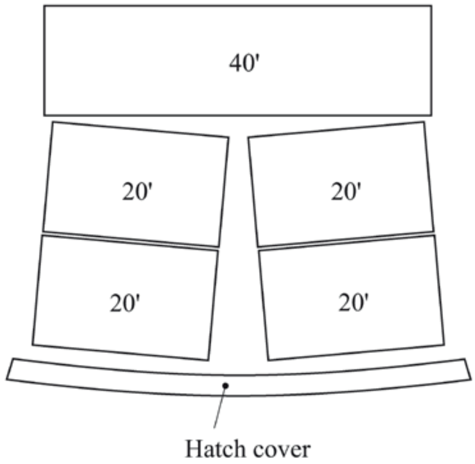

Fig. 7 Example for mixed stowage and resulting hatch cover and container stack deflection

TB S21a.4.3 Local net plate thickness (UR S21a.3.2)

The requirement for the minimum net plate thickness of hatch cover top plating subjected to the vertical weather design load is the same as used in UR S21.

The coefficient 15,8 used in the expression applies for plates under pressure with clamped edges that are free to pull in and with plastic hinges at the edges and at mid-span.

An additional factor $F_P \geq 1{,}5$ is introduced to account for co-existing compressive membrane stress in the hatch cover top plate as well as the possibility that the lateral pressure loading may locally exceed the assumed value. Factor F_P is increased linearly to 1,90 for the attached plate flange of primary supporting members stressed above 80% of the allowable stress limit.

The normal stress of the hatch cover plating is to be determined at all adjacent primary supporting members, parallel and perpendicular to the secondary stiffeners as indicated in Fig. 8.

The greatest of those stresses is to be taken for the normal stress of the hatch cover plating in the requirement for the local net plate thickness. For FE-models using plane stress or shell elements, it is sufficient to read out the stress from the centre of elements adjacent to the webs of the primary supporting members, as long as the element size is not larger than the stiffener spacing, as required by 3.5.2. (General requirements for FEM calculations).

Special loading, e.g. from project cargo, may cause unexpected shear stress in lower plating, not considered by the load cases given in this UR. For this case, the thickness requirement of t=6.5s is to be applied to ensure sufficient buckling strength of the structure.

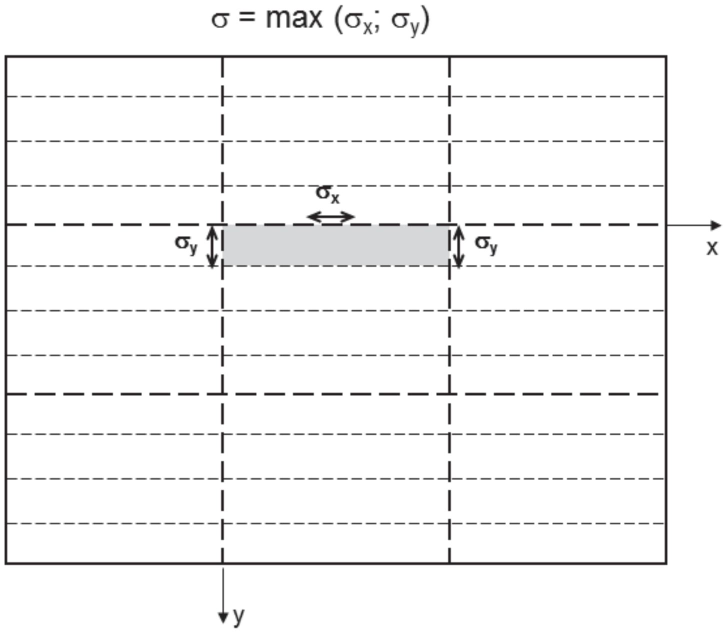

Fig. 8 Determination of normal stress of hatch cover plating

TB S21a.4.4 Net scantling of secondary stiffeners (UR S21a.3.3)

For secondary stiffeners, the minimum elastic section modulus is derived from the elastic bending moment at the fixed end. For vertical weather load the permissible stress as required by ICLL Regulation 16 (5) and for distributed cargo load the permissible bending stress is 90% of the minimum yield point of the material. Only the lateral pressure is considered, while the second order bending moment caused by the combined effect of stiffener deflection (by the lateral pressure load) and the membrane stress in the plate (from the bending of the primary supporting member) is disregarded.

If secondary stiffeners parallel to primary supporting members are regarded for calculating the cross sectional properties of these primary supporting members, it is to be verified that the combined stress of those stiffeners induced by the bending of primary supporting members and lateral pressures does not exceed the permissible stresses.

For hatch cover stiffeners under compression sufficient safety against lateral and torsional buckling is to be verified.

For flat bar secondary stiffeners, a limit on the web depth to net thickness ratio is introduced to prevent their local buckling. This requirement is adopted from UR S21.

TB S21a.4.5 Net scantling of primary supporting members - Primary supporting members (UR S21a.3.4.1)

For all components of primary supporting members sufficient safety against buckling must be verified. For biaxial compressed flange plates this is to be verified within the effective widths. For illustration, Fig. 9 shows a crossing of two primary supporting members with their effective widths. The area where a buckling proof must be carried out for biaxial compression is marked in grey. The buckling proof for parts of the hatch cover plating located in this area is to be done as a combined proof for cases 1 and 2 according to Tab. 7 of UR S21a.

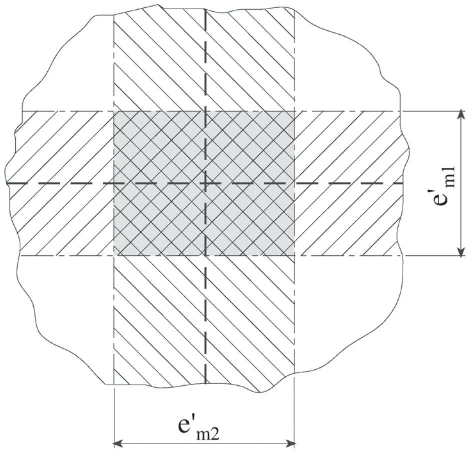

Fig. 9 Crossing of two primary supporting members and their effective widths

TB S21a.4.6 Edge girders (Skirt plates) (UR S21a.3.4.2)

For edge girders the same requirement for minimum net plate thickness is adopted as for the hatch cover top plating except for minimum thickness values that do not depend on the pressure load.

Furthermore, a stiffness requirement for edge girders similar to the requirement as given by IACS Rec. 14 is incorporated to maintain an adequate sealing pressure between securing devices.

TB S21a.4.7 Strength calculations (UR S21a.3.5)

Strength calculation for hatch covers may be carried out by either, using grillage analysis or FEM. Simple beam theory analysis shall be adopted only for hatch covers that are not designed as a grillage of longitudinal and transverse primary supporting members.
For double skin hatch covers and hatch covers with box girders, FEM is to be applied to account for shear stresses in top plating and lower plating. Grillage analysis is not able to consider these shear stresses.

TB S21a.4.7.1 Strength calculations - Effective cross-sectional properties for calculation by grillage analysis (UR S21a.3.5.1)

When determining cross-sectional properties of a primary supporting member, cross sectional areas of secondary stiffeners parallel to the primary supporting member under consideration and within the effective breadth can be included. In this case it is to be verified that the combined stress of those stiffeners induced by the bending of primary supporting members and lateral pressures does not exceed the permissible stresses.

Special calculations may be required for determining the effective breadth of one-sided or non-symmetrical flanges. This can be done by special engineering formulas or, if available, according to the individual class society's rules. In more complex cases an FEM calculation is recommended.

The cross-sectional area of flange plates under compression may be reduced by buckling of the plating. Flange plates with secondary stiffeners perpendicular to the web of primary supporting members are in particular prone to buckling failure. Thus, the effective width is to be considered for the determination of cross-sectional properties of such primary supporting members for grillage analysis or beam theory calculations. However, the effective width of plating is not to be taken greater than the value obtained for the effective breadth.

TB S21a.4.8 Buckling strength of hatch cover structures (UR S21a.3.6)

For further information regarding the buckling strength criteria refer to the technical background documents of Common Structural Rules for Bulk Carrier (CSR/BC), Chapter 6 – Hull Scantlings, Section 3 – Buckling & Ultimate Strength of Ordinary Stiffeners and Stiffened Panels.

Safety factors for the buckling strength assessment are based on the net scantling approach. To be in compliance with ICLL Regulation 16 (5) the safety factor for assessing the hatch cover when subjected to the vertical weather design load is to be taken equal to1,25. For loads other than the vertical weather design load, a safety factor equal to 1,1 is to be applied. This is justified by the more sophisticated buckling strength approach compared to the approach in UR S21. The chosen safety factor of 1,1 matches that of CSR/BC to be used with this kind of buckling strength approach.

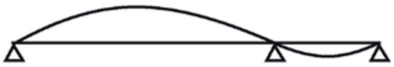
The given correction factors F_1 for boundary conditions at the longitudinal stiffeners correspond to the values given by CSR/BC.

For buckling strength assessment of the hatch coaming vertical plate and coaming stays, vertical and horizontal forces transmitted from the hatch cover should be considered.

TB S21a.4.8.1 Buckling strength of hatch cover structures - Proof of partial and total fields of hatch covers - Lateral buckling of secondary stiffeners (UR S21a.3.6.3.3)

The factor c_s accounts for the boundary conditions of transverse secondary stiffeners. It is to be 1,0 for simply supported and 2,0 for partially constraint stiffeners. Fig.10 gives examples for the factor c_s. For a stiffener, the supports of which are equally spaced, a factor $c_s = 1,0$ is to be chosen (a). If the stiffener spacing changes from a wide spacing to a much more narrow spacing, a partial constraint exists and $c_s = 2,0$ is to be chosen (b). Also when brackets are fitted at the supports of the stiffener, it is to be assumed as partially constraint.

a) c_S = 1,0 for simply supported stiffeners



b) c_S = 2,0 for partially constraint stiffeners

Fig. 10 Examples for the factor c_s accounting for the boundary conditions of transverse secondary stiffeners

TB S21a.5 Details of hatch covers (UR S21a.4)

TB S21a.5.1 Container foundations on hatch covers (UR S21a.4.1)

UR S21a requires designing substructures of container foundations for cargo and container loads applying the given permissible stresses.

Substructures are required to effectively distribute the localized support forces at the container stack corners. An example for container foundations and their substructures is given in Fig.11. The figure shows a section through a primary supporting member with supporting structural elements like brackets beneath two container foundations. The detail drawing shows a typical container foundation more closely.

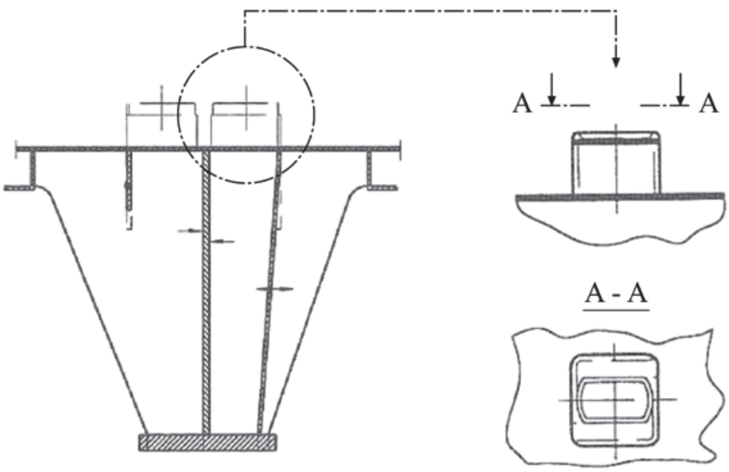


Fig. 3 Example for container foundations and their substructures

TB S21a.5.2 Weather tightness (UR S21a.4.2)

Further to the requirements as given by UR S21a the contents of IACS Rec. 14 are to be observed.

TB S21a.5.2.1 Weather tightness - Dispensation of weather tight gaskets (UR S21a.4.2.2)

For hatch covers of cargo holds solely for the transport of containers, the fitting of weather tight gaskets may be dispensed with upon request by the owners and subject to compliance with the given conditions that correspond to UI LL64.

Among others, it is to be complied with the condition that the exposed deck on which the hatch covers are located is situated above a depth H(x). H(x) is measured from the base line. The definition of H(x) is illustrated by Fig.12 for a position forward of x/L = 0,75.

Further to the requirements as given by UR S21a, Chapter 3 of IMO MSC/Circ. 1087 is to be referred to concerning the stowage and segregation of containers containing dangerous goods.

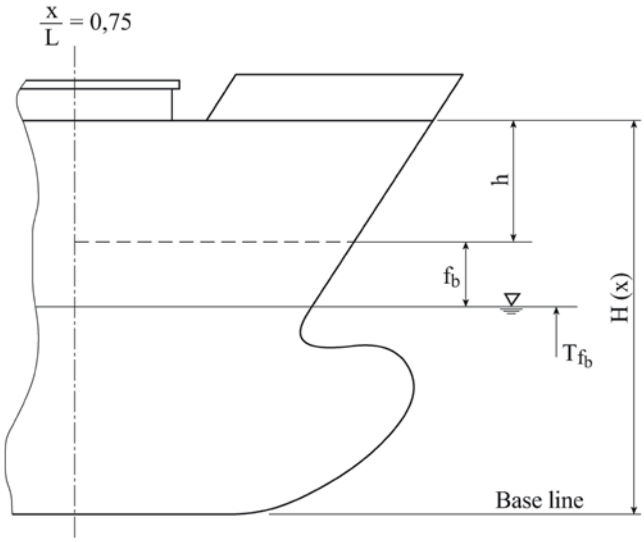

Fig. 4 Definition of H(x)

TB S21a.6 Hatch coaming strength criteria (UR S21a.5)

TB S21a.6.1 Local net plate thickness of coamings (UR S21a.5.1)

The horizontal weather design load model was adopted from UR S3. Thus, the prescriptive local net plate thickness of hatch coamings corresponds to that given in UR S3. The plate thickness required by UR S3 was assumed as a net plate thickness for UR S21a. Additionally, a minimum net plate thickness depending on the ship length was added which is not given by UR S3. Longitudinal strength aspects are to be observed as the given plate thickness formula merely covers local pressure loads.

TB S21a.6.2 Net scantlings of secondary stiffeners of coamings (UR S21a.5.3)

Similar to the prescriptive local net plate thickness, the prescriptive net scantlings for secondary stiffeners of hatch coamings correspond to those given in UR S3. Again, the stiffener section modulus required by UR S3 was assumed as a net section modulus for UR S21a. In addition, a minimum net cross sectional area of secondary stiffeners is required. The latter is based on the elastic shear force of a continuous beam under a uniformly distributed load.

TB S21a.6.3 Coaming stays (UR S21a.5.3)

Coaming stays in general are to be designed for the loads transmitted through them and permissible stresses as defined for hatch cover structures.

For stays of coamings described in Fig. 9 Examples 1 and 2 of UR S21a and subjected to the horizontal design weather load, a prescriptive minimum section modulus and web thickness of the stay at the root point are given equal to the requirements of UR S21. Formulae were derived for the elastic shear force and bending moment appropriate to a cantilever under a uniformly distributed pressure. For coaming stays described in Fig. 9 Examples 3 and 4 of UR S21a or others, prescriptive scantlings have not been formulated as a simple cantilever design cannot be assumed.

For coaming stays, which transfer friction forces at hatch cover supports, fatigue strength is to be considered according to individual class society's rules.

As a guidance, the following load spectrum (as shown in Fig. 13) is given:

$$\log N = \log N_{max}\left[1-\left(\frac{\Delta\sigma}{\Delta\sigma_{max}}\right)^{h}\right]$$

where
N = cumulative frequency (number of cycles)
N_{max} = maximum number of cycles
$\Delta\sigma$ = stress range
$\Delta\sigma_{max}$ = maximum stress range in spectrum
h = shape parameter

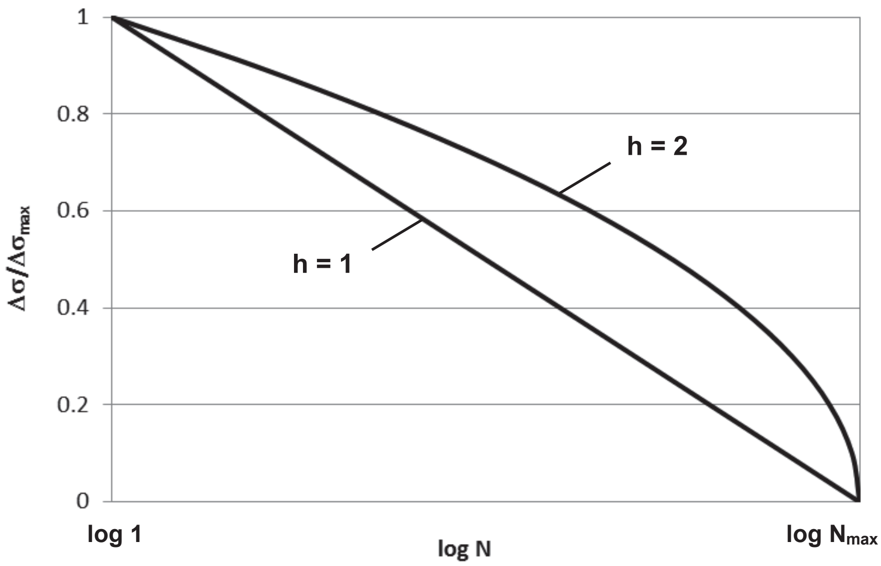

Fig. 13 Stress range sprectra

The maximum stress range $\Delta\sigma_{max}$ is to be calculated using $2P_h$ as load range. For hatch cover supports and supporting structures as well as coaming stays the following shape factors should be applied:

- h = 1 for non-metallic, frictionless material on steel contact
- h = 2 for steel on steel contact

The maximum number of cycles may be taken equal to $N_{max} = 5.0 \cdot 10^7$ for a design lifetime of 20 years. For design lifetime of 30 years the maximum number of cycles may be $N_{max} = 7.5 \cdot 10^7$. For intermediate lifetimes N_{max} should be interpolated.

TB S21a.7 Closing arrangements (UR S21a.6)

TB S21a.7.1 Securing devices - Cross-sectional area of the securing devices (UR S21a.6.1.4)

The requirements, UR S21a gives for the minimum cross-sectional area of securing devices used to maintain an adequate sealing pressure, correspond to the requirement as given by IACS Rec. 14.

For small hatch covers where the packing line pressure needs to be maintained by securing devices, typically rod type securing devices are used. For this type of securing device the given minimum cross-sectional area is applicable.

For large hatch covers securing devices may not be necessary to maintain packing line pressure as the covers are heavy enough. Securing devices then may be needed only as anti-lifting devices. These often exhibit designs which can not be sufficiently assessed only by a required cross-sectional area. They are to be designed according to the requirements for anti-lifting devices (UR S21a.6.1.5).

Where securing devices of special design are used to maintain the packing line pressure and in which significant bending or shear stresses occur, these may be designed as anti-lifting devices. As load the packing line pressure multiplied by the spacing between securing devices is to be applied.

TB S21a.7.2 Securing devices - Anti lifting devices (UR S21a.6.1.5)

For the omission of the anti lifting devices, Chapter 5.6 of IACS Rec. 14 should be referred to.

Alternatively to the proof of the absence of hatch cover lifting, imposed as a condition by Rec. 14, anti-lifting devices may be omitted for ships

- equipped with lashing bridges or similar, which properly limit lifting forces, and
- fulfilling the requirements according to 4.2.2 for non-weathertight hatch covers.

In case of lashing bridges available, attention should be paid to the hatch cover loadings with stacks having a low number of tiers that cannot be lashed to the lashing bridges. It should be proven that hatch cover lifting does not occur under loads arising from the ship's rolling motion. Furthermore, the provisions of Chapter 5.6 of IACS Rec. 14 with respect to the effective height of transverse cover guides should to be observed.

TB S21a.8 Corrosion addition and steel renewal (UR S21a.7)

The requirements for corrosion additions of hatch cover structures are consistent with UI LL70. The requirements for corrosion additions of hatch coamings are consistent with UR S21.

The requirements for steel renewal of hatch cover and coaming structures are consistent with the requirements as given by UR S21. For coaming structures, the corrosion additions t_S of which are not provided in Tab. 10 of UR S21a, steel renewal requirements are to be according to the individual class society's rules.

Report Title:	Rules Reference:
Investigation of Partial Load Cases for Each Heel Direction	Rev.1 XXX. 2015 version
	Distribution by IACS ○ External ● Internal
Project Teams: PT PH 31/2013	**Approved for Issue by:** ☑ HP Technical review
Reporting Organisation Name & Address: IACS 36 Broadway London SW1H 0BH	**No. of Pages:** 9

Summary:

Partial load cases could occur when at least one stack place remains empty on a hatch cover.

While the partial load cases are specified in draft revised UR S21A Tab. 3, it is not clear whether these cases could cover both possible heel directions, as the assessment of only one heel direction is documented by the existing background report on partial load cases.

FE analysis was performed with a variety of partial load cases and showed that the load cases in Tab. 3 could cover possible partial load cases sufficiently.

Revision History:

Content

1 Introduction

The aim of this investigation is to check the impact that the partial load cases have on hatch cover structures. FE analysis is performed under various partial load cases in each heel direction in order to investigate which load cases are severer.
The purpose of this document is to confirm whether partial load cases defined in Tab.3 in UR S21A (see APPENDIX) are appropriate for both possible heel directions, as the assessment of only one heel direction is documented by the existing background report on partial load cases.

2 Analysis

2.1 Subject ship and hatch cover

Subject ship is an 8,000TEU container ship. The subject hatch cover is in mid-ship area. In this report, the center and side hatch covers are considered.

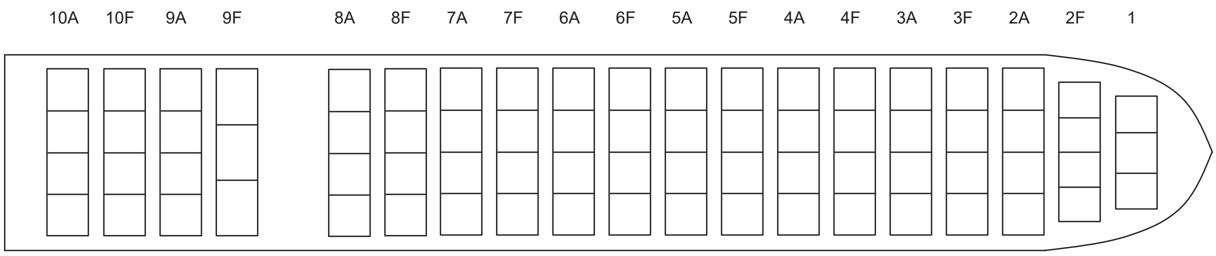

Fig.1 Hatch cover arrangement

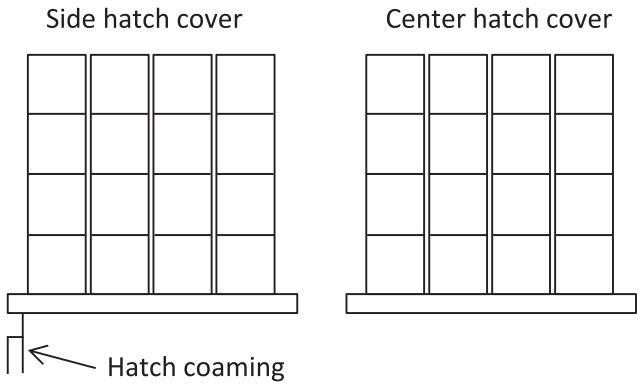

Fig.2 Subject hatch covers

Having in mind that the aim of this report is not to investigate the scantling impact but to examine which partial load cases are critical to hatch cover structures, the FE model of the center hatch cover is used for both center and side hatch covers under different boundary conditions.

2.2Load cases

Ten load cases shown in Fig. 3 are considered for each hatch cover. Heel direction is right in cases 1 to 5 and left in cases 6 to 10. In all cases, only 20 feet containers are considered because the load from 40 feet containers are fully supported by the hatch end coamings and, therefore, is not critical to the required scantling of the girder system (see Fig.4).

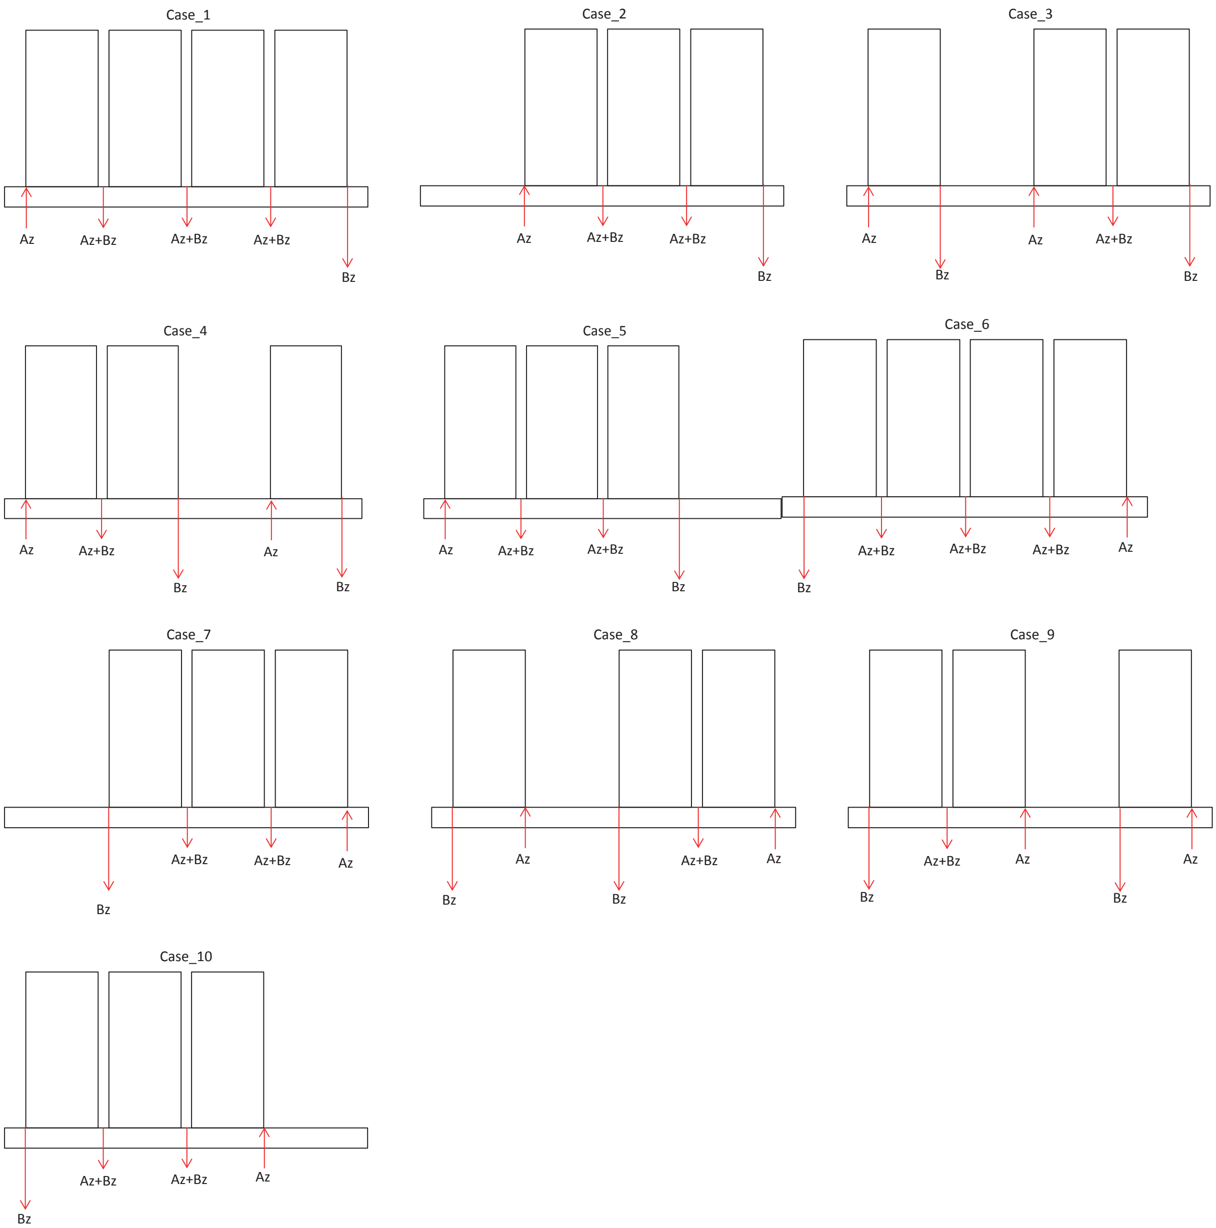

Fig.3 Load cases

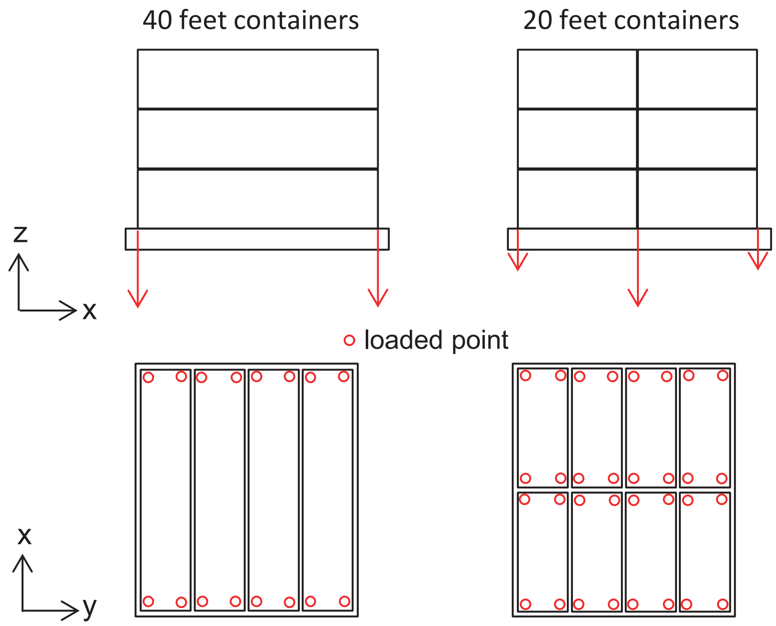

Fig.4 Loaded points of 40 feet containers and 20 feet containers

The design container loads, “A_z” and “B_z”, are calculated according to S21A 2.4. The loads and other parameters are show in Table 1.

Table 1

L (m)	323.3
V_0 (Knots)	27.7
x / L	0.5
a_V (m/s^2)	0.17
hm (m)	6.9
Stack mass (ton)	90
b (m)	2.26
A_z (kN)	435.6
B_z (kN)	900.2

2.3 Analysis results

Stress in way of the fixed nodes (as boundary conditions) are excluded in this report. Examples of equivalent stress distribution are shown in Figs. 5 to 10. Maximum equivalent stress of top plate, girders and transverse webs are show in Table 2. The analysis results show that load cases 1, 5, 6 and 7 are predominant for the strength of hatch cover structures. Load cases 5 and 7 are the same load cases specified in Tab.3 of S21A. Thus, partial load cases defined in Tab.3 of S21A are appropriate to decide the scantling of hatch cover structures.

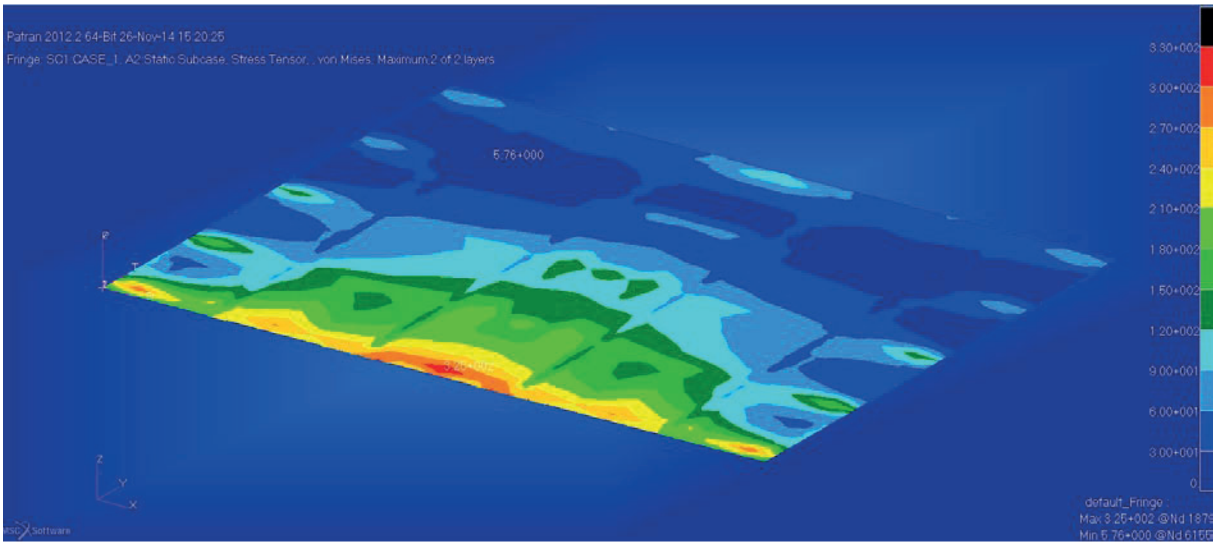

Fig.5 Stress distribution at top plate (center hatch cover: case 1)

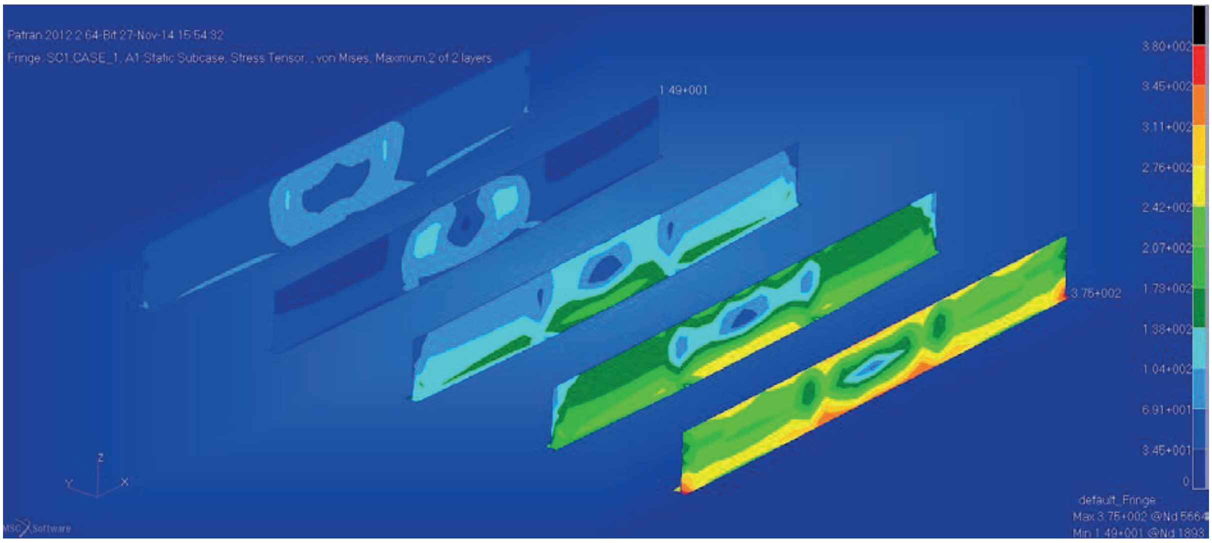

Fig.6 Stress distribution at girders (center hatch cover: case 1)

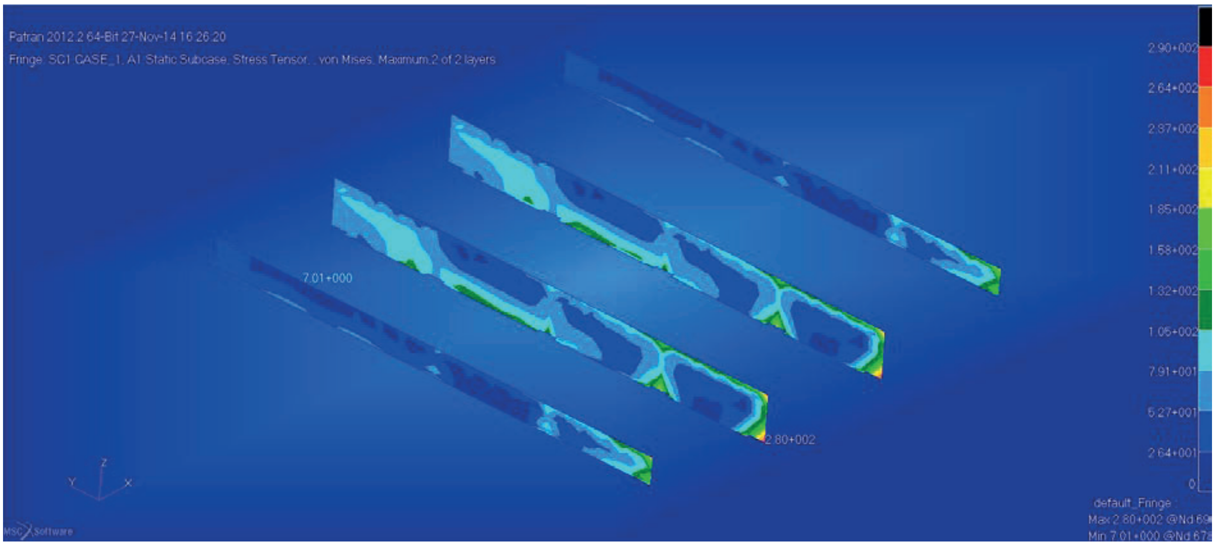

Fig.7 Stress distribution at transverse webs (center hatch cover: case 1)

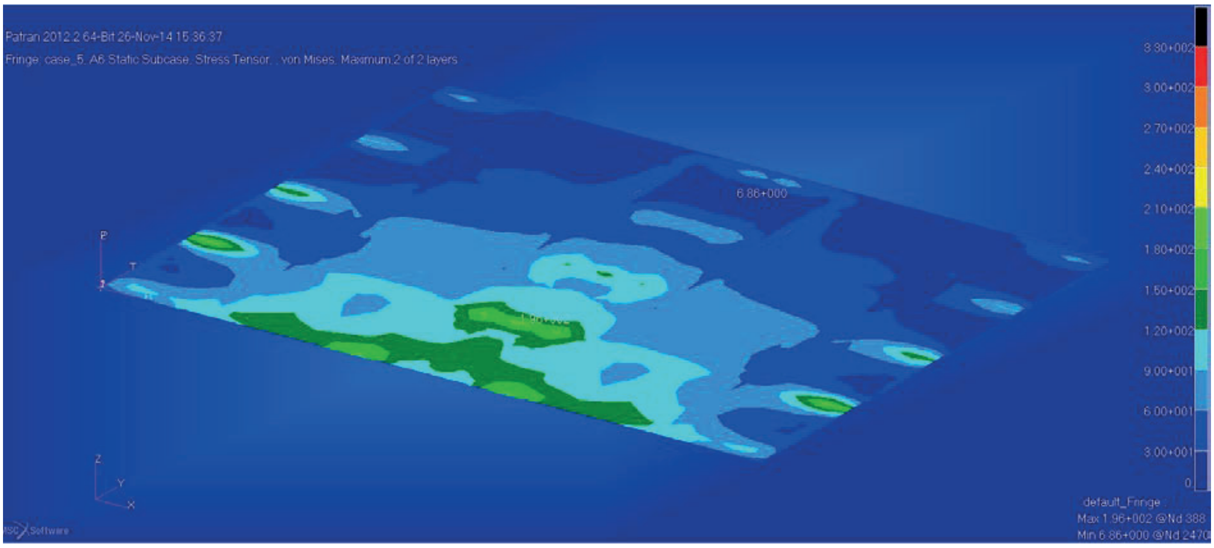

Fig.8 Stress distribution at top plate (center hatch cover: case 5)

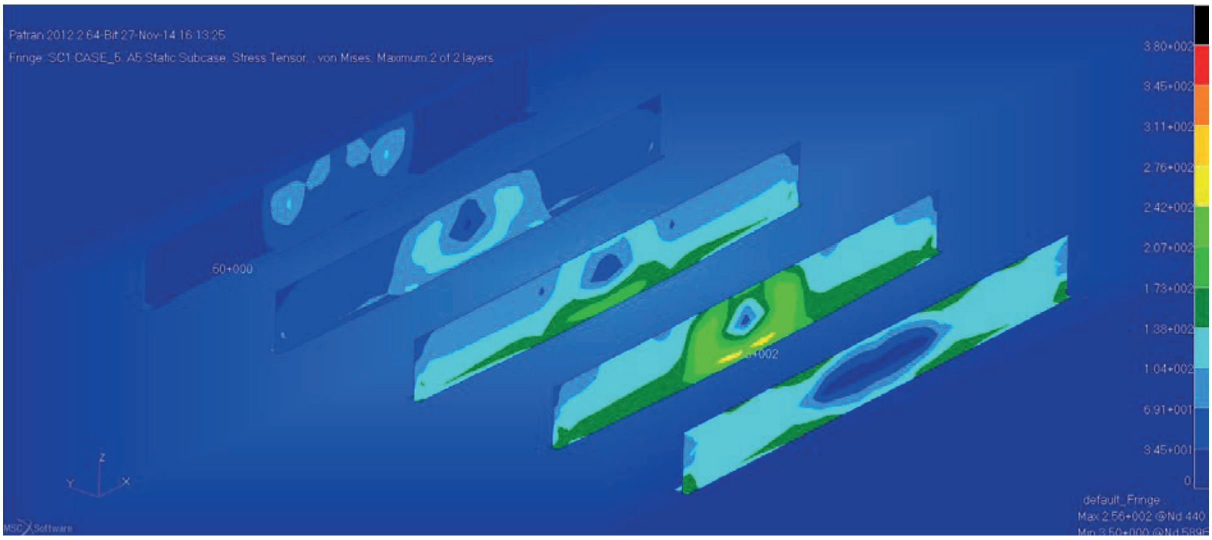

Fig.9 Stress distribution at girders (center hatch cover: case 5)

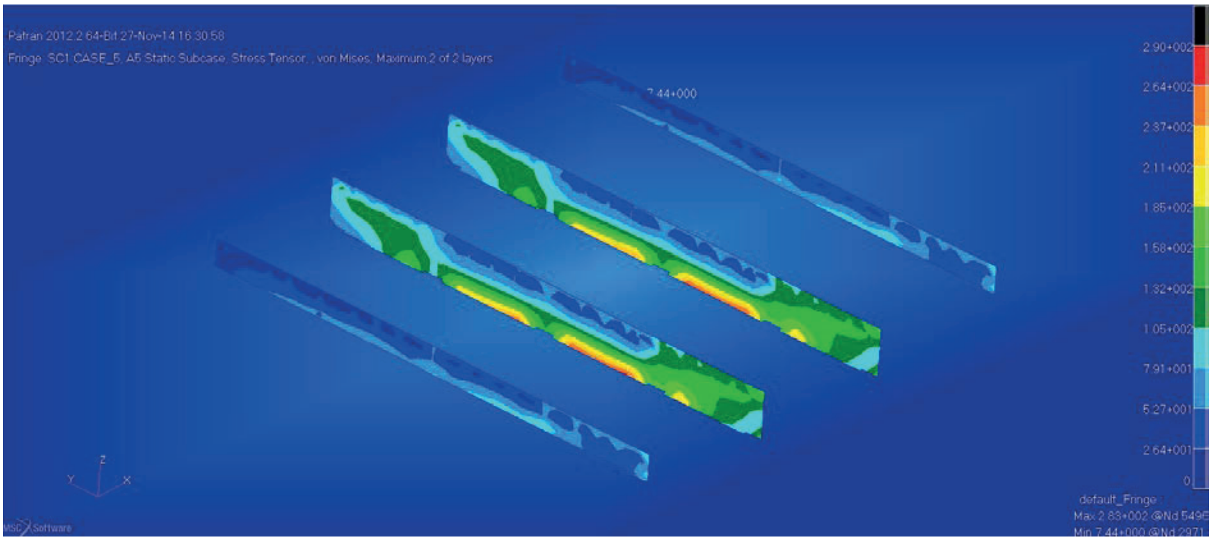

Fig.10 Stress distribution at transverse webs (center hatch cover: case 5)

Table 2 Maximum stresses in each load case (unit: MPa)

		Center hatch cover			Side hatch cover		
		Top plate	Girder	Trans web	Top plate	Girder	Trans web
Heel right	Case 1	325	375	280	311	362	271
	Case 2	309	361	268	292	346	258
	Case 3	284	326	243	273	316	236
	Case 4	256	260	225	247	255	200
	Case 5	196	256	283	196	255	270
Heel left	Case 6	326	375	280	146	234	296
	Case 7	198	256	283	150	238	375
	Case 8	257	262	225	145	228	326
	Case 9	285	326	243	141	229	208
	Case 10	310	361	268	143	230	222

3 Conclusion

FE analysis was carried out under various partial load cases. From the FE analysis results, it is clear that partial load cases defined in Tab.3 of S21A are proper load cases to decide the strength of hatch cover structures.

APPENDIX

Tab. 3 of DRAFT revisedUR S21A.

Tab. 1Partial loading of container hatch covers

Heel direction	←	→
Hatch covers supported by the longitudinal hatch coaming with all container stacks located completely on the hatch cover		Hatch covers supported by the longitudinal hatch coaming with the outermost container stack supported partially by the hatch cover and partially by container stanchions		Hatch covers not supported by the longitudinal hatch coaming (center hatch covers)		
Technical Background (TB) document for UR S21A (Corr.1 Feb 2018)

1. Scope and objectives

Clarify the utilization of permissible nominal surface pressure values and applicability of support materials including pertinent coefficients.

2. Engineering background for technical basis and rationale

The permissible nominal pressure (Pn) may be applied also for other substructures and adjacent structures, but UR S21A 6.2.2 requirement is only applicable to supports of hatch covers and not applicable to other structures. "Supports as well as the adjacent structures and substructures are to be designed such that the permissible stresses according to 3.1.1 are not exceeded. This is relevant for the forces Pv and Ph.

Where supports are composed of various materials, the permissible nominal pressure of each material needs to be considered and the acceptance criteria is to be based on the mechanical properties of weakest material.

The limitation of the permissible pressure for steel support surfaces is related to the phenomenon of fretting and friction welding and not related to the hardness of the material.

It is to be noted that the value of Pn as indicated in UR S21A 6.2.2 Table 9 is given for "Plastic materials on steel" and not for "plastic materials" alone.

The permissible nominal surface pressures are given in Table 9 for:

- Hull structural steel
- Hardened steel
- Low friction material

The permissible nominal surface pressure value given for hull structural steel material should be used where both parts of a sliding contact support are made of this material.

The permissible nominal surface pressure value given for hardened steel material should be used where at least one part of the sliding contact support is made of this material.

The permissible nominal surface pressure value given for low friction material is applicable for a wide variety of sliding support pad systems to which the first two materials (hull structural steel or hardened steel) are not applicable. The Note in 6.2.2 allows for increased surface pressures if proof is provided that the support material can resist this pressure. In addition for support pad systems where no sliding effect occurs at the contact surface but where the relative motion is taken up by the deformation of the pad material, reference may need to be made to the support pad system manufacturer.

Sea load pressures and allowable stresses, previously based on GL1997 (ICLL 66) or now from MSC 77/26/add.1 ANNEX3 (upgraded ICLL), are defined for hatch cover structures, with no link with nominal surface pressure of the supporting material. The nominal surface pressure is an intrinsic value of the supporting material.

The table 9 of UR S21A gives default values of permissible nominal surface pressure Pn, while providing the possibility to use a higher value on a case by case basis, as permitted by the “Note” in UR S21A 6.2.2.

3. Source / derivation of the proposed IACS Resolution

A hatch cover manufacturer addressed questions to IACS related to the UR S21A permissible nominal surface pressure including the meaning of the different support materials provided in table 9. The Hull Panel developed the answer to Industry questions including necessary clarifications.

4. Summary of Changes intended for the revised Resolution:

The support material designation of lower friction material in table 9 for “Plastic materials on steel” has been modified to “lower friction materials" considering that many materials with lower friction coefficient are applied for hatch cover supports, not only one plastic material.

5. Points of discussions or possible discussions

None.

6. Attachments if any

Not applicable.

Technical Background to changes proposed in respect of UR's S1A, Annex 2 to S1A, S12, S17, S18, S19, S20 and S22

The objective of the proposal is to reflect the IMO interpretation of 'single side skin construction' in the above mentioned Unified Requirements for bulk carriers. The Working Party on Strength discussions were unable to yield unanimous agreement and the following matters remain unresolved:

- The titles for UR's S17, S18, S19, S20 and S22 include the wording 'single side skin'. It was generally considered that this wording should now be deleted as the text clearly defines the scope of application and refers additionally to arrangements with double side skin construction. The GL Member does not support this view on the basis that the expression 'single side skin' appears in the text of SOLAS Chapter XII. In view of this difference, the wording 'single side skin' has been enclosed in square brackets pending further consideration by GPG.

- In order to clarify how the breadth of the side shell should be measured, the phrase 'between topside tank and hopper tank' has been used in S17.1(ii) and (iii), S18.1(ii) and (iii), S19.1(ii), S20.1(ii) and (iii), and S22(ii). This was not supported by the ABS member who considers that the IMO definition of single side skin construction does not necessarily refer only to the location between topside and hopper tanks. Also this was not supported by the CRS Member who considers that MSC 89(71), which identifies that measurements are to be made perpendicular to the side shell, provides sufficient guidance**.** For these reasons, the text has been enclosed in square brackets pending further consideration by GPG.

In addition to the above, two other issues have been raised as follows:

- The ABS Member has requested that the following be considered in respect of the deletion of reference to damage stability requirements from paragraph S17.1 of URS17. It is noted that the reference was originally included in order to cover a six months difference in implementation timetables between SOLAS and IACS. Although both implementation dates have now passed and the need for this provision is limited, there could still be cases where it is relevant due to a change of Class from a non-IACS Society to an IACS Society. It is, therefore, proposed that the present clause in URS17 be replaced by an alternative clause within a unified requirement more specifically related to stability requirements. Support for this proposal has been indicated by PRS, DNV, KR, RINA, CRS and LR.

- The GL Member has requested that consideration be given to amending URS20 and URS22 such that these requirements are only applicable when corrugated bulkheads are fitted. This matter has not received support from the other WP/S Members and is considered to be outside the scope of the present Task.

Submitted by WP/S Chair on 31 May 2000
(Note: For GPG action, refer to GPG Chair's message 0064dIGa, 31/7/00)

Technical Background Document
IACS Council – To Improve Bulk Carrier Safety
UR S 23 – Proposed Rev. 3

Objective and Scope:

To reflect the IACS Council decision to advance the implementation date of SOLAS XII requirements relating to existing bulk carriers from 15 years to 10 years.

This will bring forward reinforcement of the corrugated transverse bulkhead between No.1 and No.2 holds and the double bottom structure of No.1 hold, in accordance with S19 and S22.

Source of Proposed Requirements:

- ABS/DNV/LR put forward a set of proposed actions to improve bulk carrier safety on 5 Feb 2002 (s/n 2033).
- Council decided to revise S 23 implementation schedule in such a way as to require ships under 10 years of age, *as of 1 July 2003*, to comply by age 10, and to require ships of age 10-15 which are not already in compliance to comply at the next Intermediate or Special Survey coming due *after 3 July 2003*.

Points of Discussion:

- Care was taken to provide an adequate period of fair warning to allow owners of those ships that must comply first under the revised implementation schedule to plan, and the societies to perform the necessary plan review and preparation for modifications at the upcoming survey.

  S23.1.A.iv was carefully worded so that compliance is not required prior to 1 July 2003.

  (Compliance date of this new measure was changed from 1 Jan 03 to 1 July 03.)

- Completion, prior to 1 July 03, of an intermediate or special survey coming due after 1 July 03, cannot be used to postpone compliance. See S23.1.a.v.

- BV raised a question on the interpretation of “due date of intermediate survey”. In this case, the “due date” will be the last day of the 18 months intermediate survey window period. RINA/KR confirmed.

Conclusion

- Council approved the proposed draft UR S 23 on 19 March 2002.
- Council announced this revision to the public on 15 March 2002.

UR S 23
(Rev.3.1 Nov 2002)

Technical Background:

1. ABS brought to the attention of GPG that the amendment undertaken by Council in pursue of its measure 1, when S23.1.b. was amended to read: "Completion, prior to 1 July 2003, of an intermediate or special survey with a due date after 1 July 2003, cannot be used to postpone compliance." introduced some interpretation when applied to intermediate survey due to the fact that intermediate survey does not have a definitive "due date". ABS' interpretation was that:

> "...for the purpose of application of this requirement of UR S23, the "due date" of the intermediate survey should be understood to be the third anniversary date (and that the three months following the due date may be used to complete the survey) -- so as to require any ship with a third anniversary after 1 July 03 to comply with the requirements in conjunction with this intermediate survey regardless of whether the intermediate survey was done before that "due date" or not."

2. ABS further advised that based on reaction from owners it seemed that all other Members had a different interpretation in practice, which allowed the ship to complete the intermediate survey prior to 1 July 2003 within the window and required compliance with URs S19 and S22 at the next special survey or other controlling date.

3. Based on this ABS proposal and for consistency with other URs S31, S26 and S27, the following text was agreed:

> "S23.1(b): Completion prior to 1 July 2003 of an intermediate or special survey with a due date after 1 July 2003 cannot be used to postpone compliance. However, completion prior to 1 July 2003, of an intermediate survey the window for which straddles 1 July 2003 can be accepted."

4. No change to the implementation date.

* * *

Submitted by the Permanent Secretariat
Date of approval: 4 December 2002 (2033kICb)

TECHNICAL BACKGROUND

UR S23 (REV.4, AUGUST 2007)

1. Scope and objective

To revise UR S23 (rev.3.1) so that it can be consistent with SOLAS regulation XII/4 as amended by IMO Res. MSC.170(79).

2. Background

The Statutory Panel raised this issue which is regarding editorial amendments to UR S23 so that it can be consistent with SOLAS regulation XII/4 as amended by IMO Res. MSC.170(79).

As the maintenance of UR S23 is under Hull Panel responsibility, the Statutory Panel Chairman asked Hull Panel to take it onboard.

Upon the request from Statutory Panel, Hull Panel unanimously agreed to prepare and submit the draft revision to UR S23.2 to GPG for their review and approval.

After deliberations, the Hull Panel proposed to revise UR S23 (rev.3.1) so that it can be consistent with SOLAS regulation XII/4 as amended by IMO Res. MSC.170(79).

3. Points of discussions

The Hull Panel unanimously agreed to revised UR S23 (rev.3.1).

4. Source/derivation of proposed requirements

- ✓ PH7005XRSa
- ✓ SOLAS regulation XII/4 as amended by IMO Res. MSC.170(79).

5. Decision by voting

N.A.

Submitted by Hull Panel Chairman
19 July 2007

Permanent Secretariat note (September 2007):

Rev. 4 approved by GPG 28 August 2007, ref. 7626_IGb.

Technical Background Document
IACS Council – To Improve Bulk Carrier Safety
UR S 24 – Proposed Rev. 1

Objective and Scope:

To reflect the IACS Council decision to extend the implementation of the requirements of UR S 24 **(installation of water ingress detection and alarms)** <u>to all cargo holds on all existing ships as well as new building ships.</u>

Source of Proposed Requirements:

- ABS/DNV/LR put forward a set of proposed actions to improve bulk carrier safety on 5 Feb 2002 (s/n 2033).
- IACS Council decided to revise S 24 to achieve the above objective.

.

Points of Discussion:

- The 2m water level at which the ingress detectors shall activate detection was already provided in the existing text of S24.3.6.
- WP/MCH, in response to Council instruction, urgently reviewed the proposed revision and suggested to specify the place where the alarms are to be located.

  Hence, the positions where the detectors shall be installed are specified in the revised S24.3.2
- Implementation: For new ships, from 1 Jan 2003;

  For existing ships, see S24.1.3.

Conclusion

- Council agreed to the proposed draft UR S 24 on 19 March 2002.
- Council announced this revision to the public on 15 March 2002.

Date of submission: 28 Feb12002

UR S25 "Harmonised Notations and Corresponding Design Loading Conditions for Bulk Carriers"

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
DELETE (May 2010)	24 May 2010	-
Rev.2 (July 2004)	5 July 2004	-
Corr.1 (May 2004)	14 May 2004	
Rev.1 (Feb 2003)	12 February 2003	-
NEW (June 2002)	19 June 2002	1 July 2003

- **DELETE (May 2010)**

.1 Origin for Change:

☑ Based on IACS Requirement *(Common Structural Rules for Bulk Carriers and Double Hull Oil Tankers)*

.2 Main Reason for Change:

Following the introduction of the IACS Common Structural Rules for Bulk Carriers and Double Hull Oil Tankers, Hull Panel were tasked to review all the UR S files to consider whether or not they are applicable to ships covered by the CSR.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None.

.4 History of Decisions Made:

After review it was decided that as UR S25 is currently only applicable for CSR bulk carriers and since the requirements are replaced by those of the Common Structural Rules, UR S25 may be withdrawn.

.5 Other Resolutions Changes

All UR S files, except UR S8, S9, S15, S16, S19, S22, S23, S30 and S31.

.6 Dates:

Original proposal: *2007, made by Hull Panel Task 50*
Panel submission to GPG: *19 April 2010*
GPG Approval: *24 May 2010 (Ref. 10051_IGd)*

- **Rev.2 (July 2004)**

Addition of 'Contracted for Construction' footnote – no TB document available.

- **Corr.1 (May 2004)**

Correction to S25.4.4.1 (a) i and 4.4.1 (b) in order to correctly refer to the provisions of S11.2.1.3 – no TB document available.

- **Rev.1 (Feb 2003)**

See TB document in Part B.

- **NEW (June 2002)**

See TB document in Part B.

Part B. Technical Background

List of Technical Background (TB) documents for UR S25:

Annex 1. **TB for Original Resolution (June 2002)**

Note: *There are no separate Technical Background (TB) documents for Corr.1 (May 2004), Rev.2 (July 2004) and Delete (May 2010).*

UR S 25 - Technical Background (TB) Documents

1 Summary

The proposal covers 2 parts:

(1) To assign standard notations to new ships intended to carry dry cargoes in bulk

(2) Each standard to be based on a minimum set of design loading conditions including some optional ones

2 Suggested contents of Technical background (TB)

2.1 Scope and objectives

The assigned classes BC-A, BC-B, BC-C will create increased transparency in the shipping market, in a way similar to that already existing as regards Ice Class A, B or C or Chemical Tankers Type I, II or III, thus ensuring that bulk carriers are ordered, chartered and/or sold with adequate understanding of the type of ship and operational limitations involved. Bulk carriers categorized as BC-A are to be considered to have high flexibility in cargo loading, unloading, and carriage including Multiple Port loading as standard. Bulk carriers categorized BC-B has no density restriction of the cargo intended to carry but have some restrictions in cargo distribution on board. Bulk carriers categorized as BC-C are designed for the carriage of low density cargoes only.

The proposed draft resolution is not intended to prevent any other loading conditions to be included in the loading manual for which calculations are to be submitted as required by the relevant UR, nor is it intended to replace in any way the required loading manual/instrument.

A bulk carrier may in actual operation be loaded differently from the design loading conditions specified in the loading manual, provided limitations for longitudinal and local strength as defined in the loading manual and loading instrument onboard are not exceeded.

2.2 Points of discussions or possible discussions

(General)

.1 The intentions with the minimum design loading conditions proposed is not to define all the actual loading conditions that bulk carriers will encounter during their operational lives, but to ensure that those are designed and constructed with a strength envelope which is sufficiently wide to allow them to perform most of the transportation services that will be required during their lifetime.

.2 The owner may specify design loading conditions in addition to the minimum required, in that case such design loading conditions shall be included in a standardized summary table on the first page in the loading manual actually prepared for on board operation of the ship.

.3 During actual operation ships are to be loaded within the limits of conditions and restrictions stated in the loading manual.

(Title)

There was a discussion whether “class notation” or simple “notation” is to be used. It was noted that "class notation" is not defined and could vary from one society to another. For example, "class notations" may require action by governance bodies but simple "notation" does not. In this view, BC-A (B, C) would be a class notation but other portions relative to empty hold combinations and cargo densities may not. By deleting "class" it is intended to cover both "notation" and "class notation" without narrowing down the extent of UR. Further, for some classification societies, class notations need be in a limited size of a field which accommodate all notes shown in ( ).

(Application)

It was intention of the Committee that classification and statutory requirements such as longitudinal strength, local strength and stability criteria applicable for the design loading conditions listed under Sections 4 and 5 are not the integral part of this new URs, whilst these requirements are to be complied with according to respective statutory and class requirements.

(Maximum cargo density)

In case where a bulk cargo of which density is more than 3.0 tonnes/m3, BC-B and BC-A bulk carriers are allowed to carry such a cargo without giving annotations to such loading condition subject to compliance with strength requirements in Rules and Regulations of each Society and necessary description in the loading manual.

(Design ballast condition/ballast tank capacity)

This condition is needed to define the design ballast condition where strength of the bottom forward is assured against slamming. In achieving this condition, use of cargo hold adapted for carrying ballast water is excluded. Further, reflecting current practice, a need to obtain deeper draught where a ballast hold, if any, is utilized, is provided.

2.3 Source/derivation of proposed requirements

UR S1A is taken into consideration in developing this standard.

Technical Background Document

General Policy Group

Refinement of UR S 25 (Rev.1, Feb 2003)

Objective and Scope:

To refine UR S25

1) to provide sufficient ballast capacity for the heavy ballast condition
2) to allow appropriate flexibility in the design of capacity and disposition of ballast tanks, and
3) to eliminate the unnecessary complexity and confusion without changing the intent.
4) to achieve common understanding of para. 4.4.2(b) – longitudinal strength checks when more than 1 hold is capable of being used for ballast at sea (GPG 53 FUA 27)
5) To achieve common understanding of the application of the design conditions of Section 4 with respect to the applicable rules criteria for longitudinal strength (footnote 1 to S25.2.3).

Points of Discussion:

1) ABS put forward a set of proposals on 22 July 2002:

- pending completion of the suggested task (ABd, item 1b), to require a ballast hold for larger bulk carriers so as to retain the current design practice. (4.4.1(b)),
- to confine the BWTs 100% full requirement to strength check purposes (new 4.4.2),
- to separate BWT capacity/disposition requirement (new 4.4.1) from strength requirement (new 4.4.2) so as to allow more flexibility in designing the capacity and disposition of BWTs,
- to specify that the length for use with the trim requirement is to be LBP (4.4.1), and
- the departure condition bunker capacity is to agree with the accepted marine practice (4.5).

2) Members' reactions to the ABS proposals are summarized in the attached Table "[S25Rev_cmt_summary] ".

3) In summary, ABS proposal, with further refinements based on member's comments, was generally accepted by the Members. Concerning the conditional hold ballast/new task proposal, DNV~~’s~~ submitted a counter proposal for minimum forward draught criteria for all lengths. Following comment by one member, DNV subsequently submitted a compromise proposal.

The majority was in favour of the DNV's first proposal for a minimum draught forward, that is, the lesser of 0.03L or 8.0 meters. It was agreed that this requirements should be applicable to all bulk carriers regardless of the ship's length.

Submitted by the Permanent Secretariat
28 October 2002

(The following compromise text~~,~~ was supported by NK. GL, who proposed 0.025L/8m, did not respond to this compromise text:

4.4.1(b) v: *The forward draught in the heavy ballast condition is not to be less than the smaller of k*L and 8.0 meters where*

k = 0.00015L, but is not to be taken less than 0.025 and need not be taken larger than 0.03)

The figure, 0.03L, was chosen instead of 0.025L since Members' studies revealed, in conjunction with the proposed requirement that at least one cargo hold be 100% full, that a minimum draught forward of the smaller of 0.025L or 8m was too shallow to be compatible to the ABS proposed ballast cargo holds.

4) With regard to para.4.4.2(b) concerning longitudinal strength checks when more than one hold is capable of being used for ballast at sea, the majority of GPG at GPG 53(2-4 Oct.2002) were of the view that each hold should be addressed in turn, with all the others empty but NK argued strongly that in case where two or more holds were intended to be filled together or when arranged to facilitate ballast water exchange at sea, certain configurations were unrealistic. Therefore, applying 4.4.2(b) on a single hold-filled basis would be too harsh. A particular case was a forward ballast hold which would never be filled with all other tanks full and holds further aft empty. The forward trim would make the ship unmanageable.

At a small GPG meeting during MSC 76, it was agreed that 4.4.2(b) should be amended to make the longitudinal strength requirements for heavy ballast conditions clear and to settle the unresolved issues.

6) The loading conditions listed under Section 4 are to be used for the checking of applicable rules criteria for longitudinal strength, i.e. for BC-B and BC-A designs of single skin construction the design conditions of Section 4.1 4.2, 4.3 and 4.4 are to be considered with respect to the requirements of S17 in addition to the requirements of S11. If the requirements of S17.1 is understood to be in conflict with this view, the application requirements of S17.1 must be amended.

Following a lengthy discussion**, t**he criteria for longitudinal strength under Section 4 has been specified by adding a footnote to 2.2 as follows: *"Footnote 1: As required by S7, S11 and S17".*

*** S 17 applies to BCs carrying solid bulk cargoes with bulk density of 1.0 t/m^3 or above. However, the notation BC-C applies to BCs carrying solid bulk cargoes with bulk density of less than 1.0 t/m^3 . Therefore, S17 will not be applied to BCs assigned the notation BC-C under S25.**

Submitted by the Permanent Secretariat
28 October 2002

(S17 does not require longitudinal strength checks in the hold flooded condition for BCs carrying cargos with bulk density of less than 1.0 t/m^3 .)

7) Other proposals were considered and agreed with some modifications.

Conclusion

- Council agreed to the proposed Revision No.1 of UR S 25 on 12 February 2003.

Attached:

1) NK's study on significant wave height vs the DNV's proposed formula.

2) Summary of members' reactions

Submitted by the Permanent Secretariat

Attachment 1.

DNV compromise proposal (NVj) – 4.4.1(b) v:
The forward draught in the heavy ballast condition is not to be less than the smaller of k * L and 8.0 m. K = 0.00015 L, but is not to be taken less than 0.025 and need not be taken larger than 0.03.

0120gNKo dated 28 August 2002.

With regard to my message of 0120gNKn dated 23 Aug, 02, I would like to draw your attention to the attachment diagram, which contains a material that could support the ***DNV's*** proposed criteria of forward draught for the heavy ballast condition which is prepared for rough seas.

- The points shown in the diagram are the results of calculation on the basis of the occurrence probability of exposure of bottom at bow of bulk carriers exceeding 10-2 (1/100) against the significant wave heights.
- It is found that the significant wave heights are 2 - 3 m for smaller bulk carriers and are 6 - 7 m for larger ones, which can agree with seafarers' empirical recognition of rough seas.
- The real line as proposed in NVj is drawn in the diagram.
- From the diagram, the proposed forward draught criteria for heavy ballast conditions are found reasonable.

Further, as regards Paragraph 2.2.3 of LRc, the forward draughts in the normal ballast condition (not heavy ballast condition) of small bulk carriers without ballast hold are as follows:

df / L	L(m)
1 0.0261L	143
2 0.0213L	148
3 0.0248L	150
4 0.0209L	160

I would like to invite GPG members to consider the above and accept the DNV's proposal in NVj based on the technical background as above explained.

Best regards
H.Jin

THE REVISION OF IACS UR S25 (Rev.2, Feb 2003)

COMMENTS SUBSEQUENT TO ABd (22 JULY 2002) AND ABS REPLIES THERETO

(Comments are identified by 3 name/sequence digits, with their dates being shown in the last page)

Para.	Comment	Reply
1.3	**(**ABh) (in conjunction with change to 2.2) Add reference to stability	Proposed in ABh.
	(NVh) OK	Noted
2.2	(NKj) 2. In order to clarify the application of loading and ballast conditions for strength assessment I would like to propose to editorially amend paragraph 2.2 of UR S25 as follows. "Rule criterion regarding local strength is to be checked for the loading conditions listed under Sections 4 and 5, as applicable. Rule criterion regarding longitudinal hull girder strength and stability is to be checked for the loading conditions listed under Section 4 and those specified in the approved loading manual based on the conditions listed under Section 5."	See below reply to LRb
	(LRb) 3. We agree with NK that the text of paragraph 2.2 should be edited to make its' intent clearer. The following text is proposed: "2.2 The loading conditions listed under Section 4 are to be used for the checking of rule criteria regarding longitudinal strength, local strength and stability. The loading conditions listed under Section 5 are to be used for the checking of rule criteria regarding local strength."	Agree, with addition of capacity and disposition of ballast tanks to “under Section 4”. Also changed title of Section 5 to suit the revised 2.2, all in ABh.
	(NVh) OK (to ABi)	Noted
	(NKk) I agree to the revised wording for Paragraph 2.2 as proposed by LR in item No.3 of LR's message.	Noted
3	(ABh) (In conjunction with change to 4.1 – 4.3) In BC-A, add “at the summer load line draught” after “specified holds empty”	Proposed in ABh.
	(NVh) OK, but the words "at the summer load line draught" should be changed to "at maximum draught", which is the terminology used in the rest of S25. NB "maximum draught" is already defined in S25 2.3.	(ABk) Let us point out that “maximum draft is summer draft” in S25.2.3 is in itself an incorrect statement in that maximum draft is clearly tropical fresh or, where assigned, timber tropical fresh. It is therefore proposed that a much better formulation is to delete S25.2.3 and the phrase "***maximum draft***" be replaced, throughout S25, by the phrase "***molded summer load line draft.***" (This overrides ABi)
4.1 – 4.3	(LRb) Add “with all ballast tanks empty” after “at maximum draught”	Additions made in ABh.
	(NKk) - I support the insertion of wording "with all ballast tanks empty" after "at maximum draught" to Paragraphs 4.1, 4.2 and 4.3 as suggested by LR in item No.4 of the message in LRb.	See above
4.4.1	(NKh) **-** Add “arrangement and” to the title with corresponding change in the text.	**-**In ABf,The title is changed to read “Ballast tank capacity and disposition” to address the concern more explicitly and to the

	- Add “design” to the title of 4.4.1(a) and (b) and 4.4.2(a) and (b)	sequence of the events in design. Text changed accordingly. -the definition qualifies these terms for use with this UR and the intent of NK comment is considered fulfilled.
4.4.1(a) i	(KRd) "Slack condition" in item 4.4.1(a) and (b): - I would like to propose to use the phrase "partial filling" in line with other URS instead of "slack" - partial filling of ballast tanks is agreeable but we still tend not to allow partial filling of fore peak ballast tank. If it is to be allowed for the fore peak tank, it should at least be stated that the proper structural arrangement is to be provided to prevent sloshing load.	In ABg - Text changed to indicate partially filled. - Text also changed to refer to the last paragraph in S11.2.1.2
4.4.1(a) ii	(GLc) Add “and” at the end.	Addition made in ABg as suggested.
	(LRb) … the propeller is to be fully immersed.	Corrected in ABh as suggested
4.4.1(a) iii	(CCb) As far as length of ship is concerned, I considered that "L" should be the length of ship which is the initial consideration by SC/BCS and defined in MARPOL Convention where the coefficient of 0.015 is introduced instead of the length between perpendiculars of the ship, otherwise this coefficient should be reconsidered.	It is believed that by adhering to 0.015, the definition of waterline is maintained without any change. Use of LBP is only for the sake of convenience of clients.
	(CCb bis) The use of LBP is acceptable to CCS if majority agrees.	Noted
	(LRb)….the trim is to be by the stern and is not to exceed...	Corrected in ABh as suggested
4.4.1(b) i	(KRd) Same as 4.4.1(a) i	See reply above
4.4.1(b) ii	(LRb)...or required, is to be full.	Corrected in ABh as suggested
	(NVh) The footnote regarding bulk carriers without ballast hold(s) is redundant and may be deleted.	Accepted in Abj but confirmation of uniform understanding by all Members requested in Abm.
4.4.1(b)iii	(GLc) Delete “and to the waterline”	Deleted in ABh as suggested.
	(LRb)....immersion I/D is to be at least ...	Corrected in ABh as suggested
4.4.1(b) iv	(LRb) …the trim is to be by the stern and is not to exceed...	Corrected in ABh as suggested
4.4.1(b) last para.	(NKh) Delete the entire paragraph (NKi) NK will make further comment early next week.	Pending further comment by NK, the paragraph is retained in ABg.
	(NKj) The proposal for a mandatory requirement for installation of a ballast hold for bulk carriers of certain length and above is supported. In this connection in the fleet statistics there is a clear separation of ship length between handy size and panamax at the length of 200m. Therefore it would be more appropriate to use this	(ABh) ABS can support 180m, if supported by others, but cannot support 200m proposed by NKj, for reason that it departs from the present day practice as most recently reported by NK on 17 April 2002 reading in part; ***“2.2 Bulk carriers smaller than Panamax*** *While checking 36 bulk carriers of 172m in length and less classed by ClassNK, it was found that about 94% of them did not have ballast holds. Therefore design ballast condition of this size of bulk carriers must be normal ballast condition.* *While checking 30 Handymax bulk carrier of around 180m in length and over, all bulk carriers have ballast holds. It could not however be confirmed whether or not heavy ballast condition is used more frequently than normal ballast condition. The answer is unknown at the moment.* *Therefore we have to consider that there are two types of Handymax bulk carriers, i.e., Panamax-like Handymax bulk carriers and Handy-like Handymax bulk carriers in terms of operation or selecting ballast condition.”*

	length for requirement of a ballast hold.	which agrees with ABS finding. Please note that how often hold ballast will be used is not the issue. Rather, if such option is available in case of need is the issue of safety which need be addressed.
	(BVb) 1. It is a good thing from operational point of view to increase the range of sea states where the ship can be operated with light ballast condition (without filling the ballast hold). As defined by SC/BCS, this could be obtained by reinforcing the bottom forward against slamming, fully immersing the propeller and dealing with longitudinal strength. 2. As a matter of ship safety, it is needed , at least for Panamax and larger vessels, to allow the captain to adopt a heavy ballast (ballast hold is full) condition where storm conditions are expected. As mentioned in ABS message (1.B Capacity and parameter), the draft increase in this case is much higher than the one corresponding to 60% propeller immersion. The only fact we know with reasonable accuracy is that this heavy ballast condition generally allow present vessel designs to sail in very bad weather without major damages. Conditions like the 60% propeller immersion do not lead to the same level of safety, and may be insufficient in storm conditions. The two above principles are fully in line with the MARPOL requirements for oil tankers, taking into account the bulk carrier specific fact that the scantlings of the ballast hold are to specially designed for ballast carriage purpose. The ABS proposed revision of UR S25.4 (document 0120gABdRevS25.doc) meets the above mentioned two principles in our opinion and is therefore supported, including the length limit value of 172 - 180 m. For the same reasons, we do not support the NK and DNV proposals.	The last paragraph is retained in ABg based on this comment.
4.4.1(b) last para (cont'd)	(KRc) 3) Item 4.4.1(b) (i) - *which then read "any water ballast hold is be full"* - is suggested to delete since there is no need to define all ballast holds to be full once strength requirements and trim/draft requirements are satisfied. Therefore, NK's amendment to this item is supported. With this amendment, no length limit – *in the last paragraph* - for bulk carriers to have ballast hold can be deleted. Our record shows that ballast hold are rarely designated in a handy size bulk carrier and this deletion can enhance the designer's/operator's option.	In ABf, hold ballast is addressed in 4.4.1(b) ii with qualifier "where required or provided"
	(KRd) - with the introduction of item 4.4.1(b) ii, we can agree with the last sentence – *assumed to refer to last paragraph* - of item 4.4.1(b).	The last paragraph is retained in ABg based on this comment
	(RIc) For the same reasons as expressed by Mr Guyader in BVb and repeated by Mr McIntyre in ABf, RINA supports the view that one or more holds dedicated to the carriage of ballast are to be explicitly required in 4.4.1 (b), at least for ships above a certain length. As far as the length limit of 172 m is concerned, it results to us that a large amount of Handysize bulk carriers are concentrated in the range 170-180 m, so that a limit within this range would entail that one ship might be discriminated from another just for a matter of centimetres! We are of the opinion that 170 m is an appropriate length limit; however, we would appreciate other Societies' view on this matter	The last paragraph is retained in ABg based on this comment
	(RId) Minimum length of 170m should be retained as indicated in RIc.	The last paragraph is retained in ABg based on comments from other societies For the same reason, 180m was retained in ABh.
	(CCb) The length limit of 172 m is unnecessary as all the ships of 150 m or above can be designed and assessed under the requirements of URs.	As a matter of fact, at-sea ballast water hold is fitted for all larger ships. It was found necessary that this practice be written into UR at least pending completion of a new task being proposed at this time to establish all criteria necessary and sufficient for the safety of heavy ballast condition. For this reason, this paragraph was retained in ABg for further consideration. Or is it your opinion that all ships of 150m and above are to have ballast hold?
	(CCb-bis) As far as minimum length of ship is concerned, CCS prefers 180m.	[180m] is reflected in ABi
	(LRb) Whilst we have considerable sympathy with the amendments proposed by Mr Myklebust (0120gNVd), we consider that it would be preferable to explicitly require the provision of a ballast hold for larger bulk carriers. LR consider that a minimum length of 180 metres should be	See reply to NKj

	specified, although we could accept 200 metres as proposed by Mr Jin (0120gNKj) if this is supported by other Members.		
4.4.1(b) last para (cont'd)	(NVd) Delete the last paragraph and introduce item v reading "the draught forward is not less than the smaller of 0.03L and 8.0 meters. .	(ABi) DNV propose to replace the requirement for a ballast hold for ships above a certain length with a minimum required draught forward. We understand that the minimum draft forward criteria which DNV proposes is an empirical criteria which fits with the current DNV bulk carrier fleet (being the heavy weather ballast draught forward with ballast hold filled on ships with ballast holds). If so, then we consider it to be a surrogate for, or alternative to, simply mandating a ballast hold above a certain length limit---based on current empirical practice, but using different parameters. So, in our view, as with the ABS proposal to require a ballast hold, the DNV proposal can only be considered to be a "stop gap" measure. We cannot see that the proposal has any greater merit than simply requiring a ballast hold; and is much less direct. If adopted, it has the potential of "locking in" future design practice for a very long time to come using parameters the origin and significance of which will soon be forgotten. Also, we have not had time to check how these proposed criteria "fit" with the ABS fleet. And, since we have done that check for the length limit for mandating a ballast hold, which is supported by the NK study done for SC/BCS and which a majority of other societies have agreed to in principle, we strongly believe the ABS proposal is the better chose (particularly at this late date.) Also, what we understand is happening now is that designers are producing "standard" S25 compliance designs but with bigger ballast tanks and no ballast holds. This was never intended. It is possible that, with the DNV minimum draught forward criteria, designers will continue to provide much bigger than needed ballast tanks instead of ballast holds and present the designs to owners as IACS S25 compliant designs--any changes are at additional cost to owners. This is what we seek to avoid, while not unintentionally reducing the safety and flexibility of existing (unregulated practice) by inadequate regulation. So, we do not support the DNV proposal in this regard.	

	(NVe) For the sake of good order, DNV completely agrees that a good bulk carrier design should include cargo hold(s) adapted for ballast water. What we have argued against, and which is the reason for our suggestion in 0120gNVd of 12-08, is the need to introduce a mandatory requirement to ballast hold(s) for some types of bulk carriers into S25, a UR which is not intended to tell designers how to design the arrangement of bulk carriers, and which may introduce more questions than it solves. Please recall that most bulk carriers are today designed with ballast hold(s) even though there are no formal requirements to do so. The reason is that designers have found this to be the best compromise between providing sufficient ballast capacity and maximum cargo hold cubic capacity. We can not see that the introduction of UR S25 will make the voluntary inclusion of ballast hold(s) less likely. If ballast hold(s) are to be required, we would argue that such requirements should apply equally to single side skin and double side skin bulk carriers. For most double side skin designs, that we have been involved in, the designers have tried to retain the cargo hold cubic capacity by reducing the size of top wing tanks and hoppers to compensate for the volume occupied by the double side skin, thereby keeping the same ballast tank capacity as of a single side skin vessel, and keeping the same need for ballast hold(s). Equal applicability would also remove the need for the "special consideration" statement 4.4.1(b), which would most likely lead to different application by the various IACS members. It would also solve the problem of how to handle bulk carriers with partial double side skin, i.e.; double side skin in some cargo holds and single side skin in the rest. Finally, a bulk carrier's length is not as clear-cut a parameter as it might initially seem. For example if the size limit is set to 200 m as proposed by 0120gNKj, all modern handymax bulk carriers (50 - 55000 tdw) will fall below this size limit (around 190 metres) although they are normally provided with ballast hold(s), while a much smaller 36000 tdw lakesize bulk carrier may exceed 200 metres. If a size limit in terms of ship's length should be applied, such length limit should be below that of typical handymax bulk carriers, f. inst. 180 metres as suggested in 0120gLRb	(ABi) Regarding requiring a ballast hold above a certain length, we have explained and argued the need for this to the best of our ability in our prior messages and in 2.2.1 above. IACS has decided to "regulate" ballast conditions for bulk carriers for the first time. However, the regulation in S25 on this at present is "necessary" but "not sufficient" and will, if left as is, result in designs of bulk carriers which are less capable, less safe and less flexible in heavy weather ballast operation than is currently provided by the "unregulated" market. This is wholly unintended and counterproductive, and since it relates directly to safety--we cannot leave it as it is. Mandating a ballast hold above a certain length will simply clarify to designers not to design bulkers which "just meet" the other criteria in S25 and should steer them back on course. Owners, whose complaints we are trying to satisfy, will not take kindly to being presented with an S25 compliant design with unnecessarily large ballast tanks and no ballast holds---requiring redesign to meet owners needs. Regarding DNV's objection to allowing "special consideration" for the length at which a ballast hold is to be required on double skin bulk carriers, we understand their arguments and, in effort to reach consensus, we can agree to deleting this provision, if so agreed by other Members. I have therefore put this sentence in square brackets in the attachment. If this sentence is deleted will DNV join the majority and agree to mandating a ballast hold on bulkers of 180m length and above? Would DNV please advise? And, as indicated in ABh, we agree to the 180m Length limitation espoused by DNV.
4.4.1(b) last para. (cont'd)	(GLd) GL fully supports DNV's approach to define a minimum ballast draft at F. P. The approach focuses directly on the main issue of bottom strengthening forward due to slamming pressure . Besides, GL is of the opinion that the proposed formulation of minimum ballast draft forward might be too conservative . GL suggests to use 0,025 L instead of 0,03 L in the formulation. The revised version would therefore read as follows: "The draught forward is not less than the smaller of 0,025 L length as defined in S2 and 8.0 metres".	(ABi) We do not believe the DNV proposed forward draught criteria relates to prevention of slamming forward--we believe it is an empirical fit to the current DNV fleet of bulk carriers in the heavy ballast condition with a ballast hold filled.
	(NKk) The criterion for the draught forward of 4.4.1(b) Heavy ballast condition that is proposed by DNV in place of a mandatory requirement	(ABj) 1. Re the proposals in NVh and NKk to replace the requirement for a ballast hold for ships above a certain length with a minimum draught forward requirement for ships above a certain length:

<table>
<tr>
<td></td>
<td colspan="2">of ballast holds provides generic approach of heavy ballast condition and is supported. However it needs further examination as pointed out by Mr Jacoby in GLd that the proposed formulation of minimum ballast draught forward might be too conservative. As a result of NK's investigation on the forward draughts of NK class ships, the proposed criterion, i.e. the smaller of 0.03L and 8.0 meters, is found reasonable for larger bulk carriers like Panamax, Capesize bulk carriers. However, for handy size bulk carriers that do not have a hold adapted for ballast this criterion is too conservative. In this regard, I share ABS concept that no ballast hold is required for smaller bulk carriers. The propeller immersion criterion, taking into consideration the fact that the criterion of 60 % propeller immersion for heavy ballast condition provides sufficient criterion for handy size bulk carriers without regulating the draught forward.
I therefore consider that it would be appropriate to take the above assessment into account in the draft text by DNV (NVd) and to amend to read as follows:
"4.4.1(b) Heavy ballast condition"
i - iv no change
v "The draught forward for bulk carriers 200 m and above in length as defined in S2 is to be not less than the smaller of 0.03L and 8 meters."</td>
<td colspan="2">1.1 we reiterate our view that it is more transparent and direct to simply require the ballast hold, in line with the current (unregulated) practice. As BV pointed out: "As a matter of ship safety, it is needed, at least for Panamax and larger vessels, to allow the captain to adopt a heavy ballast (ballast hold is full) condition where storm conditions are expected. As mentioned in ABS message (1.B Capacity and parameter), the draft increase in this case is much higher than the one corresponding to 60% propeller immersion. The only fact we know with reasonable accuracy is that this heavy ballast condition generally allow present vessel designs to sail in very bad weather without major damages. Conditions like the 60% propeller immersion do not lead to the same level of safety, and may be insufficient in storm conditions."
This "safety condition" is today met, in unregulated practice, by the provision of a ballast hold. It is most appropriate to simply continue this practice (unless or until we can provide "definitive" heavy weather ballast crteria) rather than to impose an empirical, surrogate parameter such as minimum draft forward to accomplish the same objective in a more indirect and more limiting way.
Simply put, minimum draft forward in heavy ballast is not considered a reliable parameter to define a ballast capacity requirement for the purpose of ensuring safety. A draft at the center of flotation in terms of %age of maximum displacement ("Bulk Carrier Practice" indicated 50-65% of loaded displacement to be the norm for heavy weather ballast, see 0120gIAc, 9 Aug) may be.
1.2 It does not make sense for designers to design ships with unnecessarily large ballast tanks--which they may still do if the minimum forward draft criteria--is adopted in UR S25 when owners want and will require ballast holds. This potential foulup is avoided by simply mandating the ballast hold.</td>
</tr>
<tr>
<td>4.4.1(b) last para. (cont'd)</td>
<td colspan="3">(NKk) Comments to 2.1 Paragraph 4.4.1(b) of ABS comments in ABh
-1. With regard to the length criterion based on NK report, I would like to suggest that the statistics on ship length of bulk carriers contained in the attached document (0120gNKkAttach_SC3Ax6A2.doc) is to be used as the common basis.
-2. However, in line with the new approach proposed by DNV in NVd to specify the minimum forward draught using ships length, which was further elaborated in the message NVe of 14 Aug. 02 an introduction of a mandatory ballast hold requirement is taken over by the DNV's approach. In case of a need of demarcation in ship length for different approaches according to the size 200 m is a pragmatic magic number, which avoids difficult separation of bulk carries in the same category of sizes.</td>
<td>See ABl</td>
</tr>
<tr>
<td></td>
<td>(IGd) I would request that Members who have not already done so now comment on this issue, stating which proposal they</td>
<td colspan="3">(ABk) 1. With reference to Chairman's IGd, 15 Aug: Our first and foremost objective, indeed our obligation, must be to establish criteria which provide for adequate safety. We do know that the current (unregulated) design practice provides adequate safety for heavy weather ballast service--based on the historical record. However, we do not know, today, whether or to what extent that practice (in terms of heavy weather ballast capacity) can be reduced, if at all, before the boundary between "adequate safety" and "inadequate safety" would be reached. ABS has proposed a new task exactly for this reason, pending completion of which, IACS should be taking a prudent approach by adopting a UR compatible to the current design practice.
For this purpose, we must be checking heavy ballast displacement, rather than forward draft, so that rough weather performance and ship's motion can</td>

	support. In addition, if supporting the ABS proposal, please indicate whether you support a minimum length of 180 m or 200 m. If supporting the DNV proposal, please indicate whether you support a minimum draft forward of 0.025L or 0.03L.	be controlled. It is also to be noted that propeller immersion in current designs is considerably above 60% and checking forward draft alone does not provide a true picture of the ballast capacity actually provided under the current (unregulated) design practice. (See further comments on this below and the attached files.) Therefore, we reiterate our view, and urge Members to support, that a simple, straightforward and transparent mechanism for achieving the safety objectives outlined above is to require a ballast hold for the size range of ships for which current, unregulated design practice, has historically provided a ballast hold. We believe it clear from the arguments we have put forward previously, and below, that attempting to do this by specifying minimum draft forward is neither transparent nor adequate. Further, it will be seen from the information in the attached file, that (with respect to the ABS fleet) the proposed criteria for minimum draft forward constitutes a significant reduction in heavy weather ballast capacity. How can we, or indeed anyone, know whether such reduction is sound or unsound--and whether ships built to this criteria would prove to have adequate safety in heavy weather conditions or not? We cannot know the answer to that without doing the studies and work necessary to establish a rational and definitive set of minimum heavy weather ballast criteria which will "just" provide adequate safety. Unless or until that development is done, we should not reduce, either consciously or inadvertently, the heavy weather ballast capacity which the unregulated market has provided up to now.	
4.4.1(b) last para. (cont'd)	(NKl) 1. Reference in made to the Chairman's message lGd and ABS' message ABj both dated 15 Aug. 2002 and earlier messages in this regard. 2. One of the outstanding issues is the heavy ballast condition, in particular, how IACS wishes to regulate this matter in a technically accountable manner. I would like to point out that the new UR S25 is to be address the safety aspects of IACS concern in a way that designers are guided to satisfy the fit for purpose design that shipowners are happy with. At the same time IACS should avoid to restrict innovative design approaches which may come up in some time by dwelling in the design of today. 3. There are two approaches being discussed, i.e. a mandatory ballast hold arrangement or a ballast tank/hold arrangement that achieves the minimum forward draught in addition to the propeller immersion and trim requirements. Use of hold ballast in the present design certainly resulted in achieving deep draught in heavy ballast condition without being regulated to have one. This approach is in my view one of the technical solutions to satisfy a number of design and operational features that shipowners and designers considered necessary. Largest cargo capacity, sufficient propeller immersion for achieving necessary propulsion without causing propeller racing, deep forward draught to avoid slamming in heavy sea conditions, appropriate stability, maneuverability, etc. 4. The mandatory ballast hold approach for bulk carriers of certain length and above would endorse the present design practice but it falls short of regulating the relevant design parameters. It would be interesting to study the desired heavy ballast conditions in terms of stability, maneuverability, sea keeping performance, slamming frequency, propulsion and ahead speed, etc. At present those matters have been properly achieved in a satisfactory manner to all concerned by regulating some of them and there is no significant and compelling needs to attempt regulating all of them by IACS regulations and it would be sufficient to touch upon some of the key elements at least at this time under the revision of UR S25. 5. Having said above I would like to put forward my comment to the course of action in your message IGd with a view to closing the gaps and taking members' preferred approaches. I would like to request you that the NK proposals in NKk and the third item to decide should be included in the items to which GPG members are requested to indicate their views:. -1. NK's proposal in item 3.1 of its previous message NKk concerning items 3.2 and 4 of the Chairman's message IGd. As NK had proposed the applicable ship length is to be associated with the forward draught that the minimum forward draught should be the smaller of 0.03L and 8 m for bulk carriers of 200 m and above in length.		See ABl
	(NVi) 1. Mandatory requirement to ballast hold		(ABk) It is agreed that the

	We are in complete agreement with ABS and BV that a heavy ballast condition is needed for stormy weather. We also agree that to provide a ballast hold is a good way to provide a safe condition in stormy weather [provided the ballast hold has been/can be filled under safe conditions!]. As a matter of fact most bulkcarriers are provided with ballast holds today although there are no formal requirement to do so. Our objections to requiring a ballast hold are based upon other considerations: * The need to be safe in stormy weather applies to all bulkcarriers to which S25 applies [ie L above 150m]. Requirements to a heavy ballast condition should therefore be formulated so that it covers all bulkcarriers above 150m. * Requirements that apply only to some bulkcarriers [size groups/structural configurations] may create the unwanted impression that IACS do not care about the safety of other bulkcarriers in stormy weather. * IACS requirements should be formulated so that good design practices at present are supported, ie. to provide ballast hold[s], while at the same time not preventing technological innovation and alternative solutions. * The intention of by SC/BCS when developing S25 was not to instruct yards or to limit their freedom in designing the general arrangement of bulkcarriers. We believe that our proposed criteria meet the above considerations. We would be prepared to accept slight modification of the criteria, eg as suggested by GL, if that is the majority view of the members. We do, however, not understand the reason why the DNV criteria should only apply to bulkcarriers above 200m as suggested by Mr Jin in his message NKl, and would have difficulties in supporting his suggestion as our objective has been to have criteria applicable to all bulkcarriers covered by S25. We can not understand that our proposed criteria will prevent or discourage the current practice of providing bulkcarriers with ballast hold(s). Neither are we overly concerned that some designers will try to increase the size of dedicated ballast tanks in order to meet the criteria without providing a ballast hold. Such solutions will necessarily reduce the cargo hold cubic capacity, which are still one of the main parameters considered by shipowners when ordering bulkcarriers, and make such designs unattractive in the marketplace.	UR should not prevent new technologies but we also recall that DNV objected to the proposal for special consideration for double hull designs. Pending approval and completion of the task being proposed, it is our opinion that such special consideration should be allowed. We must again recall that our proposal for mandatory hold ballast above [170-180m] is in conjunction with ths SC/BCS requirement for 60% immersion and should be considered as applying to all lengths; however, we will be agreeable to additional requirements below that length. See further comments below.
4.4.1(b) last para. (cont'd)	(NKm) 1. Reference is made to DNV's message NVi, in particular to the paragraph that discussed the forward draught in ballast condition, in which DNV discussed that the forward draught in heavy ballast condition is to be applicable to all bulk carriers under UR S25. 2. First I would like to point out that the discussion about the NK's proposal in NKl is not comprehensive and only looking at the idea NK put forward partially. As NK had pointed out that the forward draught in heavy ballast condition proposed by DNV is appropriate for bulk carriers of 200 m in length or greater but too deep against the present design and safety record for bulk carriers of less than 200 m. NK's proposal was to separate the application in two parts, i.e. for bulk carriers of length 200 m or above and the rest. NK does not consider it appropriate to reduce the requirement of forward draught of the lessor of 0.03L or 8m for the group of larger bulk carriers because it gives a message to industry that the forward draught in heavy ballast condition in the present design practice is too large. 3. There will be a couple of possible approaches for the group of smaller bulk carriers, i.e. of length less than 200m. My message in NKl suggested that the forward draught in heavy ballast condition of the group of smaller bulk carriers can be left unregulated as is the present situation. The strengthening of forward bottom, minimum propeller immersion and maximum trim requirements have sufficient criteria for those vessels to navigate in heavy weather condition. NK however can accept the forward draught of 0.025L in heavy ballast condition by taking the proposal of GL as adapted for this size category as the required draught will be 5m for 200m length, the maximum ship length of this size	See ABI

<table>
<tr><td></td><td colspan="2">category.</td><td></td></tr>
<tr><td></td><td>(NVj) When DNV proposed to link the heavy ballast condition to a forward draught the proposed figure of 0.03L we knew that this was based on a rough statistics, and was prepared for small adjustments. We wanted however to avoid restricting the figure to ships over or under a given length. We therefore are reluctant to accept the proposals of NK and GL.
We have however made further studies into this, and would like to present the following revised formulation:

"The forward draught in the heavy ballast condition is not to be less than the smaller of k . L and 8,0 m.
k = 0,00015 L, but is not to be taken less than 0,025 and need not be taken larger than 0,03."</td><td colspan="2">(ABk) We have checked a number of the bulk carrier designs classed with ABS in relation to the proposed minimum draft forward criteria put forward in NVd and NVj. The results are shown in the attached files. Our survey clearly indicates that the required drafts forward and aft, and resulting displacement, are considerably less than the full hold ballast condition and cannot be accepted--unless/until confirmed by the proposed task to develop rational and definitive criteria. We therefore propose, in the spirit of compromise and in pursuit of a unanimous concensus, that our proposal to require a ballast hold above [170-180m] Length be retained and the minimum forward draft criteria proposed in NVj be applied for ships below that length that are not provided with a ballast hold. This additional requirement (minimum draft forward requirement for smaller ships which do not have a ballast hold) is considerably more than the SC/BCS provided in the original S25, and current design practice, but we are prepared to accept it if all other societies are in agreement.
We encourage all Members to carefully check their existing fleet against the proposed minimum draft forward criteria and we believe that, having done so, Members will agree that such a criteria is not preferable to our proposal to simply require a ballast hold for ships above a certain size, in line with current practice.</td></tr>
<tr><td>4.4.1(b) last para. (cont'd)</td><td colspan="2">(LRc) 1. Reference is made to my emails 0120gLRb and 0120gIGd dated 12 and 5 August 2002 respectively.
2. With regard to the questions raised in 0120gIGd, the following comments are offered:
2.1 Mandatory Requirement for Ballast Hold
2.1.1 We should think of future double hull bulk carrier designs, which may have sufficient ballast tank capacity to achieve 4.4.1 (b) of 0120gNVd. For current single skin designs, it is practically impossible for a ship in excess of 200 m to achieve the draught forward of "the smaller of 0.03L or 8 m" without having a ballast cargo hold.
2.1.2 Therefore, following a careful review of the ABS and DNV proposals, LR now support DNV's proposal for a requirement for the minimum draught forward in the heavy ballst condition.
2.1.3 The requirement for the heavy ballast condition with a minimum draught forward of "the smaller of 0.03L or 8 m" should be applicable to all bulk carriers regardless of the ship length.
2.2 0.025L or 0.03L
2.2.1 LR support 0.03L. The minimum draught forward in this requirement is not applicable to normal ballast but only to the heavy ballast condition. According to LR's studies, "the smaller of 0.025L or 8 m" is too shallow to require ballast cargo holds for single hull bulk carriers.
2.2.2 Our investigation indicates that the heavy ballast conditions of all bulk carriers with a ballast hold satisfy the "the smaller of 0.03L or 8 m" requirements as indicated below:
1 Handy size 0.044L
2 Handy size 0.038L
3 Handy size 0.038L
1 Panamax 0.032L
2 Panamax 0.037L
3 Panamax 0.033L</td><td>See ABl</td></tr>
</table>

	4 Panamax 0.037L 1 Cape size 0.031L 2 Cape size 0.029L but > 8.0 m 2.2.3 We are aware of one bulk carrier design with a ship length of 176 metres with no ballast hold. The minimum draught forward in the heavy ballast condition is 0.029L, which is very close to the proposal above. 2.2.4 We would be interested in other Members' data regarding the draught forward of bulk carriers with no ballast cargo hold.	
	(NKn) Reference is made to messages of ABS in ABk, DNV in NVj and LR in LRc 1. With regard to the approaches of DNV and ABS, I, logically, understand that: 1) Though DNV's approach may require less forward draught than the present design practice of vessels with a ballast hold, it inevitably results in a design which arranges a ballast hold to meet the proposed forward draught requirements. 2) ABS's approach does not specify the size of a ballast hold and, I think, needs to be more specific. 3) DNV's approach would help to define the desired heavy ballast condition even the formula is to be further reviewed. 2. As regards LR data on the forward draughts in Paragraphs 2.2.2 and 2.2.3 of LRc, our own data shows less forward draughts e.g. approximately 0.025L in smaller bulk carriers that have no ballast hold. I will forward our own data in the early next week. 3. As a conclusion, I may support the DNV proposal contained in NVj. 4. And I would like to propose that the technical background for the forward draught requirements should be prepared based on the studies by DNV mentioned in NVj in order to make them justifiable.	See ABI
4.4.1(b) last para. (cont'd)	(KRe) 1. Ref. is made to IGd dated 15 August, LRc of 22nd August and other commenting e-mails. I appreciate other members' comments and insight on ballast condition issue. 2. With regard to the questions in 0120gIGd, please be advised our position as follows; 1) whilst I see the valuable points of commenting members, I tend to support not to require mandatory ballast hold as has been expressed in my mail KRc dated 24 July. Instead, I support DnV's proposal to define minimum draft forward in heavy ballast condition. 2) It reveals that the forward draft under heavy ballast condition for the existing three handy size bulk carriers which have no ballast cargo hold are 0.0245L(160m), 0.0289L(172m) and 0.025L(178m). However, I support 0.03L as a minimum draft.	See ABI
	(BVc) Mandatory requirement for ballast hold UR S25 4.4.1 (b) BV fully supports the analysis and conclusions provided in Steve McIntyre's message 0120gABk dated 21/08/2002, requesting at least one hold able to be ballasted for ships of more than 180 m in length. Justification of our position is provided is our previous message (0120gBVa) Further to the comments of the other members, we emphasize two additional points: - Whatever our final position, we are now setting a standard. According to the first reactions and the questions we have received concerning UR S25, the Industry has understood this. The new standard will replace the former unregulated "generally accepted" designs. The job of the shipyards will be now to design ships within the constraints fixed by the new URs (S25, Sxx, Syy, Szz...), neither more nor less. As a consequence, if we don't require a ballast hold, we effectively prevent the present practice of providing one, except if this is an explicit requirement of the Shipowner. However, we have understood that this last point is precisely what HKSOA wanted to avoid. - In attached graphs 1 and 2, we have displayed the DNV proposed criteria (60% propeller immersion + fore draught proposal of 0120gNVj) against the present	See ABI

	practice of Heavy Ballast including ballast holds for ships referred to by NK (SC/BCS document "Investigation on Design Ballast Condition 2002-04-17) , ABS in 0120gABk, LR for Panamax of 216 m Lpp in 0120gLRc and 5 additional BV ships. Our conclusion is that the standard proposed by DNV is significantly lower than the present practice for all ships larger than 180 m in length, with regard to slamming probability of occurrence and propeller racing in harsh weather. So we cannot support this proposal .	
4.4.1(b) last para. (cont'd)	(NKo) With regard to my message of 0120gNKn dated 23 Aug, 02, I would like to draw your attention to the attachment diagram, which contains a material that could support the proposed criteria of forward draught for the heavy ballast condition which is prepared for rough seas. The points shown in the diagram are the results of calculation on the basis of the occurrence probability of exposure of bottom at bow of bulk carriers exceeding 10-2 (1/100) against the significant wave heights. It is found that the significant wave heights are 2 - 3 m for smaller bulk carriers and are 6 - 7 m for larger ones, which can agree with seafarers' empirical recognition of rough seas. The real line as proposed in NVj is drawn in the diagram. From the diagram, the proposed forward draught criteria for heavy ballast conditions are found reasonable. Further, as regards Paragraph 2.2.3 of LRc, the forward draughts in the normal ballast condition (not heavy ballast condition) of small bulk carriers without ballast hold are as follows: df / L L(m) 1 0.0261L 143 2 0.0213L 148 3 0.0248L 150 4 0.0209L 160 I would like to invite GPG members to consider the above and accept the DNV's proposal in NVj based on the technical background as above explained.	See ABI
	(NVk) Please note our comments to Hisayasu's mail: When DNV formulated the proposal in our mail NVj of 23 August 2002, this was an attempt to provide a compromise solution that does not collide unacceptably with present design practices for the heavy ballast condition of the smaller bulk carriers. However, we agree with what we understand to be the underlying position of NK on this matter, that the stipulated minimum forward draught for the heavy ballast condition in UR S25 should not be considered as a safety issue. The statistical data over bulk carriers lost while in the ballast condition provides no indication in such direction. The proposed forward draught limit in the heavy ballast condition should in DNV's opinion rather ensure that the frequency of bottom slamming will not induce the ship speed to be reduced beyond those reductions decided based on a general assessment of sea condition. The documentation provided by NK in their mail of 28 August 2002 is not entirely clear to us. We would therefore appreciate a more detailed explanation of the background.	See ABI
	(ABI) 1. Monitoring the replies from Members, we see that despite our best efforts to convince Members of the need to require a ballast hold, the majority supports the DNV proposal for a minimum draft forward requirement for the heavy ballast condition. 2. Nonetheless, we must say that we appreciate and fully support the arguments and additional points provided in Maurice's message BVc, 23 Aug and still believe requiring a ballast hold to be the better and more prudent approach for IACS to take. 3. That said, in light of the majority support for the minimum draft forward requirement, we would be prepared to accept the "..the smaller of 0.03L or 8 m..." formulation, but we cannot accept the 0.025L formulation.	-

	(IGe) 1. Reference is made to my email dated 15 August 2002 (0120gIGd) and to the further very stimulating correspondence from Members. 2. Following receipt of Mr McIntyre's message 0120gABl, seven Members now support a requirement for a minimum draught forward in the heavy ballast condition. Two Members (BV and CCS) support an explicit requirement for the provision of a ballast hold, whilst I can not trace a response from RS. 3. Of the Members supporting a requirement for a minimum draught forward, the majority prefer the lesser of 0.03L or 8.0 metres with only one Member supporting the lesser of 0.025L or 8.0 metres. Only one Member supported DNV's modified proposal for a minimum draught of the lesser 0.00015*L*L or 8.0 metres. 4. Accordingly, I propose that the requirement to be submitted to Council should be for a minimum draught forward of the lesser of 0.03L or 8.0 metres. 5. Mr Han is requested to prepare a clean and underlined texts of UR S25 incorporating the above requirement, together with the other amendments agreed by Members. 6. Members will be requested to approve the revised text for submission to Council within one week of its' circulation by Mr Han.	
4.4.1(b) last para. (cont'd)	(NKp) 1. Reference is made to my message NKo of 28 Aug 02, Arve's message NVk and Steve's message ABl of 29 Aug 02 as well as the other earlier messages. 2. I welcomed the message of Steve in particular the paragraph 3. I noted that ABS couldn't accept the 0.025L formulation. I hope that the position of ABS has carried out ramification study of smaller bulk carriers of the present design and possibly future ones. NK has difficulty in accepting the application of the greater of 0.003L or 8m for all length of bulk carriers. As communicated in my message NKn and NKo this Society supports the minimum requirement proposed by DNV in NVj of 20 Aug 02. In this connection I would like to offer the following comments. 2.1 Maneuverability of bulk carriers in sea condition is to be maintained by ahead propulsion and speed. I fully agree with DNV in NVk that frequent slamming if happens during heavy weather would induce the ship speed to be reduced beyond those restrictions. Proper forward draft that eliminates such situation to happen and sufficient propeller immersion helps to maintain ahead speed. The latter is already included in the UR S25 in the original version and no change has been proposed. Therefore it is considered accepted by all Members. 2.2 Forward draft and slamming are to be considered in a package for achieving fit for purpose design. The matter of strengthening forward bottom against slamming has already been dealt with by the revised text of paragraph 4.4.2(a)i by the discussion so far. Now the forward bottom is to be strengthened against slamming in normal ballast condition. Therefore the forward bottom is considered strong enough for voyages in heavy ballast condition, i.e. in greater forward draught. The amount of forward draught necessary in heavy ballast condition has been discussed during the past month from various angles. It was the general agreement that in the present design practice bulk carriers of certain length and above have a ballast hold without being regulated, which demonstrate that designers and shipowners agreed a need of greater forward draught than that of normal ballast and utilised a cargo hold for ballast purpose. Due to strength consideration the ballast hold is full when used for heavy ballast condition. The consequential ballast condition demonstrated to have provided sufficient forward draught for unrestricted voyages. The forward draught proposed by DNV in NVj has been tested in bulk carriers of the present design. It was found that for Panamax and Capesize bulk carriers a ballast hold would be fitted to satisfy the requirement and commercial demand of grain capacity. For other bulk carriers there are some bulk carriers in particular smaller ones that satisfy the forward draught requirement in heavy ballast condition without fitting ballast hold. The relevant risks of this design relevant to forward bottom and propeller immersion are now addressed by the UR S25 by means of the requirements for strengthening of forward bottom against slamming in normal ballast condition and the requirement of the heavy ballast condition. 2.3 Now with regard to the enquiry of Arve in NVk the data provided in the attachment to my last message NKo derived from NK's extensive study carried out on ship's maneuverability and sea keeping in heavy weather conditions with regard to deck wetness due to green sea loading, exposure of forward bottom, propeller racing, etc. Sixteen bulk carriers of all range of the sizes were used for the study. From that study it is known that ship masters take actions as they feel it necessary in heavy weather condition when for example exposure of forward bottom takes place several times per hour and/or ten times of shipping green sea on	

<table>
<tr><td rowspan="5">4.4.1(b) last para. (cont'd)</td><td colspan="2">bow deck per hour.
2.4 From the analysis NK was successful in establishing significant wave height in head sea condition when exposure of forward bottom takes place several time per hour. The information was super imposed on the diagram of the bow draught proposed by DNV as provided in the attached to the message NKo.
2.5 I do not want to open a debate on the outcome of the study but am pleased to point out that the bow draught requirement proposed by DNV matches the trend of the significant wave heights that causes exposure of forward bottom at several times per hour, over which shipmasters takes action for reducing bow exposure such as reducing head speed, changing bearing, etc.</td><td></td></tr>
<tr><td colspan="2">(NKq) 1. NK's comment in NKp of 30 August crossed the Chairman's message IGe of the same day.
I appreciate the action taken by the Chairman in summing up the discussion during the past month for the revision of UR S25 with a view to achieving the final agreement of the revised text for submission to Council. I also appreciate Mr Han in taking the role for type setting the final draft revision.
2. With regard to the provision of heavy ballast condition I do not quite agree with the Chairman's sum-up. There were two approaches, one proposed by ABS for requiring a mandatory ballast hold for bulk carriers of certain length and above and the other proposed by DNV for introducing minimum forward draught in the heavy ballast condition in UR S25.
3. Thanks to the message of Steve in ABl of 29 August all commenting members agreed to specify the design minimum forward draught in heavy ballast condition. However the requirements for the amount of the forward draught were divided in two ways. This matter as far as I see is yet to be concluded and should be further discussed and concluded by explicit comments.
4. I therefore request Mr Chairman and Mr Han to put the two proposals given below in square brackets in the final draft text to be circulated to GPG for consideration and decision by GPG, i.e. the last paragraph of section '4.4.1(b) Heavy Ballast Condition' should read as;
"The draught forward is not to be less than the smaller of [k*L and 8.0 metres, K being 0.00015*L but is not to be taken less than 0.025 and need not to be taken larger than 0.03][0.03L and 8 meters]."</td><td></td></tr>
<tr><td colspan="2">(RIe) Please note that RINA was in favour of supporting ABS/BV position not to accept bulk carriers without ballast hold.
However, following the majority of Members, we can accept DNV's figures, i.e. the smaller of 0.03 L or 8 m.</td><td></td></tr>
<tr><td colspan="2">(IAd) Reference is made to GPG Chairman's mail 0120gIGe dated 30 August 2002.
Attached herewith please find the final text of UR S25 incorporating the agreed changes and Chairman's conclusions.

GPG Chairman invites Members to confirm their agreement to the attached document by 10 September after which the documents will be submitted to Council for final approval.
Concerning 4.4.1(b)v, Mr.Jin's suggestion to put " k*L and 8.0 meters, k = ,,,," in square brackets was not supported by ABS and BV, however, it is reflected in the TB.
Permsec wrote the TB in such a way that it did not lose members' valuable comments even if they were not agreed by the majority.
Members' approval is sought by 10 September.</td><td></td></tr>
<tr><td>(BVd) Taking into account the support of the vast majority of members for the DNV proposed solution (the smaller of 0.03 L or 8 m) , please note that BV can accept this formulation, even if we still prefer not to accept bulk carriers without ballast hold.
We do not support the proposal of NKq to put the solution of "0.025 L" between square brackets, as this solution is unacceptable for us and is not the solution supported by the majority of members.</td><td colspan="2">(ABm) The views expressed by Maurice in BVd, 3 Sept, are fully supported.</td></tr>
</table>

4.4.1(b) last para. (cont'd)	(CCc) 1. Reference is made to IAd of 4 September 02. 2. Please be informed that CCS can support DNV's proposal, i.e.the smaller of 0.03L or 8m. 3. The draft URS25 as attached to IAd is acceptable to CCS.	
4.4.2	(RIc) We also agree with ABS's proposal for strength requirements in 4.4.2 (tanks 100% full). However, in order to make 4.4.2 fully in line with UR S11.2.1.2, we propose that the following sentence be added before 4.4.2(a): "The longitudinal strength is to be checked for all the partial filling of tanks that may be partially filled or empty during navigation.".	The comment is agreed and appreciated However, in ABg the change was made to 4.4.1(a) i and 4.4.1(b) i since partially full BWTs are addressed in these locations and RI suggested changes will be more appropriate if made therein.
	(RId) Although understanding Mr. McIntyre's considerations, we deem it relevant to strength requirements and strictly connected with the modifications proposed by Mr. Myklebust.	For reason indicated earlier and as supported by NVf, the reference to S11.2.1.2 is retained in 4.4.1(a) i and 4.4.1(b) i.
	(NVf) we do not see the reason for moving the reference to S11.2.1.2 from 4.4.1(a)i. and 4.4.1(b)i. to 4.4.2(a)iii. and 4.4.2(b)ii. S11.2.1.2 refers to partially filled tanks which are allowed in the conditions defined in 4.4.1, and the reference (if at all necessary) should be included here.	See above
	(NVh) 4.4.2(a) & 4.4.2(b) Longitudinal strength requirements must apply to both the condition with empty/partially filled ballast tanks and the condition with 100% full ballast tanks. See proposed wording in NVd.	See above
4.4.2(a) i	(NKj) 4.4.2(a) i needs clarification as the ballast tank filling rate contained in the main body of paragraph 4.4.2 may not be applied in the subsequent ballast conditions. I therefore would like to propose to modify 4.4.2(a) i. as follows. "the structures of bottom forward are to be strengthened in accordance with the Rules of the Society against slamming for the condition of 4.4.1(a) at the lightest forward draught, unless the condition that all ballast tanks as designated in 4.4.1(a) are to be 100% full is specified in the loading manual for this condition."	ABh now reads as follows: i. the structures of bottom forward are to be strengthened in accordance with the Rules of the society against slamming for the condition of 4.4.1(a) at the lightest forward draught, and
	(LRb) The clarification given in 0120gNKj is supported.	See above reply
	(Nve) We agree that item 4.4.2(a)i is unclear, but at the same time we do not fully understand the meaning of the text proposed in 0120gNKj. We do, therefore, believe that a complete reorganizing of 4.4.2 will give better clarity than the proposal in 0120gNKj, ref. our suggestion in 0120gNVd of 12-08.	(ABi) I think the version of 4.4.2(a)i in ABh, has the same effect as what DNV proposed.
4.4.2(b) last sentence	(NVd) Delete the last sentence.	(ABi) ABS cannot accept the DNV proposal to delete the last line of 4.4.2(b). If more than one ballast hold is designated for carriage of water ballast at sea, then the longitudinal strength needs to be checked with the ballast tanks full and each one of the designated ballast holds full, one by one, to ensure that the ship has adequate strength should any one of the designated ballast holds indeed be filled at sea. If there are two designated ballast holds for water ballast at sea, then two conditions have to be checked. It would, to our understanding, rarely be more than that.

<table>
<tr><td rowspan="3">4.4.2(b) last sentence (cont'd)</td><td>(NVh) Same comment as for 4.4.2(a).
he last sentence still seems unclear. If the sentence implies that several heavy ballast conditions are required for bulkcarriers having more than one ballast hold, we disagree. One heavy ballast condition should be the minimum IACS requirement. The owner/designer may of course specify other heavy ballast conditions if they so desire, in that case such conditions are to be approved, ref. S25 1.2. That is why we have in NVd proposed to delete the last sentence.</td><td colspan="2">(ABj) In reply to NVh and NKk, both 15 Aug:
2. Re the proposals to delete the last sentence of 4.4.2(b), we do not agree. The sentence does not imply that several heavy ballast conditions are required. Rather, if more than one ballast hold is designated by the designer/owner in the operating manual for the carriage of water ballast at sea, it must be that the master is allowed and may at some time to fill each such ballast hold, at least individually, while at sea. The purpose of the last sentence is to require that the longitudinal strength be checked for such conditions with all the other ballast tanks full--so as to ensure that the S11 criteria will not be exceeded in such conditions, and for the same reasons that we are requiring that the strength check be done with all the ballast tanks full for the normal ballast condition, even if the "all tanks full" condition is not given in the loading manual as the normal ballast condition. These are checks to ensure that strength criteria will not be exceeded if all the ballast tanks plus each ballast hold designated for carriage of water ballast at sea are full. We have modified the text slightly to try to make this clearer (see attachment).</td></tr>
<tr><td colspan="2">(NKk) Comments to ABS comments in ABg (sic; ABi)
-1. 2.2.2 Paragraph 4.4.2(b)
I support DNV's proposal to delete the last line of 4.4.2(b) because of the following reasons.
- Where a bulk carrier is provided with two ballast holds for carriage of water ballast at sea, three permutations of each ballast hold being filled are considered. In this situation, it is to be left to owner's decision based on operational convenience which permutation is used to achieve the required heavy ballast condition.
- We have no reason to force the two ballast holds be filled at the same time as the heavy ballast condition during voyage because of the two ballast holds being fitted. This means that both of two heavy ballast conditions (one ballast hold is full but another is empty and vice-versa) are not necessarily needed to meet the heavy ballast condition.</td><td>(ABj) See above</td></tr>
<tr><td colspan="2">(NKl) NK supports the modification proposed by Mr Myklebust in NVd of 12 Aug 02 with regard to the last sentence of paragraph 4.4.2(b) Heavy ballast condition, i.e. deletion of the sentence "In such instance, the longitudinal strength is to be satisfactory at least for each condition with one such hold full and all others empty" as this matter is regulated in paragraph 4.4.2(b) sub-paragraph i in the text contained in NVd.</td><td>See ABk below</td></tr>
</table>

4.4.2(b) last sentence (cont'd)	(NVi) 2. Number of ballast holds and heavy ballast conditions There is a tendency that modern bulkcarrier designs are provided with more than 1 ballast hold, normally when specified by the shipowner. We have even seen bulkcarriers with every second hold [holds 2, 4, 6, ...] designated as ballast holds. The reasons may be: * to provide increased strength of watertight bulkheads, * to provide increased flexibility to take part loads into a minimum number of holds * to provide effective ballast water management [eg. Sediment management] procedures * others. To require longitudinal strength check for any one of these ballast holds to be full while all others are empty, would discourage such excellent solutions, which we believe should not be the effect of IACS requirements. We would therefore reiterate that IACS should require only one heavy ballast condition. It should in this connection be recalled that: * Owners/designers will have the option to specify additional heavy ballast conditions if they so desire, which have to be submitted for approval, ref. S25.1.2. * All ballast holds [irrespective of how many are provided] are to be checked for local strength, ref. S25.5.5 * The master has, irrespective of the loading conditions specified in the loading manual, the freedom to load [including ballast] the vessel differently, provided limitations for longitudinal and local strength as defined in the loading manual and loading instrument onboard are not exceeded, ref. S25.1.3. No difference should be made between cargo and ballast in this connection.	(ABk) We do not agree that specifying water ballast to obtain increased scantlings of bulkheads is a proper way of design. Our point is that if a hold is designated for at-sea ballast, the longitudinal strength should be sufficient for the intended service. It is to be recalled that the original request from the industry was (and still is, we believe) to eliminate operating restrictions as much as possible, and by specifying the condition of approval, we will not require special notations for the loading restrictions. Without the last sentence of 4.4.2(b) a restricted ballasting notation will be required. We do not believe that requiring longitudinal strength check for one hold ballasted condition will in any way discourage any other arrangement that is permitted under S25.1.2.
	(BVc) 2. Longitudinal strength if more than one ballast hold is fitted – UR S25 4.4.2 (b) It is not requested to have more than one ballast hold. However, if more than one is effectively designated for ballast, it must be possible to use each of them while satisfying the longitudinal strength criteria. We understand that some ballast holds can be only used in ports or sheltered areas for air draft reasons, but in this case they are not intended for " carriage of water at sea". So the ABS text is supported by BV.	(ABl) we appreciate and fully support the arguments and additional points provided in Maurice's message BVc, 23 Aug
4.5	(NVd) Replace "bunker full (normally 95% fuel oil) and other" with "all"	(ABi) we do not believe it either realistic or prudent to define the departure condition to be "100%". Fuel oil tanks are never, in practice, filled 100% full owing to the dangers of overflow and spillage associated with expansion. Designers have already questioned whether "100% consumables" means "bunkers 95% full and other consumables 100%", in accord with normal design practice. We agree with them and believe it clearer for everyone and more prudent to state this clearly in the UR. Therefore, we do not agree to revert to the less clear and wholly hypothetical "100% consumables" ---which would very likely be interpreted to be "bunkers 95% full and other consumables 100%" in actual practice by many. It is better to state this accepted and expected "interpretation" as the requirement.
	(NKk) I support ABS proposal of departure condition with bunker full (normally 95% fuel oil).	Noted with thanks
	(NVi) 3. Departure condition We certainly agree that bunker tanks will not be 100% full in normal operation. However, the intent of S25 has never been to define how bulkcarriers shall be operated. The sole purpose of S25 is to ensure that the strength envelope is sufficiently wide for bulkcarriers to be fit for purpose. For this reason a number of design loading conditions have beendefined, all of which from a	(ABk) with respect to "departure conditions", we would not object to the proposed wording if it is acceptable to all other societies but would suggest, to eliminate dead meat,

	strength point might be seen to be somewhat severe as compared to actual operating conditions. SC/BCS has adopted the term 100% full throughout S25 on purpose, both as regards cargo holds, ballast holds, ballast tanks and fuel oil tanks [re fuel oil tanks the term 100% full is applied several times also in section 5]. The only advantage we can see for applying less than 100% bunker in the departure condition is to reduce maximum still water bending moment [in eg the normal ballast condition with all ballast tanks 100%], and saving some steel for the builder, which is contrary to the intent of S25. Trim considerations are no longer a problem after allowing empty and/or partially filled tanks in the ballast conditions To maintain the SC/BCS intent and the integrity of S25 we would prefer to retain 100% consumables [including bunker] in the departure condition. However, the capacity which shall be used under S25 must represent the maximum filling for the ship's operation. We will therefore propose a slight amendment to item 4.5: "Departure condition with bunker tanks at maximum capacity, in any case not less than 95% full, and other consumables 100%....".	"***Departure condition: with bunker tanks not less than 95% full and other consumables 100%…"*** For the record, it is to be noted that by changing from the "MARPOL condition" (no consumable) to arrival condition (10% consumables), SC/BCS de facto eased the propeller immersion requirement but tightened the forward draft requirement. We believe this decision was made based on the present design conditions rather than a fictitious condition for 100% full bunker tanks.
	(BVc) Bunker departure condition - UR S25 4.5 The proposal of DNV (0120gNVi, last sentence) is supported.	Noted
5	(ABh) (In conjunction with change to 2.2) Change title of 5 to "Design loading conditions (for local strength)	Proposed in ABh.
None	(IAc) With regard to ABg (and item 1b of ABd) with respect to a task to determine all parameters and corresponding criteria to ensure safety in heavy ballast condition, may the Secretariat suggest that early input be sought also from the Nautical Institute and from IFSMA? They are at the same address and would no doubt consult each other. An extract from the NI's book 'Bulk Carrier Practice' is attached.	-

UR S26 "Strength and Securing of Small Hatches on the Exposed Fore Deck"

Summary

The sentence has been added to specify that small hatches regarded as a non-weathertight hatch according to UI LL64 are not subject to UR S26.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev.5 (May 2023)	11 May 2023	1 July 2024
Rev.4 (May 2010)	24 May 2010	-
Rev.3 (Aug 2006)	7 August 2006	1 July 2007
Rev.2 (July 2004)	5 July 2004	-
Rev.1 (Nov 2003)	7 November 2003	-
NEW (Nov 2002)	29 November 2002	1 January 2004

- **Rev.5 (May 2023)**

1 Origin for Change:

☑ Suggestion by IACS member

2 Main Reason for Change:

A Member raised an issue regarding a possible need for amendment of UR S26 "Strength and Securing of Small Hatches on the Exposed Fore Deck" in connection with UI LL64 "Non-weathertight hatch covers above superstructure deck (Load Line Convention 1966 Regulations 2(5) and 14(2))".

In case of containerships, non-weathertight hatches can be accepted based on complying with the relevant requirement in UI LL64. For this reason, small hatches on containerships complying with the relevant requirements of the UI also can be non-weathertight. Considering that the requirements in UR S26 are applied to small hatches capable of being closed weather-tight or watertight, small hatches regarded as a non-weathertight hatch according to UI LL64 is not subject to this UR S26.

However, the requirements of clauses 4 & 5 of the UI cannot practically be applied due to the feature of small hatches, so it is decided that those are excepted.

Regarding the clause 6 in the UI LL64 for scantlings, since it is also practically difficult to be applied to small hatches while the scantling requirements for the hatches are needed, the Chair proposed the phrase of "However, for scantlings of small hatches the strength requirements in clause 4 of this UR could be applied instead of clause 6 of UI LL64."

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None

4 History of Decisions Made:

A Member raised an issue regarding a possible need for amendment of UR S26 in connection with UI LL64.

Hull Panel Chair reviewed two resolutions and shared an opinion that UI LL64 is only applicable to containerships with a number of additional conditions. Hence UI LL64 has a quite narrow field of applicability compared to the more general applicability of UR S26. Hull Panel decided to make a cross reference from UR S26 to UI LL64 for the case of Containerships.

At the same time Hull Panel Members asked for consultation of Safety Panel if the relaxation from weathertightness given in UI LL64 also can be applied to small access hatches on containerships located at the same deck and position as the cargo hatchways considering the relevant requirement in UI LL64. Majority of Safety Panel members agreed to the conclusion from Hull Panel.

Considering Hull Panel's conclusion and Safety Panel's discussion, Hull Panel Chair has prepared the draft UR S26 (Rev.5) and its associated TB. Some members pointed out the issues of which the requirements of clauses 4 & 5 of the UI LL64 cannot practically be applied due to the feature of small hatch, so it is decided that those are excepted.

Regarding the clause 6 in the UI LL64 for scantlings, since it is also practically difficult to be applied to small hatches while the scantling requirements for the hatches are needed, the Chair proposed the phrase of "However, for scantlings of small hatches the strength requirements in clause 4 of this UR could be applied instead of clause 6 of UI LL64."

5 Other Resolutions Changes:

None

6 Any hinderance to MASS, including any other new technologies:

None

7 Dates:

Original proposal:	10 November 2022	(*made by a Hull Panel Member)*
Panel Approval:	24 April 2023	(Ref: 23058_PHa)
GPG Approval:	11 May 2023	(Ref: 23058_IGb)

- **Rev.4 (May 2010)**

1 Origin for Change:

☑ Based on IACS Requirement *(Common Structural Rules for Bulk Carriers and Double Hull Oil Tankers)*

2 Main Reason for Change:

Following the introduction of the IACS Common Structural Rules for Bulk Carriers and Double Hull Oil Tankers, Hull Panel were tasked to review all the UR S files to consider whether or not they are applicable to ships covered by the CSR.

3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

4 History of Decisions Made:

After review it was decided that for CSR ships the requirements of UR S26 are superseded by those of the Common Structural Rules and therefore do not apply.

5 Other Resolutions Changes

All UR S files, except UR S8, S9, S15, S16, S19, S22, S23, S30 and S31.

6 Dates:

Original proposal: *2007, made by Hull Panel Task 50*
Panel submission to GPG: *19 April 2010*
GPG Approval: *24 May 2010 (Ref. 10051_IGd)*

- **Rev.3 (Aug 2006)**

See separate TB document in Annex 3.

Note: *There are no separate Technical Background (TB) documents for Rev.2 (July 2004), Rev.4 (May 2010) and Rev.5 (May 2023).*

UR S 26 Strength and Securing of Small Hatches on the Exposed Fore Deck

(New, Nov 2002)

Technical Background:

This technical background (TB) is developed in line with Annex 2 of IACS Internal Information No. 15.

1. Scope and objectives

1.1 The reopened Derbyshire formal inquiry published its report in December 2000. Mr Justice Coleman's Recommendations are summarised in Section 14 of the report, in which there are a number of recommendations addressed to IACS and Classification Societies.

Further to the discussion at C42 in December 2000 where it was decided to form a Small Group in order to make proposals for the way forward on Mr Justice Coleman's Recommendations. Subsequently AHG/FDF was established to initially consider two issues, which were:

- Strength Requirements for Fore Deck Fittings and Equipment; and
- Prevention of Water Ingress through Fore Deck Openings

1.2 AHG/FDF considered amongst others prevention of water ingress through a small hatch on fore deck. The objective of this UR is to introduce knowledge of good seamanship in technical design thus to reduce risk of the small hatch cover being opened in heavy seas and consequential inadvertent water ingress into the space underneath.

2. Points of discussions and possible discussions

2.1 The investigation of Derbyshire showed that the hatch cover of small hatch (used as rope hatch) was torn off and considered to have allowed subsequent sea water ingress to the space underneath.

2.2 The AHG addressed deck height above Load Water Line where green water may wash over the fore deck, and technical aspects of securing devices of small hatch covers.

2.3 In regard to the deck height, analysis put forward by a member indicated that 0.1L or 22m was too conservative in particular for larger vessels. However the AHG considered it appropriate for the purpose of eliminating fore decks of pure car carriers that are clearly above green seas, also keeping in mind the damage case to the fore deck of the passenger liner QE2.

2.4 The AHG analyzed possible cases where a small hatch cover secured by butterfly nuts may be opened in heavy weather condition and arrived at a likelihood that the hatch cover is pressed down by green sea forces causing the butterfly nuts to loosen and consequently be dislodged. This assumption was considered realistic by a report that it was not difficult to dislodge tightened butterfly nuts by hammering it outward.

2.5 The Group considered a way out and came to a conclusion that there is a need of a secondary securing (locking) device that keeps the hatch cover in place even in such a case where the primary securing device was loosened or even dislodged.

2.6 The Group also considered that the hatch cover must have a metal to metal touch for preventing further compression by green sea forces. In the method using butterfly nuts for the primary securing device the group considered that over-tightening butterfly nuts causes permanent deformation (distortion) of forks (clamps), which allows the butterfly nuts to come off easily. Preventive measures were stipulated to the effect that the forks are of robust strength, and are curved upward or raised at the free end with a view to reducing the risk of the butterfly nuts being dislodged.

2.7 The group further considered that location of hinges of small hatch covers would play an important role to keep the cover in place in green water. It has come to the group's attention that on a few ships the hinges for a small hatch cover have been located on the far side from the direction of water flow, such that the action of green seas would tend to try to open the hatch, and at least in some cases the ship's crew have turned the cover around. The group did not believe that there is any international requirement that would prevent this and therefore IACS should consider introducing a paragraph to the effect that the hinges should be arranged such that the predominant direction of green water would cause the cover to close.

2.8 The group agreed that on the fore deck the hinges should be arranged on the fore side of the hatch. The model tests suggest that away from the centre line a 45 degree orientation could be theoretically better, but this requires proper arrangement of deck stiffening. For small hatches located between the main hatches (for example between Nos. 1 and 2) the hinges might be best placed on the outboard edge in beam sea and bow quartering conditions, while hinges on fore edge are also acceptable.

2.9 The group agreed that the ship type category, general dry cargo ship, was for the carriage of dry cargo loaded through hatch covers, and did not include special purpose ships such as Container Ships, Vehicle Carriers and Ro-Ro ships.

2.10 The AHG agreed that whilst the problem of securing small hatch covers mounted on the fore deck was identified during the Derbyshire RFA, the application of this UR should be for all types of new ships, to improve their common capability to resist green sea loads. The group therefore considers that National standards, ISO 5778 and the design practice for small hatch covers should be examined with regard to this UR, and that the cost of such improvement is small.

2.11 For the illustrative primary securing arrangement shown in Figure 2, the AHG considered the possible addition of a nut or double nut on the toggle to prevent the fork from being bent downwards, or to be used for locking the butterfly nut in position.

3. Source/derivation of proposed requirements

3.1 The group established information regarding current industry standards and practices from national and international standards such as Japanese Industry Standards, Korean Industry Standards, DIN, Italian shipyards' practices and ISO standard.

3.2 The group identified three preferred types of securing devices. However, the group considered that there is a room of improvements. With regard to the widely used butterfly nuts the group felt a need to add a requirement such that butterfly nuts would not be dislodged by being loosened due to the effect of extra compression to gasket that may be caused by green sea forces. Metal to metal contact was introduced to achieve this level of security. This method was also made applicable to other preferred securing device such as quick acting cleats and central wheel locking device.

3.3 The group considered that a secondary locking device would improve securing small hatch covers in place even though such secondary device may not keep the hatch cover weather-tight. To that end the group considered that a backing bar or sliding bolt of slack fit would satisfy the objective. The group felt that specific technical requirement can be left to innovation of designers and shipyards.

3.4 Structural requirements for the small hatch cover were based on a design pressure of 150 kPa. This pressure was considered suitable for the fore deck from information provided by AHG/WD-SL to AHG/EBC (reference UR S21 Rev 1, July 2002), and corresponds to a position of about 0.04L from the forward perpendicular of a capesize bulk carrier. Plate thicknesses were derived from plastic criteria, while the stiffener requirements were assessed on elastic stresses. In view of easy maintenance of these covers, a reduced corrosion allowance of 1 mm was included for the plate and 2 mm for the stiffeners. For the purposes of providing a simple and economical standard, this design is assumed to apply to all areas specified in clause 2.

4. Decision by Voting if any

The technical requirements in this proposed UR were considered by all members of the AHG and agreed unanimously. The implementation scheme, which is contained in square brackets, is to be decided by GPG.

Note by the permanent Secretariat

1. NK proposed an annotation to Figure 2 for the metal to metal contact. Council tasked the AHG to consider. As a result, para. 6.1 was modified and new para. 6.2 added. Item 9 of Figure 2 was annotated as “bearing pad welded on the bracket of a toggle bolt for metal to metal contact”.

****

Technical Background

S26 (Rev.1, Nov 2003) & S27(Rev.2, Nov 2003)

Part A: S26.2.2 (Rev.1, Nov 2003) + S27.2.2(Rev.2, Nov 2003)

1. Objective:

To clarify the ships to which S26 and S27 shall apply.

2. Points raised by BV (s/n 3142):

.1 "Ore carriers" are not mentioned in S26/S27 para 2.2. It needs to be clarified.

.2 "Refrigerated cargo ships, livestock carriers, deck ships, dedicated forest product carriers and dedicated cement carriers" do not seem to be excluded from the scope of application. It needs to be clarified.

3. GPG Discussion

.1 Failure to explicitly include "ore carriers" in the scope of application statements in S26/27 was just an oversight. It was agreed that "Ore carriers" should be explicitly mentioned.

.2 The proposal to align the scope of application for "general dry cargo ships" with that of UR Z7.1 was not agreed. It would exempt more vessels from the application of S26/27. The scope of application of S26/S27 was based on considerations of freeboard – not on alignment with Z7.1 (3142_ABc dated 29 September 2003).
But, it was agreed to include "combination carriers(as defined in UR Z11)" in the scope of application of S26/S27 for clarity.

4. Conclusion

.1 Para 2.2 of S26 and S27 was amended to the above effect.
.2 Council approved it on 7 Nov 2003.

Part B: S27.5.1.1(Rev.2, Nov 2003)

1. **Objective**

To clarify the scope of application of S27.5.1.1 to existing ships.

2. **Points raised by ABS (s/n 3059a):**

.1 ABS suggested that S27.5.1.1 does not mean that closing devices of air pipes *(~~and ventilators~~ : this wording "and ventilators" was deleted as UR P3 does not cover "ventilators")* on all existing ships subject to S27 need to be upgraded to comply with the current UR P3. GPG agreed.

.2 GPG did not agree to the view that if an air pipe or ventilator closing device has to be replaced to comply with the other requirements of S27, the new closing device should comply with the current UR P3. (3059aABa, 25 July 2003)
NK pointed out that though some types of air pipe heads satisfying the requirements of UR P3(Rev.1) may be in the market it should be noted that a type of air pipeheads widely applied on board ships built in Asian builders is yet to fully comply the new requirement despite the effort of manufacturers. The identified problem is being addressed by the manufacturer and it is likely that an improved prototype is to be tested in a short time (3059aNKb, 3 Oct 2003).

3. **Conclusion**

.1 A footnote was added to S27.5.1.1 as indicated in para.2.1 above.
.2 Council approved it on 7 Nov 2003.

End.

Prepared by the Permanent Secretariat
30 October 2003

Technical Background of Revision to UR S26 (Rev.3)

1. Scope and objective

After the S26 (Rev. 2 July 2004) was implemented, there were the question, “For hatches designed for use of emergency escape, when fitted with central locking devices as stipulated in UR S26.5.1 (iii), they are usually fitted outside hatch covers and cannot be operated from inside. In this case, emergency escape becomes unrealistic, and securing devices that can be operated from both sides are to be fitted, for instance, dogs (twist tightening handles) with wedges as mentioned in UR S26.5.2.”(see Fig.1)

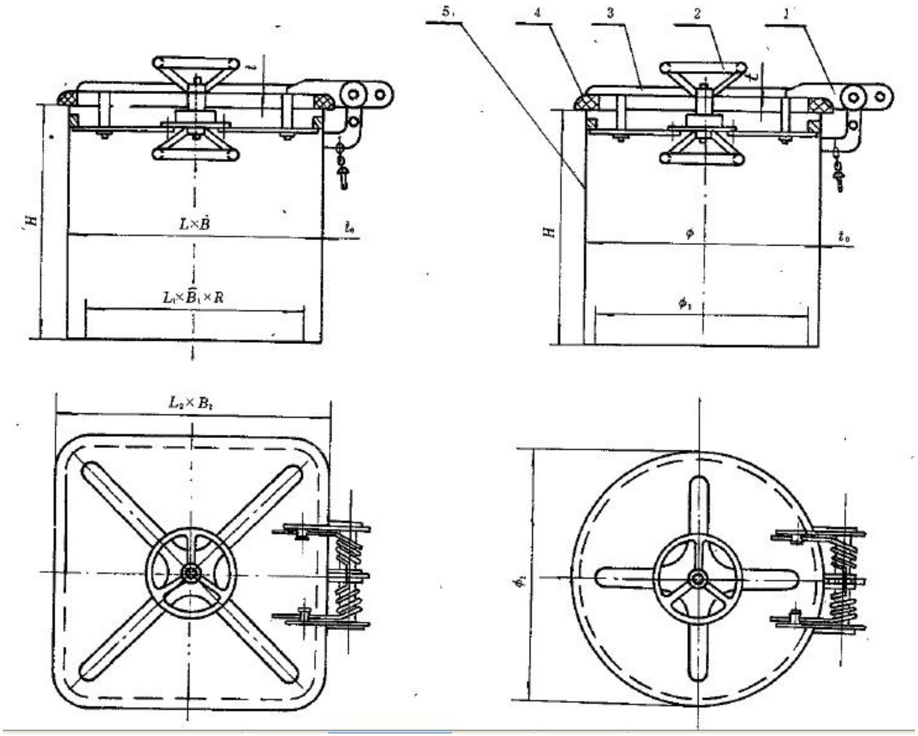

Fig.1 quick-acting type hatch cover

Having checked the plan review practice of each member society, it is confirmed that both sides operable weather-tight hatch covers are installed for emergency escape hatchways. Accordingly, it is concluded that the further clarification of the requirements of UR S26 will not have any impact to the industry practice and is more in line with the intent of the UR.

2. Points of discussions or possible discussions

The texts of S26.1.3 are modified as follows:

“Hatches designed for emergency escape need not comply with the requirements, 5.1 (i) and (ii), 6.3 and 7 of this UR. Securing devices of such hatches are to be of a quick-acting type (e.g., one action wheel handles are provided as central locking devices for latching/unlatching of hatch cover) operable from both sides of the hatch cover.”

3. Source/ derivation of proposed requirement

Hull Panel

4. Decision by voting

N.A.

Submitted by Hull Panel Chairman
9 June 2006

Permanent Secretariat's Note:

- **GPG discussion (s/n 6124, 26 July 2006)**

All members supported the amendments to UR S26 and its TB.
8 members agreed to the proposed implementation statement. BV proposed a modification with a view to clarification on application of ship types by referring to item 2 of the UR, which was supported by KR. However the GPG Chairman considered that the original implementation statement was sufficient as the changes introduced in rev.3 of UR S26 (items 1.3 and 1.4), being part of the UR, will have to be implemented in accordance with the application provisions in item 2 of the UR anyway, in addition to its implementation schedule.

- **Council discussion**

All members supported the draft UR S26 (Rev.3) and its TB.

UR S27 "Strength Requirements for Fore Deck Fittings and Equipment"

***** ***Note:***
Actual implementation date is dependent on vessel age, therefore the resolution text should be consulted for full details.

- ### Rev.6 (June 2013)

.1 Origin for Change:

☑ Suggestion by IACS Member in Statutory Panel September 2011

.2 Main Reason for Change:

A question was raised in the Statutory Panel with background in approval of a car carrier for which design pressure in UR S27 became applicable to hold ventilator on the upper deck on large car carrier, almost 22 m above summer water line. This was considered unreasonable.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None.

.4 History of Decisions Made:

After discussion within the Hull Panel, it was concluded that the pressure in UR S27 is to be modified to avoid unreasonable requirements e.g. for cargo hold ventilators on car carriers. It was agreed to prepare a transition of the pressure formula of S27.4.1.1 to eliminate the abrupt "on-off" application at 0.1L or 22m height above the summer load waterline.

.5 Other Resolutions Changes

None.

.6 Dates:

Original proposal: *2011, made by a Hull Panel member*
Panel submission to GPG: *05 June 2013*
GPG Approval: *25 June 2013 (Ref. 13145_IGc)*

- **Rev.5 (May 2010)**

.1 Origin for Change:

☑ Based on IACS Requirement *(Common Structural Rules for Bulk Carriers and Double Hull Oil Tankers)*

.2 Main Reason for Change:

Following the introduction of the IACS Common Structural Rules for Bulk Carriers and Double Hull Oil Tankers, Hull Panel were tasked to review all the UR S files to consider whether or not they are applicable to ships covered by the CSR.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None.

.4 History of Decisions Made:

After review it was decided that for CSR oil tankers the requirements of UR S27 are superseded by those of the Common Structural Rules and therefore do not apply. For CSR bulk carriers the requirements of UR S27 concerning air pipes and ventilators still apply, but those for windlasses are superseded by the Common Structural Rules and do not apply.

.5 Other Resolutions Changes

All UR S files, except UR S8, S9, S15, S16, S19, S22, S23, S30 and S31.

.6 Dates:

Original proposal: *2007, made by Hull Panel Task 50*
Panel submission to GPG: *19 April 2010*
GPG Approval: *24 May 2010 (Ref. 10051_IGd)*

- **Rev.4 (Nov 2004)**

See TB document in Part B.

- **Rev.3 (July 2004)**

Addition of 'Contracted for Construction' footnote – no TB document available.

- **Rev.2 (Nov 2001)**

Annex 4. **TB for Rev.4 (Nov 2004)**

See separate TB document in Annex 4.

Annex 5. **TB for Rev.6 (June 2013)**

See separate TB document in Annex 5.

An addendum to the Annex 5 (i.e. "7. Additional technical background 2021 – Application of green sea load on windlass") was introduced in March 2021 (Ref: 21026_IGc)

◄▼►

Note: *There are no separate Technical Background (TB) documents for Corr.1 (July 2003), Rev.3 (July 2004) and Rev.5 (May 2010).*

Technical Background

UR S 27 (New, November 2002)

This technical background (TB) is developed in line with Annex 2 of IACS Internal Information No. 15.

1. Scope and objectives

1.1 The reopened Derbyshire formal inquiry published its report in December 2000. Mr Justice Coleman's Recommendations are summarised in Section 14 of the report, in which there are a number of recommendations addressed to IACS and Classification Societies.
Further to the discussion at C42 in December 2000 it was decided to form a Small Group in order to make proposals for the way forward on Mr Justice Coleman's Recommendations. Subsequently AHG/FDF was established to initially consider two issues, which were:

- Strength Requirements for Fore Deck Fittings and Equipment; and
- Prevention of Water Ingress through Fore Deck Openings

1.2 This UR addresses recommendations 10 and 17 of the above report. During the RFA it was identified that the loss of rotating type ventilator heads on the fore deck was likely to have been one of the first events to have occurred in the ship loss sequence. Damage to air and vent pipes leading to further water ingress was also considered to have occurred. Evidence from the wreck further showed that the port windlass had been lost.

2. Points of discussions and possible discussions.

2.1 AHG/FDF determined that increasing air or ventilator pipe thickness for the smaller sizes did not in general yield sufficient strength. Hence it was decided to require additional brackets, which allows the continuance in the main of current pipe thickness standards.

2.2 For ventilators, the forces acting on the closing device should be sustainable with the head in any open or closed position. The combination of horizontal forces, vertical forces and tilting moments acting on a rotating type mushroom ventilator head are such as to render this device unsuitable for application in the areas defined in clause 2 of the UR.

2.3 AHG/FDF considered that hidden corrosion in the bolts securing the windlass was a potential problem that required inspection. However as this could not be quantified for design purposes, nor can be easily inspected, the group considered that the required safety factor should take this into account. Hence a safety factor of 2.0 on bolt proof strength was agreed. Reference for the definition of bolt proof strength is ISO 898-1.

2.4 For the calculation of windlass forces in the direction of the shaft, a factor '*f*' is included to simplify determination of the effective area exposed to the water flow, taking into consideration part shielding of one disc or component by another. A simple relationship as a function of *B/H* is determined, with a maximum value of 2.5

appropriate to a large multi-disc windlass. The applied pressure in this direction was also increased to reflect the greater shape coefficient of an actual windlass disc compared to the simplified outline shape used for the model tests.

2.5 The group agreed that the ship type category, general dry cargo ship, was for the carriage of dry cargo loaded through hatch covers, and did not include special purpose ships such as Container Ships, Vehicle Carriers and Ro-Ro ships.

3. Source/derivation of proposed requirements

3.1The group established information regarding current industry standards and practices from national and international standards such as Japanese Industry Standards, Korean Industry Standards, DIN, Italian shipyards' practices and ISO standard.

3.2 The velocity of water over the fore deck, and the pressures to be applied to the windlass were obtained from results of a program of sea keeping model tests of three bulk carriers conducted at MARIN **(Ref. 1).** AHG/WD-SL determined a water velocity over the fore deck of 13.5 m/sec (reference 'Amended formula for load model of UR S21', supplied to AHG/EBC July 2002). In these tests, the ship speed, even when operating at full engine power, was reduced by wave forces to be close to zero. The direction of water flow was found to be variable, depending on the ships heading, shape of the bow, location of the equipment etc. The requirements in the UR are therefore irrespective of any particular direction.

3.3 The shape factors for air or ventilator pipes and their closing device were based on the MODU code. The slamming factor was taken as that due to momentum. Resulting pressures were correlated with measurements from the above model tests, such that the combination of water velocity, slamming and shape factors corresponded to the maximum measured forces on a cylinder located on the fore deck, as supplied to the AHG. A further coefficient C_p provides for protection from a breakwater or forecastle, but not from the bulwark. The model tests showed that a large wall of water is formed by the presence of the ship's bow, and collapses onto the deck immediately behind the bulwark. The slope of the bulwark then tends to direct the water onto any pipes or fittings located behind, and thus effectively gives little protection in extreme seas.

3.4 Measured forces on the windlasses were supplied to the AHG, as obtained directly from the above sea keeping model tests. The pressure to be applied to the windlass perpendicular to its shaft was obtained from the maximum measured force in this direction divided by the projected area. The maximum measured force parallel to the shaft leads to a nominal pressure of about 100 kPa, but in recognition of the much increased resistance to flow in this direction for a real windlass compared to the idealised and smooth model, this was increased to 150 kPa. It was also found from comparing significant values of forces that differences between intact and flooded conditions were not large.

4. Decision by Voting if any

The technical requirements in this proposed UR were considered by all members of the AHG and agreed unanimously. The implementation scheme, which is contained in square brackets, is to be decided by GPG.

Note by the Permanent Secretariat

1. As the 1966 Load Line uses "ventilators" in Regulation 19, the term "vent" was replaced by "ventilator" except in 5.1.5 and 5.1.6 where "vent pipes" was replaced by "ventilators".
2. Council agreed that a note should be added to Table 1 and 2 for other air pipe / ventilator heights.
3. For pipe diameter 40A and 50A in Table 1, a noted was added
   "Not permitted for new ships – reference UR P1".
4. New sentence 1.3 was added to take account of the integrated windlass & winch type of design.
5. Implementation scheme was harmonized with that of URs S 31 and S 26.
6. Date of approval: 14 November 2002 (2219_ICd).

Technical Background

UR S 27 (Rev.1, March 2003)

This technical background (TB) is developed in line with Annex 2 of IACS Internal Information No. 15.

1. Scope and objectives

To provide more flexibility to the designer for air pipes and ventilators.

2. Points of discussions and possible discussions.

The AHG/FDF Chairman reported on 10 March 2003:

In 4.1.1, two values are defined for the shape coefficient Cd, namely 0.5 for pipes and 1.3 for the heads of air pipes or ventilators. Mr Cooper, ABS has raised the possibility that in order to reduce loads, a vent head may in some circumstances be designed of cylindrical form with its axis in the vertical direction. In this circumstance, the value of 1.3 which is applicable to heads with plane side surfaces becomes rather severe. However, on the other side, the value of 0.5 would not account for the effect of disturbed water flow around a short cylinder.

The Chairman AHG/FDF suggested the following in order to give more flexibility to the designer.

Cd = shape coefficient
~~(0.5 for pipes and 1.3 for air pipe or ventilator head~~)
= 0.5 for pipes, 1.3 for air pipe or ventilator heads in general, 0.8 for an air pipe or ventilator head of cylindrical form with its axis in the vertical direction.

GPG/Council approved on 24 March 2003.

• * * * *

25 March 2003

Technical Background

S26 (Rev.1, Nov 2003) & S27(Rev.2, Nov 2003)

<u>Part A: S26.2.2 (Rev.1, Nov 2003) + S27.2.2(Rev.2, Nov 2003)</u>

1. Objective:

To clarify the ships to which S26 and S27 shall apply.

2. Points raised by BV (s/n 3142):

.1 "Ore carriers" are not mentioned in S26/S27 para 2.2. It needs to be clarified.

.2 "Refrigerated cargo ships, livestock carriers, deck ships, dedicated forest product carriers and dedicated cement carriers" do not seem to be excluded from the scope of application. It needs to be clarified.

3. GPG Discussion

.1 Failure to explicitly include "ore carriers" in the scope of application statements in S26/27 was just an oversight. It was agreed that "Ore carriers" should be explicitly mentioned.

.2 The proposal to align the scope of application for "general dry cargo ships" with that of UR Z7.1 was not agreed. It would exempt more vessels from the application of S26/27. The scope of application of S26/S27 was based on considerations of freeboard – not on alignment with Z7.1 (3142_ABc dated 29 September 2003).
But, it was agreed to include "combination carriers(as defined in UR Z11)" in the scope of application of S26/S27 for clarity.

4. Conclusion

.1 Para 2.2 of S26 and S27 was amended to the above effect.
.2 Council approved it on 7 Nov 2003.

Part B: S27.5.1.1(Rev.2, Nov 2003)

1. Objective

To clarify the scope of application of S27.5.1.1 to existing ships.

2. Points raised by ABS (s/n 3059a):

.1 ABS suggested that S27.5.1.1 does not mean that closing devices of air pipes *(~~and ventilators~~ : this wording "and ventilators" was deleted as UR P3 does not cover "ventilators")* on all existing ships subject to S27 need to be upgraded to comply with the current UR P3. GPG agreed.

.2 GPG did not agree to the view that if an air pipe or ventilator closing device has to be replaced to comply with the other requirements of S27, the new closing device should comply with the current UR P3. (3059aABa, 25 July 2003)
NK pointed out that though some types of air pipe heads satisfying the requirements of UR P3(Rev.1) may be in the market it should be noted that a type of air pipeheads widely applied on board ships built in Asian builders is yet to fully comply the new requirement despite the effort of manufacturers. The identified problem is being addressed by the manufacturer and it is likely that an improved prototype is to be tested in a short time (3059aNKb, 3 Oct 2003).

3. Conclusion

.1 A footnote was added to S27.5.1.1 as indicated in para.2.1 above.
.2 Council approved it on 7 Nov 2003.

End.

Prepared by the Permanent Secretariat
30 October 2003

Technical Background
UR S 27 (Rev. 4, Nov. 2004)

1. Objective

To add a footnote to UR S 27 clarifying that UR S27 does not apply to the cargo tank venting systems and the inert gas systems of oil tankers.

2. Background

According to NK, the AHG/FDF had previously agreed that S27 was not applicable to dedicated cargo tank venting systems (3059bNKa, 24 September 2004).

3. Discussion

3.1 BV suggested that the oil tankers are submitted to the same sea condition than sustain by the bulk-carriers; so logically all vent pipes situated in the fore quarter of the existing oil tankers can be subject also to sea damages.

Therefore, these pipings should comply with UR S27, unless it is demonstrated by statistics that no damage occurred on forward part of the oil tanker in the same or less sea condition than encountered by the" Derbyshire " and there was no oil pollution consecutive to these damages (3059bBVa, 27/09/2004).

3.2 Members expressed the view that if the tanker's venting systems are to comply with UR S27, it should be demonstrated by statistics that there were reported damages on forward part of oil tankers. NK had not seen any such damage reports (3059bNKb, 01/10/2004).

3.3 Tanker vent masts are quite substantial structures owing to other design requirements and we are not aware that there is a history of wave damage of such structures (3059bABa, 01/10/2004).

3.4 GPG agreed to add a note to achieve the above objective.

3.5 Council confirmed that S27 is not applicable to the cargo tank venting and inert gas systems on all ~~**oil**~~ **tankers**. Approved on 30 November 2004(3059bICb).

29 October 2004
Prepared by the Permsec

Technical Background Document
UR S27, Rev. 6 (June 2013)

1. Objective / Scope

According to UR S27 the dimensioning velocity V of water over the fore deck is 13.5 m/s for exposed items located less than 22m or 0.1L (whichever is the lesser) above the summer load waterline. The objective of this document is to adjust the velocity V to be applied in S27-4.1.1 taking the actual height of the item into account.

2. Source of Proposed Requirements

The proposed requirements are based on the technical justifications for the current requirements, current practice within industry, and discussion within the Hull Panel (via correspondence and at Hull Panel Meetings).

3. Technical Basis and Rationale

1. Items located higher than 22m or 0.1L above the summer load waterline, whichever is the lesser, will not experience impact loads. We will refer to this limiting height of items as d_1. The background for this limiting height is not available. Taking the relevant probability level into account it is very difficult to define the limiting height based on model tests (or full scale measurements) even for very comprehensive tests. The limiting height is associated with significant uncertainties.

2. In scantling draft conditions the exposed deck items on ships with a low deck height are not expected to encounter impact velocity in excess of V=13.5 m/s. The minimum height of such items above the waterline is denoted d_2 in this document. The background for the threshold velocity 13.5 m/s applied in UR S27 is model tests of Panamax and Capesize bulk carriers with freeboards 5.4m and 6.7m.

3. Experimental studies by B. Buchner 2002 concludes that the actual velocity V at items on deck is reasonable explained by dam-breaking models. From regressions of these experiments it was proposed that $V \propto \sqrt{h}$ $V \propto \sqrt{h}$where h denotes the actual height of water above the deck. Buchner proposed a modified Rayleigh distribution of the relative motion at the bow in order to deduce extreme value distribution of h . This distribution contains heuristic ship specific constants. However, the classical Rayleigh distribution is conservative in this context and is assumed.

4. The extreme value distribution of h for various deck heights d above the waterline can be simulated assuming the classical Rayleigh distribution of relative bow motion. Monte Carlo simulations have been carried out by DNV for a reasonable range or standard deviations of relative motions at the bow. The

95% percentile h_{95} of the extreme value distribution of h indicates an approximate linear relation between h_{95} and d.

5. The forward speed is assumed small. It should be noted that the experiments by B. Buchner 2002 were carried out for FPSOs at zero forward speed. One hull panel member questioned if this is conservative or not, compared to cases where forward speed is considered? This issue is two-folded. In terms of velocity amplitudes it is usually higher loads associated with forward speed. However, in this task the essential issue is the relative variation of the impact speed with respect to d given that the limiting velocity amplitudes in the previous rule properly accounted for forward speed effects. We are not aware of studies regarding forward speed effects on the velocity shape. The forward speed effect on the shape is expected to be small for typical ULS conditions.

4. Summary of Changes

As a consequence we propose the following approximation of V

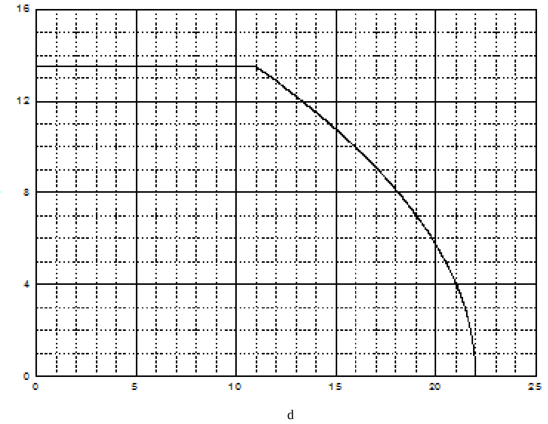
$$V = \begin{cases} 0 & , \quad d \geq d_1 \\ 13.5 \cdot \sqrt{\dfrac{d_1 - d}{d_1 - d_2}} & , \quad d_1 > d > d_2 \\ 13.5 & , \quad d \leq d_2 \end{cases}$$

The value of Zd_1 is precisely defined in 3.1. The value of Zd_2 is explained in 3.2. A lower bound of Zd_2 can be assumed by considering the minimum freeboard and forecastle on e.g. Capesize carriers. It follows that a lower value of Zd_2 could be about 7m. By increasing the parameter Zd_2 the values of V becomes more conservative. Similar to Zd_1 the value of Zd_2 should take the ship length into account. Due to limited available experimental data a conservative value of Zd_2 is needed. As a consequence we propose the following threshold.

$$d_2 = \alpha \cdot d_1 \ , \qquad \alpha = 0.5$$

Hence

$$V = \begin{cases} 0 & , \quad d \geq d_1 \\ 13.5 \cdot \sqrt{\dfrac{1 - \frac{d}{d_1}}{1 - \alpha}} & , \quad d_1 > d > \alpha \cdot d_1 \\ 13.5 & , \quad d \leq \alpha \cdot d_1 \end{cases}$$



Example: V (d) in case L=300m, α = 0.5

An addendum to the Annex 5 (Mar 2021)

Technical Background Document UR S27, Rev. 6 (June 2013)

7. Additional technical background 2021 – Application of green sea load on windlass

7.1 Background

On 29 November 2019, one IACS member asked Hull Panel for clarification about the application of the green sea loads on the windlass deck of a Pure Car Truck Carrier (PCTC), see Figure 1.

The application is given in §2.1 of UR S27, Rev.6:

"**All ship types of sea going service of length 80 m or more, where the height of the exposed deck in way of the item is less than 0.1*L* or 22 m above the summer load waterline, whichever is the lesser.**"

Initially Hull Panel reviewed three possible interpretations:

- The windlass deck shall be considered as an exposed deck and the current green sea loads shall be applied.
- The windlass deck shall be considered as an exposed deck (in some extent) and reduced green sea loads formulation needs to be developed.
- The windlass deck shall be considered as a non-exposed deck, no green sea loads shall be applied.

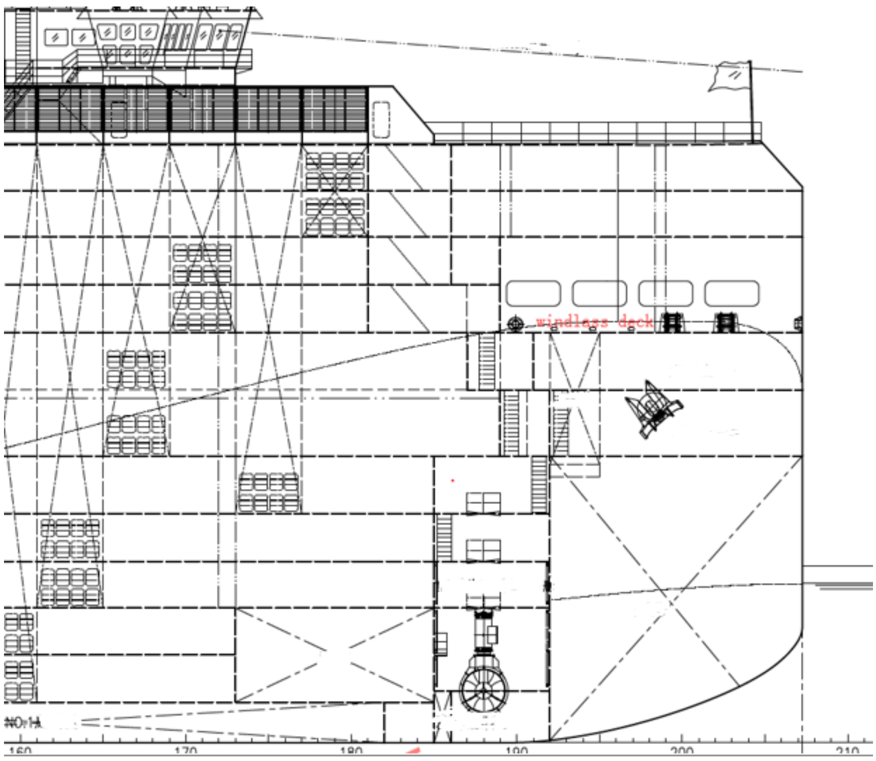

Figure 1 Typical arrangement of a PCTC with the windlass not located at the weather deck.

In the following discussion in Hull Panel, it was concluded that the meaning of “exposed deck” is the same as "weather deck", i.e. to be understood in full agreement with SOLAS II-2, Reg.3, 50: "Weather deck is a deck which is completely exposed to the weather from above and from at least two sides."

However, at this stage it was not possible to conclude on the application of green sea loads on windlass located at decks other than weather deck. Hence HP Chair tasked the HP members to:

- **review their damage databases and report damage experience of windlasses caused by green-sea loading.**

7.2 Damage experience of windlasses caused by green-sea loading

Totally eleven (11) members provided feedback. Of those, seven (7) members did not find any reported damages on windlasses caused by green-sea loading. Four (4) Classification Societies (CS) reported damages as summarized in the table below:

<table>
<tr><th>CS</th><th>Brief description of reported damages</th><th>HP Chair summary</th></tr>
<tr><td>I</td><td>CS I has reviewed its damage database and only identified one winch damage case (deformation) on a containership as a result of heavy weather.</td><td>Usually windlasses on containerships are located at exposed deck at foreship. i.e. UR S27 applies.</td></tr>
<tr><td>II</td><td>CS II found the following 3 cases of damage on windlass reported due to bad weather:
<table>
<tr><th>Global service notation</th><th>Year of build</th><th>Survey Year</th><th>Damage types</th></tr>
<tr><td>Container ship</td><td>2000</td><td>2007</td><td>Bending</td></tr>
<tr><td>Liquefied gas carrier</td><td>2008</td><td>2012</td><td>Crack at weld,Detachment</td></tr>
<tr><td>Container ship</td><td>2008</td><td>2014</td><td>Defective</td></tr>
</table>
However, it is not possible to determine whether these damages were directly the consequence of green sea loads.</td><td>Usually windlass on containerships and gas carriers are located at exposed deck at foreship, i.e. UR S27 applies.</td></tr>
<tr><td>III</td><td>CS III reports one damage case on a vehicle carrier (damage on winch/windlass seems to be an attached power unit but not attachment to deck which URS27 addresses):

1. The mooring equipment and windlass were located on No7 Deck where bounded by side wall with some opening. However, during the severe weather encountered at North Sea, side wall was distorted, and ingress of green-sea water damaged mooring equipment.

2. So even though there is deck above the mooring deck where partially protected by side wall, ingress of water can potentially damage windlass and mooring equipment. It is recommended IACS UR S27 should take account of green sea with no credit of bounded side wall or deck above out of an abundance of caution.</td><td>The sea pressure/green sea pressure has damaged the side wall/bulwark to the recess for the windlass. It seems that the damage on the power unit of the windlass is a consequence of the structural failure of the side wall/bulwark, i.e. lack of protection.

The side wall/bulwark strength might not have been sufficient to withstand the sea pressure/bow impact pressure.</td></tr>
<tr><td>IV</td><td>CS IV confirms that there is one suspicious damage report of a windlass of PCC in their database. However, since there is no detailed description about a cause of the damage, it is unknown whether the damage is due to green sea load or not.</td><td>Unless the nature of this damage is better described, it is not possible to make any conclusion from this damage.</td></tr>
</table>

7.3 Conclusion

Based on the damage experience as summarized in 7.2, it was concluded in Hull Panel Chair's message of 6 May 2020 that it is no need for updates in UR S27 with respect to the application of green sea pressure for windlass.

Hence UR S27 does not apply for the bolts, chocks and stoppers securing the windlass as well as its supporting structure of windlasses located in protected/non-exposed locations, i.e. on decks other than the weather deck.

This addendum to Part B, Annex 5 in the technical background of UR S27 is prepared to document the in-service experience provided by IACS members on this issue.

UR S28 "Requirements for the Fitting of a Forecastle for Bulk Carriers, Ore Carriers and Combination Carriers"

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev.3 (May 2010)	24 May 2010	-
Rev.2 (Sept 2005)	22 September 2005	-
Rev.1 (July 2004)	5 July 2004	-
NEW (May 2003)	6 May 2003	1 January 2004

- **Rev.3 (May 2010)**

.1 Origin for Change:

☑ Based on IACS Requirement *(Common Structural Rules for Bulk Carriers and Double Hull Oil Tankers)*

.2 Main Reason for Change:

Following the introduction of the IACS Common Structural Rules for Bulk Carriers and Double Hull Oil Tankers, Hull Panel were tasked to review all the UR S files to consider whether or not they are applicable to ships covered by the CSR.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None.

.4 History of Decisions Made:

After review it was decided that for CSR bulk carriers the requirements of UR S28 are superseded by those of the Common Structural Rules and therefore do not apply.

UR S28 is not applicable for CSR oil tankers.

.5 Other Resolutions Changes

All UR S files, except UR S8, S9, S15, S16, S19, S22, S23, S30 and S31.

UR S28 Technical background

1. Historical background

In March 2002, IACS announced eight initiatives to improve the safety of Bulk Carriers, including the fitting of a forecastle on new bulk carriers.

It was initially considered that the forecastle would provide protection for forward hatches against green sea loading acting vertically on the top of hatch covers and horizontally on the fore end of hatch covers as well as the fore end hatch coaming and to fore-deck fittings.

Information provided by the AHG/WD-SL on the basis on the continuing investigations on available model test results indicated that the forecastle height does not affect extreme vertical loads on the hatch cover significantly. As a consequence, no credit has been given to the effect of a forecastle to reduce vertical green sea loading on hatch covers.

URs S26 and S27 were developed for requiring sufficient strength of fore-deck fittings against a design load based upon the upper bound load from the results of MARIN model tests for bulk carriers without a forecastle.

UR S21 Rev.3 allows credit to be given to the beneficial effects of a forecastle fitted in accordance with UR S28 for reducing the pressures on the forward transverse hatch coaming and securing arrangements for hatch No. 1.

The 1988 Load Line Protocol addresses “Protection of the crew” in regulation 25 and “Means of safe passage of crew” in regulation 25-1. Further “Bow height” and “reserve buoyancy” required in regulation 39 were developed taking the probability of deck wetness into account.

Consequentially, taking account of the above, the intention to require a forecastle for a new ship is:

- to contribute to the provision of the reserve buoyancy required by regulation 39 of the 1988 Load Line Protocol, as amended;

- to reduce the horizontal loads in UR S21 Rev. 3 for the strength checks of the forward transverse hatch coaming and closing arrangements of hatch No. 1; and

- to protect the crew working in the forward area of the ship.

2. Forecastle characteristics

The forecastle is required to be enclosed to achieve increased buoyancy in the forward area.

The specified forecastle dimensions and locations required for reducing horizontal loads on forward transverse coaming and closing arrangements on hatch No. 1, as well as those concerning the location of the aft edge of the forecastle, are based on the following considerations:

.1 A flow of water flushing on the forecastle deck with speed v_0, reaching a point located at a distance x from the aft edge of the forecastle deck and at a depth h below the specified height, H_F, of the forecastle is defined by the following equations:

$$\begin{cases} x = v_0\, t \\ h = \dfrac{1}{2} g\, t^2 \end{cases}$$

which gives:

$$x = v_0 \sqrt{\frac{2h}{g}}$$

.2 The design pressure assumed in UR S21(Rev. 3) for forward transverse coaming protected by a forecastle fitted in accordance with UR S28 is equal to 220 kN/m^2 (S21.4.1).

.3 The analysis of the results of the MARIN model tests indicated that the water speed corresponding to the above-mentioned design pressure is equal to 11.0 m/s.

.4 Using the formula in .1 above for (see figure below):

$x = l_F$

$h = H_F - H_C$

and imposing a limitation to v_0 ($v_0 \le 11.0$ m/s) in order not to exceed the maximum design pressure for forward transverse coaming protected by a forecastle, it results:

$$l_F \le 4.97\sqrt{H_F - H_C}$$

that can be rounded to:

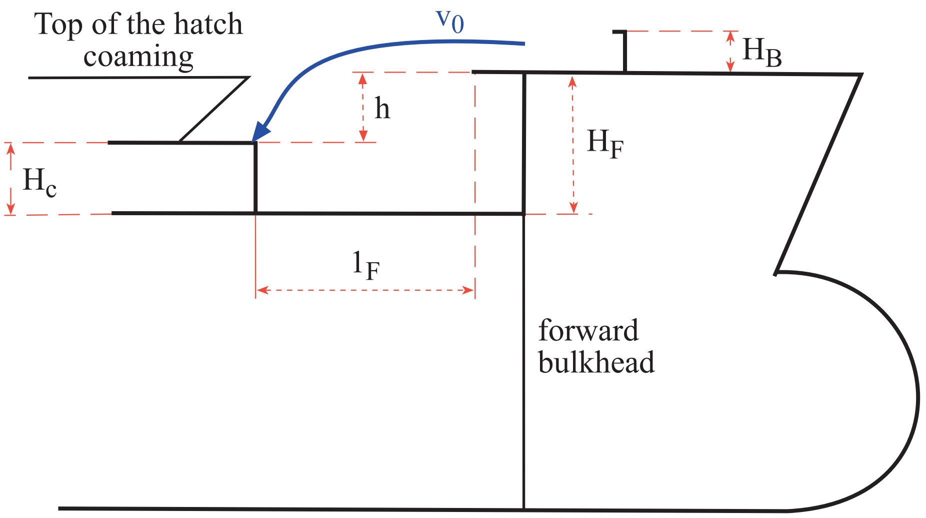
$$l_F \le 5\sqrt{H_F - H_C}$$

.5 Practical considerations based on the examination of existing hatch cover designs led to the definition of the following condition for reducing the loads on the closing arrangements of hatch No. 1:

$H_F \ge H_C + 0{,}5$ m

.6 The formula of l_F given in point .4 above and the condition on H_F given in point .5 above ensure that the actual pressure on the forward transverse coaming is less than the design pressure.

.7 To avoid increased vertical loads on the No. 1 hatch cover, which could be caused by the presence of a breakwater close to the aft edge of the forecastle deck, the minimum distance for a breakwater, if fitted, forward of the aft edge of the forecastle deck has been specified.



3. Remarks made by some Member Societies

Three Societies expressed the view that the expected effects of a forecastle for reducing safety risks associated with hatch covers, coaming, fore deck fittings and crew protection of new bulk carriers have been properly addressed by risk control options contained in regulation 39 of 1988 Load Line Protocol, as amended, and IACS URs S21(Rev.3), S26 and S27. Therefore they consider that there is no need to mandate the fitting of a forecastle in all cases. Fitting a forecastle in accordance with UR S28 may only be made mandatory for fulfilling the requirement of regulation 39 of the 1988 Load Line Protocol, as amended.

Technical Background Document

UR S28 (Rev.2, Sept. 2005)–

Scope and objectives

Scope and objectives are to resolve the following problem.

There is a small Bulk Carriers (i.e. L is less than 150m), which cannot satisfy this requirement because the distance from the forward bulkhead of the foremost hold to the forward transverse hatch coaming of foremost hold hatch cover is too short. If this requirement satisfies forcibly, hatch cover operation will be hindered.

Points of discussions or possible discussions

1 TB of UR S28 states the benefits of fitting forecastle as below:

1. to achieve the provision of the reserve buoyancy required by regulation 39 of 1988 ICLL Protocol, as amended.
2. to reduce the horizontal loads acting on the hatch coaming
3. to protect the crew

2 The purpose of the first sentence of S28.2 is to avoid a too short forecastle.

3 For small Bulk Carriers, the purpose specified in 1.1 above will usually be achieved if forecastle length is more than 0.07L, which is specified in Reg.39 of 1988 ICLL Protocol.

4 The purpose specified in 1.2 above is achieved if the forecastle satisfies the maximum distance l_F specified in S28.2

5 As the 1988 ICLL Protocol addresses specifically the Protection of the Crew issue, it is assumed that the fitting of a forecastle in accordance with 1988 ICLL Protocol achieves the purpose in 1.3.

6 Therefore, even if small Bulk Carriers with sufficient length of forecastle cannot satisfy the first sentence of S28.2, the purposes specified above are achieved.

Submitted by Hull Panel Chairman
31 July 2005

UR S30 "Cargo Hatch Cover Securing Arrangements for Bulk Carriers not Built in accordance with UR S21 (Rev.3)"

Summary

Clarification that this UR S30 is not applicable for the self-unloading bulk carrier.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Corr.1 (Mar 2019)	04 March 2019	-
Rev.1 (2003)	Aug 2003	
Corr.1 (2003)	May 2003	
New (2003)	Jan 2003	

- **Corr.1 (Mar 2019)**

1 Origin of Change:

☒ Request by GPG 15139_IGh dated 18/9/2016

2 Main Reason for Change:

The applicability of ESP to the self-unloading bulk carriers (SUBC) leads to the GPG request to identify the UR S which are NOT applicable to SUBC.

This UR applies to bulk carriers not build in accordance with UR S21 (Rev.3) i.e. mainly for bulk carriers build before 1 Jan 2004. For avoiding to introduce retroactive requirements in relation with the GPG request to specify which UR S are not applicable to self-unloading bulk carriers (SUBC), the Hull Panel decided to clarify the point with this corrigenda clarifying this UR S is not applicable to SUBC.

New UR S30 Technical background

(Jan 2003)

1. Objective

To re-draft UR S30 to cover horizontal loads and securing arrangements.

2. Reference:

1. Section 4 of Recommendation 14,
2. S21(Rev.2),
3. MSC 76/WP.16/para.23

3. Points of discussion

1. The AHG/EBC-Strength prepared a draft UR S[yy] "Requirements for existing bulk carriers' hatch covers and coamings not built in accordance with UR S21 (Rev.2)" in August 2002.

Technical Background for this UR S[yy] is **annexe**d.

However, following a more detailed cost-benefit analysis (carried out by DNV with GPG Members' input), this UR S[yy] was found not cost-effective. Council decided to keep in abeyance until after MSC 76. It was so reported to MSC 76.

2. IMO MSC 76 decisions

MSC 76 decision (MSC 76/WP.16) reads: *While recognizing that replacing hatch covers in existing ships would not be cost-effective, the group agreed that more attention should be paid to hatch cover securing mechanisms and the issue of horizontal loads only, especially with regard to maintenance and frequency of inspection. Consequently, the group agreed further that ship owners and operators should be made aware of the need to implement regular maintenance and inspection procedures for closing mechanisms in existing bulk carriers in order to ensure proper operation and efficiency at all times, and invited the Committee to instruct the DE Sub-Committee to develop standards for hatch cover securing arrangements for existing ships and that IACS UR S21 and Recommendation 14 could be used as a starting point for discussion*.

3. GPG decisions

Finally, GPG at its small group meeting on 7-8 January 2003 prepared a draft UR S30 incorporating section 4 of Recommendation 14. Horizontal loads are specified in section 3 of S30 "Stoppers".

The pressure value 175 kN/m^2 for stoppers is derived from UR S21(Rev.2) and its TB which reads as follows:

> "The stoppers are to be dimensioned against longitudinal and transverse forces arising from a pressure of 175 kN/m^2. This value takes into consideration the local reduction of pressure that occurs at the upper edge of the vertical boundary created by the coaming and hatch cover side or end plate."

The pressure value 230 kN/m^2 comes from the following provision of ex-UR S30(Syy).

> "With the exclusion of ships fitted with a forecastle complying with UR S28 or a breakwater complying with S 29 (S29 now withdrawn), No.1 hatch cover is to be effectively secured by means of stoppers, against the longitudinal forces arising from a pressure of 230 kN/m^2, which may be reduced to 175 kN/m^2 if a forecastle not complying with S28 is fitted."

4. Section 4 "Materials and Welding"

ABS proposed to have an additional section 4 "Materials and Welding" in S30.

5. Recommendation 14

GPG decided to revise Recommendation 14.

4. Conclusions

1. UR S30 was adopted on [31 January 2003] and submitted to IMO DE 46 in the same day.

2. WP/S will be asked to incorporate comparable changes in the revision of UR S21 that they are preparing (WP/S Task 70 – Revision of S21(Rev.2))

****

Annex: TB for UR S [yy] submitted by AHG/EBC.

(Date of submission: 20 August 2002)

1. Background

Following the hearings of the Re-Opened Formal Investigation into the loss of the m.v. Derbyshire, held in the U.K., the Court recommended that UR S21 should be re-appraised in the light of the latest sea-keeping model tests, and that this new standard be made applicable both to new ships and retrospectively to existing vessels. Later, in March 2002, IACS announced a series of eight initiatives to improve the safety of bulk carriers. UR Syy was developed by AHG/EBC working in association with WP/S to address the application of measure number 6 to existing bulk carriers.

The requirements for hatch covers and coamings of existing bulk carriers are generally consistent with the requirements for new bulk carriers in UR S21 Rev. 1. Exceptions to this are shown below.

2. Hatch cover load model

Based on cost benefit considerations, the hatch cover strength in the forward spaces flooding conditions are not required to be assessed. This is partially compensated by the additions made to the net thickness, which do not take into consideration the reduced life of the ship.

For the intact condition, the same load formulation as UR S21 is used.

3. Hatch cover strength criteria

In the formula for the required net plate thickness, the factor F_P for combined membrane and bending response has a minimum value of 1,35, instead of 1,50 as adopted in UR S21. This minimum value is significant in areas of the hatch cover plate subjected to low in-plane stresses from bending of primary supporting members. Therefore, the overall safety is not significantly reduced, as these areas are not susceptible to plate buckling.

The safety factor, F_S, in the formula for the required minimum section modulus of secondary stiffeners depends on the stress level, so that F_S ranges between 1,2 and 1,5. This allows more specific requirements to be included for the minimum section modulus of stiffeners on the basis of their location and the corresponding stress level.

New UR S30 Technical background

(Jan 2003, Corr.1- May 2003)

1. Objective

To re-draft UR S30 to cover horizontal loads and securing arrangements.

2. Reference:

1. Section 4 of Recommendation 14,
2. S21(Rev.3),
3. MSC 76/WP.16/para.23
4. S[yy] prepared by AHG/EBC.

3. Points of discussion

1. The AHG/EBC-Strength prepared a draft UR S[yy] "Requirements for existing bulk carriers' hatch covers and coamings not built in accordance with UR S21 (Rev.3)" in August 2002.

Technical Background for this UR S[yy] is **annexe**d.

However, following a more detailed cost-benefit analysis (carried out by DNV with GPG Members' input), this UR S[yy] was found not cost-effective. Council decided to keep in abeyance until after MSC 76. It was so reported to MSC 76.

2. IMO MSC 76 decisions

MSC 76 decision (MSC 76/WP.16) reads: *While recognizing that replacing hatch covers in existing ships would not be cost-effective, the group agreed that more attention should be paid to hatch cover securing mechanisms and the issue of horizontal loads only, especially with regard to maintenance and frequency of inspection. Consequently, the group agreed further that ship owners and operators should be made aware of the need to implement regular maintenance and inspection procedures for closing mechanisms in existing bulk carriers in order to ensure proper operation and efficiency at all times, and invited the Committee to instruct the DE Sub-Committee to develop standards for hatch cover securing arrangements for existing ships and that IACS UR S21 and Recommendation 14 could be used as a starting point for discussion*.

3. GPG decisions

Finally, GPG at its small group meeting on 7-8 January 2003 prepared a draft UR S30 incorporating section 4 of Recommendation 14. Horizontal loads are specified in section 3 of S30 "Stoppers".

The pressure value 175 kN/m^2 for stoppers is derived from UR S21(Rev.3) and its TB which reads as follows:

> "The stoppers are to be dimensioned against longitudinal and transverse forces arising from a pressure of 175 kN/m^2. This value takes into consideration the local reduction of pressure that occurs at the upper edge of the vertical boundary created by the coaming and hatch cover side or end plate."

The pressure value 230 kN/m^2 comes from the following provision of ex-UR S30(Syy).

> "With the exclusion of ships fitted with a forecastle complying with UR S28 or a breakwater complying with S 29 (S29 now withdrawn), No.1 hatch cover is to be effectively secured by means of stoppers, against the longitudinal forces arising from a pressure of 230 kN/m^2, which may be reduced to 175 kN/m^2 if a forecastle not complying with S28 is fitted."

4. Section 4 "Materials and Welding"

ABS proposed to have an additional section 4 "Materials and Welding" in S30.

5. Recommendation 14

GPG decided to revise Recommendation 14.

4. Conclusions

1. UR S30 was adopted on 30 January 2003 and submitted to IMO DE 46.

2. At the same time, WP/S was asked to incorporate comparable changes in the revision of UR S21 that they are preparing (WP/S Task 70 – Revision of S21(Rev.3))

IACS Unified Requirement S 30 (Rev.1)

Technical Backgrounds:

a) Objective/Scope

To amend the existing text of UR S30 to eliminate ambiguity

b) Source of Proposed Requirements

ABS GPG put forward a draft amendment to UR S30.1.1 (2248jABa of 22 July 2003).

c) Points of Discussion

1. S30.1.1 reads that *these requirements apply.....and are for steel hatch cover securing devices and stoppers for cargo hold hatchways within 0.25 L of the fore perpendicular, except pontoon type hatch cover.*

   However, S30.3 on stoppers specifically addresses hatch covers 1 and 2.

   Hatch cover no.3 may be at least partially within 0.25L from FP on some bulk carriers. GPG/Council agreed that in such cases, S30 applies only to hatch covers 1 and 2 if they are within 0.25L of the FP.

2. S30.1.1 has been so amended.

   - S30 does not apply to hatch cover no.3 if it is partially within 0.25L.
   - S30 does apply to hatch cover no.1 and 2 whenever they are wholly or partially within the forward 0.25 L aft the FP.
   - Since UR S21, Rev.3 applies to all position 1 hatch covers, the ambiguity being corrected in S30 does not occur in S21, Rev. 3.

UR S31 (Sww) Technical Background

1. Background

In March 2002, IACS announced eight initiatives to improve the safety of bulk carriers. UR S31 was developed by AHG/EBC, working together with members of WP/S, to address measure number 7. The objective of UR S31 is to establish steel renewal criteria for the side frames of pre-S12 (Rev 1) bulk carriers that are generally equivalent to the application of the renewal criteria of UR S12.

2. Renewal thickness

Two thickness values, as indicated below, are defined for the purpose of establishing the steel renewal criteria for the side frames of existing pre-S12 bulk carriers.

- The thickness t_{COAT}, which corresponds to the renewal thickness applicable to S12 ships. In accordance with UR S12, t_{COAT} is therefore defined as 75% of the thickness required according to S12.3 and S12.4. When measured thickness is below this value, actions as described below are required.

- The renewal thickness t_{REN}, obtained by reducing t_{COAT} by an amount t_C. The t_C values have been established from a review of the current practices of the IACS members.

  However, the renewal thickness is never to be taken less than 75% of the thickness adopted at the new building stage in order to avoid corrosion wastage in excess of that anticipated in the design.

Different minimum thicknesses are defined in UR S12 depending on the hold to which any frame belongs and on the part of the frame under consideration. As a consequence, different t_{COAT} and t_C values, and thus t_{REN} values, are defined separately for:

- the span and the upper bracket,

- the lower bracket,

distinguishing between hold No. 1 and the other holds.

The renewal criteria, based on the measured thickness t_M, are as follows:

a) When $t_M \leq t_{REN}$, steel renewal is required. This is consistent with the present Society practice.

b) When $t_{REN} < t_M \leq t_{COAT}$, measures are to be taken, consisting of all the following:

   – sand blasting, or equivalent, and coating ,

   – fitting tripping brackets,

   – maintaining the coating in “as-new” condition, or equivalent (i.e. without breakdown or rusting), at Special and Intermediate Surveys.

The above measures may be waived if the structure and coating are in “as-new” condition.

These criteria aim to ensure adequate strength of the side frames of pre S-12 ships when their measured thickness is lower than the corresponding renewal thickness of S12 ships.

However, in order that these criteria may be considered as being generally equivalent to the UR S12 renewal criteria, the renewal thickness t_{REN} is also to satisfy simple yield strength and buckling checks. The yielding strength checks are explicitly defined in UR S31 and their background is reported in 4.

The buckling checks are covered through the introduction of limiting web depth to thickness ratios for both the frames and the lower brackets. These limits are the same as those established in UR S12for renewal, the only difference being retention of the k factor for asymmetrically flanged frames, since this could have been applied in the design of pre-S12 ships.

3. Thickness measurements, steel renewal and reinforcing measures

The effectiveness of steel renewal or alternative measures relies on an adequate extent of the structure being treated. Measures adopted for the lower and upper brackets are individually required to extend over at least 25% of the overall span. In addition, for the reasons given in 2. above, different renewal thicknesses are defined for the span and upper bracket and for the lower bracket.

The necessity to combine these principles led to the identification of four zones A, B, C and D, as shown in Figure 1 of UR S31, and to the definition of thickness measurements and renewal or reinforcement criteria for each zone.

Reinforcing measures involve the fitting of tripping brackets at the lower part and at midspan of side frames. Frame tripping is considered as being one of the major causes of side frame collapse and the efficiency of tripping brackets in preventing catastrophic failures has been demonstrated in some near miss cases.

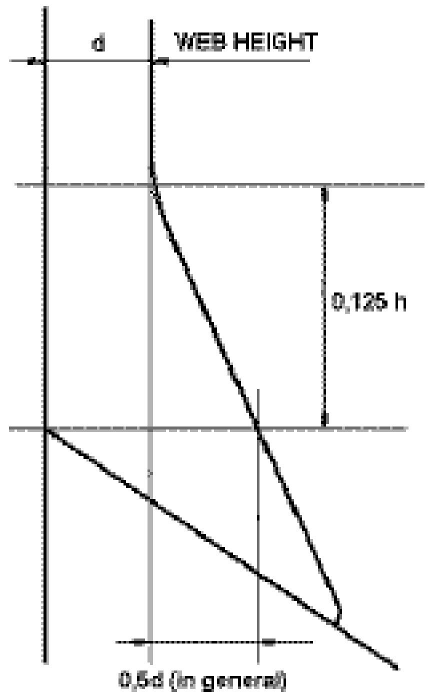
The criteria for dealing with pitting and grooving are the same as in UR S12.

4. Yield strength checks

Shear and bending strength checks are required to be carried out at two transverse sections a) and b), specified in Figure 2 of UR S31. Section a) is representative of the lower bracket strength, while section b), located at the connection between frame and lower bracket, is representative of the frame strength at its lower part.

Some strength analyses carried out by Members in the course of the development of UR S31 showed that the bending check is significant when small brackets (length less than about 10% of the frame span) are fitted. For this reason, and for consistency with UR S12, the bending check is not required when the bracket length and depth comply with the requirements of UR S12 shown in Figure 1.

Figure 1 – Minimum bracket dimensions according to UR S12



NK placed a reservation on the bending strength check required in S31.3.4.

While the other Members agreed that the definition of t_{REN} and the acceptability of measured thickness t_M have always to account for the results of the strength checks, including the bending moment check, NK deem that the bending check is to be carried out only when t_M is less than t_{COAT}.

The strength checks are based on the following considerations.

a) The side pressure only is considered for calculating the shear force and bending moment in the side frame lower part. The side pressure load model was developed by the AHG/WD-SL and is reported in their document “Dynamic sea pressure for Bulk Carriers” of 30 January 2002. In this model, the pressure loads are defined through a coefficient f, which accounts for any load probability of exceedance. The side pressures in UR S31 are defined for the following probabilities of exceedance:

   – 10^{-6}, for the head sea condition,

   – 10^{-4}, for the beam sea condition.

b) In order to simplify the procedure, certain approximations, as described below, are involved in the assessment of the applied shear forces and bending moments.

   The shear force at section a) is obtained by integrating the still water and wave pressures over the frame span h. It is assumed that the sum of the still water and wave pressures is uniform along the span h. It is also assumed that 60% of the total lateral force on the frame is carried by the lower end support: for this reason, a coefficient k_S = 0,6 is introduce d in the formulae for $t_{REN,Sa}$ and $t_{REN,Sb}$ in S31.3.4.

The shear force at section b) is assumed to be equal to that at section a)multiplied by a factor. The factor is equal to (the frame span "h" minus twice the length of the lower bracket) divided by "h" (it is assumed here that the upper and the lower brackets have the same length).

The bending moment at sections a) and b) are obtained by multiplying the total lateral force on the frame by the frame span and dividing it by coefficients "m_a" and "m_b", derived from the results of Finite Element calculations. The "m_a" and "m_b" values depend on the loading condition of the hold to which the frame under consideration belongs.

The analyses carried out showed that, for loaded holds, the side frames may be considered as being clamped at the lower end (m_a = 12). The coefficients "m_b" depends, of course, on the distance from the support and hence on the bracket length.

In the case of empty holds of ships navigating in non homogeneous loading conditions (i.e. at the maximum draft) the sea pressure acting on the double bottom is not counterbalanced by internal cargo. This induces significant rotation of the hopper tanks and hence of the side frame lower ends. This rotation increases the bending moment (i.e. reduces the "m_a" and "m_b" values) and consequently lower coefficients have been included for this case.

c) The load probabilities defined in a) are based on the assumption that the following probabilities:

- 10^{-7}, for the head sea condition,
- 10^{-5}, for the beam sea condition

represent extreme sea conditions. This is based on a comparison of the 10^{-8} probability loads obtained by the AHG/WD-SL with the Marin model test results and a judgement of the beam sea loads justified as follows.

In severe sea states, a Master would normally operate his ship in the head seas condition. However, a beam seas condition might occur in an emergency situation, due for instance to engine or shaft failure. In the latter case, the use of a higher load probability is justified by the need for a joint probability of occurrence of two rare events. On basis of this assumption, a stress level corresponding to yield was applied to these levels of probability.

However, the sea load formula proposed by the AHG/WD-SL gives considerably higher values of side pressure than those given by current class rules of some societies and/or calculation results of long term predictions carried out by some societies. The values of probability have been modified as specified in a) above and the stress levels have been reduced accordingly.

Both the load probability of exceedance and the "m_a" and "m_b" values are consistent with an elastic behaviour of the side frames. Consequently, the normal and shear allowable stresses are obtained by multiplying the yield stress by appropriate safety factors (0,90 for the normal stresses and 0,40 for the shear stresses).

IACS AHG/EBC

UR S31

Notes by the Permanent Secretariat

1. In order to lift its reservation to the bending strength check in S31.3.4, NK put forward the following amendment to the renewal thickness in S31.2.1.

   the strength check is to be carried out when $t_M <= t_{COAT}$.

   GPG 53 (Oct.2002) agreed this and further decided that $t_{REN.S}$ need not be taken as more than $0.75t_{S12}$, allowing that Members were free to apply the stricter requirements should they wish. Hence, the following was added to S31.2.1:

   but the $t_{REN.S}$ *as obtained from S31.3.3 need not be taken more than 0.75* t_{S12}

2. At the time of approval of S31, revision of S12 had not been completed. WP/S was expected to complete the remaining task to develop shear and bending checks for inclusion into S12 which would be similar to those given in S31. See S12 (Rev.4).

3. Implementation schedule is the same as that for URs S26 and S27.

4. Date of approval of S31: 14 November 2002 (2219_ICd).

****

UR S31 Technical background

(Rev.1, June 2003)

1. Background

NK Council Member proposed that S31 should be revisited with regard to shear buckling of hold frame webs. It reported that the S31 requirement on the renewal thickness in regard to shear buckling of hold frame web used an assumption that the as-built design was subjected to the allowable stress, however, there were a number of bulk carriers that the assumption was not in reality.

Council tasked WP/S to undertake an urgent review of S31 on 4 March 2003 (during GPG 54).

ABS drew Council attention to the need to clarify some vague language used at the end of S31.2.1. ABS also proposed to add the requirements for bulk carriers subject to UR S31 that are ice strengthened. S31.1.1 refers.

2. S31.2.1: Web depth to thickness ratio

A number of bulk carriers have the depth of side frames immediately abaft the collision bulkhead much greater than that of ordinary frames by classification requirements. Such design has been widely applied to provide significantly large moment of inertia for restricting undesirable flexibility of side shell and achieving smooth continuation of the side shell structural stiffness of fore peak tank to that of the foremost cargo hold.

Working shear stresses of the deep hold web frames in that area are quite lower than the assumed maximum working shearing stresses, i.e. $0.4\sigma_y$.

Section S31.2.1 of the original UR S31, therefore, has been amended by introducing a new text and formula taking into a web depth to thickness ratio into account in the procedure for determining renewal thickness t_{REN}.

The shear capacity of hold frame web plate used in S31.2.1 can be given by the following formula.

$$\tau_{cr} = K\,\frac{\pi^2 E}{12(1-\upsilon^2)}\left(\frac{t}{b}\right)^2 = S_f \tau_a \quad (1)$$

where:

τ_{cr} = critical shear buckling stress

t = $t_{REN.d/t}$, web thickness satisfying the required shear buckling criteria corresponding to the assumed allowable shear stress τ_a with safety factor.

τ_a = allowable shear stress (= 0.4 σ_y)

S_f = safety factor

In case where the working shear stress τ_w is smaller than allowable shear stress, critical shear buckling stress may be reduced by replacing τ_a with τ_w in (1):

$$\tau_{cr} \geq S_f \tau_w$$

where:

$$\tau_w = \frac{t_{REN,S}}{t_{REN,d/t}} \tau_a$$

$t_{REN,S}$ is as obtained from S31.3.3,

$t_{REN,d/t}$ is the web thickness that satisfies the web depth to thickness ratio specified in the original S31.2.1 for t_{REN} as follows:

for frames:

- 65 $k^{0.5}$ for symmetrically flanged frames
- 55 $k^{0.5}$ for asymmetrically flanged frames

and for the lower brackets at section a) of Figure 2 of UR S31:

- 87 $k^{0.5}$ for symmetrically flanged frames
- 73 $k^{0.5}$ for asymmetrically flanged frames

where k = 1.0 for ordinary hull structural steel and k < 1 for higher tensile steel according to UR S4.

However, when $t_{REN,d/t}$ is greater than $t_{REN,S}$, it means that the maximum working shear stresses τ_w is less than the allowable shear stress τ_a and the corresponding $t_{REN,\ d/t}$' will be obtained by the following formula,

$$t_{REN,\ d/t}' = \sqrt[3]{t_{REN,d/t}{}^2 t_{REN,S}}$$

For the reader's easy understanding the following explanation is given:

The relationship between critical shear stresses and the web plate thickness is given by the formula (1)

$$\tau_{cr} = K \frac{\pi^2 E}{12(1-\upsilon^2)}\left(\frac{t}{b}\right)^2 = S_f \tau_a \qquad (1)$$

In case where working shear stresses τ_w are less than the allowable shear stress τ_a the corresponding critical shear stress τ_{cr}' , while maintaining the same safety factor, is given by

$$\tau_{cr}' = K \frac{\pi^2 E}{12(1-\upsilon^2)}\left(\frac{t'}{b}\right)^2 = S_f \tau_w \qquad (2)$$

where, *t'* is the web plate thickness giving the critical shear stress τ_{cr}'

Consequently the working shear stresses τ_w is given by formula (3)

$$\tau_w = \frac{t_{REN,S}}{t'}\tau_a \qquad (3)$$

where, $t_{REN,S}$ is as given in S31.3.3

The following equation is obtained by substituting τ_w in formula (2) by that of formula (3):

$$K\ \frac{\pi^2 E}{12(1-\upsilon^2)}\left(\frac{t'}{b}\right)^2 = S_f\ \frac{t_{REN,S}}{t'}\tau_a = S_f\tau_a\ \frac{t_{REN,S}}{t'} \qquad (4)$$

Combining equations (1) and (4) give the following relationship between t and t':

$$\left(\frac{t'}{b}\right)^2 = \frac{t_{REN,S}}{t'}\left(\frac{t}{b}\right)^2 \qquad (5)$$

Equation (5) gives t' as follows:

$$t' = \sqrt[3]{t^2 t_{REN,S}} \qquad (6)$$

t' given by the formula (6) gives the renewal web thickness for side frames and lower brackets satisfying the shear buckling criteria corresponding to the working shear stresses, where t is greater than $t_{REN,\ S}$.

The formula for t' is based on the formulation of the elastic shear buckling stress. For as built thicknesses t_{AB} greater than $1{,}65 \cdot t_{REN,\ S}$, the side frame web works in the elastic domain, also considering an actual thickness of about 75% of the as built one, and the formula in (6) is applicable.

t above is denoted as $t_{REN,\ d/t}$, while t' is denoted as $t_{REN,\ d/t}$' in UR S31.2.1.

3. Alternative to steel renewal

The fitting of tripping brackets, in accordance with S31.2.3, is allowed as an alternative to steel renewal, when the measured thickness is less than $t_{REN,\ d/t}$ required by the web depth to thickness ratio check for the frame web.

This measure is considered an efficient solution for the stability of the web and flange at the upper termination of the lower end bracket, subjected to the combined effects of the sea pressure loads, the compressive force of the lower end bracket flange and the shear stress of the side frame web.

4. S31.2.1: Measurement of depth of lower bracket

It was raised by WP/S meeting in February 2003 that it would be necessary to modify the definition of depth of lower bracket for the calculation of d/t in association with revision of UR S12. WP/S agreed that the depth may be measured perpendicular to the face plate of lower bracket from the intersection of sloping plating of hopper tank and side shell plate.

For the measurement of depth of lower bracket, the WP/S agreed to give credit to the possible secondary stiffeners fitted on the lower bracket plate for buckling prevention.

5. S31.2.1: Steel renewal

The test of the original S31.2.1 addressed only $1.2t_{COAT}$ for the minimum plate thickness for the renewed parts. It should also address $1.2t_{REN}$ to be comprehensive. Therefore a new wording “or $1.2t_{REN}$ whichever is the greater” is inserted after “$1.2t_{COAT}$” in the paragraph next to the last in S31.2.1.

6. S31.2.1: Meaning of “as-new” condition

It is clarified that the structure is in “as-new” condition when the thicknesses are as per the approved drawings.

The coating is in “as-new” condition when it is without breakdown or rusting exists.

7. S31.2.2: Zone of sand blasting and coating

With regard to the requirement of sand blasting and coating for frames in the 5th paragraph of S31.2.2, considering the consistency with the other requirements, zone B is added for sand blasting and coating, when zone C is required sand blasting and coating.

8. Notes by the Permanent Secretariat

8.1 Other changes

- S31.2.1.2.a)”tripping bracket alternative”: Fitting of tripping brackets, as an alternative to the requirements for the web depth to thickness ratio of side frames, does not exclude that the other checks for renewal (corrosion and strength) are to be performed. Amendments to S31.2.1.2a) and S31.2.1.2d.

- S31.2.1.2.c) “thickness of renewed webs of frames and lower brackets” - the requirement “t_{ren} need not be taken more than $0.5t_{S12}$” has been retained.

- The expression “frames” throughout in S31 was re-checked and modified so that it is changed to “frames and brackets” where the requirements address both frames and brackets.

(“brackets” are added to 1st sentence in S31.1, 3rd paragraph in 31.1, the penultimate paragraph in S31.2.2, and 2nd paragraph in S31.2.5.)

8.2 An information paper was submitted to MSC 77 on 8 April 2003 advising them that:

- S31 has been revised to amongst others explicitly limit the renewal thickness to be not less than the as-built thickness.
- The shear and bending checks carried out under S31 as revised will, in a majority cases, govern the thickness of the replaced portion of the web.

8.3 NK proposed to add the following to the TB (2219cNKg of 19/06/03)

- **S31.2.1.3** Criteria for frames and brackets (Bending check)

  DNV pointed out that side frame with insufficient bending strength may go unnoticed since the bending requirements will not be checked until the web thickness is less than t_{COAT}. Therefore, it is incorrect to use t_{COAT} as reference for section modulus control. (2219cNVd of 26 May 2003) At C47, the majority of members shared the views of DNV comments.

  But NK stated as follows: The matter of bending stress check had been discussed and agreed by GPG in October 2002 with a view to resolve the reservation lodged by NK. On the technical side of the bending stress check, the timing for carrying out the bending stress check is linked to the result of thickness measurement. The actual web thickness has little to do with the section modulus of hold frames and it may seem to be illogical to use such criteria for a need of bending stress check. However, the provision of S31.2.1.3 contained in Mr. Han's message 2219cIAa of 17 April 2003, i.e. "Where t_M in the lower part of side frames, as defined in Figure 1, is equal to or less than t_{COAT}", gives a pragmatic approach of the application of the bending check when diminution of the hold frame has modestly progressed. NK's investigation into hold frame failure indicated extensive corrosion of hold frames being the major contributor to hold frame failure and the requirement of S31.2.1.3, contained in UR S31 attached to th e message of Mr. Han, provides the right timing for taking action for risk reduction of hold frame failure by a pragmatic use of modest progress in diminution of hold web. NK consider that there would be a very limited risk reduction if well maintained hold frames in nearly as built condition are to be renewed due to the age of bulk carriers and not due to the condition of the structure. NK, therefore, did not agree the proposal of DNV."

- NK made the following statements at Council 47 meeting (10-12 June 2003):

  1) The introduction of the bending/shear buckling checks, which had been introduced into S31 needs to be carefully examined.

  2) According to NK’s data extensive corrosion in hold frames is an identified primary contributor to hold frame failures. There are still a number of well-maintained ships with good coating condition albeit not satisfying the new bending check requirements. Such a new requirement may well be applied for risk reduction purposes once cargo hold frames have shown a start of deterioration. The criteria “where t_M in the lower part of side frames is equal to or less than t_{COAT}” is considered to provide the sign of a start of deterioration.

3) NK would examine the integrity of existing BCS' hold frames structures, using such criteria contained in the former draft version of UR S31.2.1.3 (May 2003), which read as follows:

S31.2.1.3 Criteria for frames and brackets (pre-S31.2.1.3(Rev.1))

Where t_M in the lower part of side frames, as defined in Figure 1., is equal to or less than t_{COAT} and the length or depth of the lower bracket does not meet the requirements in S12, a bending strength check in accordance with S31.3.4 is to be carried out and renewals or reinforcements of frames and/or brackets are to be effected as required therein.

****

Annexed: TB of the first issue of S 31(Nov 2002).

UR S31 (Sww, Nov 2000) Technical Background

1. Background

In March 2002, IACS announced eight initiatives to improve the safety of bulk carriers. UR S31 was developed by AHG/EBC, working together with members of WP/S, to address measure number 7. The objective of UR S31 is to establish steel renewal criteria for the side frames of pre-S12 (Rev 1) bulk carriers that are generally equivalent to the application of the renewal criteria of UR S12. UR S12 in this TB refers to UR S12 (Rev.1, 2 and 3).

2. Renewal thickness

Two thickness values, as indicated below, are defined for the purpose of establishing the steel renewal criteria for the side frames of existing pre-S12 bulk carriers.

- The thickness t_{COAT}, which corresponds to the renewal thickness applicable to S12 ships. In accordance with UR S12, t_{COAT} is therefore defined as 75% of the thickness required according to S12.3 and S12.4. When measured thickness is below this value, actions as described below are required.

- The renewal thickness t_{REN}, obtained by reducing t_{COAT} by an amount t_C. The t_C values have been established from a review of the current practices of the IACS members.

  However, the renewal thickness is never to be taken less than 75% of the thickness adopted at the new building stage in order to avoid corrosion wastage in excess of that anticipated in the design.

Different minimum thicknesses are defined in UR S12 depending on the hold to which any frame belongs and on the part of the frame under consideration. As a consequence, different t_{COAT} and t_C values, and thus t_{REN} values, are defined separately for:

- the span and the upper bracket,

- the lower bracket,

distinguishing between hold No. 1 and the other holds.

The renewal criteria, based on the measured thickness t_M, are as follows:

a) When $t_M \leq t_{REN}$, steel renewal is required. This is consistent with the present Society practice.

b) When $t_{REN} < t_M \leq t_{COAT}$, measures are to be taken, consisting of all the following:

  – sand blasting, or equivalent, and coating ,

  – fitting tripping brackets,

  – maintaining the coating in “as-new” condition, or equivalent (i.e. without breakdown or rusting), at Special and Intermediate Surveys.

The above measures may be waived if the structure and coating are in “as-new” condition.

These criteria aim to ensure adequate strength of the side frames of pre S-12 ships when their measured thickness is lower than the corresponding renewal thickness of S12 ships.

However, in order that these criteria may be considered as being generally equivalent to the UR S12 renewal criteria, the renewal thickness t_{REN} is also to satisfy simple yield strength and buckling checks. The yielding strength checks are explicitly defined in UR S31 and their background is reported in 4.

The buckling checks are covered through the introduction of limiting web depth to thickness ratios for both the frames and the lower brackets. These limits are the same as those established in UR S12for renewal, the only difference being retention of the k factor for asymmetrically flanged frames, since this could have been applied in the design of pre-S12 ships.

3. Thickness measurements, steel renewal and reinforcing measures

The effectiveness of steel renewal or alternative measures relies on an adequate extent of the structure being treated. Measures adopted for the lower and upper brackets are individually required to extend over at least 25% of the overall span. In addition, for the reasons given in 2. above, different renewal thicknesses are defined for the span and upper bracket and for the lower bracket.

The necessity to combine these principles led to the identification of four zones A, B, C and D, as shown in Figure 1 of UR S31, and to the definition of thickness measurements and renewal or reinforcement criteria for each zone.

Reinforcing measures involve the fitting of tripping brackets at the lower part and at midspan of side frames. Frame tripping is considered as being one of the major causes of side frame collapse and the efficiency of tripping brackets in preventing catastrophic failures has been demonstrated in some near miss cases.

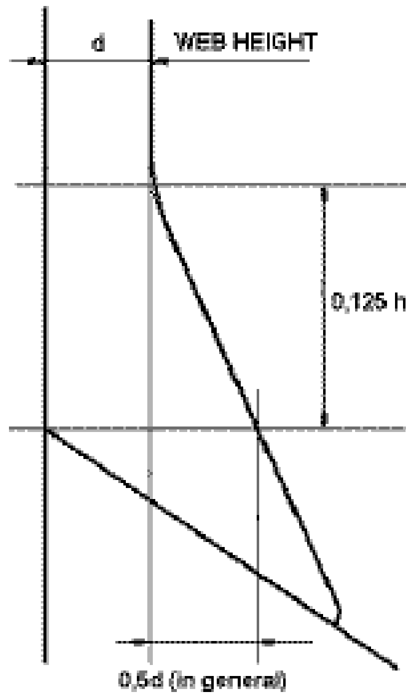
The criteria for dealing with pitting and grooving are the same as in UR S12.

4. Yield strength checks

Shear and bending strength checks are required to be carried out at two transverse sections a) and b), specified in Figure 2 of UR S31. Section a) is representative of the lower bracket strength, while section b), located at the connection between frame and lower bracket, is representative of the frame strength at its lower part.

Some strength analyses carried out by Members in the course of the development of UR S31 showed that the bending check is significant when small brackets (length less than about 10% of the frame span) are fitted. For this reason, and for consistency with UR S12, the bending check is not required when the bracket length and depth comply with the requirements of UR S12 shown in Figure 1.

Figure 1 – Minimum bracket dimensions according to UR S12



NK placed a reservation on the bending strength check required in S31.3.4.

While the other Members agreed that the definition of t_{REN} and the acceptability of measured thickness t_M have always to account for the results of the strength checks, including the bending moment check, NK deem that the bending check is to be carried out only when t_M is less than t_{COAT}.

The strength checks are based on the following considerations.

a) The side pressure only is considered for calculating the shear force and bending moment in the side frame lower part. The side pressure load model was developed by the AHG/WD-SL and is reported in their document "Dynamic sea pressure for Bulk Carriers" of 30 January 2002. In this model, the pressure loads are defined through a coefficient f, which accounts for any load probability of exceedance. The side pressures in UR S31 are defined for the following probabilities of exceedance:

   – 10^{-6}, for the head sea condition,

   – 10^{-4}, for the beam sea condition.

b) In order to simplify the procedure, certain approximations, as described below, are involved in the assessment of the applied shear forces and bending moments.

   The shear force at section a) is obtained by integrating the still water and wave pressures over the frame span h. It is assumed that the sum of the still water and wave pressures is uniform along the span h. It is also assumed that 60% of the total lateral force on the frame is carried by the lower end support: for this reason, a coefficient k_S = 0,6 is introduce d in the formulae for $t_{REN,Sa}$ and $t_{REN,Sb}$ in S31.3.4.

The shear force at section b) is assumed to be equal to that at section a)multiplied by a factor. The factor is equal to (the frame span "h" minus twice the length of the lower bracket) divided by "h" (it is assumed here that the upper and the lower brackets have the same length).

The bending moment at sections a) and b) are obtained by multiplying the total lateral force on the frame by the frame span and dividing it by coefficients "m_a" and "m_b", derived from the results of Finite Element calculations. The "m_a" and "m_b" values depend on the loading condition of the hold to which the frame under consideration belongs.

The analyses carried out showed that, for loaded holds, the side frames may be considered as being clamped at the lower end (m_a = 12). The coefficients "m_b" depends, of course, on the distance from the support and hence on the bracket length.

In the case of empty holds of ships navigating in non homogeneous loading conditions (i.e. at the maximum draft) the sea pressure acting on the double bottom is not counterbalanced by internal cargo. This induces significant rotation of the hopper tanks and hence of the side frame lower ends. This rotation increases the bending moment (i.e. reduces the "m_a" and "m_b" values) and consequently lower coefficients have been included for this case.

c) The load probabilities defined in a) are based on the assumption that the following probabilities:

– 10^{-7}, for the head sea condition,

– 10^{-5}, for the beam sea condition

represent extreme sea conditions. This is based on a comparison of the 10^{-8} probability loads obtained by the AHG/WD-SL with the Marin model test results and a judgement of the beam sea loads justified as follows.

In severe sea states, a Master would normally operate his ship in the head seas condition. However, a beam seas condition might occur in an emergency situation, due for instance to engine or shaft failure. In the latter case, the use of a higher load probability is justified by the need for a joint probability of occurrence of two rare events. On basis of this assumption, a stress level corresponding to yield was applied to these levels of probability.

However, the sea load formula proposed by the AHG/WD-SL gives considerably higher values of side pressure than those given by current class rules of some societies and/or calculation results of long term predictions carried out by some societies. The values of probability have been modified as specified in a) above and the stress levels have been reduced accordingly.

Both the load probability of exceedance and the "m_a" and "m_b" values are consistent with an elastic behaviour of the side frames. Consequently, the normal and shear allowable stresses are obtained by multiplying the yield stress by appropriate safety factors (0,90 for the normal stresses and 0,40 for the shear stresses).

Notes by the Permanent Secretariat

1. In order to lift its reservation to the bending strength check in S31.3.4, NK put forward the following amendment to the renewal thickness in S31.2.1.

   the strength check is to be carried out when $t_M <= t_{COAT}$.

   GPG 53 (Oct.2002) agreed this and further decided that $t_{REN,S}$ need not be taken as more than $0.75t_{S12}$, allowing that Members were free to apply the stricter requirements should they wish. Hence, the following was added to S31.2.1:

   but the $t_{REN,S}$ *as obtained from S31.3.3 need not be taken more than 0.75* t_{S12}

2. At the time of approval of S31, revision of S12 had not been completed. WP/S was expected to complete the remaining task to develop shear and bending checks for inclusion into S12 which would be similar to those given in S31. See S12 (Rev.4).

3. Implementation schedule is the same as that for URs S26 and S27.

4. Date of approval of S31: 14 November 2002 (2219_ICd).

****

Technical Background
UR S 31 (Rev. 2)

1. Objective

To make UR S31 apply to OBOs of single side skin construction not built to S12(Rev.1) and its subsequent revisions (s/n 2219j).

2. Background

GPG found that:

There are OBOs of single side skin construction not built to S12(Rev.1) or subsequent revisions;

Hence, these OBOs may be subject to much the same risk of side shell frame damage and corrosion as single side skin bulk carriers.

GPG decided that the scope of application of UR S31 should be expanded to OBOs, as defined in UR Z11, of single side skin construction.

3. Amendment

Permanent Secretariat and WP/S Chairman prepared a draft revision.

The implementation schedule for OBO carriers is given in the text.

2 July 2004
Prepared by the Permsec

UR S31, Technical Background Document

(Rev.3, Nov 2005)

Revision of UR S31 Renewal Criteria for Side Shell Frames and Brackets

Scope and objectives

1) The difficulty that was observed in the uniform implementation of UR S31 (Rev.2 July 2004) by surveyors/class societies due to unclear descriptions was questionable.

2) Verification of UR S31 by UK MCA is reported in DE48/INF.6.

Taking the above into consideration, modify UR S31 based on experience gained from its implementation and review UK's verification.

Points of discussions or possible discussions

Ex-WP/SRC clarified the operational issues/problems which were obtained from each member's experiences gained from its implementation, and suggested ex-WP/S to revise UR S31.

Ex-WP/S modified UR S31 Rev.2 based on the comments and the consideration of UK MCA report as follows:

1) The following underlined texts are added:

S31.1 Application and definitions

In the case a vessel as defined above does not satisfy above definition in one or more holds, the requirements in UR S31 do not apply to these individual holds.

S31.2.1.1 Symbols used in S31.2.1

t_{S12} = thickness, in mm, as required by UR S12 (Rev. 3) in S12.3 for frame webs and in S12.4 for upper and lower bracket webs

S31.2.1.2

(c) $t_{REN,d/t}$ (applicable to Zone A and B only)

S31.2.1.2.1

a) Lower brackets

Lower brackets are to be flanged or face plate is to be fitted.

c) Immediately abaft collision bulkhead

For the side frames, including the lower bracket, located....

S31.2.1.2.4

When the measured frame webs thickness t_M is such that $t_{REN} < t_M \le t_{COAT}$ and the coating is in GOOD condition, sand blasting and coating as required in a) above may be waived even if not found in "as-new" condition, as defined above, provided that tripping brackets are fitted and the coating damaged in way of the tripping bracket welding is repaired.

S31.2.2 Thickness measurements,….

When flanges of frames or brackets are to be renewed according to S31, the outstanding breadth to thickness ratio is to comply with the requirements in UR S12.5.

S31.2.6 Renewal of all frames in one or more cargo holds

When all frames in one or more holds are required to be renewed according to UR S31, the compliance with the requirements in UR S12 (Rev. 1) may be accepted in lieu of the compliance with the requirements in UR S31, provided that:

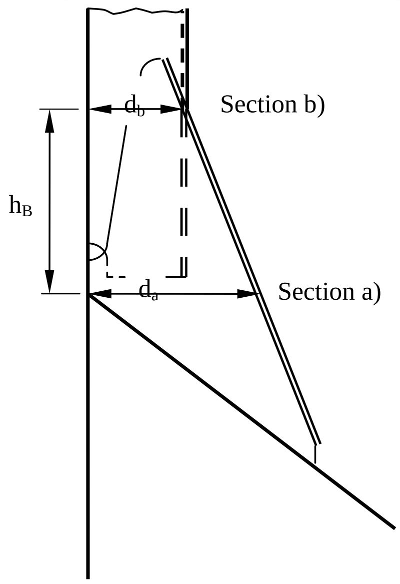
- *It is applied at least to all the frames of the hold(s)*
- *The coating requirements for side frames of "new ships" are complied with*
- *The section modulus of side frames is calculated according to the Classification Society Rules.*

S31.3.4 Bending strength check

Table 2 – Bending moment coefficient m_a and m_b

m_b		
$h_B \leq 0,08h$	$h_B = 0,1h$	$h_B \geq 0,125h$

S31.3.4 Figure 2 (following sketch showing lapped connection to be added)



2) The following correction is made as underlined:

S31.2.1.2.1

b) Tripping bracket alternative

When t_M is less than $t_{REN,d/t}$ ~~at section b)~~ in zone A of the side frames, ...

Source/ derivation of proposed interpretation

Ex-WP/S

Decision by voting

N.A.

Appendix

N.A.

Submitted by Hull Panel Chairman

1 July 2005

Permsec's Note (03/11/2005):

1. S31.2.1.2.1b

Based on the recommendation from the Hull Panel Chairman, GPG agreed that no change be made to S31.2.1.2.1b in Rev.3.

Hull Panel was instructed to further clarify this item. Hull Panel advised that it would be incorporated in the internal guidelines for UR S31 which was being developed under Hull Panel Task No. 21. Hull Panel was also instructed to propose, if found necessary, a suitable amendment to S31.2.1.2.1b) for a future revision of S31, once they clarify the matter in the internal guidelines.

2. Uniform implementation date

Council agreed that the uniform implementation date should be '1 July 2005' (5028hICa, 5028hBVc of 16 Nov 2005).

END

UR S32[DRAFT] "Local Scantlings of Double Side Skin Structure of Bulk Carriers"

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
DELETE (May 2010)	-	-
DRAFT (Nov 2004)	-	-

- **DELETE (May 2010)**

Draft UR S32 was never issued (although the draft was made available on the IACS website for public information) since it was superseded by the IACS Common Structural Rules for Bulk Carriers produced by the IACS Joint Bulker Project (JBP). Following a review of all UR S files to consider whether or not they are applicable to ships covered by the CSR (Hull Panel Task 50) it was decided to withdraw the draft UR S32 [GPG approval ref. 10051_IGd (24 May 2010)].

- **DRAFT (Nov 2004)**

See TB document in Part B.

Part B. Technical Background

List of Technical Background (TB) documents for UR S32[DRAFT]:

Annex 1. **TB for Draft Resolution (Nov 2004)**

See separate TB document in Annex 1.

◄▼►

Note: *There is no separate Technical Background (TB) document for Delete (May 2010).*

Technical Background – UR S32(not adopted)

Annex 1. TB prepared by WP/S, 29 November 2003.

Annex 2. IACS submission to IMO DE 47, 23 December 2004.

Annex 3. AHG/WD-SL's proposed LCF Table, 16 March 2004.

Note: Summary of GPG discussion (October 2004)

1. The GPG Chairman's message 3056fIGf of 06/10/2004 is quoted:

Quote:

6 October 2004

Considering all received answers (ABS, RINA, GL, NK, DNV, LR and CCS) , there is unanimous agreement to support the course of action proposed under point 5 of my mail IGe. Permsec is then invited to act accordingly. In addition, five members (ABS, GL, DNV, LR and CCS) supported the proposal made by Steve in his message ABb.

Message ABb deals with the LCF table contained in GPG 56/8.1.3/WP-1, annex 2. This table was intended to modify the text of UR S32 by introducing LCF values explicitly dependent of the loading condition (column 2 full load and column 4 ballast condition).

This idea was further developed and generalised by JTP and JBP in two slightly different ways:

1. JTP provides different tables for the full load and ballast cases, and modifies LCF values of GPG 56/8.1.3/WP-1, annex 2
2. JBP has LCFs explicitly dependant of the loading condition through the ratio: loading condition draft / full load draft, based on results of AHG/WD-SL and other experimental (test model basin) results as explained in the load TB document available on the JBP website.

In both cases, the table given in GPG 56/8.1.3/WP-1, annex 2 was an intermediate step in the process leading to the present load formulations of JTP and JBP. These two formulations are now under review by a small JTP/JBP group on loads under the auspices of RTH in order to harmonise them.

Based on the above, my suggestion is to consider task FUA 28.2 as closed, considering that the conditions in ABb item 1 are met, simply adding GPG 56/8.1.3/WP-1 annex 2 in the TB document of UR S32 as suggested by Laura.

If members prefer to apply item 2 of ABb and modify the text of UR S32, I simply insist on the fact that it is better to add two different tables in UR S32, one for full load, the other one for ballast condition, keeping the numerical values of GPG 56/8.1.3/WP-1, annex 2 of course, as the substantial difference mentioned hereabove is not obvious and even partly masked reading the table formatted as in document GPG 56/8.1.3/WP-1, annex 2, which looks superficially similar to the one presently in the UR (you have to read the explanations under the table and notice that column 2 is now under beam sea). I doubt that Permsec is able to perform this task without proper technical support.

Members opinion on application of item 1 or 2 of ABb is requested in order to definitely close this task during GGP 57 meeting.

Best regards,

Jean-françois Segretain
IACS GPG Chairman

Unquote

2. GPG finally decided at its 57th meeting (18-20 October 2004):

GPG 57 FUA 18: To insert the LCF Table (GPG 56/8.1.3/WP-1/Annex 2) to the Technical Background document for the draft UR S32 with the following statement:

The LCF Table has been considered in the development of the Bulker Rules by JBP and in the rule harmonization between JBP and JTP rules by the AHG/RTH.

With this action, WP/S Task 71 is closed.

See Annex 3.

Annex 1.

IACS WP/S Task 71

UR Sxx on the local scantling of DSS structures of Bulk Carriers

Chairman Submission to GPG

Genoa, 29 November 2003

1. Outcome of IACS WP/S Task 71

UR Sxx finalised by the WP/S, which includes the criteria for local scantling of DSS structures of Bulk Carriers, is submitted to GPG for approval.

In considering this UR, please note that:

1.1 The criteria for the evaluation of the net scantlings of double side structures of Bulk Carriers, excluding fatigue, have been agreed by the WP/S.

1.2 The criteria relevant to the fatigue check of longitudinal and transverse side shell stiffeners have agreed by all Members except NK. The motivation of the NK reservation is reported in Appendix.

It is to be pointed out that WP/S Members, except NK, agreed on the fatigue check criteria provided that these criteria could be further considered and improved during the development of IACS common Rules. In particular, ABS considers that it is questionable to include these fatigue criteria in UR Sxx as more time is needed to refine them.

1.3 Two different approaches for the evaluation of the corrosion additions and, therefore, for calculating the gross scantlings from the net scantlings have been considered by WP/S:

a) The first one was originally proposed by NK and is based on the statistics provided by the WP on Hull Damages some years ago. This approach was discussed under WP/S Task 22.

b) The second one was proposed by ABS, during the last WP/S meeting, which was held at RINA H.O. from 28 to 30 October 2003. This proposal is based on the ABS corrosion statistics and experience, as well as those of DNV and LR.

The main differences between the two approaches a) and b) are relevant to the following aspects:

- value of corrosion additions, to be added to the net scantlings. The major difference is in the side shell plating corrosion addition,
- rounding of net thickness and corrosion additions,
- calculation of the steel renewal thickness on the basis of the net thickness and corrosion additions.

A document reporting the differences between the two proposals in term of total corrosion additions for each hull structural element is enclosed for prompt reference.

Since a unanimous consensus was not reached within the WP/S, both documents are presently submitted to GPG:

- UR Sxx proposal 1, including corrosion additions as per proposal in 1.3 a),
- UR Sxx proposal 2, including corrosion additions as per proposal in 1.3 b).

These two documents have already been submitted to WP/S Members for voting. The vote results is that BV, CCS, KR, NK and RINA support proposal 1, whilst ABS, DNV, GL, LR and RS support proposal 2.

<u>The WP/S requests the GPG to task the IACS WP/SRC to examine the matter in order to define the corrosion addition approach that best fits with IACS Societies' experience on corrosion and steel renewal criteria.</u>

2. Double side space length

During the last WP/S meeting, Members raised the question whether UR Sxx should require double side spaces having length not greater than the hold in way.

After discussion, Members agreed to request the GPG to task IACS WP/SSLL to give advice on this aspect, which involves also stability related problematic.

Anyway, while waiting for the WP/SSLL advice, the WP/S agreed to include the two following options in UR Sxx regarding the position of transverse bulkheads in double side spaces:

1. the first option requiring transverse bulkheads (tight or non-tight) to be fitted and aligned with the cargo hold transverse bulkheads,

2. the second option requiring transverse tight bulkheads to be fitted and aligned with the cargo hold transverse bulkheads.

A final decision on the option to be considered should be taken after receiving the WP/SSLL advice.

3. Actions requested to GPG

The following actions are kindly requested to GPG:

1. Approve UR Sxx as far as the net strength criteria are concerned.

   The WP/S deems that, when submitting UR Sxx to IMO, IACS should point out that the net strength criteria in UR Sxx, in particular those regarding the fatigue checks, will be further progressed and improved in the course of the on-going development of the IACS common Rules on Double Side Skin Bulk Carriers.

2. Note the NK reservation and ABS considerations relevant to the fatigue checks of longitudinal and transverse side shell stiffeners.

3. Task the WP/SRC to define the corrosion addition approach, between the two proposed by WP/S Members, that best fits with IACS Societies' experience on corrosion and steel renewal criteria.

4. Task the WP/SSLL to give advice on the double side spaces length.

Appendix – Details of NK reservation on UR Sxx fatigue criteria

The following text has been extracted from NK's message to WP/S of 28/11/2003.

NK expresses their disagreement with the fatigue criteria incorporated in the draft UR Sxx, while NK agree with the other part of UR Sxx, for the following reasons:

1. NK checked the information given by DNV e-mail received on 2003/11/28 5:26 at Tokyo and made comparison of the estimated damage Minor sum with damage experience for the vessel DNV1 engaged in North Atlantic route as shown in the enclosed file. This comparison shows the same tendency of damage experience as NK showed for many oil tankers engaged in PG-Japan route that ballast water tanks sustains many fatigue cracks on the longitudinals in the vicinity under the ballast water line but not under the full load water line. However, the estimated damage given by UR Sxx fatigue criteria appears maximum in the vicinity under the full load water line. This crucial discrepancy gives unacceptable loss of credibility to IACS because the draft UR requires to make reinforcement to the structure which is not likely to sustain fatigue damage while leaving the structure of high risk of fatigue damage not reinforced.

2. NK reviewed the impact of UR Sxx (finalised at the last meeting of ISG/F) given to the current design of DSS bulk carrier and it shows that maximum damage is over 17 for handysize and over 12 for overpanamax and that they resulted in the increase of section modulus of side longitudinals by 20% to 40% in addition to the modification of angle section to T type section of longitudinals for almost all the side longitudinals within the DSS space. This impact is recognised too much.

3. After consult with NK AHG/WD-SL member for the modification of load formula, which was made at the last meeting, it was realised that the modification made was not discussed nor agreed in AHG/WD-SL. Therefore, it needs discussion within AHG/WD-SL.

4. Load model including LCF and stress combination factor was not discussed in an appropriate manner and still needs discussion within AHG/WD-SL.

5. In view of the above, the fatigue criteria should be discussed spending some more time because WP/S have some time to submit it to IMO DE 47.

DOUBLE-SIDE SKIN CONSTRUCTION OF BULK CARRIERS

Structural requirements for bulk carriers of double-side skin construction

Submitted by the International Association of Classification Societies (IACS)

SUMMARY

Executive summary:-	This paper summarises the work carried out by IACS for the development of unified strength requirements for double-side skin bulk carriers and provides information to the Sub-Committee on the IACS requirements under development.
Action to be taken:-	Paragraph 13.
Related documents:-	DE 46/32 paragraphs 24.14 and 24.15.

1. DE 46 noted that the information available on longitudinal strength of double-side skin bulk carriers was not sufficient for thorough examination of strength aspects of such ships and invited Members and international organisations to provide information to DE 47 on aspects of local, longitudinal and global strength for further discussion.

2. At DE 46, the IACS observer informed that IACS is currently developing scantling standards for double-side skin bulk carriers. This paper aims at providing information to the Sub-Committee on the IACS requirements under development.

3. The IACS on going work on the structural scantling of double-side skin bulk carriers includes the criteria for the local scantling of the double-side structures comprised between the hopper and the topside tanks, as well as the criteria for direct strength analyses of cargo hold structures.

4. In elaborating their requirements, IACS took into account the definitions and characteristics of double-side skin bulk carriers agreed at MSC 77.

5. The criteria for the local scantlings of the double-side structures, intended to be applied to side shell, inner side, transverse bulkheads, web frames and stringers, are defined in draft IACS Unified Requirement S32. They are based on the yielding, buckling and fatigue strength criteria, adopting a net scantling approach.

6. The criteria for the direct analysis of cargo hold structures are under development in IACS Unified Requirement S33. They are based on the Finite Element analysis of cargo hold structures and the yielding and buckling strength criteria, adopting the net scantling approach to be consistent with UR S32.

7. The net scantling approach entails that the scantlings obtained from the draft UR S32 strength requirements do not include any corrosion margin. The required scantlings, to which a ship is to be built, are obtained by adding appropriate corrosion additions to these net scantlings. The corrosion additions are to be defined as a function of the corrosive severity of the environment (cargo holds, ballast tanks, void space, outside sea and air) in which each structural element is located. Steel renewal criteria are specified for each structural element by defining the thickness at which steel renewal is required or, in other words, its corrosion margin which is within the corrosion additions.

8. The load model adopted in draft UR S32 and S33 has been developed on the basis of extensive work carried out by IACS, including seakeeping direct calculations carried out for a number of bulk carriers of different sizes.

9. The requirements contained in the draft UR S32 and S33 are intended to be included as part of a comprehensive set of common structural Rules that IACS is developing on double-side skin bulk carriers. In this sense, the requirements in the draft UR S32 and S33 will be revised and updated in the course of the development of these IACS common Rules.

10. In particular, the present text of draft UR S32 incorporates two alternatives for the corrosion additions and steel renewal criteria. Both alternatives are based on the experience gained by IACS Members in surveying their classed fleets. Further work is already ongoing to resolve which criteria are to be used in the IACS common structural Rules.

11. The fatigue strength criteria included in the draft UR S32 are based on a simplified formulation and will be subject to further improvements as a result of the on-going IACS common Rules developments.

12. The above-mentioned draft UR S32 is available on the IACS website at www.iacs.org.uk for information.

Action requested of the Sub-Committee.

13. The Sub-Committee is requested to note the above information.

* * *

Annex 3 (TB for UR S32)

1. The LCF Table for UR S32 is contained in the AHG/WD-SL 2003 Progress Report. This table was intended to modify the text of UR S32 by introducing LCF values explicitly dependent of the loading condition (column 2 full load and column 4 ballast condition). This idea was then further developed and generalised by JTP and JBP in two slightly different ways:

a) JTP provides different tables for the full load and ballast cases, and modifies LCF values of the AHG/WD-SL Table;

b) JBP has LCFs explicitly dependant of the loading condition through the ratio: loading condition draft / full load draft, based on results of AHG/WD-SL and other experimental (test model basin) results as explained in the load TB document available on the JBP website.

In both cases, the Table prepared by the AHG/WD-SL was an intermediate step in the process leading to the present load formulations of JTP and JBP. These two formulations are now under review by a small JTP/JBP group on loads under the auspices of the AHG/RTH in order to harmonise them. GPG 57 decided that this LCF Table should be included in the TB document for UR S32. WP/S Task 71 is thereby completed.

2. The following is quoted from the AHG/WD-SL 2003 Progerss Report (3019aGLa, AHG/WD-SL Annual Progress Report 2003, 17 March 2004).

* * *

AHG/WD-SL new task 12: To develop the load model for the UR on double side skin structures of bulk carriers.

Most of the group's acticities in the last year were dealing with their new task 12. Here, especially the development of a load model to be used to determine the local scantling of double side skin structures of Bulk Carriers was pursued. This task may be subdivided into two main subtasks:

1) To determine rule formulations for local loads, ship motion parameters, ship accelerations and horizontal wave-induced bending

2) To accomplish a load combination factor table for general wave load cases

The outcome of those activities is given in chapter Sxx2 of the UR Sxx files as attached to an email referenced "3056fRIa: Outcome of IACS WP/S Task 71 - UR Sxx on the local scantling of DSS structures of Bulk Carriers" of the WP/S chairman Dino Cervetto from the 1st of December 2003. An excerpt containing the load formulations are given in annex 1.

However, the AHG/WD-SL recommended updating some figures in the UR Sxx according an email referenced “IACS AHG/WD-SL Task 12: FUA 15.3 from GPG 55” from the AHG/WD-SL chairman dated 9th of November 2003. The respective recommendations may be deduced from annex 2.
According to C48 FUA5 this task had to be closed. However, the preparation of the technical background paper for the loads documented in annex 1 and annex 2 has not finalised yet. Because most of the load formulations are the basis for JTP and JBP rule formulations GPG is requested to agree to finalise the preparation of the technical background documentation by third quarter of this year.

GPG is requested to note the progress.

Annexed. AHG/WD+SL Comments on UR Sxx (S32)

1) UR Sxx: Table 1 – Load combination factors (LCFs)

		Head Sea	Beam Sea			Oblique Sea
Load parameter	Load combination factor	1: Max external pressure	2: Max internal pressure	3: Max external pressure	4: Max internal pressure	5: Max horizontal bending moment
p_w	C_w	1,0;1,0;1,0 1,0 [1,0]	0,9;0,8;0,8 0,8 [0,1]	1,0;1,0;1,0 1,0 [1,0]	0,6;0,6;0,5 0,5 [0,5]	0,4;0,7;0,2 0,7 [0,7]
a_V	C_{Av}	0,5;0,3;0,4 0,5 [0,3]	1,0;1,0;1,0 1,0 [1,0]	1,1;1,0;0,8 1,0 [1,0]	0,8;0,9;0,9 0,9 [0,7]	0,4;0,2;0,3 0,4 [0,2]
a_T	C_{AH}	0,0;0,0;0,0 0,0 [0,0]	0,7;1,0;0,9 1,0 [0,0]	0,6;0,5;0,5 0,5 [0,5]	1,0;1,0;1,0 1,0 [1,0]	0,5;0,0;0,2 0,5 [0,0]
a_L	C_{AL}	1,0 [0,5]	0,1 [1,0]	0,1 [0,0]	0,1 [0,0]	0,5 [0,5]
M_V	C_{wvbm}	0,4;1,0;0,2 1,0 [1,0]	0,3;0,4;0,7 0,4 [1,0]	0,4;0,3;0,6 0,3 [0,25]	0,1;0,1;0,1 0,1 [0,1]	0,2;0,2;0,2 0,2 [0,2]
M_H	C_{whbm}	0,0;0,0;0,0 0,0 [0,0]	0,3;0,2;0,1 0,2 [0,0]	0,1;0,3;0,1 0,3 [0,1]	0,3;0,2;0,8 0,2 [0,2]	1,0;1,0;1,0 1,0 [1,0]

The first LCF stands for the foremost hold, the second LCF for the amidships hold and the third LCF for the aftermost hold. The **LCFs marked in blue** represent values merged from all three holds whereas the LCFs in square brackets represent the current UR Sxx values.

<u>The LCFs for the foremost hold and amidships hold were developed from direct calculations performed for a handy size, a panamax and a capesize bulk carrier. Here, following procedure was applied</u>:

Columns 1, 3 and 5: Full load condition to maximise loads on side shell
Column 2: Full load condition or heavy ballast condition for inner bottom
Column 4: Heavy ballast and Normal ballast to maximise internal liquid loads on inner side

<u>The aftermost hold merely developed from direct calculations for panamax bulk carrier. Here following procedure was applied:</u>

Columns 1, 2, 3 and 5: Full load condition to maximise loads on side shell and inner bottom
Column 4: Normal ballast to maximise internal liquid loads on inner side

<u>The considered loading conditions comprise:</u>

- Full load homogenous heavy cargo
- Heavy ballast
- Normal ballast

2) The roll amplitude in UR Sxx is recommended to read:

$$\theta[\deg] = \frac{9000 \cdot (1{,}25 - 0{,}025 \cdot T_{roll}) \cdot k_b}{(B + 75) \cdot \pi}$$

$$with:$$

$$T_{roll}[\sec] = \frac{2{,}3 \cdot k_r}{\sqrt{GM}}$$

All parameters are denoted according to UR Sxx.

3) Cr in "Sxx.2.2 – Wave pressure load" is recommended to read:

$$Cr = \left(1{,}25 - 0{,}025 \frac{2{,}3 \cdot k_r}{\sqrt{GM}}\right) \cdot k_b$$

4) GM and kr in UR Sxx are recommended to read:

Following values are recommended to be used in UR Sxx for the initial metacentric height GM and the roll radius of gyration kr:

	Full load homogenous heavy cargo	Full load homogenous light cargo or alternate heavy cargo	Heavy ballast	Normal ballast
GM	0,12 B	0,18 B	0,25 B	0,33 B
kr	0,35 B	0,38 B	0,40 B	0,45 B

UR S33 “Requirements for Use of Extremely Thick Steel Plates in Container Ships”

Summary

The Rev.3 is issued to take into account the deletion of Recommendation 20 and adoption of new UR W33, which are effective from 01 July 2021.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev.3 (Feb 2020)	18 February 2020	01 July 2021
Rev.2 (Dec 2019)	2 December 2019	01 January 2021
Rev.1 (Sept 2015)	30 September 2015	01 January 2017
New (Jan 2013)	21 January 2013	01 January 2014

- **Rev.3 (Feb 2020)**

1 Origin of Change:

☒ Based on IACS Requirement

2 Main Reason for Change:

Changes made to reflect the adoption of new UR W33 and deletion of Recommendation 20.

3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

4 History of Decisions Made:

GPG instructed the Hull Panel to proceed to the Corrigenda (19120_IGe). Hull Panel vide PHc dated 23 Dec 2019 provided the draft Corr.1 to Rev.2 of the UR S33 and its associated HF/TB to GPG for approval. However, considering that the UR W33 has an implementation date of 01 July 2021, and Rec.20 is still applicable till the implementation of UR W33, GPG decided to adopted a revision instead of correction, so that the implementation dated of the revision (i.e Rev.3) of UR S33 matches with the implementation date of UR W33.

5 Other Resolutions Changes:

UR Z23, Rec.47

6 Any hinderance to MASS, including any other new technologies:

None

7 Dates:

Original Proposal : December 2019
Panel Approval : 23 December 2019 (Ref: PH16017_IHr)
GPG Approval : 18 February 2020 (Ref: 19120_IGi)
GPG Approval for TB Annex 3: 29 January 2021 (Ref: 21004_IGb)

- **Rev.2 (Dec 2019)**

1 Origin for Change:

☑ Other (GPG 81 FUA 27 tasks HP to review UR S33)

2 Main Reason for Change:

Put in consistency the UR S33 in line with the update of UR W31 for brittle crack arrest steels.
The EG/M&W and HP agreed to split the requirements for ship design into the UR S33 and those covering the steel material characteristics and approval into the UR W31.

3 List of non-IACS Member Classification Societies contributing through the TC Forum and/or participating in IACS Working Group:

N/A

4 History of Decisions Made:

During the development of the UR W31, the EG/M&W asked confirmation to Hull Panel that the large test conditions were in line with design of container ships. The confirmation given by HP allowed to adjust the restrictions of application of BCA steel in the URs W31 and S33.

5 Other Resolutions Changes:

UR W31

6 Any hinderance to MASS, including any other new technologies:

None

7 Dates:

Original Proposal: October 2016 (Made by GPG 81)
Panel Approval: 8 November 2019 (Ref: 19120_PHb)
GPG Approval: 3 December 2019 (Ref: 19120_IGe)

- **Rev.1 (Sept 2015)**

.1 Origin for Change:

☑ Suggestion by an IACS member

.2 Main Reason for Change:

Address the comments raised following the publication of UR S33.
Amend UR S33 by removing material related content and transferring this to UR W31.
Amend UR S33 by transferring design related content from UR W31.

.3 List of non-IACS Member Classification Societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

Members concurred that annex 2 standard ESSO test in UR S33 should be transferred to UR W31. Also they agreed that the paragraph 1.4 hull structures (for the purpose of design) should be transferred from UR W31 to UR S33.

One member suggested to remove the paragraph 4.3.1(e) because they thought that the application of enhanced NDT particularly time of flight diffraction (TOFD) technique might be a high risk option.

One member proposed "FCAW" in Table 1 of Annex 1 to be replaced to "welding procedures other than EGW".

Members agreed to include Fig. 2 and details in order to explain other weld areas in the paragraph 4.2.1(b).

Panel agreed that the crack arrest properties for brittle design should be transferred from UR S33 and defined in UR W31. Two members argued that they would prefer the crack arrest properties for brittle design should be included in UR S33.

Panel approved the proposal to include the brittle crack arrest properties for YP36 and YP40 in UR S33 4.1.3. A member commented that the proposal should be reconsidered depending on the EG/M&W position about inclusion or not of brittle crack arrest properties for YP36 and YP40 in the revised W31.

A member supported the proposal of asking EG/M&W to find the best place for definition of crack arrest properties for YP36 and YP40.

No TB is expected for the present revision.

.5 Other Resolutions Changes

None

.6 Dates:

Original Proposal: *20 September 2013* made by*: Panel Member*
Panel Approval: *09 July 2015 (Ref: PH13026_IHy)*
GPG Approval: *30 September 2015 (Ref: 14139_IGf)*

- **New (Jan 2013)**

.1 Origin for Change:

☑ Suggestion by the Japan Society of Naval Architects and Ocean Engineers (JASNAOE)

.2 Main Reason for Change:

None - new document.

Technical Background document for UR S33 (New, Jan 2013)

1. Scope and objectives

An increase in the size of container ships has led to the application of thicker steel plates to their hull structures.
Safety-related issues regarding the use of extremely thick steel plates concerning brittle fracture toughness and brittle crack arrestability have been identified with the above trend.
Under this situation, some classification societies have developed their own guidelines related to the issues which need to be unified.
IACS has recognized that it is necessary to develop unified requirements for the safety use of extremely thick steel plates.

2. Engineering background for technical basis and rationale

The following issues were highlighted that IACS needed to address:

(1) Application of the safety measures on extremely thick steel plates is to be determined (Steel grade, minimum and maximum thickness of plates, targeted structural members etc.)

(2) Countermeasures to prevent brittle crack initiation including NDT are to be specified for both new ships and existing ships.

(3) Countermeasures to prevent brittle crack propagation are to be specified.

(4) Related guidelines already developed by some classification societies can be referred to.

Taking the above into account, a project team PT52 was asked to draft a new IACS UR, UR S33, to specify the application of safety measures and the countermeasures to prevent initiation and propagation of brittle cracks.

Based on review comments made during development, the following TB items are noted:

Section 2.2.2: This text is related to crack initiation prevention and is also covered in Annex 1 Measures 1 and 2 as clarified by Notes * and **.

Section 4.3.1(e) Enhanced NDT other than TOFD may be accepted in accordance with each Class Society's procedures, provided proof of equivalence to TOFD is given.

4. Summary of Changes intended for the revised Resolution:

Not applicable

5. Points of discussions or possible discussions

For existing ships members have decided to remove the initially intended requirements from this UR text due to following reason:

Retrospective examination of existing ships was considered, but based on variable testing experiences carried out by a number of members and the lack of in-service problems, it was decided not to introduce requirements for inspection of existing ships.

6. Attachments if any

Technical Background document for UR S33 (Rev 2, Dec 2019)

1 Scope and objectives

This rev.2 is made to provide clarifications on the conditions to use the brittle crack arrest steels (BCA steels) for the design of container ships in agreement with the large scale tests performed by the Japanese industry (Ref [1]) which allow to define the material properties requested in the UR W31 such as:

- Stress limit at the level of the deck
- Type of BCA as a function of the structural members and the corresponding thickness (BCA1 or BCA2)
- Weld detail between hatch coaming side and deck.

The objectives of this revision were, when brittle crack arrest steel method is used, to introduce requirements for avoiding the actual stresses of the ship at the deck do not overpass the reference stresses used for the large scale tests defining the BCA steel properties (Kca values) in UR W31.

2 Engineering background for technical basis and rationale

The BCA steel applications are based on a joint industry research project (JIP) organised by the Japanese Industry (Ref [1]). The report and results of this JIP have been used to determine the required Kca value of the brittle crack arrest steels (BCA steels) specifically for steel plates with thickness of over 80 mm. This report has been provided by the JIP to IACS for its own use but without allowing IACS to disclose it outside.

Large scale tests have been performed for measuring the conditions in which the brittle crack are stopped in the steel plates. The real designs of container ships with thick plates are to comply with the conditions of the tests; outside the test conditions, it is not sure the BCA steel will have the capacity to play its role, i.e. to stop the crack propagation.

Two main scenarios were considered:

- A crack initiation in the deck propagating into the hatch coaming side plate,
- A crack initiation in the hatch coaming side plate propagating into the deck plating.

No tests were performed for checking that a crack initiation in the hatch coaming side plate may or not propagate into the hatch coaming top plating. This explains why no requirement is provided for the BCA steel application in the hatch coaming top plating.

The longitudinal stiffeners are not supposed to be in BCA steels.

At the time of the tests, the Japanese industry used the permissible stress defined at the deck in the UR applicable for checking the hull girder strength of the container ships, i.e. UR S11. A close link is therefore established between the tests and the UR S11. The UR S11 defined the permissible stress as 175/k MPa, k being the material factor defined in the UR S4 which depends on the material yield stress (ReH). For the tests, the reference stress used by the Japanese industry for EH40 steel fitted at deck was consequently equal to 175/0.68 = 257 MPa.

It is important to note and remember the strong link between the performed tests and the permissible stress defined in UR S11 in the event the UR S33 or W31 for BCA steels are updated in future or if the design of containerships evolves with arrangements different from those used for the tests.

The use of BCA steels for the deck and hatch coaming side plates is based on the fact that the stress at the deck level is not exceeding the reference stress used for the tests, i.e. the permissible stress defined in the UR S11 for the deck plate. The justification that the stress at deck of containerships does not go beyond the permissible stress of the UR S11 is given in the appendix of this annex.

The tests were performed with:

- deck thickness up to 100 mm and the reference stress applied at the deck level and
- hatch coaming thickness up to 100 mm and a grade up to EH47.

The test specimens include groove shaped T-joint simulating a typical actual joint such as fillet weld or partial penetration weld between hatch coaming side and upper deck of very large container ships for thickness between 80 and 100 mm. The requested weld detail is a partial penetration weld allowing the BCA steel to stop the crack.

3 Source / derivation of the proposed IACS Resolution

Joint industry research project (JIP) organised by the Japanese Industry (Ref [1])

4 Summary of Changes intended for the revised Resolution:

Editorial changes:

- Replacement of “each Classification Society” by “the Classification Society”,
- Harmonisation with UR S4 for the notation k (material factor), instead of HT(K),
- Definition of “upper deck region” for several uses and text simplification,

- Symbols used for the table in annex 1 put in a table note instead of a paragraph.

Technical changes:

- The use of BCA steel method may be used provided the steel grade material of the deck is not higher than YP40. It is implicitly agreed that the ship design must comply with the UR S11A. If the ship design incorporates steel grade materials with permissible stress greater than those corresponding to YP40, the BCA steel brittle crack arrest properties are not defined in UR W31. If BCA steels are considered in this case, such BCA steels and/or other means for preventing the crack initiation and propagation shall be agreed by the Classification Society.

- Reference to UR W31 entire document for the BCA steel instead of a specific paragraph of W31 to avoid future possible updates due to paragraph numbering.

- Introduction of a new paragraph 4.4 for defining:

    - the BCA properties as a function of the structural members and their thickness,

    - the BCA steels are not applicable to the hatch coaming top plate nor to the longitudinal stiffeners connected to the considered plating,

    - the weld joint detail (partial penetration) is to be used.

5 Points of discussions or possible discussions

The content of the changes have been discussed between the Chairs of EG/M&W and Hull Panel before submitting the text to the HP Members.

Application to the longitudinal stiffeners

Application of BCA steels to the hatch coaming top plate

Appendix

Condition for BCA steel plate fitted at the deck be used within the test assumptions

Ships considered for this study

For checking the application of the BCA steel on deck of containerships, several vessels having deck thickness greater than 70 mm but less than 100 mm have been considered.
The recent design of large containerships are made with deck thickness ranging from 70 to 95mm.

The deck material is either steel with ReH of 390 or 355 MPa (i.e. EH40 or EH36). The hatch coaming side plates have higher steel grades corresponding to ReH of 460 or 390 MPa (i.e. EH47 or EH40).

Seven container ships of different size (design approved from 2016 to 2018) have been considered for this study: 23000, 22000, 20600, 16000, 14500, 12700 and 8500 TEU. All those ships have deck and hatch coaming material within the scope of application for BCA steels as defined in the UR S33 (Rev.2).

Stress distribution for S11 and S11A

Main Differences between S11 and S11A

The main differences for the stress distributions in S11 (Rev.8) and S11A (New June 2015) are summarised in the following table:

Item	UR S11	UR S11A
Wave Bending Moment		Larger than for S11
Total BM= $M_{SW} + M_W$		4 to 6 % greater than S11
Inertia	Gross	Net (0.5 tc)
Permissible stress	175/k	235/1.24/k

The wave bending moment is larger in the UR S11A than in the S11 resulting in a total bending moment larger from 4 to 6 %.

Moreover the hull girder stress is calculated differently, in gross thickness in the S11 and in net thickness (0.5 tc) in the S11A.

However the permissible stress are comparable in both S11 and S11A provided the gross thickness approach is switched to the net thickness one. For a global corrosion of about 8 %, the permissible stress defined in S11 in gross becomes: $175/k*1.08 = 189/k = 234.4/1.24*1/k \approx 235/1.24*1/k$ which is equal to the permissible stress in S11A in net.

In the following the focus is made on the hogging bending moment only as the bending moment in sagging is much lower than the one in hogging.

Ships characteristics

The following units have been considered in the below tables:

- Length/distance: m
- Bending Moment: kNm
- Inertia: m^4
- Stress: MPa

Table 1: Ship characteristics

The permissible stresses and stress distributions are given in the Table 2 for the application of the UR S11A and S11 to the 7 ships.

Table 2: Midship section Hull Girder strength

	S1	S2	S3	S4	S5	S6	S7
Perm stress according to UR S11A							
ZHCTop	305.7	305.7	305.7	305.7	305.7	287.1	278.7
ZDeck	287.1	287.1	278.7	278.7	287.1	263.2	263.2
Perm stress according to UR S11							
ZDeck	265.2	265.2	257.4	257.4	265.2	243.1	243.1
Actual HG Stress according to S11A							
ZHCTop Hog	292.6	283.7	296.8	298.8	299.1	275.8	267.1
ZDeck Hog	258.0	256.6	265.3	265.5	266.1	242.0	234.1
Actual HG Stress according to S11							
ZDeck Hog	235.2	241.7	247.1	245.3	249.0	226.1	219.6

Table 3: Ratios between actual and permissible stresses

	S1	S2	S3	S4	S5	S6	S7
σ_{app} / σ_{perm} according to S11A							
ZHCTop Hog	0.957	0.928	0.971	0.978	0.978	0.961	0.959
ZDeck Hog	0.899	0.894	0.952	0.953	0.927	0.919	0.889
σ_{app} / σ_{perm} according to S11							
ZDeck Hog	0.887	0.912	0.960	0.953	0.939	0.930	0.904

The Table 3 shows the ratio between the actual and permissible stresses of the Table 2. It appears that the most severe criteria ($\sigma_{app}/\sigma_{perm}$) is obtained at the top of the hatch coaming for all ships for the UR S11A application. The application of the UR S11 at the deck is less severe giving a ratio below 0.96 (between 0.887 and 0.960).

However, the actual stresses in Table 2 are based on the SWBM considered for the design approval. For the HG criteria only the SWBM can be increased until this maximum stress ratio (at the hatch coaming top) reaches 1.

Note: it is to be noted that this increase of the SWBM concerns the HG criteria only for checking what should be the impact on the stress obtained at the deck level for the UR S11. The other criteria used for the design approval such as local strength verification or FE analysis are based on the SWBM mentioned in Table 1.

For this increase of the SWBM, the stress distribution is given in the Table 4.

Table 4: Stress distribution when the stress ratio at HCT is 1.0

	S1	S2	S3	S4	S5	S6	S7
Actual HG Stress according to S11A							
ZHCTop Hog	305.7	305.7	305.7	305.7	305.7	287.1	278.7
ZDeck Hog	269.6	276.5	273.2	271.6	271.9	251.9	244.2
Actual HG Stress according to S11							
ZDeck Hog	246.4	261.2	254.8	251.3	254.8	235.8	229.5

Table 5: Stress Ratio when the stress ratio at HCT is 1.0

	S1	S2	S3	S4	S5	S6	S7
$\sigma_{app} / \sigma_{perm}$ according to S11A							
ZHCTop Hog	1.000	1.000	1.000	1.000	1.000	1.000	1.000
ZDeck Hog	0.939	0.963	0.980	0.975	0.947	0.957	0.928
$\sigma_{app} / \sigma_{perm}$ according to S11							
ZDeck Hog	0.929	0.985	0.990	0.976	0.961	0.970	0.944

When the SWBM is artificially increased until the stress ratio reaches 1 at the top of the hatch coaming for the stress distribution calculated according to UR S11A, the stress ratio at the deck according to S11 remains below 1 (between 0.929 and 0.990), which means that the actual stress at deck remains always below the corresponding permissible stress according to S11.

Conclusions

Seven ships have been used for this study ranging from very large container ships size of 23,000 TEU to ships of 8,600 TEU which are considered as representative of the current containership designs. All these ships are within the scope of application of the UR S33 for BCA steel in term of arrangement, deck thickness and steel materials. All of them have their maximum stress at deck complying with the UR S11 permissible stress when the ship design complies also with hull girder strength criteria of the UR S11A at the deck and hatch coaming top.

In conclusion, when the ship design complies with the hull girder strength criteria at the deck and the top of the hatch coaming according to UR S11A, the stress at the deck level made of steel grade material not higher than YP36 or YP40 remains also within the acceptable limit used by the Japanese Industry (Ref [1]) for defining the BCA steels characteristics referred in W31.

In the event the hull girder strength criteria of the UR S11 (Rev.8) and/or UR S11A (New June 2015) are modified, the above conclusion should be reconsidered.

Technical Background document for UR S33 (Rev.3 Feb 2020)

(29 January 2021 separately approved by GPG (Ref: 21004_IGb))

1 Scope and objectives

The below background is made to provide clarifications on the application of the UR S33 requirements. Basic assumptions and the general safety concept of the requirement are explained.

2 Engineering background for technical basis and rationale

Rationale of UR S33 requirements:

The purpose of UR S33 is to avoid a sudden brittle crack of the hull structure by providing measures to control crack propagation due to design or other measures.

Assumption:

Cracks will mainly be initiated in the vicinity of weld lines, especially from block-to-block butt weld joints on hatch side coaming or on upper deck. Brittle cracks may propagate along the weldline of the block joint or may deviate from the weld line. In addition, cracks may be initiated and may propagate from other welds such as fillet and attachment welds.

Safety concept:

In principle two options

1. Avoid of crack initiation

2. Ensure crack arrest, if crack is initiated

A combination of these two principles is applied in UR S33 in dependency of the material and thicknesses used in the design of the upper deck region. Avoidance of crack initiation is mainly addressed by NDT during construction and if found appropriate by the Classification Society, after delivery. Furthermore, the effects and impacts of the applied welding procedure are considered.

Ensuring crack arrest is addressed by application of crack arrest design measures. The main idea behind the crack arrest design measures is to limit the crack propagation to the plate strake where the crack initiation has taken place.

For both crack initiation avoidance as well as for arresting an initiated crack, dedicated toughness requirements for the weld and base material are applied in combination with the a.m. measures.

The application of required measures is controlled by the table in Annex 1 of UR S33 in dependency of the yield strength and the thickness of the hatch coaming top and side plate. If one of these plates exceeds the controlling parameters as given in columns 1 and 2 of the table, measures to be applied are indicated. Measures 1 and 2 refer to NDT requirements while measures 3, 4 and 5 refer to the crack arrest design measures to avoid crack propagation as required by the functional requirement given in UR S33 4.2.1.(b).

If the as built thickness of the hatch coaming top plating and side plating is less than 50 mm, counter measures against brittle cracking are not necessary regardless of the thickness and yield strength of the upper deck plating.

Measures given under UR S33 4.3.1 a) to e) are "concept examples". This means that also other solutions / new designs might be possible, providing that the functional requirements under 4.2.1 are fulfilled and that the measures are accepted by the Classification Society.

Requirements for Hatch Coaming Top Plate

Crack arrest steel (BCA) is not required for hatch coaming top plate for the following reasons:

- Due to the stress gradient within the coaming it is unlikely that a crack will be arrested when it is initiated in coaming side plate and propagates into the coaming top plate.

- K_{ca} values for applicable BCA steels were determined based on the geometry and stress levels of upper deck. Therefore, for hatch coaming top plate no reliable K_{ca} values are available.

- No evidence was found neither from practical experience nor from theoretical point of view justifying the need for crack arrest ability of the hatch coaming top plate.

Application of NDT

Reference is made to Annex 1, where it is stated, that enhanced NDT other than TOFD (e.g. Phased Array UT) may be accepted. This comprises also combinations of NDT methodologies.

By excluding EGW as single pass high heat input welding procedure for brittle crack arrest design solutions (refer to the table in UR S33 Annex 1, where option B is only allowed for FCAW) high toughness values of the weld as well as limitation of the physically possible defect sizes can be ensured independent from any NDE and in addition to any NDE.

Technical Background document for UR S34 (New, May 2015)

1. Scope and objectives

Following recent structural failure incidents on large container ships, an Expert Group on container ship (EG/Container Ships) was established. EG/Container Ships reported recommended actions for enhancing the requirements of post-Panamax container ships to the IACS Council.

In response to the report, at 68th Council Meeting held in December 2013 the Council decided to expand the scope of its current URs for container ships, by introducing functional requirements on structural strength for new container ships. Specifically, the project team (PT) for Hull Panel Task No. 33 (PT PH33/2014, hereinafter referred to as "the PT") was tasked to develop a new UR that prescribes the following:

- Functional requirements on load cases
- Minimum set of loading conditions

The purpose of these new requirements is to attain an acceptable level of consistency among all Classification Societies by defining the unified load cases, which are to be used while performing strength assessment for container ships by Finite Element (FE) analysis. The intention is not to prescribe an overall FE analysis standard, but rather "functional requirements" to ensure that respective analysis is undertaken with suitable load cases considered.

2. Engineering background for technical basis and rationale

This UR is aimed to prescribe functional requirements on FE loads which shall be considered when FE analyses are carried out in accordance with the rules by the Classification Society. By prescribing high-level "functional requirements" on FE loads, the bottom line of structural strength becomes unified at a certain level across all Classification Societies.

The other aim of this UR is to develop a minimum set of common loading conditions for Cargo Hold Analysis in midship region. By developing common loading conditions for Cargo Hold Analysis, the base line of structural strength at cargo hold in midship region are achieved among IACS member societies and therefore the flexibility of container cargo loading comes to the equal level.

3. Source / derivation of the proposed IACS Resolution

· The information obtained through work performed by PT PH33/2014

· UR S11A Longitudinal Strength of Standard for Container Ships" prepared by PT56 in parallel with the development of this UR
· Additional input from the Hull Panel regarding the work performed by PT PH33/2014 and PT56

4. Summary of Changes intended for the revised Resolution:

Not applicable

5. Points of discussions or possible discussions

The UR was developed by the project team (PT) for Task No. 33. Discussions on the draft documents prepared by the PT were reviewed and discussed within the Hull Panel at Panel meetings and via email correspondence.

6. Attachments if any

Detailed technical background document is attached (Attachment 1).

Attachment 1
Technical Background for UR S34

Functional Requirements of Load Cases for Strength Assessment of Container Ships by Finite Element Analysis

Technical Background for UR S34 "Functional Requirements of Load Cases for Strength Assessment of Container Ships by Finite Element Analysis

TB S34.1 Functional Requirements on FE Load

This UR is aimed to prescribe functional requirements on FE loads which shall be considered when FE analyses are carried out in accordance with the rules by the Classification Society. By prescribing high-level "functional requirements" on FE loads, the bottom line of structural strength becomes unified at a certain level across all Classification Societies.

In order to develop functional requirements at a reasonable level, a set of questionnaires was distributed within IACS member societies to collect information on the existing analysis procedures for container ships.

Based on the collected information, the PT discussed the principles behind each society's container ship rules, particularly focusing on the requirements that relate to FE load, and established functional requirements in this UR. The outline of this UR is as follows:

UR S34.1 Application
The application of this UR is defined as container ships and ships dedicated primarily to carry their cargo in containers.

UR S34.2 Principles
This section states that the loads in this UR are to be considered when performing structural strength assessments (yielding and buckling assessments) while the detailed procedure is to be in accordance with the Rules of the Classification Society. This section also describes that the aspects and principles not mentioned in this UR are to be in accordance with the Rules of the Classification Society.

UR S34.3 Definition
Global Analysis and Cargo Hold Analysis and their target structural members are defined in this section.

UR S34.4 Analysis
The application of Global Analysis and Cargo Hold Analysis as well as loads to be considered are defined in this section. The application for Global Analysis has been [settled to be in line with that for UR S11A.6.1, where functional requirements in UR S11A are prescribed]. On the other hand, the application for Cargo Hold Analysis has been settled with reference to CSR application. In addition, two methods are introduced regarding Global Analysis since there are various possible approaches for carrying out Global Analysis.

UR S34.5 Load Principles
Wave environment and ship operating conditions are defined in this section. Yielding and buckling assessments are to consider waves that are expected for ships to encounter during their actual voyage in the North Atlantic environment. With regard to ship operating conditions, seagoing condition is required in this UR as a minimum requirement, since it is the most representative condition throughout a ship's life.

UR S34.6 Load Components
Static and dynamic load components to be considered in each analysis are defined

in this section based on the load components considered in container ship rules currently adopted by Classification Societies.

UR S34.7 Loading Conditions
Loading conditions to be considered for each analysis are defined in this section. The table indicating the minimum set of loading conditions for Cargo Hold Analysis has been developed through the comparative study within the PT, which was conducted as explained in TB S34.2.

UR S34.8 Wave Conditions
Dynamic wave conditions for each analysis are defined in this section. The wave conditions are described as waves that are considered to be severe for each analysis respectively.

TB S34.2 Minimum Set of Loading Conditions for Cargo Hold Analysis

The other aim of this UR is to develop a minimum set of common loading conditions for Cargo Hold Analysis in midship region. By developing common loading conditions for Cargo Hold Analysis, the base line of structural strength at cargo hold in midship region are achieved among IACS member societies and therefore the flexibility of container cargo loading comes to the equal level.

For this purpose, a comparative study was conducted within the PT to investigate loading conditions that are significant to the scantling of primary supporting members in a cargo hold FE model. The following steps were taken in order to effectively screen the suitable loading conditions.

1. Collecting loading conditions in IACS member societies' container ship rules
2. Narrowing down the initial set of loading conditions for further investigation
3. Conducting a comparative study based on direct strength analysis
4. Determining a minimum set of loading conditions based on the analysis results

TB S34.2.1 Collecting loading conditions in IACS member societies' container ship rules

As the beginning step of determining a minimum set of loading conditions, the PT distributed a questionnaire among IACS member societies and collected a wide variety of loading conditions that are currently considered in their existing container ship rules.

TB S34.2.2 Narrowing down the initial set of loading conditions for further investigation

The loading conditions collected from the IACS member societies were investigated and categorized into 5 broad types of loading conditions: full load conditions, ballast conditions, flooded conditions, one bay empty conditions, and other loading conditions. Due to time constraints, PT members narrowed down the loading conditions to those which are most common among all societies and those which container ships could experience during ordinary seagoing conditions. Thus, full load conditions and one bay empty conditions were selected for further discussion. It is to be noted that other cases (such as ballast and flooded conditions) may still be taken into consideration by the Classification Society if considered necessary.

The PT selected 6 loading conditions to be further investigated, as shown in Figure 1.

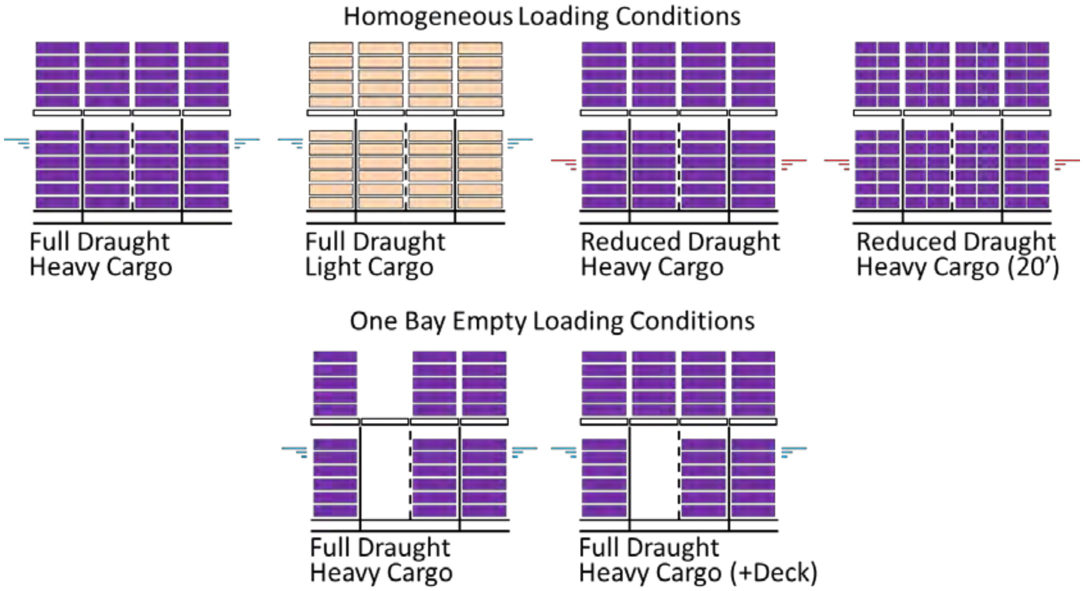

Figure 1: Set of Loading Conditions Selected for Comparative Study

Each loading condition in Figure 1 was selected for this study for the following reasons:

- Homogeneous (Full Draught, Heavy Cargo (40’ containers), Hogging):
  This condition is generally considered to be the most common loading condition in practice, where both external load from sea pressure and internal load from container cargo are large.

- Homogeneous (Full Draught, Light Cargo (40’ containers), Hogging):
  This condition is considered to be one of the severest conditions since light 40’ containers would induce smaller internal load due to container cargo, which leads to larger external/internal pressure difference.

- Homogeneous (Reduced Draught, Heavy Cargo (40’ containers), Sagging):
  This condition was selected for investigating the effect of sagging loading condition (minimum hogging loading condition), where external load due to sea pressure is smaller and internal load due to heavy cargo is larger.

- Homogeneous (Reduced Draught, Heavy Cargo (20’ containers), Sagging):
  The condition similar to the above but with 20’ containers was also selected for investigating the effect of loading heavy 20’ containers instead of heavy 40’ containers.

- One Bay Empty (Full Draught, Heavy Cargo (40’ containers), Hogging):
  This condition is considered to be another one of the severest loading conditions, because the double bottom structure below the empty bay receives the largest external/internal pressure difference due to the absence of container cargo, whereas the adjacent bays receives large internal pressure.

- One Bay Empty (Full Draught, Heavy Cargo (40’ containers) with Deck Fully Loaded, Hogging):
  This one bay empty condition was selected for investigating the effect of loading containers on top of the hatch cover above the empty bay.

TB S34.2.3 Conducting a comparative study based on direct strength analysis

The comparative study was carried out within the PT in order to investigate which of the 6 loading conditions chosen in TB S34.2.2 would become relatively significant to scantling of each structural member in a container ship.

Upon conducting the comparative study, utilisation factors (ratio between reference stresses and allowable stresses) for yielding and buckling assessments in each structural member were compared among PT member societies, rather than comparing the actual stress values calculated from direct strength analysis. This is because every Classification Society differs in FE load application and strength evaluation methods, and the purpose of this study is to investigate the loading conditions in the order of their dominance while applying the rules adopted by individual Classification Societies.

Taking the above into account, each PT member society performed direct strength analysis in accordance with their rules while referring to the common study procedures. Direct strength analysis was carried out under the following conditions:

- One container ship FE model from each PT member societies' class-registered ships in the range basically from 8,000 to 10,000 TEU (or large container ship, if none available in the range, but preferably post Panamax) is selected individually as a subject ship for the comparative study.
- FE loads, boundary conditions, etc. for 6 loading conditions shown in Table 1 are configured in accordance with the Rules of the Classification Society.
- Utilisation factors, evaluated from yielding and buckling assessments in accordance with the Rules of the Classification Society for 6 loading conditions in Table 1, are collected from each PT member society. For this purpose, 68 representative evaluation points (see Table 2) in structural members of a container ship were selected, which are considered to be relatively severe among the structural members.

Table 1: Details of 6 Loading Conditions for the Comparative Study

Condition name	Loading pattern	Draught	Types and weight of container	Ballast and FO	Still water hull girder moments
FH4		Scantling draught	Heavy cargo weight, 40’ containers	Empty	Permissible hogging
FL4		Scantling draught	Light cargo weight, 40’ containers	Empty	Permissible hogging
RH4		Reduced draught	Heavy cargo weight, 40’ containers	Empty	Permissible sagging (minimum hogging)
RH2		Reduced draught	Heavy cargo weight, 20’ containers	Empty	Permissible sagging (minimum hogging)
OH4E		Scantling draught	Heavy cargo weight, 40’ containers (one bay empty)	Empty	Permissible hogging
OH4D		Scantling draught	Heavy cargo weight, 40’ containers (one bay empty + loaded deck)	Empty	Permissible hogging

Table 2: Representative Evaluation Points

Structural member	# of points	Top/Side view	Front view
Inner bottom	5		Bottom shell	9		Bottom girders	7		Bottom floors	3		Inner hull	8		Side shell	8		Tiered stand (side)	3		Tiered stand (top)	3		
Structural member	# of points	Top/Side view	Front view
Transverse bulkhead	5		Partial bulkhead	1		Vertical webs	4		Horizontal girders	4		Transverse webs	3		Stringers	2		Bilge webs	3		
TB S34.2.4 Determining a minimum set of loading conditions based on the analysis results

The results of calculated utilisation factors were collected from PT members and were compared for investigation. Figure 2 shows an example of results submitted by a PT member. In Figure 2, the solid line in the graph represents the envelope curve of the utilisation factor in respective evaluation point among 6 loading conditions for the Classification Society.

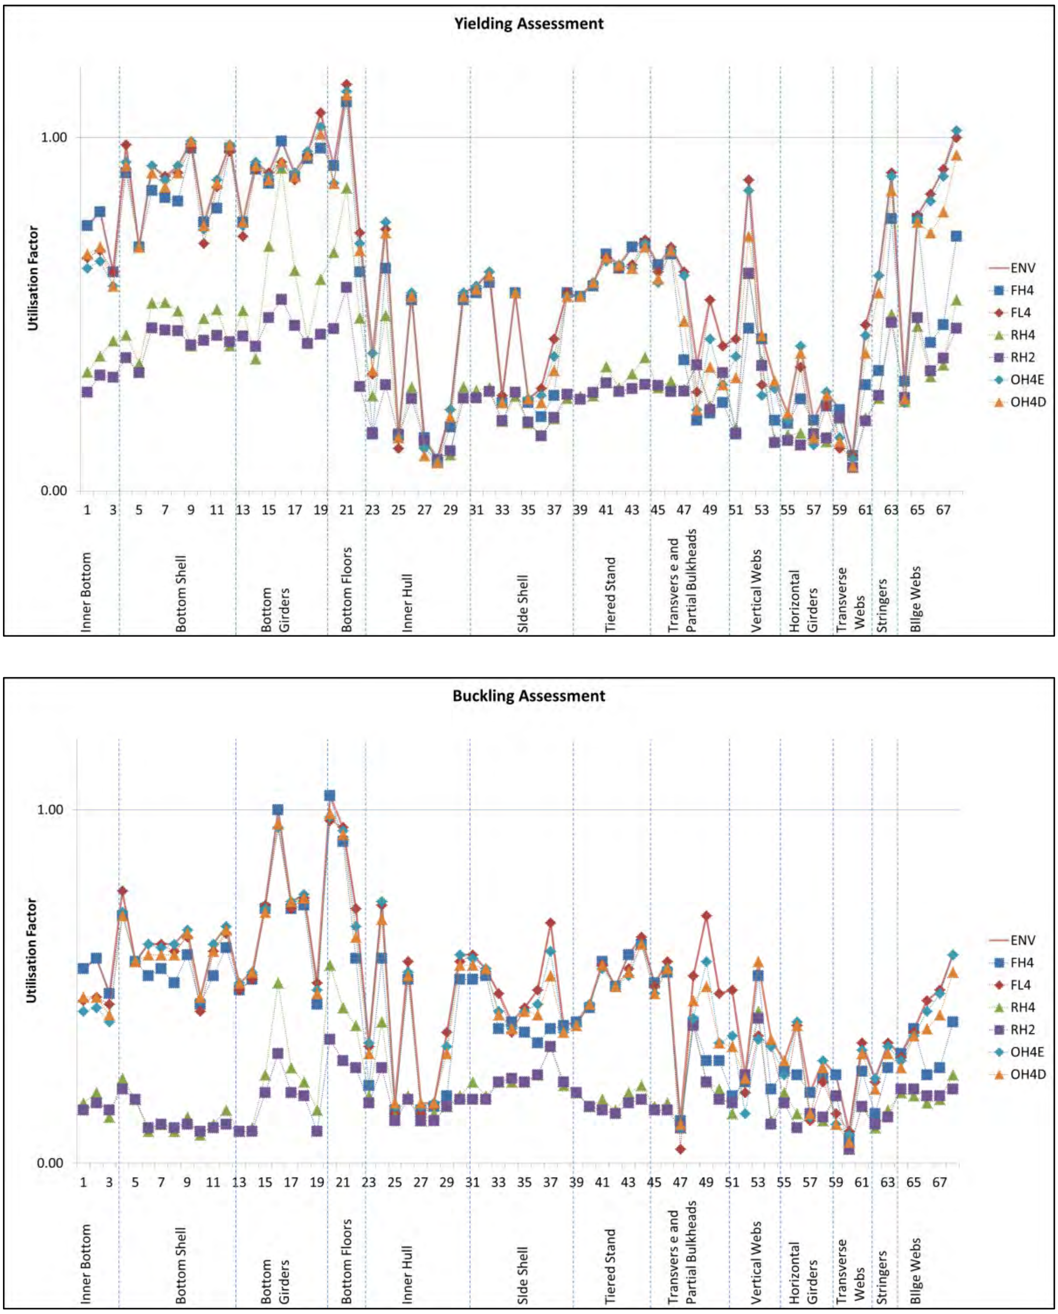

Figure 2: Example of Results Collected from PT Members

The results showed that the trend of utilisation factors to each structural member calculated for different loading conditions does not significantly differ among PT member societies. Furthermore, the PT proceeded with the investigation by comparing the loading conditions that showed similar results (RH4 and RH2, and OH4E and OH4D in particular) to further narrow down the number of loading conditions.

As a result of the study, the 4 loading conditions shown in Table 3 were chosen as a minimum set of loading conditions to be used only for evaluating the structural strength at midship region. For reference, Figure 3 indicates which loading conditions become relatively significant to each structural member. According to Figure 3, it can be confirmed that the strength of all of the structural members can be evaluated using the 4 loading conditions determined through the PT's study.

Table 3: Common Design Loading Conditions for Container Ships

Loading condition	Loading pattern	Draught	Container weight	Ballast and FO tanks	Still water hull girder moments
Full Load Condition (1) (FH4)		Scantling draught	Heavy cargo weight, 40' containers	Empty	Permissible hogging
Full Load Condition (2) (FL4)		Scantling draught	Light cargo weight, 40' containers	Empty	Permissible hogging
Full Load Condition (3) (RH2)		Reduced draught	Heavy cargo weight, 20' containers	Empty	Permissible sagging (minimum hogging)
One Bay Empty Condition (OH4E)		Scantling draught	Heavy cargo weight, 40' containers (one bay empty)	Empty	Permissible hogging

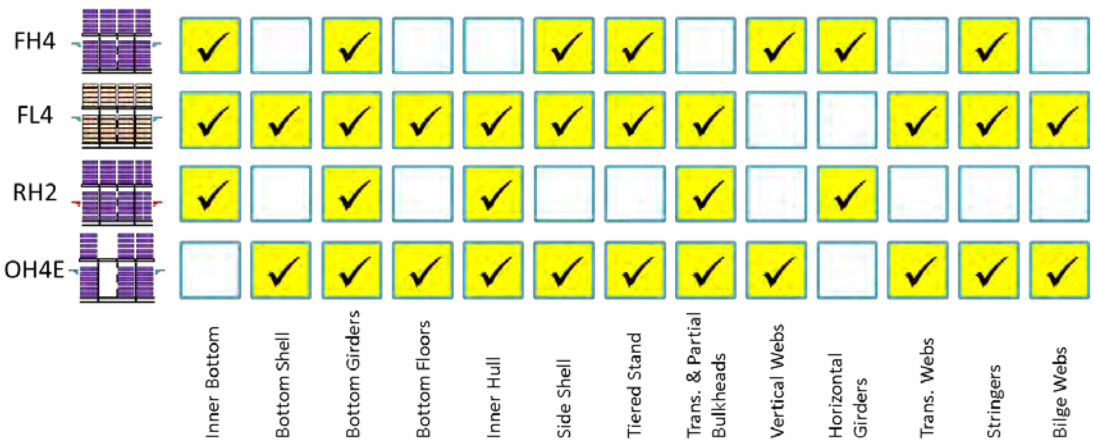

Figure 3: Structural Members where Each Loading Condition Becomes Significant

TB S34.2.5 Maximum and Minimum Values for Cargo Weights

The cargo weights corresponding to loading conditions in Table 3 are defined so that they depend on the ship's design, because container ships generally differ in their design. The calculation conditions in the comparative study, which were to be in accordance with the Rules of the Classification Society, were referred to upon settling the descriptions of the cargo weights.

In particular, light cargo weight was defined on the basis of the maximum ratio of light cargo to heavy cargo weight among PT member societies. Table 4 shows the trend of light cargo and heavy cargo weights configured by the PT members in the comparative study. With this regard, the maximum weight of a container unit in hold is defined as 55% of heavy cargo weight in hold. On the other hand, containers on deck are usually planned to have less permissible stack weight than those in hold. Thus, in order to prevent light cargo weight largely differing from the weights used in the comparative study, the maximum weight of a container unit on deck is defined as 90% of heavy cargo weight on deck while it is also not to be heavier than 17 ton per unit.

Table 4: Cargo Weight Configuration among PT Member Societies

PT Member		1	2	3	4	5	6
FH4	On Deck (ton)	30.00	30.00	21.80	32.00	150.00 per stack	30.00

TB S34.3 Expected Impact to the Scantlings

- Impact due to functional requirements on load cases
  The minimum acceptable FE load requirements were developed as high-level functional requirements on the basis of FE load principles for existing container ship rules currently adopted by individual Classification Societies. For this reason, functional requirements on load cases in this UR have minimal effect to IACS Classification Societies.

- Impact due to minimum set of loading conditions
  Although the degree of impact to individual Classification Societies due to this UR would depend on the difference between loading conditions adopted in each Classification Society's rules and this UR, the scantling impact would not become significantly large since the loading conditions investigated during the comparative study were selected primarily based on those already adopted by most Classification Societies. This has been confirmed by the results obtained in the comparative study, which is described in TB S34.2.

UR S35 "Buckling Strength Assessment of Ship Structural Elements"

Summary

An application statement in note.1 of UR S35 are updated for further clarification.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Corr.1 (Sept 2024)	16 September 2024	-
New (Feb 2023)	09 February 2023	1 July 2024

- **Corr.1 (Sept. 2024)**

1 Origin of Change:

☑ Suggestion by IACS Member

2 Main Reason for Change:

A member announced reservations against Section 2 & 3 of UR S35 (New Feb 2023). The member's buckling strength assessment currently aligns with UR S11 Rev.10. It is advised that the reservation be retained until the completion of UR S11, which is currently undergoing revision.

3 Surveyability review of UR and Auditability review of PR

None

4 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None

5 History of Decisions Made:

Hull Panel Chair has views that UR S35 will be used as a general-purpose buckling toolbox in conjunction with other relevant individual UR-Ss. It is also noted that the applicable ship types are defined in these relevant UR-Ss. In addition, he pointed out that S35 is applied as is, it could be interpreted that all vessels must use S35 for buckling calculations, which could cause issues with classification societies' applications.

Hull Panel reviewed the issue and generally understood that UR S35 is currently applicable only for UR S21 and it will not be applicable for UR S11/ UR S11A until they will be updated.

Some HP members have views that an additional application sentence could be added in UR S35 for clarification while other members have expressed there is no reason why a reservation should be raised since it is quite clear that UR S35 is currently only applicable to UR S21.

HP Chair has consulted with the initiator of this discussion, on HP members' understanding, however the member still has a concern that external audits may raise this issue on the application of UR S35.

It is concluded that an application statement in note.1 of UR S35 are updated for further clarification to remove the reservation.

6 Other Resolutions Changes:

None

7 Any hinderance to MASS, including any other new technologies:

None

8 Dates:

Original Proposal	: 18 June 2024	(Made by GPG)
Panel Approval	: 29 August 2024	(Ref: PH24020_IHd)
GPG Approval	: 16 September 2024	(Ref: 24127_IGb)

• New (Feb 2023)

1 Origin of Change:

☑ Suggestion by IACS Member

2 Main Reason for Change:

Different buckling assessment methods have been included in the relevant UR-Ss, such as UR S11, S11A, S21 and S21A. With the development of the harmonized buckling method in the Common Structural Rules for Bulk Carriers and Oil Tankers(CSR), it's considered necessary to also harmonise the buckling methods among all the different UR-Ss based on the CSR buckling methodology.

For the introduction of the new buckling methodology, it's to be carried out as part of the comprehensive work package on the harmonisation of buckling requirements in different IACS Resolutions, with a newly proposed UR S35-Buckling as a common unified buckling toolbox and simultaneous amendments to the Relevant UR-S including UR S21 and S21A.

For this new UR S35-Buckling specifically, for consistency and easy maintenance of related IACS Resolutions, this harmonization brings about a necessity to provide a common set of buckling requirements following the CSR buckling methodology, which is applicable for all relevant UR-S resolutions, such as UR S21 and S21A.

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None

4 History of Decisions Made:

The Hull Panel at the 23rd meeting (Sept 2015) considered for the first time the need for harmonising the different IACS Resolutions. A comment received from shipyards is that the IACS approaches regarding buckling requirements were different in the UR S11, S11A, S21, S21A and CSR.

The decision to propose this new UR S35-Buckling and to simultaneously revise UR S21, S21A and CSR is an outcome of the work of IACS GPG Meeting 83.

Therefore, a Project Team PT PH43 was ad hoc nominated by the Hull Panel and tasked for the harmonization of buckling requirements in the UR-Ss, as well as for making improvements in the formulation itself.

5 Other Resolutions Changes:

Revised UR S21 (merged with S21A) requiring changes in the buckling part and making reference to this UR S35-Buckling.

6 Any hinderance to MASS, including any other new technologies:

None

7 Dates:

Original Proposal	: 08 August 2022	(Made by PT PH43)
Panel Approval	: 02 December 2022	(Ref: PH17036aIHk)
GPG Approval	: 09 February 2023	(Ref: 18058_IGy)

****

Part B. Technical Background

List of Technical Background (TB) documents for UR S35:

Annex 1. **TB for New (Feb 2023)**

See separate TB document in Annex 1.

Note: There are no separate Technical Background (TB) documents available for Corr.1 (Sept. 2024).

Technical Background (TB) document for UR S35 (New Feb 2023)

1. Scope and objectives

This UR S35-Buckling is newly proposed as a major part of the comprehensive work package on the harmonisation of buckling requirements in different IACS Resolutions, simultaneously with amendments to the Relevant UR-S including UR S21 and S21A.

Within this new framework of buckling rule requirements, UR S35-Buckling takes as a general purpose buckling toolbox, consisting of a full set of unified requirements for "Buckling Strength", which is made generally by adopting the most preferred buckling methodology in the latest Common Structural Rules for Double Hull Oil Tankers and Bulk Carriers (CSR).

In UR S35-Buckling, it consists of five sections and one appendix, giving Application and Definitions, Slenderness Requirements, Buckling Requirements for Hull Girder Prescriptive Analysis, Buckling Requirements for Direct Strength Analysis of Hatch Covers, Buckling Capacity, and the Stress-based Reference Stress calculation method, respectively.

For the application of UR S35-Buckling to specific ship types or structural members requesting buckling assessment, definition of loading conditions, standard corrosion deductions, hull girder stresses, stress combinations, safety factors should be given in the individual UR-Ss; based on these definitions as input parameters, wherever applicable it links to UR S35-Buckling for buckling assessment with respect to slenderness requirements, prescriptive buckling requirements and buckling requirements for direct strength analysis. With this framework of general rule organization and a standardized interface of reference to the same UR S35-Buckling for buckling assessment in all relevant UR-S (S21, S21A, etc.), the goal of Harmonisation of Buckling Requirements in IACS Resolutions is achieved.

2. Engineering background for technical basis and rationale

2.1 On the harmonisation of buckling requirements in IACS Resolutions

The Hull Panel at the 23rd meeting (Sept 2015) considered for the first time the need for harmonising the different IACS Resolutions. As a main cause of initiation, for many years the shipyards had been complaining that the IACS approaches regarding buckling requirements are different in the UR S11, S11A, S21, S21A and CSR. Therefore, since then the Hull Panel reiterated the need to perform this task during each subsequent Hull Panel Meeting.

For this purpose, it was well recognized that CSR with a sound technical basis, obtained through technical co-operation within IACS harmonization groups and continuous improvements and maintenance based on various feedback from Industry, offer the chance to adopt one single methodology to the buckling verification of different structural types and different ship types.

Therefore, a newly proposed task titled Harmonisation of the IACS Resolutions is approved by Hull Panel and to be carried out by a designated PT PH43. It was highlighted that IACS needs to address through the following work, according to the following programme developed by the PT, in particular a Work Package, as below:

WP-A:
The objective is to harmonize the buckling methodology in UR S21 and S21A, and the CSR buckling approach, with detailed Technical Background documents, is generally to be adopted for all relevant UR S.

Consequently, a new UR S specifically dedicated for buckling using the net thickness approach will be developed for detailing the buckling modes, capacity and checking criteria from CSR. With reference to this new UR S Buckling, amendments are to be proposed to UR S21 and S21A respectively. Specifically, the following two steps are to be performed:

WP-A1:
Review of the relevant documents (S21, S21A and CSR) with regard to the buckling modes and the corresponding capacities, applied stresses and checking criteria.

Based on CSR approach, make a proposal for a new UR S Buckling, introducing the relevant buckling modes and the corresponding capacities and checking criteria.

With the new UR S Buckling, propose amendments to UR S21 and S21A respectively. The corrosion margins and applied stresses, which depend on ship types, may need to be kept in each of the original UR S.

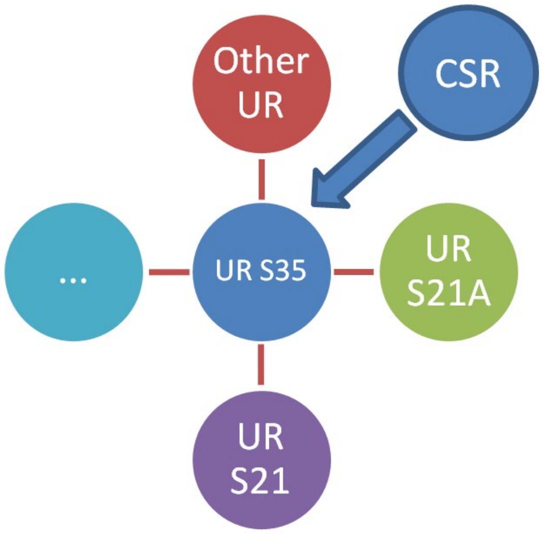
Consequently, with this rule change proposal, in each UR S (S21 and S21A) the buckling check will require the application of the common UR S Buckling for the appropriate mode(s) and criteria, while using the corrosion margins and applied stress already defined in each UR S.

It’s also required to issue a Technical Background separately for each modified document to explain the reasons for rule changes and technical justification of the modifications.
WP-A2:

Perform Consequence Assessment regarding the introduction of both the new UR S Buckling and amendments to relevant UR S, which may affect structural scantlings.

2.2 Framework and general rule organization for the harmonisation

For the harmonization, while introducing the CSR buckling methodology into different IACS Resolutions, it’s not to revise the buckling requirements in each Relevant UR-S independently. Generally, it’s to adopt the buckling methodology of CSR, and the most updated buckling requirements are to be adapted and included in a separate UR S35-Buckling. Compared with CSR, the major difference is that UR S35-Buckling is organized as a buckling rule package relatively independent of ship types, well serving as a unified buckling toolbox for the updates of UR S21 and S21A or future UR-Ss requesting buckling assessment wherever applicable, as shown in the figure below.



With this unified rule organisation, all relevant URs specific to some ship types or structural components can thereby be improved with respect to buckling in a more simplified manner. However, this also requires to carry out the extensive rule harmonisation task concerning several UR-Ss and CSR as a whole work package. Therefore, it needs be implemented based on properly coordinated general guidelines on the organization of the harmonized buckling rule requirements. Generally, the principle is to eliminate repeated rule text in different UR-Ss as much as possible, and use same rule requirements for same type of structural members crossing different ship types. Surely, this not only makes the buckling check of different ship types easier for Industry by using a unified approach, but also brings about good maintenance of future buckling rule improvement for IACS.

Consequently, a maximum set of buckling requirements are identified and included in UR S35-Buckling, and only a minimum set of related requirements remains necessarily to be kept in each of the Relevant UR-S. As a major part of the latter set, the interface of each Relevant UR-S to UR S35-Buckling is also standardized as much as possible, which not only makes it easier for rule application by Industry but also more convenient for further harmonisation of some Relevant UR-Ss by IACS in the future, such as possibly combination of UR S11 and S11A or S21 and S21A.

Following the above principle and considerations, the following steps had been carried out.

(1) To identify and classify all the buckling-related requirements in both CSR and Relevant UR-Ss. The identified items include different sets of slenderness requirements, DSA (direct strength analysis) or prescriptive type of buckling assessment, buckling capacity formulae based on different fundamental theories, both of global and local buckling modes to be considered, different definitions of net scantling or corrosion margins, applied stresses or stress combinations for buckling check, different stress calculation methods,

different buckling check criteria, etc., all of which need to be harmonised and included in either UR S35-Buckling or the Relevant UR-S.

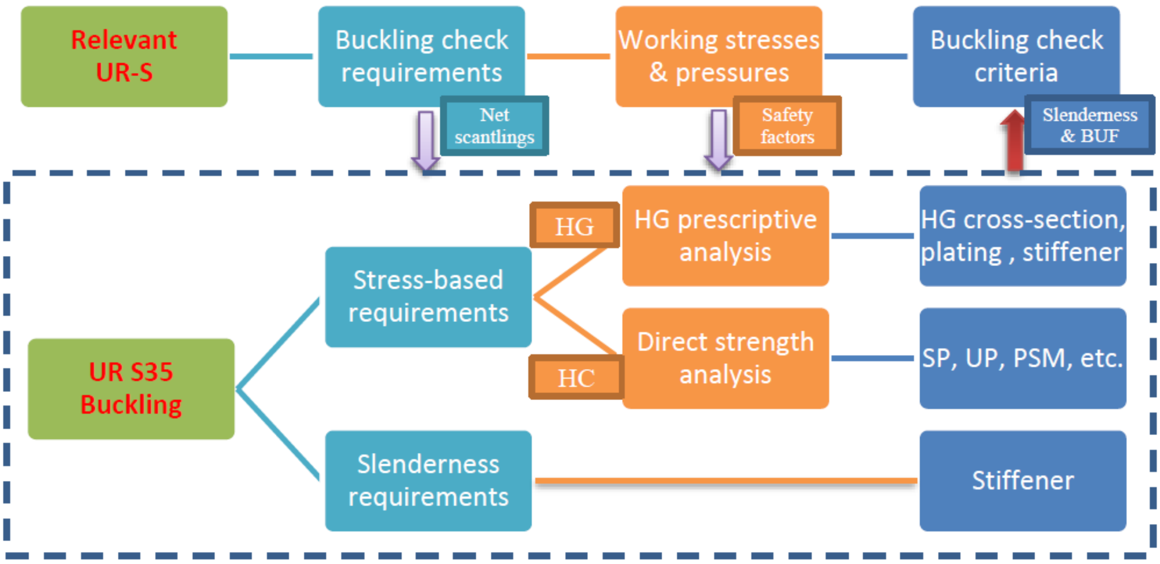
(2) On the general organization of the harmonized buckling rule requirements, regarding which part to be included in each rule text, as approved by Hull Panel on the HP-30 meeting, in UR S35-Buckling it should gather a maximum set of buckling requirements as following:

- General definitions and assumptions for buckling strength assessment
- Slenderness requirements
- Common requirements on hull girder prescriptive buckling assessment
- Common requirements on direct strength buckling assessment
- Buckling methodologies for the calculation of buckling capacity of plane panels, curved panels, corrugated panels, columns, etc.

On the other hand, in each of the Relevant UR-S it should contain the following remaining buckling-related requirements:

- Corrosion margin or net scantlings required for buckling check.
- Applied stressed or stress combinations for stress-based buckling assessment,
- Reference to specific sections of UR S35-Buckling for slenderness requirements, or stress-based buckling assessment requirements.
- Safety factors applicable for the ship types or structural members targeted in the Relevant UR-S.
- Buckling acceptance criteria

(3) Based on the general guideline and classification of all the buckling-related requirements, a framework as shown in the figure below is proposed to develop the new UR S35-Buckling and amendments to the Relevant UR-S.



(4) Based on the framework, for more specific organization of the buckling-related requirements in each rule text and different sections of the UR S35-Buckling, it is preferably to be taken as similar to that of CSR with reference to different sections of CSR Pt1, Ch 8-Buckling as shown in the table below.

Buckling-related requirements	CSR	UR S11 & S11A	UR S21 & S21A	UR S35-Buckling
General definition and assumptions on buckling assessment	Pt 1, Ch8, Sec1			Sec1
Corrosion addition for buckling assessment	Pt 1, Ch8, Sec1	√	√	
Safety factors	Pt 1, Ch8, Sec5	√	√	
Allowable buckling utilisation factors	Pt 1, Ch8, Sec1	√	√	
Buckling check criteria	Pt 1, Ch8, Sec1	√	√	
Slenderness requirements	Pt 1, Ch8, Sec2	Ref		Sec2
Prescriptive buckling requirements for Hull girder assessment	Pt 1, Ch8, Sec3	Ref		Sec3
DSA buckling requirements for hatch covers assessment	Pt 1, Ch8, Sec4 Pt 2, Ch1, Sec5	Ref		Sec4 Sec5
Buckling capacity formulas	Pt 1, Ch8, Sec5			Sec5

Note: a √ or Ref in the above table means the specific rule requirements of the first column or a reference to the requirements respectively are included in the corresponding Rule set listed in the first row. However, for CSR BC&OT and UR S35-Buckling, it also lists the specific section containing the corresponding rule requirements.

(5) As illustrated in the figure below, with a standardized interface in each of the proposed/revised Relevant UR-S, there is both a reference to UR S35-Buckling and also definitions of necessary parameters as input to UR S35-Buckling to perform detailed calculations and buckling check.

S21
(cont)

S21.3.6 Buckling strength

S21.3.6.1 General

Buckling strength of all hatch cover structures is to be checked. Buckling assessments are to be performed in compliance with the requirements in UR S35 for the conditions specified in S21.3.6.2 and S21.3.6.3.

UR S35-BUCKLING

The net scantlings as defined in S21.1 are to be used for buckling check.

S21.3.6.2 Slenderness requirements

The slenderness requirements are to be in accordance with those specified in UR S35/Sec 2

S21.3.6.3 Buckling requirements

S21.3.6.3.1 Application

These requirements apply to the buckling assessment of hatch cover structures subjected to compressive and shear stresses and lateral pressures. The buckling assessment is to be performed for the following structural elements:

- Stiffened and unstiffened panels, including curved panels and panels stiffened with U-type stiffeners.
- Web panels of primary supporting members in way of openings.

The buckling strength assessment of coaming parts is to be done according to the individual Society's rules.

For rule application, the panel types and assessment methods, the applied stresses, safety factors and buckling check criteria are defined in S21.3.6.3.2, S21.3.6.3.3, S21.3.6.3.4 and S21.3.6.3.5, respectively. The procedure and detailed requirements for buckling assessment are given in UR S35/Sec4, including idealization of irregular plate panels, and additional definitions such as reference stresses and buckling criteria.

Unless otherwise specified, the symbols used in S21.3.6.3 are defined in UR S35.

S21.3.6.3.2 Panel types and assessment methods

……

S21.3.6.3.3 Applied stresses and pressure

……

S21.3.6.3.4 Safety factors

……

S21.3.6.3.5 Buckling acceptance criteria

A structural member is considered to have an acceptable buckling strength if it satisfies the following criterion:

$\eta_{act} \leq \eta_{all}$

2.3 Related technical background materials on buckling requirements

As shown above, UR S35-Buckling is generally established by adopting the buckling methodology of CSR, with the most updated buckling requirements in CSR being adapted to form a common unified buckling toolbox. Therefore, all the latest version of technical background materials on the CSR buckling requirements are also equally applicable to this UR S35-Buckling.

Furthermore, this UR S35-Buckling is part of the comprehensive work package on the harmonisation of buckling requirements in different IACS Resolutions, simultaneously with amendments to the Relevant UR-S including UR S21 and S21A. Therefore, the TB for this harmonisation can be reasonably taken as a whole for the common part, and this part is better to be included in the TB of UR S35-Buckling. For simplicity and avoiding repetition, only the part specific to each Relevant UR-S will be included in the respective UR S while making a major reference to this document.

Generally, there are two categories of technical background (TB) materials for the newly proposed UR S35-Buckling and this revision of all Relevant UR-Ss as a whole.

(1) Category I: TBs corresponding to related CSR buckling requirements.

Category I consists of the major part of the TB since the new UR S35-Buckling and this revision of all Relevant UR-Ss share the same methodology with CSR for buckling assessment. Such as in UR S21, it's to check the buckling strength of hatch covers based on direct strength analysis, it's identified that two parts of CSR requirements are mostly concerned, i.e. the buckling requirements for direct strength analysis in CSR Pt 1, Ch 8, Sec 4 and the requirements for hatch cover analysis in CSR Pt2, Ch1, Sec 5. Correspondingly, the CSR TBs on these requirements should equally apply to this revision of UR S21, including those in the TB Rule Reference document and more detailed collection of TB Reports. This is also the case for the revised UR S21A.

Note that during the process of carrying out this buckling rule harmonisation task, some common issues and key technical points were identified, for which it had been decided to be preferably investigated in the context of CSR, leading to several further improvements on some CSR buckling requirements. Therefore, the TB corresponding to all these RCNs (Rule Change Notices) should also be referred to and be included in this category I.

Also note that some mechanism might need to be established by IACS to ensure that future improvement of the CSR buckling requirements should also be continuously synchronized in UR S35-Buckling and all Relevant UR-S.

(2) Category II: TBs specific to this revision of each Relevant UR-S.

Generally, TBs for some specific technical points related to a Relevant UR-S are to be provided for this category, together with consequence assessment if it's considered necessary. Such as for UR S21, additional TBs on the definition of allowable buckling utilizations are available in the TB for the proposed rev. 6 of

UR S21, together with some consequence assessment reports regarding several typical hatch covers.

3. Source/derivation of the proposed IACS Resolution

The framework and specific requirements of the newly proposed UR S35-Buckling are generally based on CSR Pt 1, Ch 8, Sec 5 and App 1. Background information to the general approach is therefore same as the corresponding parts in the technical background documentation of CSR, available via the IACS web-site.

4. Summary of Changes intended for the revised Resolution:

As a newly proposed UR S35-Buckling, this is the original version of this UR.

5. Points of discussions or possible discussions

This original version of UR S35-Buckling was made through discussions of the draft version provided by the project team within the Hull Panel, which mainly involved incorporating individual comments on specific technical points, updates based on corresponding CSR improvements and accepting the consolidated text.

Major points of discussions and conclusions during the development of this UR S35-Buckling have been the following:

<table>
<tr><th>No</th><th>Section</th><th>Points of discussion and conclusions</th></tr>
<tr><td>1.</td><td>General organization</td><td>For the drafting of UR S35-Buckling, the same rule organizational structure as in CSR Pt1, Ch8 is generally to be followed, i.e. with 5 Sections and 1 Appendix.</td></tr>
<tr><td>2.</td><td>Sec1/1.2.1</td><td>Conceptually, hatch cover direct strength analysis in current Rules includes finite element method(FEM), grillage analysis and isolated beam analysis method as tabled below. However, investigation of some hatch cover makers and Societies indicates that only FEM is currently used, which is considered necessarily to be used especially for some specific structural members to get more accurate results.
Finally, this corresponds to CSR 2022 which keeps only FEM for hatch cover analysis.
<table>
<tr><th>Methods</th><th>CSR Pt2(2020)</th><th>UR S21</th><th>UR S21A</th></tr>
<tr><td>FEM</td><td>√</td><td>√</td><td>√</td></tr>
<tr><td>Grillage</td><td>√</td><td>√</td><td>√</td></tr>
<tr><td>Isolated beam</td><td>√</td><td></td><td></td></tr>
</table>
For additional information, Regarding the proposal of removing the isolated beam method and grillage method used for hatch cover analysis, it’s based on a careful investigation and discussion both within a dedicated IACS work group and with Industry including several experts from hatch cover makers and shipyards. The main considerations are as below:</td></tr>
</table>

<table>
<tr><td></td><td></td><td>(1) The finite element method generally provides higher level of accuracy and minimizes the numbers of approximations/assumptions. Compared with finite element method, the isolated beam method and grillage method are more simplified, which makes them more dependent on very critical assumptions regarding the idealization of some key parameters such as the effective width of attached plate, even with different definitions in various IACS Resolutions.
(2) Limitations inherent in the grillage/isolated beam methods are deemed not acceptable for some very critical cases. For example, the shear stress in the hatch cover plate panels is not available or not very well considered in the grillage/isolated beam methods, but it has been found as an important issue leading to some serious structure collapses, especially at the hatch cover corners.
(3) For drawing approval purpose, it’s considered that FE software is nowadays available and usually applied by both Societies and Industry. Application of two different methods, equally acceptable by the Rule, might bring in undesirable discussions on the scantling check between related Parties.</td></tr>
<tr><td>3.</td><td>Sec1/3.2.2</td><td>For the conceptual definition of buckling utilization factor, the original formulas of Applied equivalent stress and Equivalent buckling capacity in CSR2020 are numerically incorrect. Therefore, the formulas are revised.
Finally, this corresponds to CSR 2022 which uses correct formulas and definitions.</td></tr>
<tr><td>4.</td><td>Sec1/3.3.1</td><td>For Struts, pillars and cross ties, it’s considered that no buckling requirements are included in original UR S11, S11A, S21, S21A, so the definition of Allowable buckling utilisation factor for these structural members are not included.</td></tr>
<tr><td>5.</td><td>Sec2</td><td>Different slenderness requirements are included in UR S11, S11A, S21 and S21A as tabled below.
<table>
<tr><th>Rule</th><th>Slenderness requirements</th></tr>
<tr><td>UR S11/ S11.5.2</td><td>For flanges on angles and T-sections of longitudinals, buckling is taken care of by the following requirement:
$\frac{b_f}{t_f} \leq 15$
b_f = flange width, in mm, for angles, half the flange width for T-sections.
t_f = as built flange thickness.</td></tr>
<tr><td>UR S11A / S11A.4.2</td><td>For all structural elements, the slenderness requirements are to be in accordance with the Society requirements.
No slenderness requirements except a formula as defined in the stiffener capacity formula of CSR, as below
$$I \geq \frac{s t_p^3}{12 \cdot 10^4}$$</td></tr>
<tr><td>UR S21/</td><td>For flat bar secondary stiffeners and buckling stiffeners, the ratio h/t_W should satisfy the</td></tr>
</table></td></tr>
</table>

<table>
<tr><td></td><td></td><td>
<table>
<tr><td>S21.3 .6.2</td><td>following criteria:
$$\frac{h_w}{t_w} \le 15\sqrt{235/R_{eH}}$$</td></tr>
<tr><td>UR S21A / 3.6.2</td><td>For lower plating of double skin hatch covers on which are intended to carry project cargos and PSM web, the net plate thickness should satisfy the following criteria:
$$t_p \ge 6.5s/1000$$
For flat bar secondary stiffeners and buckling stiffeners, the ratio h_W/t_W should satisfy the following criteria:
$$\frac{h_w}{t_w} \le 15\sqrt{235/R_{eH}}$$
For edge girder (skirt plates), the net plate thickness should satisfy the following criteria:
$$t_p \ge 8.5s/1000$$</td></tr>
</table>

In CSR, however, there is an extensive set of slenderness requirements covering many kinds of structural members. Considering that slenderness requirements are usually dependent on ship types, while the current stress-based buckling check can cover almost all buckling modes, it’s decided to include a minimum set of necessary CSR slenderness requirements into UR S35-Buckling. Finally, it’s decided that only the slenderness requirements for stiffeners are to be included in UR S35-Buckling, because this is the only local buckling mode that is not covered by the buckling formulas which perform buckling check based on actually applied stresses.</td></tr>
<tr><td>6.</td><td>Sec3/1.1.2</td><td>In the future, if necessary, the longitudinal extent of hull girder structures to be assessed for buckling strength is to be defined in the respective UR S11 and S11A.</td></tr>
<tr><td>7.</td><td>Sec3/1.1.3</td><td>Lateral pressure definition is necessary for stiffener buckling check. Since no explicit Design Load Sets are defined in UR S11 or S11A a general conceptually correct definition is included in UR S35-Buckling.
Finally, following S11A practice and as approved by Hull Panel, lateral pressure is to be defined in both UR S11 and S11A as static design pressure.</td></tr>
<tr><td>8.</td><td>Sec4</td><td>Section 4 is tailored for hatch cover direct strength analysis since no DSA of other ship structures are required in related UR S11, 11A, 21 and 21A.</td></tr>
<tr><td>9.</td><td>Sec4/1.1.1</td><td>As indicated in Sec1/1.2.1, only FEM is to be used as the direct analysis method for hatch cover analysis.</td></tr>
<tr><td>10.</td><td>Sec4/2.1.1</td><td>Based on investigation of some hatch cover makers and Societies, the SP-A/SP-B/UP-A/UP-B models are used for the buckling assessment of hatch cover structures. Some typical pictures for illustration are prepared, just as the case for ship hull structural members in CSR.
Finally, this corresponds to CSR 2022 which had been revised based on the corresponding rule change proposal.</td></tr>
</table>

11.	Sec5/ SYMBOLS	S: Partial safety factor for different structural members of different ship types, to be taken as the value defined in the respective URs, or optionally to be taken as 1.0.
12.	Sec5	The latest rule requirements in CSR2022 and RCP1 to CSR2022 are adapted in UR S35-Buckling, which includes the major CSR buckling rule improvements proposed while developing this UR S35-Buckling and making amendments to the Relevant UR-S including UR S21 and S21A, such as rule improvements on the global elastic buckling capacity, elastic torsional buckling capacity, stiffener buckling capacity, buckling capacity of panels with opening, buckling capacity of panels with U-type stiffeners, hatch cover buckling assessment, etc. Consequently, the final round of consequence assessments are carried out based on this updated set of buckling requirements.
13.	Sec5/2.2.7	For grillage beam analysis where the stresses in the attached plating are obtained based on beam theory, the Poisson Effect needs to be taken into account typically when a beam model producing stresses in x- and y-direction without the Poisson Effect, i.e. σ_{xb} and σ_{yb}. Normally a grillage beam analysis is used for local structures subjected to lateral loads only. In such a case the shear stresses in the attached plating may be neglected as assumed in the rule text, i.e. $\tau=0$. In case the attached plating is subjected to overall shear and/or other membrane stress components in addition to stresses caused by the lateral load, such overall stress components are to be considered in addition to the stresses from lateral load for the buckling check.

UR W1 “Material and welding for ships carrying liquefied gases in bulk and ships using gases or other low-flashpoint fuels”

Summary

As per IACS Policy for the relationship between IACS Resolution and IMO instruments, IMO IGC Code requirements have been deleted in the new IACS UR W1 revision so to include amendment to tables 1, 2 and 3 only.

This revised UR W1 extends the material thickness range above 40mm to a maximum of 50mm, and the tables contained within this UR (corresponding to the applicable tables contained in IGC and IGF instruments) reflect this extended material thickness range.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev.4 (Apr 2021)	6 April 2021	1 July 2022
Rev.3 (Aug 2016)	18 August 2016	1 January 2017
Rev.2 (May 2004)	24 May 2004	-
Rev.1 (1984)	No record	-
New (1975)	No record	-

- **Rev.4 (Apr 2021)**

1 Origin of Change:

☒ Suggestion by IACS member

2 Main Reason for Change:

Material manufacturers have contacted some IACS Members seeking approval of use of some material in the scope of IACS UR W1 up to 50 mm.

As per IACS Policy for the relationship between IACS Resolution and IMO instruments, IMO IGC Code requirements have been deleted in the new IACS UR W1 revision so to include amendment to tables 1, 2 and 3 only.

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None

4 History of Decisions Made:

In December 2018, the IACS EG/M&W agreed that UR W1 needed to be updated due to request from material manufacturers.
Form A – with the designated task Number EG/M&W 1809 was recorded by GPG in May 2019.

First draft was prepared in June 2019. Final draft was agreed by EG/M&W in October 2020.

5 Other Resolutions Changes:

None

6 Any hinderance to MASS, including any other new technologies:

None

7 Dates:

Original Proposal:	26 April 2019 (Made by: EG/M&W)
Panel Approval:	12 March 2021 (Ref: 19083_EMWb)
GPG Approval:	6 April 2021 (Ref: 19083_IGc)

- **Rev.3 (Aug 2016)**

.1 Origin for Change:

☒ Suggestion by IACS member

2 Main Reason for Change:

IMO Resolution MSC.370(93) (revised IGC code) adopted in May 2014 comes into force for the ships whose keels are laid on after 1 July 2016. The relevant requirements of UR W1 are to be updated in line with the revised IGC Code.

3 List of non-IACS Member Classification Societies contributing through the TC Forum and/or participating in IACS Working Group:

None

4 History of Decisions Made:

In March 2015, the IACS EG/MW agreed that UR W1 needs to be updated in line with the revised IGC Code. Form A – with the task Number EMW 15-01 was approved by GPG in May 2015. First draft was prepared in July 2015. Final draft was agreed by EG/MW in June 2016.

5 Other Resolutions Changes

None

6 Dates:

Original proposal:	16 April 2015 made by EG/M&W
EG/MW Approval:	08 July 2016

IACS Unified Requirement W1 (Rev.2)
Technical Background

Material and welding for gas tankers

a) **Objective/Scope**
The objective was to rationalize all UR Ws procedures on mechanical testing by reference to the new UR W2 (Rev.2, 2003).

b) **Source of Proposed Requirements**
The revised draft UR was developed referring to the existing requirements of the UR W1 "Material and welding for gas tankers" and the UR W2 "Test specimens and mechanical testing procedures for materials".

c) **Points of Discussion**
Nil.

* * * * *

Technical Background (TB) document for UR W1 (Rev.3 Aug 2016)

1. Scope and objectives

IMO Resolution MSC.370(93) (revised IGC code) adopted in May 2014 comes into force for the ships whose keels are laid on or after 1 July 2016. UR W1 is to be revised in line with the revised IGC code in order to update the relevant requirements on materials and welding specified in UR W1.

2. Engineering background for technical basis and rationale

UR W1 has been revised in line with the revised IGC Code which is a modern and fit-for-purpose version of the Code taking into account the latest technologies.

3. Source / derivation of the proposed IACS Resolution

IMO Resolution MSC.370(93) (revised IGC code)

4. Summary of Changes intended for the revised Resolution:

The changes made to UR W1 are summarized as follows:

- Requirements of chemical composition
- Restriction of maximum of minimum yield stress (410N/mm^2 or below)
- Addition of FH grade for hull structural steels
- Addition of condition of supply for the relevant materials
- Deletion of drop weight test as alternative test for Charpy V-notch impact test of production test
- Requirements for welding procedure tests for secondary barriers
- Requirements for castings and forgings intended for cargo and process piping for design temperature above 0 degree C
- Ultrasonic testing in lieu of radiographic testing.

5. Points of discussions or possible discussions

Due to this revision incorporating the requirements of the revised IGC Code, there are no relevant points for discussion associated with this revision.

6. Attachments if any

N/A.

Technical Background (TB) document for UR W1 (Rev.4 Apr 2021)

1. Scope and objectives

Due to the general market trend for increased sizes of independent type C gas tanks, the actual specification for low temperature steels with a maximum plate thickness of 40 mm does not suffice the design demands of current projects. For example, in the area of the fixed saddle / longitudinal key a plate thickness above 40 mm has become a common design. Thus, impact requirements for materials with thickness up to 50 mm are specified in tables 1, 2a, 2b, 3.

As per IACS Policy for the relationship between IACS Resolution and IMO instruments, IMO IGC Code requirements have been deleted in the new IACS UR W1 revision so to include amendment to tables 1, 2 and 3 only.

2. Engineering background for technical basis and rationale

Technical background of some Classification Societies and most commonly used international standards for design and manufacturing of pressure vessels have been analysed in order to amend the new requirements for impact tests for materials with thickness up to 50 mm specified in tables 1, 2a, 2b, 3.

3. Source / derivation of the proposed IACS Resolution

EN 13445-2:2018 - Unfired pressure vessels - Part 2: Materials
ASME BPVC Section VIII:2019 - Rules for Construction of Pressure - div. 1
CODAP:2015 - Code for construction of unfired Pressure Vessels

4. Summary of Changes intended for the revised Resolution:

Charpy V notch impact requirements tests in the thickness range $40 < t \leq 50$ in the following tables:

- Table 1 Plates, pipes (seamless and welded), sections and forgings for cargo tanks and process pressure vessels for design temperatures not lower than 0°C.
- Table 2a Plates, sections and forgings for cargo tanks, secondary barriers and process pressure vessels for design temperatures below 0°C and strictly down to -10°C
- Table 2b Plates, sections and forgings for cargo tanks, secondary barriers and process pressure vessels for design temperatures below -10°C and down to -55°C
- Table 3 Plates, sections and forgings for cargo tanks, secondary barriers and process pressure vessels for design temperatures below –55°C and down to –165°C.

Deletion of IMO IGC Code requirements so to include amendment to tables 1, 2 and 3 only.

5. Points of discussions or possible discussions

Criteria for the definition of notch impact requirements tests in the thickness range $40 < t \leq 50$ are based on the technical background of some Classification Societies and on the approach of some international standards.

Additional requirement of a further set of impact test at mid thickness for products with $t>40$mm have been agreed.

Criteria for exemption to post-weld stress relief heat treatment based on alternative approach (e.g. Engineering Critical Assessment) to be approved by the Classification Society or to be in compliance with recognized standards have been considered.

IACS Unified Requirement W2 (Rev.2)

Test specimens and mechanical testing procedures for materials

Technical Backgrounds:

a) Objective/Scope

The objective were as follows:

1. To amend the existing UR W2 in accordance with the UR W14 (Rev.1).
2. To update the existing UR W2 to bring in line with today's National and International Standards.
3. To rationalize all relevant sections of other UR Ws that detail general testing requirements into one document.

b) Source of Proposed Requirements

This revised draft UR was developed referring to the existing requirements of the UR W2 "Test specimens and mechanical testing procedures for materials".

c) Points of Discussion

The discussion on the following technical points had been made and achieved full agreement of the members:

Testing machines;

Tension/compression and impact testing machines are to be calibrated in accordance with ISO or other recognized standard.

Tensile test specimens;

Dimensions of tensile test specimens for various kinds of products are to be specified in accordance with ISO standard. For through thickness tensile test specimens, round test specimens including built-up type by welding are to be specified in accordance with the UR W14 (Rev.1).

Tensile properties at ambient temperature;

Testing procedures to determine yield stress, tensile strength and fracture elongation are to be specified in accordance with ISO standard.

Sub size Charpy requirements;

Dimensions of sub size Charpy V-notch specimens and the acceptance criteria are to be specified for each size of specimen.

Retest procedure

Retest procedures for tensile and Charpy V-notch impact tests are to be specified accordingly.

Ductility tests for pipes and tubes;

Requirements for the several kinds of ductility tests are to be specified in accordance with ISO standard.

Other UR Ws;

Other UR Ws are to be amended by reference to this revised UR W2 in the 2003 meeting.

UR W7 "Hull and machinery steel forgings"

Summary

Due to feedback from manufacturers indicating that the sampling requirements for ring and disc forgings may cause confusion in understanding, the requirement regarding the sampling position for ring and disc forgings has been clarified. Furthermore, the requirements for Charpy V-notch impact tests have been reconsidered based on their intended purpose, which is to verify the quality control of the heat treatment process.

Part A. Revision History

Version no.	**Approval date**	**Implementation date when applicable**
Rev.5 (Feb 2025)	28 February 2025	01 January 2027
Rev.4 (Jan 2022)	14 February 2022	01 July 2023
Rev.3 (May 2004)	May 2004	-
Rev.2 (July 2002)	July 2002	-
Rev.1 (1980)	1980	-
New (1978)	1978	-

- **Rev.5 (Feb 2025)**

1 Origin of Change:

☑ Suggestion by an IACS member.

2 Main Reason for Change:

The sampling requirements for ring and disc forgings have conflicting descriptions of the sampling positions in the text and the diagrams, which may cause confusion in understanding.

For QT steels, strength and toughness is decreasing with increasing distance from heat treatment surface.
The mechanical properties of test specimens taken from positions too close to the heat-treated surface may not adequately represent the properties of the ring forging at positions farther from the heat-treated surface.

3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

4 History of Decisions Made:

- IACS obtained industry feedback from a manufacturer about the distance from the test specimen to heat treated surface in Figure 1 UR W7 rev.4. All EG members were invited to consider the issue and feedback on 23 November 2023.
- Proposal to revise IACS UR W7 was confirmed by EG/MW Chairman and task was assigned on 26 December 2023.
- "Clarification of the Charpy V-notch (CVN) test requirements in UR W7 Table 3" was discussed during 13th IACS EG/M&W meeting(25th -27th September 2024). It was decided during this meeting to include the proposed revision as part of this task.

5 Other Resolutions Changes

None.

6 Any hinderance to MASS, including any other new technologies:

None.

7 Dates:

Original Proposal	: 20-22 September 2023	(Made by: IACS member)
EG M&W Approval	: 03 February 2025	(Ref: 2349_EMWo)

Technical Background (TB) document for UR W7 (Rev.1 1980)

1. Objective/Scope

The objectives was to revise the existing UR W7 from the viewpoint of the consistency between the requirements and current techniques.

2. Source of Proposed Requirements

This revised draft UR was developed referring to the existing requirements of UR W7 “Hull and machinery steel forgings”.

3. Points of Discussion

The discussion on the following technical points had been made and achieved full agreement of the members:
<u>Chemical composition;</u>
Chemical composition is to be specified for each steel type of hull and machinery steel forgings respectively. As details of chemical composition for alloy steel forgings for hull are not specified, the manufactures are to submit the specification for approval.
<u>Direction of test specimen;</u>
Two sampling direction of test specimen are to be defined, i.e. parallel (longitudinal test) or tangential (tangential test) to the principle axial direction of each product.
<u>Mechanical properties;</u>
Mechanical properties are to be specified for each steel type of hull and machinery steel forgings respectively. However, mechanical properties for C, C-Mn steel forging for hull are to be the same with those for machinery from design and metallurgical aspect. Charpy V- notch impact test is to be required only for propeller shaft intended for ships with ice class notation except the lowest one in UR W27.
<u>Inspection;</u>
Regarding requirements on non-destructive tests, IACS Recommendation No.68 which was adopted in 2000 is to be used as a sample of an acceptable standard. Rectification;
Repair welding of forgings, such as crankshaft forgings may be permitted subject to prior approval of the Society.

* *

Technical Background (TB) document for UR W7 (Rev.3 2004)

1. Objective/Scope

The objective was to rationalize all UR Ws procedures on mechanical testing by reference to the new UR W2 (Rev.2, 2003).

2. Source of Proposed Requirements

The revised draft UR was developed referring to the existing requirements of the UR W7 “Hull and machinery steel forgings” and the UR W2 “Test specimens and mechanical testing procedures for materials”.

3. Points of Discussion

Nil.

* * * *

Technical Background (TB) document for UR W7 (Rev.4, January 2022)

1. Scope and objectives

In UR W7, the requirements of steel forgings intended for hull and machinery applications have been specified, e.g. chemical composition limits, position of test specimens, mechanical properties.

The objectives of this revision were to perform a general review to assess the following aspects and recommended any necessary changes:

- Its relevance to current industry standards, including the specified data/version of that standard
- Its relevance to other current IACS publications, since 2004 (and past versions)
- The requirements of position of test specimens for hollow ring forgings
- Edit, review, update where necessary, by preparing a new (revised) draft
- Review the current acceptance criteria, and revise if considered necessary

2. Engineering background for technical basis and rationale

The latest UR W7 (Rev.3) was published in 2004, with no further revisions until this revision task was implemented. IACS GPG and EG/MW agreed that a review was required to assess the technical relevance compared with industry standards and IACS Resolutions.

The following technical points were considered in the presentation of this revision:

- A comprehensive literature review was carried out to attempt to align (and reference, if appropriate) any relevant external standards, e.g. mechanical properties, delivery conditions
- For materials exposed to seawater temperature with relevant Ice Class notations, the latest Trafi Regulations (2017) were reviewed as a valuable reference document
- The review also consisted of considerations and references to other IACS documents (e.g. UR W28, UR W32, UR W34, Rec. 68)
- The positions of test specimens were discussed and decided based on review of any relevant external standards and feedback from industry.

3. Source/derivation of the proposed IACS Resolution

Existing Classification Societies Rules as well as the international standards have been considered:

- The origin why 27 J (L) was set as requirement for CMn steel grades for hull forgings cannot be retrieved since this criterion was stipulated for many years ago.
  It is assumed that the value was copied from the requirements for rolled normal strength steel grades A to E as per UR W11.
- Trafi Regulations (2017) provided a valuable reference for CVN test temperature and required values, for applicable materials with relevant Ice Class notations.

4. Summary of Changes intended for the revised Resolution:

The content of UR W7 has been fully reworked and revised with major changes summarized hereafter:

- Update language and terminology (where applicable) to reflect general industry nomenclature, and alignment with other revised IACS documents
- Update or introduce new standards references (external and IACS) to current version, and to reflect new or revised UR's published since Rev. 3
- Deletions/additions, and general formatting for clarity
- Delivery conditions for alloy steels were added to align any relevant external standards
- The positions of test specimens were determined considering feedback from industry and any relevant external standards, e.g. slewing rings

- The requirements of Charpy V-notch impact test were stipulated to check the effectiveness of heat treatment to products
- The above requirements were determined based on existing Classification Societies
- Update or introduce the inspection scheme regarding NDT to current version considering revised IACS Rec. 68 and UR W34
- Updated exclusions to weld repair rectification on forgings subjected to torsional fatigue (e.g. propeller shaft forgings – in additional to the existing exclusion of weld repair to crankshaft forgings).

5. Points of discussions or possible discussions

- Fully annealed as delivery conditions for alloy steels were not added due to the possibility of insufficient strength
- The requirements of Charpy V-notch impact test were stipulated based on existing Classification Societies, not alignment with any relevant external standards
- The positions of test specimens and requirements of criterion for products may be changed depending on design and application with agreement by each Classification Society

6. Attachments if any

None.

* * *

Technical Background (TB) document for UR W7 (Rev.5 Feb 2025)

1. Scope and objectives

The objectives were to clarify the sampling position for ring and disc forgings mentioned in section 6.4 c) and to reconsider the requirements of Charpy V-notch impact test, aligning them with their purpose of verifying the quality control of the heat treatment process, as specified in UR W7 rev.4.

2. Engineering background for technical basis and rationale

The latest UR W7 (Rev.4) published in 2022 specifies the test specimen sampling position, but the explanation regarding that sampling position only specifies “the distance from the specimen to heat-treated surface”, without clarifying whether it is the distance from the surface of the test specimen to the heat-treated surface or the distance from the axis of the test specimen to the heat-treated surface. This ambiguity may cause confusion when taking the test specimens.

For QT steels, strength and toughness is decreasing with increasing distance from heat treatment surface.
The mechanical properties of test specimens taken from positions too close to the heat-treated surface may not adequately represent the properties of the ring forging at positions farther from the heat-treated surface. Therefore, the UR needed to accurately reflect this position.

The Charpy V-notch (CVN) impact test is introduced to confirm the quality control of heat treatment processes rather than to evaluate the mechanical properties of forgings. Accordingly, it is proposed to reconsider and clarify the requirements to ensure alignment with this specific purpose.

3. Source/derivation of the proposed IACS Resolution

The revised draft UR was developed referring to the description in section 6.4 of UR W7 and the proposal from IACS members and industry feedback.

ISO 683-2: Heat-treatable steels, alloy steels and free-cutting steels - Part 2: Alloy steels for quenching and tempering.

4. Summary of Changes intended for the revised Resolution:

The requirements for the sampling positions of ring and disc forgings, as well as the Charpy V-notch impact test, have been clarified to ensure a more precise understanding and application.

5. Points of discussions or possible discussions

The discussion on the following technical points was made and achieved full agreement of the members:

Sampling position:
To reflect the mechanical properties of the forged parts more accurately, the specimens for ring and disc forgings with no part of them shall be closer than 12.5mm to any heat-treated surface.

Requirement of Charpy V-notch impact test:
To ensure clarity regarding the special consideration for alternative requirements related to the Charpy V-notch impact test, the purpose of this test, which is to verify the quality control of the heat treatment process for forgings, shall be explicitly included in the description of "special consideration."

UR W8 "Hull and machinery steel castings"

Summary

The current of UR W8 has been revised with following changes:

- New requirements and clarifications regarding test block dimensions

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev.4 (Mar 2024)	15 Mar 2024	1 January 2025
Rev.3 (Mar 2022)	31 Mar 2022	1 July 2023
Rev.2 (May 2004)	May 2004	-
Rev.1 (July 2002)	July 2002	-
NEW (1978)	1978	-

- **Rev.4 (Mar 2024)**

1 Origin of Change:

☒ Suggestion by IACS member
☒ Industry feedback

2 Main Reason for Change:

Due to industry feedback regarding the size and location of the test block arrangements in Rev.3, IACS concluded that there was an urgent need to issue a new revision of UR W8 (Rev. 4) to specifically address the UR W8 requirements for test block size in Clause 6.3, by taking into account industry feedback.

The specific feedback from industry regarding UR W8 Rev.3 test block size is that the test block size (and subsequent weight) required by Clause 6.3 in UR W8 Rev 3 is considered too demanding and, in some cases, impractical for manufacturers to produce.

For quality purposes, it was argued that smaller coupon sizes can adequately represent the casting in the case of most shipboard and machinery castings.

As a whole, industry had opined that the current Clause 6.3 for test blocks is not a practical way forward. The urgent nature of the required revision to modify Clause 6.3 has arisen as shipyards and Class Societies have already invoked UR W8 Rev. 3 to fulfil the IACS implementation cycle and implementation date of 1 July 2023.

3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

4 History of Decisions Made:

- Original proposal to revise IACS UR W8 was agreed in October 2023 after correspondence following the IACS EG/M&W meeting in September 2023.
- IACS members sought direct industry feedback.
- IACS EG/M&W proceeded to modify the UR W8(rev.4) to account for the test block size.
- A new clause was inserted to recognise there may be a need for an alternative test block size (alternative to the new revised standard size), where specific mechanical properties need to be achieved. This may be determined by a variety of means, as per the Rev.4 requirements.
- Seven drafts have been discussed by the group.

5 Other Resolutions Changes:

None

6 Any hinderance to MASS, including any other new technologies:

None.

7 Dates:

Original Proposal	: 02 September 2023	Made by: EG/M&W Member
Panel Approval	: 22 February 2024	Ref: 2335_EMWza
GPG Approval	: 15 March 2024	Ref: 23152bIGg

- **Rev.3 (Mar 2022)**

1 Origin of Change:

☑ Suggestion by IACS EG/M&W Member

2 Main Reason for Change:

IACS UR W8 specifies the requirements for steel castings intended for hull and machinery applications such as stern frames, rudder frames, crankshafts, turbine casings, etc. The last revision was carried out in 2004.

Sampling practice (dimensions) and testing scope (no impact tests required) appear to be not in line with industry practice.

Further, larger scope of cast steel grades in industry has to be evaluated.

3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

4 History of Decisions Made:

Original proposal to revise IACS UR W8 was agreed in January 2019 after correspondence following the IACS EG/MW meeting in September 2018. Seven drafts have been discussed by the group. Discussions took place during the reviews for the items as stated in TB paragraphs 4 and 5.

5 Other Resolutions Changes:

None

6 Any hinderance to MASS, including any other new technologies:

None.

7 Dates:

Original Proposal	: 28 September 2018	(Made by: EG M&W member)
EG/M&W Approval	: 13 January 2022	(Ref: 1807_EMWzh)
GPG Approval	: 31 March 2022	(Ref: 19136_IGd)

Part B. Technical Background

List of Technical Background (TB) documents for UR W8:

Annex 1. **TB for Rev.1 (July 2002)**

See separate TB document in Annex 1.

Annex 2. **TB for Rev.2 (May 2004)**

See separate TB document in Annex 2.

Annex 3. **TB for Rev.3 (Mar 2022)**

See separate TB document in Annex 3.

Annex 4. **TB for Rev.4 (Mar 2024)**

See separate TB document in Annex 4.

Note: *There is no Technical Background (TB) document available for the New (1978).*

Technical Background (TB) document for UR W8 (Rev.1 July 2002)

a) Objective/Scope

The objectives was to revise the existing UR W8 from the viewpoint of the consistency between the requirements and current techniques.

b) Source of Proposed Requirements

This revised draft UR was developed referring to the existing requirements of UR W8 "Hull and machinery steel castings"

c) Points of Discussion

The discussion on the following technical points had been made and achieved full agreement of the members:

Chemical composition: Chemical composition is to be specified according to their applications. Carbon content of steel castings for welded construction is to be max. 0.23% for its weldable quality.

Mechanical properties: Mechanical properties for normal quality steel castings in the original UR are to be applied. No Charpy V-notch impact test is to be required.

Inspection: Regarding requirements on non-destructive tests, IACS Recommendation No.69 which was adopted in 2000 is to be used as a sample of an acceptable standard.

Rectification: Procedure of removal of defect and weld repair is to be in accordance with IACS Recommendation No.69.

Technical Background (TB) document for UR W8 (Rev.2 May 2004)

a) Objective/Scope

The objective was to rationalize all UR Ws procedures on mechanical testing by reference to the new UR W2 (Rev.2, 2003).

b) Source of Proposed Requirements

The revised draft UR was developed referring to the existing requirements of the UR W8 "Hull and machinery steel castings" and the UR W2 "Test specimens and mechanical testing procedures for materials".

c) Points of Discussion

None

Technical Background (TB) document for UR W8 (Rev.3 Mar 2022)

1. Scope and objectives

Some class societies have experienced failures related to castings with inferior mechanical properties, where test coupons show acceptable results, but actual properties are low. Thus there is a need to define parameters for manufacturers to produce castings with acceptable properties and quality.

Define and further clarify appropriate dimensions of the sample for obtaining mechanical properties representative of the product.

UR W8 shall be extended to other steel grades (including steel alloy grades) which are common in industry.

Several industrial standards for steel castings require notch bar impact testing, which are not required according to current UR W8. Consideration was given whether notch bar impact testing should be introduced into UR W8, depending on the application.

2. Engineering background for technical basis and rationale

Designers consider specified mechanical properties as verified by mechanical tests to be representative for the casting itself. However, for castings with higher thickness the actual properties of the cast component are often inferior to those obtained by testing due to the current non-representative test sample design.

Notch bar impact testing is considered to be a suitable measure for control of appropriately performed heat treatment.

C-Mn grades with higher strengths, and alloy steel grades are common in industry. Therefore, it is considered relevant that these castings should be represented within this UR, to have alignment with industry grades.

3. Source/derivation of the proposed IACS Resolution

The following external industry standards were referenced as a source for technical rationale and preparation of this UR:

- ISO 4990:2015 – "General technical delivery requirements"
- EN 10293:2015 – "Steel castings - Steel castings for general engineering uses"
- ISO 683-1:2016 – "Heat-treatable steels, alloy steels and free-cutting steels - Part 1: Non-alloy steels for quenching and tempering"
- ISO 683-2:2016 – "Heat-treatable steels, alloy steels and free-cutting steels - Part 2: Alloy steels for quenching and tempering"
- ISO 148-1:2016 – "Metallic materials — Charpy pendulum impact test — Part 1: Test method"

4. Summary of Changes intended for the revised Resolution:

a) Addition of requirements for representative sample with dimensions representative for the ruling section of the casting. Requirements for the test block for alloy castings are added.

b) Extension of UR W8 to C-Mn grades for castings for hull and machinery with higher specified min. strengths than currently Rm = 600 MPa and Rp = 320 MPa. Extension of UR W8 to alloy grades for castings for hull and machinery.

c) Implementation of relevant requirements for chemical composition and tensile properties.

d) A differentiation in mechanical property requirements between castings 'intended for welding' and those 'not intended for welding' (this has resulted in additional tables being inserted into this UR)

e) Implementation of impact test requirements. Ambient temperature was introduced to be 23°C±5°C as per ISO 148-1:2016.

f) For welding of cast steels for hull construction and marine structures references to UR W28 and UR W32, as well as recommendation for consideration of carbon equivalent Ceq were added. Requirements for temporary welds are added.

g) Requirements for rectification for grinding and for repair welding added.

h) IACS Rec. No.69 is referred to as an example of an acceptable standard for requirements for NDT.

5. Points of discussions or possible discussions

In addition to the items under paragraph 4, the following items were discussed:

Due to the variety of possible national/international standards it was agreed to set up tensile test requirements and impact test requirements which were deduced from EN 10293 "Steel castings - Steel castings for general engineering uses".

Condition "fully annealed" for C-Mn castings was agreed to be kept.
For alloy castings it was agreed that the condition "fully annealed" is not applicable.

6. Attachments if any:

None.

Technical Background (TB) document for UR W8 (Rev.4 Mar 2024)

1. Scope and objectives

- Develop practical requirements for representative quality test coupon size based upon critical casting cross section and material.
- Edit existing clause 6.3 and update where necessary, by preparing a new draft Rev.4.

2. Engineering background for technical basis and rationale

The test results represent the material from which the castings poured and the subsequent heat treatment process and may not necessarily represent the properties of the castings.
These properties can be affected by solidification conditions and the rate of cooling during heat treatment, which are in turn influenced by casting thickness, size, complexity and shape.
The purpose of the test bock is to provide a qualitative check to demonstrate the effective control of existing heat treatment processes and procedures.

Also, the feedback from industry regarding UR W8 Rev.3 test block size is that the test block size (and subsequent weight) required by Clause 6.3 in UR W8 Rev 3 is too demanding and impractical for manufacturers to produce.

In light of the above, UR W8 Rev.3, Clause 6 was updated.

3. Source/derivation of the proposed IACS Resolution

The following external industry standards were referenced as a source for technical rationale and preparation of this UR:

- ISO 4990:2023 – "General technical delivery requirements"
- ISO 4885,2018 – "Ferrous materials -- Heat treatments -- Vocabulary"
- EN 10293:2015 – "Steel castings - Steel castings for general engineering uses"
- ISO 683-1:2016 – "Heat-treatable steels, alloy steels and free-cutting steels - Part 1: Non-alloy steels for quenching and tempering"
- ISO 683-2:2016 – "Heat-treatable steels, alloy steels and free-cutting steels - Part 2: Alloy steels for quenching and tempering"

4. Summary of Changes intended for the revised Resolution:

- Change in requirements for test block size.
- Providing requirements for an alternative regime or test block size, where certain applications may need specific properties to be achieved and demonstrated.
- Making reference to the casting ruling section in a variety of standards, to support alternative test block size.
- In addition, for determination of alternative test block sizes, recognition of supporting data from a variety of means, e.g. by historical and statistical test data, production of a representative test block or a component, simulation software, or a combination of these items

5. Points of discussions or possible discussions

- Test block size requirements (UR W8, Clause 6.3)
- Recognising industry feedback on the limitations of Rev.3 test block requirements, and establishing an acceptable quality regime for Rev.4.
- Establishing a suitable, practical and agreed test block size (and location) for applications where specific mechanical properties need to be achieved.

6. Attachments if any:

None.

UR W9 "Grey iron castings or flake graphite iron castings"

Summary

This latest revision (revision 3) of IACS UR W9 seeks to align and harmonise the requirements for specifying the properties of unalloyed and low-alloyed grey cast irons with international standards consistent with industry practice.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev.3 (Feb 2025)	4 February 2025	1 January 2027
Rev.2 (May 2004)	May 2004	1 January 2005
Rev.1 (1995)	No record	No record
1978	No record	No record

- ### Rev. 3 (Feb 2025)

1 Origin of Change:

Select a relevant option and delete the rest.

- Other *(Specify: Industry best practice and feedback from industry)*
- Based on Other Standard (Specify: ISO 185, ISO 945-1 and EN 1561)

2 Main Reason for Change:

- Current UR W9 has not been updated since 2004, however the technology and recommended best practices used in the iron casting industry has advanced.
- This revision seeks to align the UR W9 scope and requirements to reflect current industry practice. This is also to ensure strong alignment with international standards such as ISO 185 consistent with most foundry datasheets for grey iron castings.
- To provide a unified requirement for the approval of the manufacture of grey iron castings.

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None.

4 History of Decisions Made:

1. Reference is made to GPG email dated 25 April 2023. In response to the request made from GPG, all Members agreed with the draft Form A of the task to be carried out by the EG to revise UR W9 (Rev.2 May 2004): Grey iron castings.

2. One member proposed to add the bullet point "Industry feedback" in the 'Objectives' section in line with the 'Background' section. The proposal is considered reasonable and acceptable to all Members.

3. Task leader was therefore requested to prepare 1st draft revision UR W9 (EG/M&W task 2309).

4. Six drafts have been presented which were reviewed by members.

5. Summary of topics that have been revised and updated during this task:

   - Revision to the UR scope to improve clarity and the intended application of the grey iron casting grades.
   - UR document title changed to: 'Grey iron castings or flake graphite iron castings'.
   - Provision of acceptable methods for removing surplus materials from the castings including suitable thermal cutting processes consistent with recognised best practices.
   - Provision of suitable heat treatment requirements.
   - Provision of definitions of test block types, shape and dimension for mechanical tests including re-test requirements for test pieces.
   - Provision of mechanical properties for test specimens machined from cast test blocks.
   - Provision of new paragraph on the requirements for metallographic examination.
   - Provision of additional requirements for the inspection and rectification of defective castings, identification of castings as well as certification.

5 Other Resolutions Changes:

None

6 Any hinderance to MASS, including any other new technologies:

None.

7 Dates:

Original Proposal:	23 April 2023	Made by: EG M&W

Part B. Technical Background

List of Technical Background (TB) documents for UR W9:

Annex 1. **TB for Rev. 2 (May 2004)**

See separate TB document in Annex 1.

Annex 2. **TB for Rev.3 (Feb 2025)**

See separate TB document in Annex 2.

Annex 1: Technical Background (TB) document for UR W9 (Rev.2 May 2004)

1. Scope and objectives

The objective was to rationalize all UR Ws procedures on mechanical testing by reference to the new UR W2 (Rev.2, 2003).

2. Source of Proposed Requirements

The revised draft UR was developed referring to the existing requirements of the UR W9 'Grey iron castings' and the UR W2 'Test specimens and mechanical testing procedures for materials'.

3. Resolution Points of Discussion

Nil

Annex 2: Technical Background (TB) document for UR W9 (Rev.3 Feb 2025)

1. Scope and objectives

A holistic change to IACS UR W9 was required to ensure strong alignment with the latest technology advancements in the iron casting industry and the accompanying international standards governing these materials.
The current provisions in the UR W9 are not fully aligned with the advancements in industry practices and were considered unsuitable by industry.

The objectives of the current revisions were;

- Develop a unified approach for the approval of grey iron castings carried out by each Classification Society.
- Unify the requirements for the material properties, the test block type with the accompanying dimensions and inspection of grey iron castings in order to meet the industry specification.

2. Engineering background for technical basis and rationale

Apart from the significant role the test block plays in providing qualitative checks to demonstrate effective control of heat treatment processes and procedures, the choice of test block type and dimension also play significant role in determining the mechanical properties of castings. There is therefore the need to provide a unified requirement for classification, to ensure quality in the manufacture and testing of iron castings which are fit for purpose and acceptable to industry.

Regarding the scope of application, the grey iron castings are commonly intended for use in machinery components and piping fittings. The grey iron castings are generally not intended for use in hull structure for ships, offshore units and low temperature service applications due to their lower toughness.

Within the scope mentioned above, the requirements focussed specifically on the manufacturing process, chemical and mechanical properties, sampling and test frequency, surface and internal soundness, inspection for production test and metallographic examination. These have all been revised, reflective of the latest international standards.

The revised W9 (Rev. 3) has now the unified requirements on grey iron castings to meet the needs of marine, offshore and the cast iron industry.

3. Source/derivation of the proposed IACS Resolution

Marine, offshore and iron casting industry use the international material standard for grey iron castings such as:

- ISO 185:2020 - Grey cast irons – Classification
- EN 1560:2011 - Founding - Designation system for cast iron - Material symbols and material numbers
- EN 1561:2023 - Founding - Grey cast irons
- ISO 945-1:2019 - Microstructure of cast irons Part 1: Graphite classification by visual analysis

4. Summary of Changes intended for the revised Resolution:

This is a full revision of the UR which introduces the following major changes that reflect advances in iron casting foundry technologies and quality assurance in product testing, and in manufacturing process approval, in particular the elements of relevant international standards;

- Scope of application and product form
- Manufacturing and heat treatment process
- Chemical composition
- Test block dimensioning and mechanical tests.
- Mechanical properties: Tensile strength and acceptance criteria
- Metallographic examination
- Inspection test procedure
- Surface quality and defect rectification
- Identification of castings and certification

5. Points of discussions or possible discussions

During the development the main discussion points were;

- Visual inspection and verification of dimensions should be the responsibility of the manufacturer. The castings accepted by the manufacturer and which are subject to certification by the Society shall additionally be presented to the Surveyor for visual examination before final acceptance.
- Where the product is to be certified by the Society, the Surveyor is to be given the opportunity to witness these tests.
- Proposal to give an opening for Class Society to request microstructural examination.
- Several types of test blocks (separately cast test blocks, side-by-side cast test blocks, cast-on test blocks) can be used.
- Test block dimensions and the test block type shall be agreed upon between the manufacturer and the purchaser. The UR provides the minimum specific values for standardized 30 mm test block. However, the minimum specific values for other size test blocks need to be agreed by the Classification Society.
- It is the responsibility of the manufacturer to ensure that heat treatment is suitable to obtain the mechanical properties for the material grade specified. However, the surveyors must be satisfied with the proposed heat treatment procedure, and for large castings, alternative heat treatment methods may be considered by the Classification Society.

6. Attachments if any

None.

UR W10 "Spheroidal graphite iron castings or ductile iron castings"

Summary

This latest revision (revision 3) of IACS UR W10 seeks to align and harmonise the requirements for specifying the properties of spheroidal graphite or ductile cast irons with international standards consistent with industry practice.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev. 3 (Feb 2025)	3 February 2025	1 January 2027
Rev.2 (May 2004)	May 2004	1 January 2005
Rev.1 (1995)	No record	No record
New (1978)	No record	No record

- **Rev. 3 (Feb 2025)**

1 Origin of Change:

Select a relevant option and delete the rest.

- Other *(Specify: Industry best practice and feedback from industry)*
- Based on Other Standard (Specify: ISO 1083, ISO 945-1 and ISO 945-4)

2 Main Reason for Change:

- Current UR W10 has not been updated since 2004, however the technology and recommended best practices used in the iron casting industry has advanced.
- This revision seeks to align the UR W10 scope and requirements to reflect current industry practice. This is also to ensure strong alignment with international standards such as ISO 1083 and ISO 945 (various parts), consistent with most foundry datasheets for spheroidal graphite iron castings.
- To provide a unified requirement for the approval of the manufacture of spheroidal graphite iron castings.

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None.

4 History of Decisions Made:

1. Reference is made to GPG email dated 25 April 2023. In response to the request made from GPG, all Members agreed with the draft Form A of the task to be

carried out by the EG to revise UR W10 (Rev.2 May 2004): Spheroidal or nodular graphite iron castings.

2. One member proposed to add the bullet point "Industry feedback" in the 'Objectives' section in line with the 'Background' section. The proposal is considered reasonable and acceptable to all Members.

3. Task leader was therefore requested to prepare 1st draft revision UR W10 (EG/M&W task 2310).

4. Seven drafts have been presented which were reviewed by members.

5. Summary of topics that have been revised and updated during this task:

   - Revision to the UR scope to improve clarity and the intended application of the spheroidal graphite iron casting grades.
   - UR document title changed to: 'Spheroidal graphite iron castings or ductile iron castings'.
   - Provision of acceptable methods for removing surplus materials from the castings including suitable thermal cutting processes consistent with recognised best practices.
   - Provision of suitable heat treatment requirements.
   - Provision of test block types, shape and dimension for mechanical tests including re-test requirements for test pieces.
   - Provision of mechanical properties for test specimens machined from cast test blocks.
   - Provision of new paragraph on the requirements for metallographic examination, including the minimum level of graphite nodularity.
   - Provision of additional requirements for the inspection and rectification of defective castings, identification of castings as well as certification.

5 Other Resolutions Changes:

None

6 Any hinderance to MASS, including any other new technologies:

None.

Part B. Technical Background

List of Technical Background (TB) documents for UR W10:

Annex 1. **TB for Rev. 2 (May 2004)**

See separate TB document in Annex 1.

Annex 2. **TB for Rev.3 (Feb 2025)**

See separate TB document in Annex 2.

Annex 1: Technical Background (TB) document for UR W10 (Rev.2 May 2004)

1. Scope and objectives

The objective was to rationalize all UR Ws procedures on mechanical testing by reference to the new UR W2 (Rev.2, 2003).

2. Source of Proposed Requirements

The revised draft UR was developed referring to the existing requirements of the 'UR W10 Spheroidal or nodular graphite iron castings' and the UR W2 'Test specimens and mechanical testing procedures for materials'.

3. Resolution Points of Discussion

Nil

Annex 2: Technical Background (TB) document for UR W10 (Rev.3 Feb 2025)

1. Scope and objectives

A holistic change to IACS UR W10 was required to ensure strong alignment with the latest technology advancements in the iron casting industry and the accompanying international standards governing these materials.
The current provisions in the UR W10 are not fully aligned with the advancements in industry practices and were considered unsuitable by industry.

The objectives of the current revisions were to;

- Develop a unified approach for the approval of spheroidal graphite iron castings carried out by each Classification Society.
- Unify the requirements for the material properties, the test block type with the accompanying dimensions and inspection of spheroidal graphite iron castings in order to meet the industry specification.

2. Engineering background for technical basis and rationale

Apart from the significant role the test block plays in providing qualitative checks to demonstrate effective control of heat treatment processes and procedures, the choice of test block type and dimension also play significant role in determining the mechanical properties of castings. There is therefore the need to provide a unified requirement for classification, to ensure quality in the manufacture and testing of iron castings which are fit for purpose and acceptable to industry.

Regarding the scope of application, the spheroidal graphite iron castings are commonly intended for use in machinery components and piping fittings. The spheroidal graphite iron castings are generally not intended for use in hull structure for ships and offshore units service applications.

Within the scope mentioned above, the requirements focussed specifically on the manufacturing process, chemical and mechanical properties, sampling and test frequency, surface and internal soundness, inspection for production test and metallographic examination. These have all been revised, reflective of the latest international standards.

The revised W10 (Rev. 3) has now revised the unified requirements on spheroidal graphite iron castings to meet the needs of marine, offshore and the cast iron industry.

3. Source/derivation of the proposed IACS Resolution

Marine, offshore and iron casting industry use the international material standard for grey iron castings such as:

- ISO 945-1:2019 - Microstructure of cast irons Part 1: Graphite classification by visual analysis
- ISO 945-4:2019 - Microstructure of cast irons Part 4: Test method for evaluating nodularity in spheroidal graphite cast irons.
- EN 1083:2018 - Spheroidal graphite cast irons — Classification

4. Summary of Changes intended for the revised Resolution:

This is a full revision of the UR which introduces the following major changes that reflect advances in iron casting foundry technologies and quality assurance in product testing, and in manufacturing process approval, in particular the elements of relevant international standards;

- Scope of application and product form
- Manufacturing and heat treatment process
- Chemical composition
- Test block dimensioning and mechanical tests.
- Mechanical properties: Tensile strength and acceptance criteria
- Metallographic examination
- Inspection test procedure
- Surface quality and defect rectification
- Identification of castings and certification

5. Points of discussions or possible discussions

During the development the main discussion points were;

- Visual inspection and verification of dimensions should be the responsibility of the manufacturer. The castings accepted by the manufacturer and which are subject to certification by the Society shall additionally be presented to the Surveyor for visual examination before final acceptance.
- Where the product is to be certified by the Society, the Surveyor is to be given the opportunity to witness these tests.
- Proposal to give an opening for Class Society to request microstructural examination.
- Several types of test blocks (separately cast test blocks, side-by-side cast test blocks, cast-on test blocks) can be used.
- Test block dimensions and the test block type shall be agreed upon between the manufacturer and the purchaser. The UR provides the minimum specific values for standardized 30 mm test block. However, the minimum specific values for other size test blocks need to be agreed by the Classification Society.
- It is the responsibility of the manufacturer to ensure that heat treatment is suitable to obtain the mechanical properties for the material grade specified. However, the surveyors must be satisfied with the proposed heat treatment procedure, and for large castings, alternative heat treatment methods may be considered by the Classification Society.
- Discussions and agreement on the microstructure, and graphite nodularity minimum levels.

NEW (1979)	*No record*	-

- ### Rev 9 (May 2017)

.1 Origin for Change:

☑ Suggestion by an IACS member

.2 Main Reason for Change:

The main change relates to the incorporation of IACS Rec 12 into UR W11. The reason for this is to introduce requirements for surface quality of plates supplied to shipyards. Other changes consist of a review of the definitions of steel delivery conditions against current industry standards, and a revision to table 9 with consistent requirements for plates and sections made in steel grades A32, A36 refined with Al alone or with Ti.

.3 List of non-IACS Member Classification Societies contributing through the TC Forum and/or participating in IACS Working Group:

None.

.4 History of Decisions Made:

Original proposal to revise UR W11 to review delivery conditions was made at IACS EG/MW meeting in November 2012. Form A with task Number EMW1308 was agreed by GPG in January 2014. Additional proposal to revise UR W11 was to include IACS Recommendation 12 into the UR W11. Form A with task number EMW1410 was agreed by GPG in December 2014. The group decided to merge the two tasks into EMW1410 with the agreement of GPG in October 2015. Four drafts have been discussed by the group, final draft was agreed by EGMW in March 2017.

.5 Other Resolutions Changes

IACS Rec 12 to be deleted.

.6 Dates:

Original Proposal: January 2014 Made by: an IACS Member
EG M&W Approval: March 2017
GPG Approval: 19 May 2017 (Ref: 14167_IGh)

• Rev 8 (Apr 2014)

.1 Origin for Change:

☐ Suggestion by an IACS member

.2 Main Reason for Change:

This change relates to the incorporation of IACS UR W30 into UR W11. The reason for this is that the majority of UR W30 refers back to UR W11 and it has been decided that it is more logical to add the relatively small number of differences into W11 and have avoid the need to cross referencing to other UR documents.

.3 List of non-IACS Member Classification Societies contributing through the TC Forum and/or participating in IACS Working Group:

None.

.4 History of Decisions Made:

Original proposal was made at IACS EG/MW meeting in November 2012. Form A – with task Number EMW1301 was agreed by GPG. First draft was completed in September 2013. Final draft was agreed by EGMW in March 2014.

.5 Other Resolutions Changes

IACS UR W30 to be deleted.

.6 Dates:

Original Proposal: March 2014 Made by: an IACS Member
EG M&W Approval: March 2014
GPG Approval: 30 April 2014 (Ref: 10105_IGq)

IACS Unified Requirement W11 (Rev.3, 2000.)

Normal and higher strength hull structural steels

Technical Backgrounds:

a) Objective/Scope

The objective was to introduce the “manufacturer’s responsibility concept” to the existing UR W11, from the viewpoint of production control in order to secure the more uniformed quality of hull steel products.

b) Source of Proposed Requirements

This revised draft UR was developed referring to the existing requirements of UR W11 “Normal and higher strength hull structural steels”(Rev.2).

c) Points of Discussion

The discussion had been mainly made on the following technical points and achieved full agreement of the members:

<u>Manufacturer’s responsibility concept</u>;

The manufacturer’s responsibility concept is to be specified in the revised Clauses 2.2 and 3.3, which require that:

- Manufacturer is to control and assure the in-operation processes and production conditions.
- Where deviation from the controls and/or inferior quality of the products were found, the manufacturer is required to take further measures to the Surveyor’s satisfaction.

<u>Definition of the rolling procedures</u>;

As conventional rolling and heat treatment procedures, “As rolled (AR)” and “Normalising (N)”, are to be newly defined in the revised Clause 3.3 in order to cover all the procedures that apply to the present production of hull steels.

—

TB

IACS Unified Requirement W11 (Rev.4 May 2001)

Normal and higher strength hull structural steels

Technical Backgrounds:

a) Objective/Scope

The objective was to develop the "manufacturing approval scheme of hull structural steels" as an Appendix of UR W11, from the viewpoint of production control to secure more uniformed quality of hull steel products.

b) Source of Proposed Requirements

The above Appendix was developed to supplement the relative requirements of UR W11 "Normal and higher strength hull structural steels" (Rev. 3).

c) Points of Discussion

The discussion on the following technical points had been made and achieved full agreement of the members:

<u>Manufacturing approval</u>;
The manufacturing approval scheme is valid for verifying the manufacturer's capability to produce satisfactory products stably.

<u>Manufacturing documents</u>;
Where the programmed rolling (CR or TM) is applied, the technical details of rolling practice are to be reviewed, in addition to general documents relevant to the outline of steel works, manufacturing facilities, manufacturing process, quality control, etc.

<u>Approval tests</u>;
Test program should be confirmed before testing. For grades E, AH, DH and EH, weldability tests are to be additionally carried out. In case of new type of steels, conformable tests may be required to evaluate their quality and properties.

<u>Approval documentation</u>;
The validity of the approval is to be a maximum of five years. Renewal can be carried out by audit and assessment. The approval is to be re-considered where the major problems on manufacturing process or finished products are found.

Remark: GPG 50 (March 2001) expressed its concern over a possible lack of uniformity in practice with reference to renewal of approval in para.6 of Appendix A. At the request of GPG, WP Chair came up with an explanatory note to the second sentence of para.6.

GPG/Council agreed that the revision history in the Note to Appendix B, should be deleted from UR W 11 and added to the TB on 11 May 2001. See the annex.

* * * * *

Annex: Revision history of W 11

Revision History of UR W 11

These requirements were first adopted as
UR.1 Requirements for Hull Structural Steels (1959) and
UR.12 Requirements for High Tensile Hull Structural Steels (1971)
These were subsequently revised to incorporate S1 units and were adopted as
UR 128 Normal Strength Hull Structural Steel (1977) and
UR 132 Requirements for High Tensile Hull Structural Steel (1977).

In 1979 these requirements were further revised and combined as UR 162 which was subsequently re-printed and issued as Unified Requirement W11.

In 1994, these requirements were revised on the basis of the contents of
W11. Normal and higher strength hull structural steels
W19. Normal and higher strength hull structural steel grades E and E36 with thickness above 50 up to 100 mm.
W20. Higher strength hull structural steels with a minimum yield strength of 390 N/mm2 and
W21. Hull structural steels for low temperature application and reissued as Unified Requirement W11.

* * * * *

Technical background
IACS Unified Requirement W11 (Rev. 5)

Normal and higher strength hull structural steels

Technical Backgrounds:

a) Objective/Scope

The objectives were as follows:

1. To amend the requirement concerning manufacturer's responsibility in order to remove the reservation lodged by ABS.
2. To develop the requirements in the existing UR W11 for grades AH40, DH40, EH40 and grades FH hull structural steel plates with thickness over 50mm up to 100mm.

b) Source of Proposed Requirements

This revised draft UR was developed referring to the existing requirements of UR W11 "Normal and higher strength hull structural steels" (Rev. 4).

c) Points of Discussion

The discussion on the following technical points had been made and achieved full agreement of the members:

<u>Manufacturer's responsibility</u>;
Where imperfection of process and production controls occurs, the manufacturer is to identify the cause and establish a countermeasure to prevent its recurrence.

<u>Definition of heat treatment process</u>;
Heat treatment process "Quenching and Tempering (QT)" is also to be defined in clause 3.3 and Appendix B as well.

<u>Chemical composition</u>;
Maximum carbon equivalent is to be specified for the grades concerned according to each strength level.

<u>Type of applicable heat treatment</u>;
Applicable heat treatments, i.e. Normalizing, Thermo-Mechanical Rolling and Quenching and Tempering are to be specified for the grades concerned.

<u>Toughness requirement</u>;
Minimum average impact energy is to be specified for each the grade concerned according to the range of thickness. In addition, the above energy values for HT40 grades with thickness up to 50mm are to be modified from the viewpoint of well-balanced toughness requirement.

<u>Number of impact test specimens</u>;
Batch size of impact test for each the grade concerned is to be specified respectively according to the heat treatment applied.

Annex : Revision history of UR W11

Annex

Revision History of UR W11

These requirements were first adopted as
UR.1 “Requirements for Hull Structural Steels” (1959) and
UR.12 “Requirements for High Tensile Hull Structural Steels” (1971)

These were subsequently revised to incorporate S1 units and were adopted as
UR 128 “Normal Strength Hull Structural Steel” (1977) and
UR 132 “Requirements for High Tensile Hull Structural Steel” (1977).

In 1979, these requirements were further revised and combined as UR 162, which was subsequently re-printed and issued as Unified Requirement W11.

In 1994, these requirements were revised on the basis of the contents of
W11 “Normal and higher strength hull structural steels”
W19 “Normal and higher strength hull structural steel grades E and E36 with thickness above 50 up to 100 mm”
W20 “Higher strength hull structural steels with a minimum yield strength of 390 N/mm^2” and
W21 “Hull structural steels for low temperature application”
and reissued as Unified Requirement W11.

* * * *

submitted by WP/MCH to GPG 52, 12-15 March 2002

IACS Unified Requirement W11 (Rev.6)
Technical Background

Normal and higher strength hull structural steels

a) Objective/Scope

The objective were as follows:

1. To rationalize all UR Ws procedures on mechanical testing by reference to the new UR W2 (Rev.2, 2003).
2. To develop a manufacturing approval scheme of hull structural steels welded with high heat input as an Appendix of UR W11.

b) Source of Proposed Requirements

The revised draft UR was developed referring to the existing requirements of the UR W2 "Test specimens and mechanical testing procedures for materials" and the UR W11 "Normal and higher strength hull structural steels" including the Appendix A "Manufacturing approval scheme of hull structural steels".

c) Points of Discussion

The discussion on the following technical points for the above a) objective/Scope 2 had been made and achieved full agreement of the members:

<u>Scope</u>;

The approval scheme specifies weldability confirmation scheme of hull structural steels intended for welding with high heat input over 50kJ/cm and is valid for certifying that the steels have satisfactory weldability for high heat input welding concerned under testing conditions. This approval scheme is to be generally applied by manufacturer's option and does not apply to qualification of welding procedures to be undertaken by the shipyards.

<u>Range of certification</u>;

Range of certification for steel grades is to be specified with the following key concepts:

- Approval tests on the lowest and highest toughness levels cover the intermediate toughness level.
- Approval tests on normal strength level cover that strength level only.
- For higher tensile steels, approval tests on one strength level cover strength level immediately below.

<u>Test plate</u>;

For each manufacturing process route, two test plates with different thickness (t and less than or equal to t/2) proposed by the manufacturer are to be selected.

<u>Charpy V-notch Impact test</u>;

Requirements for notch location, test temperature and average impact energy are to be the same as those specified for base metal, i.e. the requirements of the UR W11 including the Appendix A.

<u>Certification</u>;

The Classification Society issues the certificate to the manufacturer (steel mill), including the information of steel grade designation with notation of heat input, manufacturing process, plate thickness tested and welding conditions etc.

<u>Grade designation</u>;

Upon issuance of the certificate, the notation indicating the value of heat input applied in the confirmation test may be added to the grade designation of the test plate, e.g. "E36-W300" (in the case of heat input 300kJ/cm applied).

* * * *

TECHNICAL BACKGROUND OF UR W11 (REV.7, APRIL 2008)

1. Scope and objective

To develop procedures for the approval of manufacturers of semi finished products intended for subsequent rolling at approved steel mills into ship steel plate, sections and bars.

2. Background

There has been a considerable increase in the number of cases where non-approved manufacturers have produced and supplied semi-finished products which have been subsequently rolled by approved manufacturers, no unified requirement exists to cover this situation. Different class societies deal with such manufacturers in different ways. Issues of quality variation have also been noted in the semi-finished products delivered.

The approved manufacturers would prefer a unified approach and in is therefore proposed to develop the requirements for approval of steel slabs and for approval of rolled steels using the slabs as an amendment to UR W11 Appendix A.

3. Points of discussions

The project team found common ground on the procedures to be followed.

Discussion on the necessary links between the manufacturer of the semi-finished product and the subsequent manufacturer of the rolled steel product provided more varied debate. The outcome agreed being a simple approach of approving a semi-finished manufacturer in isolation, allowing supply after approval to all approved finishing mills. One society had a strong view that both manufacturers should have a fixed link, it was agreed that this latter approach could be applied by the individual society within its own Rules as their enhanced requirement.

A number of points were raised by the Hull Panel on the first draft submitted. These were reviewed by PT2 and where appropriate amendments made or reasons for rejecting the suggestions given.

4. Amendment.

The Hull Panel and its PT2 agreed to revise UR W11 Appendix A to include the necessary procedures for the "approval of manufacturers semi finished products" and define the necessary links with approved manufacturers of rolled steels products.

5. Source/Derivation of proposed interpretation

N.A.

6. Decision by voting

N.A.

Submitted by Hull Panel Chairman
14 March 2008

Permanent Secretariat note, May 2008:
UR W11 Rev. 7 was approved by GPG on 3 April 2008, ref. 8554_IGb.

Interpretation given to POSCO on UR W11 (Jan 2012)

(i) Question:
In the description of the AR process, does the word "typically" indicate that the temperature condition is recommended or compulsory? POSCO believes that it does not compel any temperature control in the AR process as described in EN10025-2. Please advise the exact meaning.

You are correct in your assumption that the "as rolled" IACS definition does not imply any form of temperature control. The word "typically" indicates neither a recommendation nor a compulsory requirement. It rather indicates the same as the description given in the EN 10025-2, i.e. there is no strict control of the rolling temperature.

(ii) Question:
Please advise the proper finishing rolling temperature for the chemical composition provided.

Classification Societies are not in a position to specify the finishing rolling temperature to be applied. It is the responsibility of the steel mill to determine the finishing rolling temperature based on the local processes and well known metallurgical effects.

The role of Classification Societies is to approve different material grades based on approval testing and review of documentation, e.g. rolling schedule, and make sure that the Classification Rules are complied with. The finishing rolling temperature for the "as rolled" process is part of the manufacturer's rolling process, which is to be documented at approval stage per UR W11, Appendix A2, Article 2.1(g).

(Ref: 11161_IGd dated 20th January 2012)

Technical Background (TB) document for UR W11 (Rev. 8, Apr 2014)

1. Scope and objectives

UR W30 was previously introduced in relation to approval and certification of corrosion resistant steel in accordance with MSC.289 (87) of Regulation 3-11, Part A-1, Chapter II-1 of the SOLAS Convention (Corrosion protection of cargo oil tanks of crude oil tankers). Based upon the level of repetition and cross references to UR W11, and to avoid unnecessary complication, the requirements of UR W30 have been incorporated into W11 to have all identical requirements in the same location.

2. Engineering background for technical basis and rationale

The general requirements of UR W30 are identical to those of UR W11. To avoid unnecessary duplication and the potential of failing to update both UR documents as appropriate in the future, the unique requirements related to corrosion resistant steel have been added to UR W11.

3. Source/derivation of the proposed IACS Resolution

Documents relevant to these changes are:

- IACS UR W30: Normal and higher strength corrosion resistant steels for cargo oil tanks

4. Summary of Changes intended for the revised Resolution:

The changes added to W11 are summarised as follows:

- References to MSC.289 (87) of Regulation 3-11, Part A-1, Chapter II-1 of the SOLAS Convention (Corrosion protection of cargo oil tanks of crude oil tankers) an scope of thickness applicable to corrosion resistant steel
- Definition of corrosion resistant steel grading
- Additional certification requirements
- Addition of Annex C which specifies the requirements for manufacturer approval of corrosion resistant steel.

5. Points of discussions or possible discussions

Due to this revision incorporating all requirements of UR W30 into UR W11 without any change in technical content there are no relevant points for discussion associated with this revision.

6. Attachments, if any

None

Technical Background (TB) document for UR W11 (Rev.9 May 2017)

1. Scope and objectives

To review and amend the definitions of steel delivery conditions used in UR W11 against current industry standards.
To develop the appropriate requirements for surface quality of plates in order to include the IACS Recommendation 12 into the UR W11.
To revise table 9 to have consistent requirements for plates and sections made in steel grades A32, A36 refined with Al alone or with Ti.

2. Engineering background for technical basis and rationale

Permitted rolling procedures are defined within UR W11 section 3.3 in the following ways: As Rolled (AR), Normalised (N), Controlled Rolled (CR) / Normalized Rolled (NR), Quench and Tempered (QT), and Thermo-Mechanically Rolled (TM) / Thermo-Mechanically Controlled Processed (TMCP).
The definitions for AR and CR/NR are no longer found to represent the definitions that are widely used in the steelmaking industry resulting in approval and certification of steels that do not comply with the definitions in UR W11.
Based upon the above there is a need to review the IACS definitions of all rolling procedure against the definitions commonly used in industry and modify UR W11 as appropriate.

Sometimes dispute occurs over the surface quality of plate supplied to shipyards. Therefore it is found necessary to harmonise the requirements to include the surface quality given in Rec 12 into URW11. To make clear what surface imperfections are considered as defects, and identify the permissible extent of surface imperfections. Identify that the manufacturer is responsible for the surface quality.
Indicate the allowable repair techniques.

3. Source / derivation of the proposed IACS Resolution

Reference is made to IACS Recommendation 12 "Guidelines for Surface Finish of Hot Rolled Steel Plates and Wide Flats".

4. Summary of Changes intended for the revised Resolution

The definitions of steel delivery conditions As Rolled, Normalising, Controlled Rolling, Quenching and Tempering have been reviewed and updated. The diagram of Thermo-Mechanical and Conventional Processes has been amended. The article 7 "Surface quality" has been added to the UR W11.
Table 9 has been revised to align requirements for plates and sections made in steel grades A32, A36 refined with Al alone or with Ti.

5. Points of discussions or possible discussions

The definitions of steel delivery conditions were discussed and agreed with general consensus of the group. Discussions took place about the need to keep the internal soundness requirements as they are in the URW11 and the group concluded positively. The group discussed the permissible limits for imperfections and decided to refer to the Class A of the standard EN 10163-2 while allowing to refer to a recognised equivalent standard.

6. Attachments if any

Nil.

UR W13 "Thickness tolerances of steel plates and wide flats"

Summary

Review and update industry standards format according to GPG instructions

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev.7 (Sep 2021)	21 September 2021	1 January 2023
Rev.6 (June 2018)	06 June 2018	1 July 2019
Corr.1 (May 2012)	22 May 2012	-
Rev.5 (Feb 2012)	02 February 2012	1 January 2013
Rev.4 (Oct 2009)	2 October 2009	1 January 2011
Rev.3 (1995)	1995	-
Rev.2 (1992)	1992	-
Rev.1 (1989)	1989	-
New (1981)	1981	-

- **Rev.7 (Sep 2021)**

1 Origin of Change:

☒ Suggestion by IACS member

2 Main Reason for Change:

To update industry standards format according to GPG instructions given in GPG Vice-chair message 19000_IRC.

3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None.

4 History of Decisions Made:

Original proposal was made according to GPG Vice-chair message 19000_IRc. Proposal to revise the IACS URs and RECs only to refer to a dated version of the industry standard as per GPG instructions was made at IACS EG/MW meeting in September 2019. Three drafts have been discussed by the group.

5 Other Resolutions Changes:

None.

6 Any hinderance to MASS, including any other new technologies:

None.

7 Dates:

Original Proposal : April 2019Made by: GPG
EG M&W Approval : July 2021
GPG Approval : 21 September 2021 (Ref: 19000_IGq)

- **Rev.6 (June 2018)**

.1 Origin for Change:

☑ Alignment and consistency with UR W16.

.2 Main Reason for Change:

After UR W16 having been revised, UR W13 needed amendment for consistency with UR W16. Increased steel plate thickness up to, and exceeding 250 mm has to be covered. The class of minus tolerances for the steel grades in the scope of UR W16 needed to be treated. Further minor changes were needed.

.3 List of non-IACS Member Classification Societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

The EG M&W decided that this UR is not applicable to lifting appliances.

.5 Other Resolutions Changes

None.

.6 Dates:

Original Proposal : December 2016
EG M&W Approval : 11 May 2018 (Ref: EMW1605)
GPG Approval : 06 June 2018 (16172aIGe)

Corr.1 (May 2012)

.1 Origin for Change:

☑ Suggestion by Hull Panel Chairman

.2 Main Reason for Change:

To correct a Typographical error - in Section W13.1.3, the reference to 'Table B.2' in ISO 7452 should be changed to 'Table 2'.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

Hull panel pointed out this error. PermSec made editorial change in the text. Since the correction was of purely editorial in nature, a separate technical background document was not prepared.

.5 Other Resolutions Changes

None

.6 Dates:

Original proposal: April 2012 made by: Hull panel
GPG Approval: 22 May 2012 (Ref. 11158_IGi)

- ## Rev.5 (Feb 2012)

.1 Origin for Change:

☑ Suggestion by IACS members

.2 Main Reason for Change:

UR W13 was amended to clarify two items:

1) The thickness measuring locations for steel plate and cut steel products.
2) The minus tolerance for thickness when ISO 7452 Class C is applied in lieu of W13.3.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

1) UR W13 was amended at the request of some Hull Panel members. These requests were taken into consideration and a proposal was developed.

2) At the end of December 2010, one Hull Panel member requested a clarification from the Hull Panel regarding the required measuring points for steel rolled plates and cut steel products. After Hull Panel discussion, the Hull Panel handed a clarification to the member. The Member took the opportunity to formally document this clarification by delivering a proposal to modify UR W13.

3) Early in May 2011, another Hull Panel member requested a clarification regarding the intent of W13.1.3 and ISO 7452 Table 2 Class C and the minus tolerance for thickness. After discussion within the Hull Panel, original proposal was modified to reflect comments made by Hull Panel Members regarding clarifications given.

.5 Other Resolutions Changes

None

.6 Dates:

Original proposal : Dec 2010& May 2011 made by: Members of Hull panel
Panel Approval : October 2011 by: Hull panel
GPG Approval : 02 February 2012 (Ref. 11158_IGg)

- **Rev.4 (Oct 2009)**

.1 Origin for Change:

☑ Request by non-IACS entity: *Union of Greek Shipowners*

.2 Main Reason for Change:

UR W13 Rev.3 is amended to require that the measured average plate thickness in a group of neighbouring plates is equal to or greater than the plates' specified nominal thickness.

.3 History of Decisions Made:

Revision 4 of UR W13 was unanimously agreed within the PT3 of Hull Panel and thereafter approved by the Hull Panel.

.4 Other Resolutions Changes

None

.5 Any dissenting views

None

.6 Dates:

Original Proposal	: April 2009, made by PT3 of Hull Panel
Hull Panel Approval	: August 2009
GPG Approval	: 2 October 2009 (ref. 9560_IGh)

- ## Rev.3 (1995)

Part B. Technical Background

List of Technical Background (TB) documents for UR W13:

Annex 1. **TB for Rev.4 (Oct 2009)**

See separate TB document in Annex 1.

Annex 2. **TB for Rev.5 (Feb 2012)**

See separate TB document in Annex 2.

Annex 3. **TB for Rev.6 (June 2018)**

See separate TB document in Annex 3.

Annex 4. **TB for Rev.7 (Sep 2021)**

See separate TB document in Annex 4.

Note: *There are no separate Technical Background (TB) documents for the original resolution (1981), Rev.1 (1989), Rev.2 (1992), Rev.3 (1995) and Corr.1 (May 2012).*

Technical Background (TB) document

UR W13, Rev.4 (October 2009)
[Hull Panel Task 34]

1. Scope and objectives

Amend IACS UR W13 to:

- require that the measured average plate thickness in a group of neighbouring plates is equal to or greater than the plates' specified nominal thickness;
- require that no individual thickness measurement will be more than 0.3 mm below the specified nominal thickness;
- require that, where plates are not shot-blasted and primed at the steel-mills, the shipyard is to take adequate precautions during storage and handling to ensure average thickness is maintained prior to use during the vessels construction.

2. Engineering background for technical basis and rationale

HP PT3 reviewed available standards for plate measurement and thickness determination with a view to using them as a basis to specify the number and location of the required thickness readings to give confidence that the batch of plates meets the requirements as specified in Scope and Objectives.

3. Source / derivation of the proposed IACS Resolution

3.1 Industrial/national/international standards for the thickness measurement of steel plates:

- There are no standards about the method of thickness measurement for hot rolled plates or defining what is average thickness.
- There are some standards for the thickness tolerances.
    1. ISO 7452: Hot-rolled structural steel plates – Tolerances on dimensions and shape
    2. EN10029: Tolerances on dimensions, shape and mass for hot rolled steel plates 3mm thick or above
    3. ASTM A6: Specification for General Requirements for Rolled Structural Steel Bars, Plates, Shapes and Sheet Piling

3.2 Current practice for thickness measurement:

- Thickness measurement techniques are either on-line automated or off-line manual methods for hull structural steel plates.
- Plate is rejected if, at any confirmation point, thickness reading is below the lower tolerance limit.
- Number of measuring points, measuring locations and measuring time are very much diverse between on-line automated or off-line manual methods.
- The statistics show that the mean of average plate thickness measured during some periods is well above the nominal thickness.

4. Summary of Changes intended for the revised Resolution:

- require that the measured average plate thickness in a group of neighbouring plates is equal to or greater than the plates' specified nominal thickness;
- define the average thickness and measuring locations
- require that, where plates are not shot-blasted and primed at the steel-mills, the shipyard is to take adequate precautions during storage and handling to ensure average thickness is maintained prior to use during the vessels construction
- In case where the steel mills apply zero minus tolerance, i.e. Class C of ISO 7452, their present recording procedure may be allowed.

5. Points of discussions or possible discussions

- Although the minus tolerance is 0.3 mm irrespective of nominal thickness, actual minus tolerance is expected to be close to 0.0 mm in consideration of the requirement that the measured average plate thickness is equal to or greater than the plates' specified nominal thickness.
- Definition of ‘a group of neighbouring plates’ and ‘average plate thickness’ could not be decided in a concrete manner due to the diversity of the steel mill production system.
- Standardization of the systematic thickness measurements is difficult due to the diversity of measuring method and measuring equipment.

6. Attachments if any

Technical Background for UR W13 Rev.5, Feb 2012

1. Scope and objectives

Amend IACS UR W13 to:
- Clarify the thickness measuring locations for steel plate and subsequent cut steel products.
- Clarify the minus tolerance for thickness when ISO 7452 Class C is applied in lieu of W13.3.
- Provide general modifications or reorganization to sections affected by the above changes.

2. Engineering background for technical basis and rationale

2.1 Intent of ISO 7452 Class C:
- W13 allows for the application of ISO 7452 Class C in lieu of W13.3.
- ISO 7452 Table B2 has a footnote which Part of which reads: "Also a minus side of thickness of 0,3 mm is permitted." However, Class C allows no minus tolerance, which is contradicted by the footnote.
- To avoid confusion in ensuring no minus tolerance is allowed and to prevent incorrect interpretations of the thickness measurement method used, an amendment was made to Section W13.1.3 advising that the part of the footnote referenced above is not applicable.
- If ISO 7452 is to be applied, UR W13.4 and W13.5 need not be applied. Since the ISO 7452 does not include specification for the number and location of measurements to establish that the plates are at or above the specified nominal thickness, and W13.4 and W13.5 are not applied, the number and location of measurements when ISO 7452 is used is left up to the satisfaction of each individual Class Society (see the second paragraph of W13.1.3).

2.2 Thickness Measuring Locations:
- There was confusion about the application of measure locations for steel plate rolled directly from one slab or ingot (steel plates) and the products cut from those plates (cut steel products).
    - o Although it was understood that the steel plate needed to be measured per UR W13, it was unclear whether or not the cut steel products needed to be measured.
- Based on common practice and the general intent of the UR, it was agreed that the measuring locations and requrements need only apply to the steel plate and not the steel products cut from the plate.
- This clarification was made in UR W13 via a NOTE in section A.2 and Figures A1 and A2.

3. Source / derivation of the proposed IACS Resolution

ISO 7452

4. Summary of Changes intended for the revised Resolution:

- Section 13.1.1: Definition of wide flats provided.

- Section 13.1.2: The in-text note was moved to Sect. 13.1.1
- Section 13.1.3: This section was amended to describe the minus tolerance for thickness when applying Class C of ISO 7452
- Footnotes: Footnote 1 was modified to reflect the current revision.
- A.2: An in-text NOTE was added to describe the application of the thickness measurement on steel plate.
- Figure A.1, Figure A.2: Figure A.1 was modified and Figure A.2 added to reflect the clarification on the location of thickness measurement for steel plate and the relation to the cut steel products

Technical Background (TB) document for UR W13 (Rev.6 June 2018)

1. Scope and objectives

Amend IACS UR W13 to:

- Apply the same criteria regardless of thickness for tolerance on nominal thickness to the following types of steel plates (same as UR W13 revision 5):
    1) Hull structural steel plates as per UR W11
    2) High strength steel plates for welded structure as per UR W16

- Clarify the minus tolerance for thickness up to, and exceeding 250 mm for products for machinery structures.

2. Engineering background for technical basis and rationale

After UR W16 having been revised, UR W13 needed amendment for consistency with UR W16. The class of minus tolerances for the steel grades in the scope of UR W16 needed to be treated. Further minor changes were necessary.

3. Source / derivation of the proposed IACS Resolution

IACS UR W16

4. Summary of Changes intended for the revised Resolution:

- Section 13.1.1: Proposal for thickness tolerances for thickness below 5 mm is given.
- New section 13.1.2 added, indication that UR W13 is not applicable to lifting appliances.
- Section 13.1.4: Year of edition for applicable ISO 7452 is added, i.e. 2013.
- Section 13.3.3: minus tolerances added for nominal thicknesses t between 3-5, 40-80, 80-150, 150-250, and above 250 mm for products for machinery structures.
- Section 13.3.4: Added that for repair by grinding UR W11.7.4.1 has to be applied.
- Section 13.3.5: Added that for plus tolerances Classification Society or purchaser may apply other requirements than national/international standards.

.5 Points of discussions or possible discussions

New section 13.1.2: The group discussed the question of minus tolerance for plates in steel grades covered by UR W16. The group recognised that the use for main offshore structures would correspond to a minus tolerance of 0.3mm while other minus tolerances may be acceptable for other types of constructions, typically lifting appliances. Therefore the group agreed that IACS UR W13 is not applicable to lifting appliances.

UR W14 Steel plates and wide flats with specified minimum through thickness properties ("Z" quality)

Summary

Review and update industry standards format according to GPG instructions

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev.3 (Sep 2021)	21 September 2021	1 January 2023
Rev.2 (May 2004)	May 2004	-
Rev.1 (July 2002)	July 2002	-
New 1982	1982	-

- **Rev. 3 (Sep 2021)**

1 Origin of Change:

☒ Suggestion by IACS member

2 Main Reason for Change:

To update industry standards format according to GPG instructions given in GPG Vice-chair message 19000_IRC.

3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None.

4 History of Decisions Made:

Original proposal was made according to GPG Vice-chair message 19000_IRc. Proposal to revise the IACS URs and RECs only to refer to a dated version of the industry standard as per GPG instructions was made at IACS EG/MW meeting in September 2019. Three drafts have been discussed by the group.

5 Other Resolutions Changes:

None.

6 Any hinderance to MASS, including any other new technologies:

None.

7 Dates:

Original Proposal	: April 2019	(Made by: GPG)
EG M&W Approval	: July 2021	
GPG Approval	: 21 September 2021	(Ref: 19000_IGq)

Part B. Technical Background

List of Technical Background (TB) documents for UR W14:

Annex 1. **TB for Rev.1 (July 2002)**

See separate TB document in Annex 1.

Annex 2. **TB for Rev.2 (May 2004)**

See separate TB document in Annex 2.

Annex 3. **TB for Rev.3 (Sep 2021)**

See separate TB document in Annex 3.

Note: *There are no Technical Background (TB) documents available for New (1982).*

Technical Background (TB)
IACS Unified Requirement W14 (Rev. 1)

Steel plates and wide flats with specified minimum through thickness properties ("Z" quality)

Technical Backgrounds:

a) Objective/Scope

The objective was to revise the existing UR W14 from the viewpoint of the consistency between the existing requirements and current best practice.

b) Source of Proposed Requirements

This revised draft UR was developed referring to the existing requirements of UR W14 "Steel plates and wide flats with improved through thickness properties".

c) Points of Discussion

The discussion on the following technical points had been made and achieved full agreement of the members:

<u>Scope</u>;

Two "Z" quality steels are to be specified, Z25 for normal ship application and Z35 for more severe applications.

<u>Manufacture</u>;

The approval should follow the procedure given in UR W11 Appendix A but take into account various improved steelmaking process and the control of centre-line segregation during continuous casting.

<u>Chemical composition</u>;

Maximum sulphur content determined by the ladle analysis is to be specified.

<u>Test sampling</u>;

Batch size is to be specified according to type of product and sulphur content.

<u>Acceptance values for reduction of area</u>;

Minimum average and minimum individual values for reduction of area are to be specified for Z25 and Z35 respectively.

<u>Re-test procedure</u>;

Acceptable test result, retest-permitted result and acceptable retest result are to be specified using the schematic diagram.

Note: At the request of ABS, WP Chairman suggested further amendment to be added to W14.3.4 for clarity: "Round test specimens including built-up type by welding are to be prepared in accordance with a recognized standard" (1058aIGb, 10 May 02). Aprroved.

submitted by WP/MCH to GPG 52, 12-15 March 2002

IACS Unified Requirement W14 (Rev.2)
Technical Background

Steel plates and wide flats with specified minimum through thickness properties ("Z" quality)

a) Objective/Scope
The objective was to eliminate the difficulty of the member's implementation.

b) Source of Proposed Requirements
The revised draft UR was developed referring to the existing requirements of the UR W14 "Steel plates and wide flats with specified minimum through thickness properties ("Z" quality)", EN 10160 and ASTM A578.

c) Points of Discussion
The discussion on the following technical point had been made and achieved full agreement of the members:
Ultrasonic tests;
The requirement level of EN10160 is to be Level S1/E1 from the viewpoint of the conformance with ASTM A578 Level C.

* * * * *

Technical Background (TB) document for UR W14 (Rev.3 Sep 2021)

1. Scope and objectives

Review and update industry standards format according to GPG instructions.

UR W16 "High Strength Steels for Welded Structures"

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev.3 (Mar 2016)	1 March 2016	1 July 2017
Rev.2 (May 2004)	24 May 2004	-
Rev.1 (1994)	*No record*	-
New (1984)	*No record*	-

- **Rev.3 (Mar 2016)**

.1 Origin for Change:

☑ Suggestion by IACS member
☑ Based on Other Standard *(EN 10025 and EN10225, and ISO 630)*
☑ Other *(Offshore and marine Industry demands for including S890 steel grade, also the steelmaking industry considered the current UR W16 obsolete)*

.2 Main Reason for Change:

1) Current UR W16 has not been updated since 2004, however the manufacturing technology of steelmaking of high strength steels has advanced;
2) Updates to the requirements in UR W16 are required in line with the international material standards for high strength steels;
3) A unified procedure is required for the approval of the manufacturer of high strength steels;
4) The scope of UR W16 needs to be expanded to include steels with yield strength higher than 690 N/mm^2 which have been successfully used by the offshore industries for decades.

.3 List of non-IACS Member Classification Societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

In October 2013, the IACS EGMW agreed in their annual meeting that UR W16 urgently needs updating in order to meet the industry requirements and provide appropriate requirements on material properties.

GPG agreed to Permsec's proposal that the revision be published as a Complete Revision.

.5 Other Resolutions Changes

None

.6 Dates:

Original Proposal: October 2013 by EG/M&W
Panel Approval: 14 December 2015 (Ref: EG task No. EMW1205)
GPG Approval: 1 March 2015 (Ref: 13202_IGj)

IACS Unified Requirement W16 (Rev.2)
Technical Background

High Strength Quenched and Tempered Steels for Welded Structures

a) Objective/Scope
The objective was to rationalize all UR Ws procedures on mechanical testing by reference to the new UR W2 (Rev.2, 2003).

b) Source of Proposed Requirements
The revised draft UR was developed referring to the existing requirements of the UR W16 “High Strength Quenched and Tempered Steels for Welded Structures” and the UR W2 “Test specimens and mechanical testing procedures for materials”.

c) Points of Discussion
Nil.

* * * * *

Technical Background (TB) document for UR W16 (Rev.3 Mar 2016)

1. Scope and objectives

A thorough amendment of IACS UR W16 was urgently needed to keep the UR updated with the development of manufacturing technology of high strength steels; and latest international standards and codes for the manufacturing of these high strength steels. The definitions and requirements in the current W16 have not kept up with changes in industry standards and were considered inappropriate by industry.

The objectives of the amendment were:

1) Develop a unified approach for the approval of manufacturers of high strength steel carried out by each Classification Society.
2) Unify the requirements for the material properties, the delivered conditions and inspection of high strength steels in order to meet the increasing demand from the industry. There are material standards, such as ASTM, EN, ISO and other numerous national and/international standards having been developed for high strength grades.
3) Incorporation of steels with yield strength higher than 690 based on these grades having been applied in certain parts of structures by offshore and marine industries.

2. Engineering background for technical basis and rationale

Regarding the scope of steel manufacturing, the requirements apply to hot-rolled, fine-grain, weldable high strength structural steels, specified in yield strength levels of 420, 460, 500, 550, 620, 690, 890 and 960 N/mm2, delivered in Normalized (N)/Normalised rolled (NR); Thermo-mechanical controlled rolled (TM) or Quenched and Tempered (QT) condition. Product forms include plates, wide flats, sections, bars and seamless tubulars.

Regarding the scope of application, the steels are intended for use in marine and offshore structural applications, and are not intended for ship hull structure.

Within the scope mentioned above, the requirements specifically on the manufacturing process, chemical and mechanical properties, sampling and test frequency, surface and internal soundness, inspection for both production test and initial manufacturer approval have been updated based on the latest international standards, as listed in Para 3. "Source/derivation of the proposed IACS resolution".

The revised W16 (Rev. 3) has now the unified requirements on the high strength steels to meet the needs of marine, offshore and steelmaking industries.

3. Source / derivation of the proposed IACS Resolution

Marine, offshore and steelmaking industries use the international material standards for structural steels such as:

ISO 630-3 - Part 3 Technical delivery conditions for fine – grain structural steels
ISO 630-4 - Part 4 Technical delivery condition for high-yield-strength quenched and tempered structural steel plates

EN 10025-3 - part 3 technical delivery conditions for normalized rolled weldable fine grain structural steels
EN 10025-4 - part 4 technical delivery conditions for thermomechanical rolled weldable fine grain structural steels
EN 10025-6 - part 6 technical delivery conditions for flat products of high yield strength structural steels
EN 10225 Weldable structural steels for fixed offshore structures - Technical delivery conditions
EN 10210-1 Hot finished structural hollow sections of non-alloy and fine grain structural steels – Part 1: Technical delivery requirements
EN 10297-1 Seamless steel tubes for mechanical and general engineering purposes – Technical delivery conditions - part 1: Non-alloy and alloy steel tubes

The applicability of the abovementioned standards was investigated and agreed by the EG M&W group for the reference and suitability for the general marine and offshore applications.

4. Summary of Changes intended for the revised Resolution:

This is a full revision of the UR, and introduces the following major changes that reflect advances in steelmaking technology and quality assurance in steel product testing and in manufacturing process approval, in particular the elements of relevant international standards for weldable structural steels.

- Scope of application and product form
- Steelmaking and heat treatment process
- Chemical composition / Carbon equivalent specifications
- Mechanical properties testing: Tensile test and Charpy impact toughness test and acceptance criteria
- Inspection test procedure
- Surface quality
- Internal soundness
- Appendix A for procedure of approval of manufacturers

5. Points of discussions or possible discussions

All the revisions or additions have been discussed by the Group by correspondence or during the EG MW meetings and reached a final agreement.

Rev.5 (Mar 2018)	19 March 2018	1 July 2019
Rev.4 (Jan 2016)	15 January 2016	1 July 2017
Rev.3 (June 2005)	27 June 2005	-
Rev.2 (May 2004)	24 May 2004	-
Rev.1 (1993)	1993	-
New (1986)	1986	-

- **Rev.6 (Sep 2021)**

1 Origin of Change:

☒ Suggestion by IACS member

2 Main Reason for Change:

To update industry standards format according to GPG instructions given in GPG Vice-chair message 19000_IRC.

3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None.

4 History of Decisions Made:

Original proposal was made according to GPG Vice-chair message 19000_IRc. Proposal to revise the IACS URs and RECs only to refer to a dated version of the industry standard as per GPG instructions was made at IACS EG/MW meeting in September 2019. Three drafts have been discussed by the group.

5 Other Resolutions Changes:

None.

6 Any hinderance to MASS, including any other new technologies:

None.

7 Dates:

Original Proposal	: April 2019	(Made by: GPG)
EG M&W Approval	: July 2021	
GPG Approval	: 21 September 2021	(Ref: 19000_IGq)

- **Rev.5 (Mar 2018)**

.1 Origin for Change:

☑ Alignment and consistency with UR W16.

.2 Main Reason for Change:

In order to keep consistency UR W17 needed to be aligned with UR W16 changes. The opportunity has also been taken to include grade 5Y40 based on the demands of industry and the need for consistent approval acceptance criteria across Societies, as it was not originally tasked in the FORM A.

.3 List of non-IACS Member Classification Societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

None

.5 Other Resolutions Changes

None

.6 Dates:

Original Proposal: September 2016
Panel Approval: 27 February 2018 (Ref: EMW1606)
GPG Approval: 19 March 2018 (Ref: 16172bIGb)

- **Rev.4 (Jan 2016)**

.1 Origin for Change:

☑ Suggestion by IACS member

.2 Main Reason for Change:

In the existing UR W17, the mercury method is the only test method for determining hydrogen content of welding consumables with H5 rating. However, due to environmental factors, the mercury method has been severely restricted. Some new acceptable methods are to be added to replace the mercury method.

.3 List of non-IACS Member Classification Societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

See separate TB document in Annex 3 for details.

.5 Other Resolutions Changes

None

IACS Unified Requirement W17 (Rev.2)
Technical Background

Approval of consumables for welding normal and higher strength hull structural steels

a) Objective/Scope
The objective was to rationalize all UR Ws procedures on mechanical testing by reference to the new UR W2 (Rev.2, 2003).

b) Source of Proposed Requirements
The revised draft UR was developed referring to the existing requirements of the UR W17 "Approval of consumables for welding normal and higher strength hull structural steels" and the UR W2 "Test specimens and mechanical testing procedures for materials".

c) Points of Discussion
Nil.

* * * * *

Technical Background Document
UR W17 (Rev.3 June 2005)

Approval of consumables for welding normal and higher strength hull structural steels

a) Objective/Scope

The objective was to amend requirements of welding consumables for YP40 steels with a view to being consistent requirements for welding joints.

b) Source of Proposed Requirements

The revised draft UR was developed referring to the existing requirements of the UR W17 "Approval of consumables for welding normal and higher strength hull structural steels" and UR W11 "Normal and higher strength hull structural steels".

c) Points of Discussion

The discussion on the following technical points for the above a) objective/Scope had been made and achieved full agreement of the members:

Required energy for impact tests;
Required energy for impact tests on welding consumables for YP40 steels is to be amended based on those of steels in UR W11(Rev.6).

Typeset errors;
Several typeset errors found during consideration are to be rectified.

Submitted by WP/MW Chair
28/12/2004

Technical Background (TB) document for UR W17 (Rev.4 Jan 2016)

1. Scope and objectives

The objective is to introduce the measuring hydrogen content methods for the deposited metal of welding consumables, which is adopted in ISO 3690:2012.

2. Engineering background for technical basis and rationale

In the existing UR W17 , the mercury method is the only method allowed for measuring hydrogen content of welding consumables with hydrogen content less than 5ml/100g. However, due to environmental factors, the mercury method has been severely restricted. In order to meet the need for measuring hydrogen content of welding consumables, thermal conductivity detector method listed in ISO 3690:2012 is introduced into UR W17.

3. Source/derivation of the proposed IACS Resolution

The revised draft UR was developed from the existing IACS UR W17 “Approval of consumables for welding normal and higher strength hull structural steels”, and referring to ISO 3690 “Welding and allied processes — Determination of hydrogen content in arc weld metal”.
CCS: Comparative tests between mercury method and thermal conductivity detector method.
NK: Effect of diffusible-hydrogen measurement conditions per ISO 3690:2012 (three parts).

4. Summary of Changes intended for the revised Resolution:

The thermal conductivity detector methods specified in ISO 3690:2012 are introduced into UR W17. The typical test conditions for gas chromatography method and prerequisite conditions for the application of hot carrier gas extraction method are specified in UR W17.

5. Points of discussions or possible discussions

The group discussed the test temperature and minimum holding time of the hot carrier gas extraction method.

Some test data showed that differences exist in the results obtained from the test by hot carrier gas extraction method in accordance with ISO standard in different laboratories. It was considered that there may be some uncertainty in instrument calibration methods and the test procedures for this method. It was agreed to introduce requirements to check the testing procedure for this method.

6. Attachments if any

N/A.

Technical Background (TB) document for UR W17 (Rev.5 Mar 2018)

1. Scope and objectives

The initial task was to align this UR with the changes from UR W16, Rev. 3, which were revised in March 2016, as requested by IACS GPG.

Eventually, the EGMW group considered it was necessary to incorporate the consumable grade of 5Y40 in the current revision.

2. Engineering background for technical basis and rationale

UR W17 specifies the normal and higher strength grade consumables, and that the high strength grade consumables for steels covered in UR W16 were to be incorporated into UR W23. The revision for consistency with W16 was minor in nature. Further, the adoption of grade 5Y40 was considered of necessity, based on that EG MW's remark that Class Societies have received requests from the industries for type approval of this grade 5Y40. This grade may be used in offshore cases where FH40 grade is used.

3. Source/derivation of the proposed IACS Resolution

Grade 5Y40 was introduced with the mechanical properties in consistency with the existing 1,2,3 and 4Y40, apart from the Charpy V-notch test temperature of -60°C which is in line with 5Y grade. The specifications of Grade 5Y40 consumable is in line with current industrial practice.

4. Summary of Changes intended for the revised Resolution:

New grade of 5Y40 consumable was introduced into the Rev. 5.

5. Points of discussions or possible discussions

The group discussed on the necessity and the specification of 5Y40 introduced.

Anchor Chain Cables and Accessories

Technical Backgrounds

a) **Objective / Scope**

The objective was to revise the requirement on the break load test for chain accessories specified in the Unified Requirement for anchor chain cables and accessories. The existing UR W18 requires that the chain accessories, which are break load tested, have to be scrapped except in certain condition. This condition has been re-considered in this revision.

b) **Source of Proposed Requirements**

This revised draft UR was elaborated referring to the existing UR W18 "Anchor Chain Cables and Accessories" and UR A1 "Requirements concerning Mooring and Anchoring"(Rev.4, 1994).

c) **Points of Discussion**

The discussions had been held mainly upon the following point of view and achieved full agreement in the AHG/MW :

<u>Conditions on the chain accessories which are break load tested to be put to further use</u> ;

To prevent plastic deformation resulted from the break load test, the existing UR W18 requires only to use the material with the higher grade. In addition to that, as a result of re-consideration, the increased dimensions also have been introduced as a condition on further use in service.

ΔΔ

Technical Background

IACS Unified Requirement W18 (Rev.3)

Anchor chain cables and accessories

Technical Backgrounds:

a) Objective/Scope

The objectives was to revise the existing UR W18 from the viewpoint of the consistency between the requirements and current techniques.

b) Source of Proposed Requirements

This revised draft UR was developed referring to the existing requirements of UR W18 "Anchor chain cables and accessories" (Rev.2).

c) Points of Discussion

The discussion on the following technical points had been made and achieved full agreement of the members:

I. For rolled steel bars for chain cables

<u>Chemical composition</u>;

Chemical composition for Grade 3 steel bar is not specified. Material suppliers or chain cable manufacturers are to submit the specification for approval.

<u>Mechanical test</u>;

Mechanical test is to be normally carried out by the steel mill.

<u>Retest</u>;

Where a retest for tensile test or Charpy V-notch impact test fails to meet requirements, the test unit represented is to be rejected.

II. For chain cables and accessories

<u>Heat treatment</u>;

"Normalized and tempered" is newly added as heat treatment for chain cables and accessories.

<u>Breaking load test</u>;

Each manufacturing batch for the test is to be comprised of accessories which are same accessory type, grade, size and heat treatment charge. But it is not necessarily representative of each heat of steel or individual purchase order.

<u>Mechanical tests;</u>

For Grade 2 forged or cast <u>chain cables</u>, Charpy V-notch impact test is not needed. However, for Grade 2 forged and cast <u>accessories</u>, the test is to be required.

* * * *

submitted by WP/MCH to GPG 52, 12-15 March 2002

IACS Unified Requirement W18 (Rev.4)

Anchor chain cables and accessories

Technical Backgrounds:

a) **Objective/Scope**
The objective was to develop the requirements for the manufacture and certification of chain cables and their accessories for ETA equipment.

b) **Source of Proposed Requirements**
The requirements in the revised draft UR were developed referring to the IMO Resolution MSC35(63) and the corresponding specifications of individual Societies Rule.

c) **Points of Discussion**
The discussion on the following technical points had been made and achieved full agreement of the members:
General;
The requirements for chafing chains used in ETA were specified as an Appendix of UR W18 "Anchor chain cables and accessories".
Grade of chains;
The chains are to be Grade 2 and 3 chain cables in the UR W18. The minimum size of common link and breaking load for test are to be specified in accordance with the IMO Resolution MSC35(63) and the members' specifications.
Design, manufacture, testing and certification;
The chains are to be designed, manufactured, tested and certified in accordance with the corresponding requirements of the UR W18.
Chafing chain end onboard;
Typical arrangement of the chain end was developed referring to on members' practices. A pear-shaped open link is to be considered so that it allows connection to a shackle corresponding to the type of ETA and chain grade.

* * * * *

IACS Unified Requirement W18 (Rev.5)
Technical Background

Anchor chain cables and accessories including chafing chain for emergency towing arrangements

a) Objective/Scope
The objective was to rationalize all UR Ws procedures on mechanical testing by reference to the new UR W2 (Rev.2, 2003).

b) Source of Proposed Requirements
The revised draft UR was developed referring to the existing requirements of the UR W18 “Anchor chain cables and accessories including chafing chain for emergency towing arrangements” and the UR W2 “Test specimens and mechanical testing procedures for materials”.

c) Points of Discussion
Nil.

UR W22 "Offshore Mooring Chain"

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev.6 (June 2016)	2 June 2016	1 July 2017
Corr.1 (June 2011)	4 June 2011	-
Rev.5 (Dec 2009)	1 December 2009	1 July 2011
Rev.4 (Sept 2006)	24 September 2006	-
Rev.3 (May 2004)	24 May 2004	-
Rev.2 (July 1999)	28 July 1999	-
Rev.1 (1997)	14 February 1997	-
NEW (1993)	*No record*	-

- **Rev.6 (June 2016)**

.1 Origin for Change:

☑ Suggestion by IACS member

.2 Main Reason for Change:

To update and add requirements for mooring chain.

.3 List of non-IACS Member Classification Societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

See Form A for task EMW 1313, minutes of EG MW meetings in 2013, 2014, 2015 and technical background.

.5 Other Resolutions Changes

None

.6 Dates:

Original Proposal: 10 December 2013 by EG/M&W
Panel Approval: 29 December 2015 (Ref: Task EMW 1313)
GPG Approval: 2 June 2016 (Ref: 16057_IGd)

- **Rev.5 Corr.1 (June 2011)**

.1 Origin for Change:

☑ Suggestion by a non-IACS entity (PRS) and PermSec

.2 Main Reason for Change:

To correct the typos in the paragraph numbering (3.2.7 & 3.2.8) and the reference to the figure 3 in 3.2.7.2.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

PRS pointed out the wrong reference to the figure 3 in Para 3.2.7.2 and PermSec found some other editorial corrections required in paragraph numbering (3.2.7 & 3.2.8). PermSec made the corrections and Hull Panel approved it. As the corrections were purely editorial, no technical background document was prepared.

.5 Other Resolutions Changes

None

.6 Dates:

Original proposal: *19 April 2011 Made by: PRS/PermSec*
Panel Approval: *23 May 2011 by: Hull Panel*
GPG Approval: *4 June 2011 (Ref. 11077_IGb)*

- **Rev.5 (Dec 2009)**

.1 Origin for Change:

☑ Suggestion by IACS member

.2 Main Reason for Change:

To develop the requirements for higher strength mooring chains in Grade R5 and also studless mooring chains.

.3 History of Decisions Made:

The old IACS WP/MW was aware of industrial need for higher strength offshore mooring chains other than those specified in the present the existing UR W22 and also a requirement for studless offshore mooring chains. WP/WM raised the Form A but the work was not initiated before reorganisation of the old IACS working groups. The work item was taken over by Hull Panel as their Task 27 and allocated to Project Team 2 under the chair of LR, the working document was drafted by ABS.

Following a period required to discuss issues with manufacturers, analysis of issues raised by Authorities and collation of supporting technical information, the project

team found common ground on the procedures to be followed.
Fracture toughness testing, for example CTOD testing, has been a requirement in UR W22 for initial approval tests of chain manufacturers since original adoption. Acceptance values have now been included in the UR and are extended to initial approval tests of the forges and foundries for accessories. These values, established through design and operational experience, are considered to give sufficient resistance against unstable fracture in general. As CTOD values can be related to design issues, other values may be considered for specific cases of specific projects. Specifying these acceptance levels in the UR enables the manufacturer to establish Charpy impact toughness and fracture toughness relationships based on the increase in strength and thickness seen in this amendment. This allows the continued use of the Charpy V-notch impact test as the measurement of toughness during quality control release testing of the product.

.4 Other Resolutions Changes

None

.5 Dates:

Original Proposal: *2004, made by WP/MW Task No.57*

IACS UR W22 (Rev.2)
Offshore Mooring Chain

Technical Backgrounds

a) **Objective / Scope**

The objective was to revise the requirement on the break load test for chain accessories specified in the Unified Requirement for offshore mooring chains. The existing UR W22 requires that the chain accessories, which are break load tested, have to be scrapped, however, the revised one allows them to be put to further use in case they satisfy the certain conditions.

b) **Source of Proposed Requirements**

This revised draft UR was elaborated referring to the existing UR W22 "Offshore Mooring Chain", the existing/ revised UR W18 "Anchor Chain Cables and Accessories" and UR A1 "Requirements concerning Mooring and Anchoring"(Rev.4, 1994).

c) **Points of Discussion**

The discussions had been held mainly upon the following point of view and achieved full agreement in the AHG/MW :

<u>Conditions for the chain accessories which are break load tested to be put to further use</u> ;

To prevent plastic deformation resulted from the break load test, the conditions on materials grade and dimensions of chain accessories were developed. These conditions are the same as ones specified in the proposed UR W18 (Rev.2).

△△

IACS Unified Requirement W22 (Rev.3)
Technical Background

Offshore mooring chain

a) Objective/Scope
The objective was to rationalize all UR Ws procedures on mechanical testing by reference to the new UR W2 (Rev.2, 2003).

b) Source of Proposed Requirements
The revised draft UR was developed referring to the existing requirements of the UR W22 “Offshore mooring chain” and the UR W2 “Test specimens and mechanical testing procedures for materials”.

c) Points of Discussion
Nil.

* * * * *

Technical Background of UR W22 (Rev.4)
Appendix A: Chafing Chain for Single Point Mooring Arrangements

1. Scope and objective

OCIMF has requested IACS by their email of 7 June 2006 to consider some exemptions in application of IACS UR W22 for manufacturing of short lengths of chafe chains for conventional tanker’s single point moorings. IACS GPG Chairman tasked Hull Panel to consider OCIMF’s request/proposal and if supportive, whether UR W22 needs to be amended to acknowledge/address the OCIMF Guidelines in his message 6114_IGa, dated 13 June 2006. Consequently, Hull Panel unanimously agreed to develop an Appendix to IACS UR W22, which specifies the requirements for chafe chains for single point mooring arrangements and incorporates the concerns that OCIMF has in manufacturing the chains.

2. Points of discussions or possible discussions

The following OCIMF’s concerns are considered in development of the Appendix:

.1 *Comments*: W22.1.5.1 can be waived due to the requirement for small quantities of bar stock. Such materials should be subject to full chemical and mechanical testing to prove grade compatibility and 100% Non Destructively Tested (NDT) before release into production. The material should meet or exceed the requirements of W22 Table 1 and comply with 1.5.2

Proposals: A.2 specifies the materials of the chafe chain are to satisfy the requirements of materials as required by W22.2. The approval of the manufacturer by the society is no longer a condition of approval of chafe chain product.

.2 *Comments*: The OCIMF recommended chafe chain configurations including the oblong plate and pick up shackle component should be accepted. Individual links should comply with the dimension tolerances specified in W22 3.7.

Proposals: A.4.2 specifies that the arrangements of the end connections are to be in accordance with the recognized standards, such as OCIMF. A4.1 covers the dimensional tolerances of individual links by referring to W22.3.

.3 *Comments*: Batch heat treatment will be accepted as an alternative to linear heat treatment.

Proposals: The acceptance of batch heat treatment is specified in A4.1.

.4 *Comments*: Break load testing of 3 link samples can be waived on provision that the manufacturer can provide documented evidence that for each size of bar stock used to manufacture the chafe chain, that the break load tests were satisfactorily performed on a sample from the same bar stock of raw material.

Proposals: The statement of waiver of the break load tests is provided in Note 1 of the Appendix.

.5 *Comments*: Break load testing of chafe chain accessories including oblong plate and 42 tonnes shackle can be waived on the provision that the manufacturer can demonstrate that a destructive test of the same size and grade accessory has been performed in the last 6 months.
Proposals: Same proposal as above 2.4. The statement of waiver of the break load tests is provided in Note 1 of the Appendix.

.6 *Comments*: Note: In accordance with W22 sections 4.5 and 5.5, chafe chains, including accessories should be shot blasted and 100% Non Destructively Tested (NDT) for cracks and deformation after proof load testing and prior to coating.
Proposals: These are the condition of acceptance of the materials. A4.1

.7 Other specific concerns are provided in A.1, A.4.3, A.4.4, and A.4.5.

3. Source/ derivation of proposed requirement
OCIMF

4. Decision by voting
N.A.

Submitted by the Hull Panel
1 September 2006

Permanent Secretariat note (29 September 2006):

GPG discussion led to a number of changes being made to the draft text:

- ABS proposed that a reference should be made to the new Appendix from the main text of W22.
- LR requested that the reference to specific industry standards be removed in paragraph 4.2 since they did not recall this being normal practice for IACS URs.
- LR also proposed that Note 1 in the Appendix be amended to better clarify the requirement.

These changes were agreed by members together with a minor typographical amendment in para 1 of the Appendix.

CCS made a proposal to replace the time-based Note with a quantity-based one, but this proposal did not gain support from the other members.

GPG and Council agreement was reached on 24 September 2006.

Technical Background (TB) document

UR W22, Rev.5 (December 2009)
[Hull Panel Task 27]

1. Scope and objectives

To develop the requirements for higher strength mooring chains in Grade R5 and also studless mooring chains.

2. Engineering background for technical basis and rationale

The old IACS WP/MW was aware of industrial need for higher strength offshore mooring chains other than those specified in the present the existing UR W22 and also a requirement for studless offshore mooring chains. WP/WM raised the Form A but the work was not initiated before reorganisation of the old IACS working groups. The work item was taken over by Hull Panel as their Task 27 and allocated to Project Team 2.

3. Source / derivation of the proposed IACS Resolution

Following a period required to discuss issues with manufacturers, analysis of issues raised by Authorities and collation of supporting technical information, the project team found common ground on the procedures to be followed.

4. Summary of Changes intended for the revised Resolution:

Fracture toughness testing, for example CTOD testing, has been a requirement in UR W22 for initial approval tests of chain manufacturers since original adoption.

Acceptance values have now been included in the UR and are extended to initial approval tests of the forges and foundries for accessories. These values, established through design and operational experience, are considered to give sufficient resistance against unstable fracture in general. As CTOD values can be related to design issues, other values may be considered for specific cases of specific projects. Specifying these acceptance levels in the UR enables the manufacturer to establish Charpy impact toughness and fracture toughness relationships based on the increase in strength and thickness seen in this amendment. This allows the continued use of the Charpy Vnotch impact test as the measurement of toughness during quality control release testing of the product.

5. Points of discussions or possible discussions

A number of points were raised on the final draft submitted. These were valid points and amendments were made. The CTOD acceptance values for accessories were deleted based on ongoing experience, clarifications made to the numbers and location of CTOD specimens and the inclusions of a test location diagram. Furnace calibration procedures were also amended.

6. Attachments if any

No attachment.

Technical Background (TB) document for UR W22 (Rev.6 June 2016)

1. Scope and objectives

The objective is to revise the requirements for offshore mooring chain and accessories in order to update them and to add requirements based on industry feedback where found appropriate.

2. Engineering background for technical basis and rationale

Experience feedback and various joint industry projects (JIPs) showed that there were issues arising with offshore mooring chain quality, manufacturing practices and design requirements. The EG MW considered that the UR W22 needed to be reviewed for a global update and for developing additional requirements about key points of the manufacturing process for chain cables and mooring accessories.

3. Source / derivation of the proposed IACS Resolution

The revised draft UR was developed from the existing IACS UR W22 "Offshore Mooring Chain".

4. Summary of Changes intended for the revised Resolution:

The scope of the UR has been revised to add "subsea connectors".
The documentation to be submitted to the Classification Society for approval has been revised to request additional information about manufacturing procedures.
Requirements have been added to the manufacturing approval conditions for heat treatment furnaces and processes for chain and accessories. Additional details have been defined for CTOD testing conditions.
Additional requirements for approval, manufacturing and testing of forged and cast accessories have been incorporated.
Additional requirements for non-destructive examination of chain cables, forged and cast accessories have been incorporated.
Requirements for dimensions and dimensional tolerances of chain links have been further detailed. Various updates of referenced standards were done.

5. Points of discussions or possible discussions

All the revisions or additions have been discussed by the Group by correspondence or during the EG MW meetings and reached a final agreement. The requirements about CTOD testing at manufacturing approval stage have been discussed in details, as well as the requirements for non-destructive examinations and those for forged accessories.

6. Attachments if any

None.

UR W23 "Approval of Welding Consumables for High Strength Steels for Welded Structures"

Summary

Clarify that grades Y89 and Y96 may be subject to particular consideration on specific projects where design requirements permit undermatching weld joints.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Corr.1 (June 2019)	22 June 2019	-
Rev.2 (Apr 2018)	30 April 2018	01 July 2019
Rev.1 (1997)	No record	-
New (1995)	No record	-

- **Corr.1 (June 2019)**

1 Origin of Change:

☒ Other (External query from European Welding Association (EWA))

2 Main Reason for Change:

Clarify that grades Y89 and Y96 may be subject to particular consideration on specific projects where design requirements permit undermatching weld joints.

3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

Part B. Technical Background

List of Technical Background (TB) documents for UR W23:

Annex 1. **TB for Rev.2 (Apr 2018)**

See separate TB document in Annex 1.

◄▼►

Note: *There are no Technical Background (TB) documents available for New (1995), Rev.1 (1997) and Corr.1 (June 2019).*

Technical Background (TB) document for UR W23 (Rev.2 Apr 2018)

1. Scope and objectives

The task requested by IACS GPG was to align this UR with the changes from UR W16, Rev. 3, after it was revised in March 2016.

2. Engineering background for technical basis and rationale

High strength grade consumables for steels covered in UR W16 were to be incorporated into UR W23. Therefore, two new consumable grades Y89 and Y96 have been introduced into this UR together with the associated requirements. Annual repeat test to confirm diffusible hydrogen content for grades Y69 to Y96 has been introduced in order to maintain regular checks of this parameter which has a critical importance in welded joints of base metal at this strength level due to their increased sensitivity to hydrogen induced cracking. Also, the standard values of tensile strength for the weld metal and welded joint have been revised as same as that of base metal specified in UR W16 Rev. 3. Furthermore, the adoption of undermatching condition was considered of necessary or high strength steels, based on Class Societies remarks.

The further revision for consistency with UR W16 was minor in nature.

3. Source / derivation of the proposed IACS Resolution

The specified requirements for the two new consumables were based on base metal specifications, consumable manufacturer specifications and relevant international standards, where available.

The undermatching conditions were introduced in order to be in line with the industry practice for high strength steel applications.

4. Summary of Changes intended for the revised Resolution:

Two new consumable grades were introduced.
New reference to undermatching conditions was introduced into Rev. 2
Requirement to repeat diffusible hydrogen test at annual frequency has been added for grades Y69 to Y96.

5. Points of discussions or possible discussions

The EG/MW discussed on the necessity of adding reference to the undermatching conditions and also the future alignment of the bending angle across relevant UR's.

6. Attachments if any

None.

UR W24 – Cast Copper Alloy Propellers

Summary

This UR provides requirements for the manufacture, inspection and repair procedures of cast copper alloy propellers, blades and bosses. This revision has the following technical change:

Paragraph 11.3: Repair of defects in zone A:
- the permissibility of a modified Zone A, is now deleted.

Opportunity was taken to carry out other minor edits and clarifications.

Updated the definitions of linear and non-linear indications to align with ISO 23277:2015

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev.5 (Sep 2023)	11 September 2023	1 January 2025
Rev.4 (July 2020)	16 July 2020	1 July 2021
Corr.1 (Jan 2013)	17 Jan 2013	-
Rev.3 (May 2012)	11 May 2012	1 July 2013
Rev.2 (May 2004)	24 May 2004	-
Rev.1 (1997)	*No records*	-
NEW (1996)	*No records*	-

- ### Rev.5 (September 2023)

1 Origin of Change:

✓ Suggestion by IACS member

2 Main Reason for Change:

To revise paragraph 11.3 of UR W24 Rev.4 to exclude such a permissibility of a modified Zone A.

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

No contribution by non-IACS Member classification societies.

4 History of Decisions Made:

The previous (Rev.4) Resolution introduced the permissibility of modification of Zone A in case of repair by welding on an individual approach. However, the lack of criteria for the application of these modification and the inconsistency of the applied approach (with feedback from the IACS Machinery Panel) caused several IACS Members to have difficulties in implementing UR W24 Rev.4 in their Classification Rules.

Responding to statements of interest from a number of IACS members, EG/M&W decided that it is necessary to revise the above Unified Requirements to exclude this permissibility. Since there are no detailed requirements for the basis of a modified Zone A, it is left to the Classification Society to decide any technical basis for such a decision. Every effort should be made to rectify a discontinuity within Zone A without recourse to welding.

5 Other Resolutions Changes:

None.

6 Any hinderance to MASS, including any other new technologies:

None.

7 Dates:

Original Proposal	: 10 February 2022	(Made by: EG/M&W)
EG/M&W Approval	: 24 August 2023	(Ref: EMW2105_)
GPG Approval	: 11 September 2023	(Ref: 22023_IGf)

- **Rev.4 (July 2020)**

1 Origin of Change:

Suggestion by an IACS member

2 Main Reason for Change:

Review and harmonize non-destructive testing requirements in URW24 and URW27. Review the repair welding requirements.

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

No contribution by non-IACS Member classification societies.

4 History of Decisions Made:

Original proposal to revise IACS UR W24 and UR W27 for consistency of the definition of liquid penetrant indications and for evaluation of technical requirements was made at IACS EG/MW meeting in September 2016. Four drafts have been discussed by the group.

Discussions took place about UR W24 article 11.3 & UR W27 article 11.5- repair of defects in Zone A. Members decided to reword these articles to introduce cases where propeller designer submit technical documentation to propose a modified Zone A.

Discussions took place about UR W24 Appendix A – article 5.2- base metal. Members decided to use the principles of ISO 15614-6 for base metal range approval.

Discussions took place about UR W24 Appendix A – Table 9 range of qualification for thickness. Members decided to keep a pragmatic approach as changing to the ISO would require requalification of current PQRs for repairs lower than 15mm thick.

5 Other Resolutions Changes:

None

6 Any hinderance to MASS, including any other new technologies:

None

7 Dates:

Original Proposal:	September 2016 Made by: EG M&W
EG M&W Approval:	30 June 2020 (Ref: 18149_EMWe)
GPG Approval:	16 July 2020 (Ref: 18149_IGh)

- **Corr.1 (Jan 2013)**

1 Origin for Change:

☑ Request from the Industry (Pipavav Shipyard)

2 Main Reason for Change:

To correct the definition of area "A" in Figure 3 as requested by the Industry. Figures 4, 5 and 6 were also improved by the Machinery Panel.

3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

4 History of Decisions Made:

PermSec received the request for correction from the Industry (Pipavav Shipyard). Hull Panel reviewed the request and forwarded it to Machinery Panel with some additional suggestions for corrections. Machinery Panel carried out the corrections as requested. Figures 4, 5 and 6 were also improved by the Machinery Panel.

PermSec prepared a HF section to record this correction.

5 Other Resolutions Changes

None

6 Dates:

Original proposal: *19 May 2012 made by: Pipavav Shipyard*
Panel Approval: *21 November 2012 by: Machinery Panel*
GPG Approval: *17 January 2013 (Ref. 12057aIGb)*

- **Rev.3 (May 2012)**

1 Origin for Change:

☑ Suggestion by an IACS member

2 Main Reason for Change:

To align Table 1 (Typical chemical compositions of cast copper alloys for propellers) with industry standards.

3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

4 History of Decisions Made:

In the Hull Panel, proposals were submitted to amend Table 1 as follows:
(a) Removal of the lower limit of Sn for CU1
(b) Correction of maximum limit of Sn for CU2 from 0.15% to 1.5%.
(c) Correction of maximum limit of Sn for CU3 from 0.1% to an undetermined percentage.

The Hull Panel agreed with the proposals for amending CU1 and CU2, but rejected the proposal to amend CU3. This decision was passed onto the Machinery Panel, which is responsible for this UR.
For Technical Background, see Annex 2.

5 Other Resolutions Changes

None

6 Dates:

Original proposal: *08 February 2012 made by: HP member*

IACS Unified Requirement W24 (Rev.2)
Technical Background

Cast Copper Alloy Propellers

a) Objective/Scope

The objective was to rationalize all UR Ws procedures on mechanical testing by reference to the new UR W2 (Rev.2, 2003).

b) Source of Proposed Requirements

The revised draft UR was developed referring to the existing requirements of the UR W24 "Cast Copper Alloy Propellers" and the UR W2 "Test specimens and mechanical testing procedures for materials".

c) Points of Discussion

Nil.

* * * * *

Technical Background for UR W24 Rev.3, May 2012

1. Scope and objectives

The objective was to align Table 1 (Typical chemical compositions of cast copper alloys for propellers) with industry standards.

2. Engineering background for technical basis and rationale

It was brought to the attention of the Hull Panel that the Sn limits for certain alloys in Table 1 of UR W24 were not in line with comparable/similar alloys specified in Industry Standards. Therefore, the Table 1 was amended to better align with these standards.

3. Source/derivation of the proposed IACS Resolution

- ASTM B584-2000
- BS1982-2008
- JIS H5120-2006
- GB 1178-1987

4. Summary of Changes intended for the revised Resolution:

- Lower limit of Sn for CU1 removed.
- Upper limit of Sn for CU2 corrected.

5. Points of discussions or possible discussions

<u>Removal of the lower limit of Sn for CU1</u>
- In many national standards, the Sn content of typical CU1 has no lower limit.
- Some reports show that tin is an enhancing element for corrosion resistance and strength of yellow brass, but the content of tin should not exceed 1.5% in brass. Some information shows that if the tin content is less than 0.25%, its anticorrosive effect will be non-apparent.
- Therefore, the proposal to remove the lower limit of Sn for CU1 was accepted.

<u>Correction of upper limit of Sn for CU2</u>
- Some information shows that if the tin content is less than 0.25%, its anticorrosive effect will be non-apparent.
- Therefore, the proposal to correct the upper limit of Sn for CU2 from 0.15% to 1.5% was accepted.

<u>Correction of upper limit of Sn for CU3</u>
- Based on the background of the correction to CU2, the proposal to correct CU3 was submitted.
- In general, Hull Panel Members were not aware of technical issues or problems raised by manufacturers and do not see a necessity for the change.
- Additionally, the proposal did not specify a new upper limit.
- Therefore, the proposal to correct the upper limit of Sn for CU3 was rejected.

6. Attachments if any

None

Technical Background (TB) document for UR W24 (Rev.4 July 2020)

1. Scope and objectives

The objectives were to review:
- the definition of severity zones with regards to current propeller design established by the marine industry.
- the status of sampling and testing requirements for mechanical properties.
- the repair welding requirements.

Review and harmonize non-destructive testing requirements in URW24 and URW27.

2. Engineering background for technical basis and rationale

UR W24 "Cast copper alloy propellers" and UR W27 "Cast steel propellers" have been reviewed for consistency and for evaluation of technical requirements. It was noted that non-destructive testing requirements are to be harmonized between both URs. The conditions for the execution of welding repair procedure qualification must be revised with regards to the recognized standards and current foundries practice.

3. Source/derivation of the proposed IACS Resolution

Existing Classification Societies Rules as well as international standard ISO 15614-6:2006 have been considered.

The UR refers to the following international standard:
ISO 3452-1:2013 "Non-destructive testing -- Penetrant testing -- Part 1: General principles".

4. Summary of Changes intended for the revised Resolution:

The content of UR W24 has been fully reworked and revised with major changes summarised hereafter:
- Revised and update requirements for NDT,
- Revised and develop requirements for welding procedure qualification tests for repairs.

5. Points of discussions or possible discussions

UR W24 article 11.3 & UR W27 article 11.5- repair of defects in Zone A: Requirement has been discussed and reworded to introduce cases where propeller designer submit technical documentation to propose a modified Zone A.

UR W24 12.3 - welding repair procedure: it was agreed to reword the text to say that the article is intended for repairs by arc welding.

UR W24 article 13.2- hot straightening: it was agreed to introduce a text to prevent hot straightening when weld repairs are in the concerned area.

UR W24 Appendix A – article 5.2- base metal: it was agreed to use the principles of ISO 15614-6 for base metal range approval.

UR W24 Appendix A – Table 9 range of qualification for thickness: it was agreed to keep a pragmatic approach as changing to the ISO would require requalification of current PQRs for repairs lower than 15mm thick.

6. Attachments if any

None.

***

Technical Background for UR W24 (Rev.5 Sep 2023)

1. Scope and objectives

The objectives were to:
- either provide detailed requirements for the basis of a modified zone A, or;
- to exclude such permissibility of modifying the zone A

2. Engineering background for technical basis and rationale

The lack of detailed criteria for the application of a modified zone A, and the inconsistency of the applied approach (upon discussions with the IACS Machinery Panel) caused several IACS Members to have difficulties in implementing UR W24 in their Classification Rules.

Responding to statements of interest from a number of IACS members, a decision was taken by EG/M&W that it was necessary to revise UR W24 to either detail the requirements for the permissibility of modification of Zone A (and agree the chosen approach with the Machinery Panel), or to exclude such a permissibility.

2a. Specification of the data utilised in the development/revision of the proposed IACS Resolution, if any

None

3. Source/derivation of the proposed IACS Resolution

Existing Classification Societies Rules
IACS UR W24
IACS UR W27
ISO 23277:2015. Non-destructive testing of welds — Penetrant testing — Acceptance levels.

4. Summary of Changes intended for the revised Resolution:

- Referring to paragraph 11.3: Repair of defects in zone A - it was unanimously agreed to exclude such a permissibility of a modified Zone A, and it is left to the member Society to decide the technical basis for such a decision. Therefore the text relating to this clause is deleted.

- Minor (non-technical) typographical/editorial changes were made to other paragraphs

- Updated the definitions of linear and non-linear indications to align with ISO 23277:2015

5. Points of discussions or possible discussions

- Members unanimously agreed that it was not possible to specify detailed requirements within this UR as to how (or on what basis) a modified zone A could be achieved.
- IACS Machinery Panel were also consulted, and they agreed that no detailed requirements could be included in this UR for such a modified zone A
- It was noted amongst members that other paragraphs within the UR make some provision that upon special agreement with the Classification Society, weld repair may take place (it is left to the member Society to decide the technical basis for such a decision)
- It was further noted amongst members that the UR advises that effort should be made to consider other repair methods (e.g., blending or grinding, where possible) without resulting to welding, to rectify defects within zone A.

UR W25 "Aluminium Alloys for Hull Construction and Marine Structure"

Summary

Review and update industry standards format according to GPG instructions

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev.6 (Sep 2021)	21 September 2021	1 January 2023
Rev.5 (June 2014)	30 June 2014	1 July 2015
Rev.4 (Dec 2011)	02 Dec 2011	1 January 2013
Rev.3 (May 2006)	16 May 2006	-
Rev.2 (Dec 2004)	27 Dec 2004	-
Rev.1 (May 2004)	24 May 2004	-
NEW (May 1998)	28 May 1998	-

- ### Rev.6 (Sep 2021)

1 Origin of Change:

☒ Suggestion by IACS member

2 Main Reason for Change:

To update industry standards format according to GPG instructions given in GPG Vice-chair message 19000_IRC.

3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None.

4 History of Decisions Made:

Original proposal was made according to GPG Vice-chair message 19000_IRc. Proposal to revise the IACS URs and RECs only to refer to a dated version of the industry standard as per GPG instructions was made at IACS EG/MW meeting in September 2019. Three drafts have been discussed by the group.

5 Other Resolutions Changes:

None.

6 Any hinderance to MASS, including any other new technologies:

None.

7 Dates:

Original Proposal	: April 2019	(Made by: GPG)
EG M&W Approval	: July 2021	
GPG Approval	: 21 September 2021	(Ref: 19000_IGq)

- ## Rev.5 (June 2014)

.1 Origin for Change:

☑ Suggestion by IACS EG/MW

.2 Main Reason for Change:

To remove the requirement for the corrosion testing of aluminium temper conditions H111 and H112.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

In November 2012, the IACS EG/MW agreed in their annual meeting that the corrosion testing of aluminium alloys listed in UR W25 for temper conditions H111 and H112 was not technically necessary.

For Technical Background, see Annex 5.

.5 Other Resolutions Changes

None

.6 Dates:

Original proposal: January 2014 Made by: EG/MW
GPG Approval: 30 June 2014 (Ref. 13202bIGb)

- ## Rev.4 (Dec 2011)

.1 Origin for Change:

☑ Suggestion by non-IACS entities (The Aluminum Association and European Aluminium Association)

.2 Main Reason for Change:

- To add reference to ASTM standards for corrosion testing
- To add Temper H111 for Alloys 5083, 5383, 5059, 5086, and 5754 in Table 2
- To update UR W25 as necessary

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

1) Two separate requests were made to IACS by outside organizations to update or modify UR W25. These requests were taken into consideration by the Hull Panel and a proposal was developed.

2) In November 2010, The Aluminum Association requested a modification to Section 8.5: Corrosion Testing. There were two main requests.
    a) References to ASTM B928 in Section 8.5.2 and 8.5.3.
    ASTM B928 provides instructions for the preparation of reference photomicrographs and the batch acceptance of metallography. The Aluminum Association was concerned that UR W25 had neither of these instructions nor references to them. Therefore, a reference to ASTM B928, Section 9.4.1 was added to Section 8.5.2 for the photomicrographs and a reference to ASTM B928, Section 9.6.1 was added to Section 8.5.3 for the metallographic examination.
    b) Acceptance criteria in Section 8.5.3 for the Corrosion tests.
    The Aluminum Association was concerned that the acceptance criteria for the corrosion tests was neither stated explicitly nor contained within the referenced standards, ASTM G66 and G67. These standards only contained the detailed instruction for conducting the corrosion tests. Therefore, the acceptance criteria (as set in ASTM B928) were added to Section 8.5.3.

    In addition to the changes in UR W25, the Aluminum Association requested clarification of the origin of the under-thickness tolerances for rolled products, as the tolerances specified in UR W28 are stricter than the current industry standards. The Hull Panel was in favour of maintaining the current UR W25 underthickness tolerances. A response was sent to the Aluminum Association.

3) In August 2011, the European Aluminium Association (EAA) requested an update to the alloys and tempers covered by UR W25 (Section 3: Aluminium Alloys and Their Temper Conditions) to Table 2: Mechanical Properties for Rolled Products, 3mm $\leq t \leq$ 50mm. The EAA requested that Temper H111 for Alloy 5083 for rolled products be reintroduced into the UR W25 and that corrosion tests, as specified for H116 and H321, be required for Tempers H111 and H112

    Even though their mechanical properties are the same, Temper H111 was separated from temper O for all alloys and relocated to a new line in Table 2 and Table 3 during Rev.3 to avoid any conflict with dual certification. At this time, Temper H111 was removed from Alloy 5083 for rolled products (Table 2) because it was not registered or specified by ASTM for sheets and plates (ASTM B209 and B928). However, it was also removed from all of the rolled product alloys.

Since several of these alloys with temper H111 are specified by European Standards (EN 13195 and EN 485-2) for rolled products, they have been reintroduced into Table 2. The alloys that now specify temper H111 are: 5083, 5383, 5059, 5086, and 5754. Alloy 5456 was not specified in the European Standard.

In Section 8.5.1, Tempers H111 and H112 were added to the list of tempers that require corrosion testing for exfoliation and intergranular corrosion resistance.

4) Additional to the requested modifications, Table 2 was updated. In the "Elongation" columns, missing values were added and values not applicable for given thickness ranges were deleted for alloy 5059. In the "Yield Strength" header, the phase "or range" was added, since several values are given as ranges. This phase was originally in the header, but was dropped during Rev.3.

   In Section 14; Documentation, "h) Corrosion Test Results" was added to the list of details to be supplied by the manufacturer.

For Technical Background, see Annex 4.

.5 Other Resolutions Changes

None

Note: *There is no separate Technical Background (TB) document for New (May 1998).*

IACS Unified Requirement W25 (Rev.1):
Technical Background

Aluminium Alloys for Hull Construction and Marine Structure

a) Objective/Scope

The objective were as follows:

1. To rationalize all UR Ws procedures on mechanical testing by reference tothe new UR W2 (Rev.2, 2003).
2. To revise the UR W25 from the viewpoint of the consistency between the special requirements and industry practices regarding thickness tolerances and use of alloy 5083-H321 in marine environments.

b) Source of Proposed Requirements

The revised draft UR was developed referring to the existing requirements of the UR W25 "Aluminium Alloys for Hull Construction and Marine Structure" and ASTM G66 and G67.

c) Points of Discussion

The discussion on the following technical points for the above a) objective/Scope 2 had been made and achieved full agreement of the members:

<u>Aluminium alloys;</u>

The alloys of type 5383 and 5059 are to be newly specified for both rolled and extruded products.

<u>Chemical composition and Mechanical properties;</u>

Chemical composition and mechanical properties of the above alloys are also to be specified accordingly.

<u>Tolerances;</u>

Dimensional tolerances other than underthickness tolerances for rolled products are to be in accordance with the requirements of recognized international or national standard.

<u>Corrosion testing;</u>

1. Rolled 5xxx-alloys of type 5083, 5383, 5059 and 5086 in the H116 and H321 tempers intended for use in marine hull construction or in marine applications where frequent direct contact with seawater is expected are to be corrosion tested with respect to exfoliation and intergranular corrosion resistance.
2. The corrosion tests are to be in accordance with ASTM G66 and G67 or equivalent method.
3. The manufacturers shall establish the relationship between microstructure and resistance to corrosion when the above alloys are approved. A reference photomicrograph shall be established and approved for each of the alloytempers and thickness ranges relevant.
4. For batch acceptance, metallographic examination of one sample selected from the product is to be carried out. The microstructure of the sample is to be compared to the reference photomicrograph of acceptable material in the presence of the Surveyor.

<u>Branding;</u>

Tempers corrosion-tested are to be marked "M" after the temper condition, e.g. 5083 H321 M.

Note: GPG added the changes to W25.1.4(..or ANSI H35.1) and W25.4.3 (chemical composition – product analysis). 3004aIGd of 4 May 2004 refers.

* * *

Technical Background
Unified Requirement W25 (Rev.2)

Aluminium Alloys for Hull Construction and Marine Structure

a) Objective/Scope
To review comments from ASTM Task Group and relevant standards, in particular ASTM B 928-04, and propose changes to UR W25 Rev.1.

b) Source of Proposed Requirements
The revised draft UR was developed referring to the existing requirements of the UR W25 "Aluminium Alloys for Hull Construction and Marine Structure" and ASTM B 209-04 and B 928-04.

c) Points of Discussion
The discussion on the following technical points for the above a) objective/Scope had been made and achieved full agreement of the members:
<u>Tempers;</u>
- To delete the temper H32 from UR W25 Rev.1, since this temper will be exempted from corrosion testing in the ASTM standards.
- To add temper H116 for alloy 5086.
<u>New grades;</u>
- To add alloy 5456 with the tempers 0, H116 and H321.

* * * * *

Submitted by WP/MW Chairman
17 September 2004

TECHNICAL BACKGROUND DOCUMENT
IACS UR W25 (REV.3, MAY 2006)

1. Scope and objective

To modify the unified requirements UR W25 in accordance with the newly developed ASTM standard for marine aluminium alloys – ASTM B928.

2. Background

Recent changes have been made to IACS UR W25 at Rev.2, these were based on problems experienced in service with corrosion, and subsequent investigations by the US Coast Guard. Minor issues have been raised with Rev. 2, including the need for the provision of a US alloy that is used in the marine market, this need to be addressed.

The US alloy referred to above is 5456, which actually was included in connection with the previous revision of UR W25 (Rev.2). However, we also received a number of comments from the ASTM Marine Task Group regarding other issues that needed to be changed/modified (see email from 2006-12-12). One of the important issues was to list the different tempers (e.g. O/H111) separately to discourage dual certification, as the processing of the tempers is different. Further, the ASTM Marine Task Group/Harold Bushfield proposed to change some of the specified properties to be more in line with recognised ASTM standards.

3. Points of discussions or possible discussions

- H111 was deleted from Table 2 due to the fact that the H111 temper is not registered and not specified by ASTM for sheets and plates. However, if it is used we may include H111 in a separate row with values taken from the EN-standard.
- NV 5086 H321 is neither specified in ASTM B209M/B928 nor in EN 485-2, and is therefore deleted from Table 2.
- IACS should not specify higher values than the ones specified in recognised standards, especially in standards like ASTM, hence some of the specified strength values have been somewhat modified.
- Previously the values for the O and H111 tempers were identical. This is not considered correct as pointed out by the ASTM Task Group. They are separated in the present proposal to discourage dual certification, due to the fact that these tempers actually represent different processing.

4. Source/derivation of proposed requirements

- ASTM B928

5. Decision by Voting

A member expresses their reservation to UR W25(Rev.3) with the following comments:

> *_n the past it was our understanding of IACS objectives to establish own technical regulations valid for the specific fields of application for ship classification.*
>
> *The consideration and to some extent the implementation of international standards had been done as deemed necessary and based on an internal approach. The adjustment to one single national standard such as ASTM seems to be quite questionable as other national standards do exist too.*
>
> *Any change of strength and elongation values or cancellation of temper conditions within the UR shall be done based on technical investigations. The formal change*

and following one national standard does not consider the good experience gained with the "old" UR W 25 or other existing standards.

Therefore we still prefer that H111 temper condition shall remain in the table as it is produced today by the manufacturers and applied in the industry.

With respect to our point of view both temper condition O/H111 shall remain in the same line of table 2 and 3 as this table does not reflect certification status of the plates. The mechanical properties of the products mentioned in the tables are one part of certification. Dual certification just exist if both conditions are mentioned on the material certificate which is not the intention of these tables.

The cancellation of temper condition H321 for 5086 is accepted.

Any other change shall be considered on a technical base or kept as it was proposed recently for Rev. 02.

6. Appendix

N.A.

Submitted by Hull Panel Chairman
10 April 2006

Note:
The member removed its reservation at GPG level as follows:

Quote:

```
To: IACS GPG Chairman,                          2006-04-28
CC: IACS GPG Members
CC: IACS Permanent Secretariat

1. Regarding the acceptance of UR W25 Rev. 3 GL is
going to accept the modifications.

2. In addition to the material specifications as
listed in Table 2 we will continue to use the
temper conditions
H111 for grades 5083, 5383, 5059, 5086, 5754
H321 for grade 5086

3. We account these temper conditions as equivalent
or even superior (with regard to fabrication
aspects) to the materials as listed in Table 2 of
Rev. 3.

Best regards,

IACS GPG Member
```

Unquote:

Technical Background for UR W25 Rev.4, Dec 2011

1. Scope and objectives

To modify the unified requirements UR W25, following multiple requests from industry associations.

2. Engineering background for technical basis and rationale

Two industry associations, the Aluminum Association and the European Aluminium Association, requested modification to UR W25.

The Aluminum Association requested:
(1) References to ASTM B928 be added in Section 8.5.2 and 8.5.3, to provided instructions for the preparation of reference photomicrographs and the batch acceptance of metallography.
(2) Acceptance criteria for the corrosion test be added in Section 8.5.3.
(3) Clarification of the origin of the under-thickness tolerances for rolled products and the reason the IACS requirements differ from industry requirements.

The European Aluminium Association requested
(1) H111 temper for Alloy 5083 be included for rolled products in Table 2.
(2) Corrosion tests be required for temper H111.

3. Source / derivation of proposed IACS Resolution

- ASTM B928
- EN 13195
- EN 485-2

4. Summary of changes intended for the revised Resolution

Alloys:
- Temper H111 was added to the list of temper conditions covered by UR W25 in Section 3.1
- Temper H111 was added to Table 2 for the alloys 5083, 5383, 5059, 5086, and 5754, as specified by European Standard EN13195 and EN 485-2 . Alloy 5456 was not specified in the European Standards.
- Table 2 was corrected to specify that yield strength may be given as a range.
- In Table 2, missing values were added and values not applicable for given thickness ranges were deleted from the Elongation column.

Corrosion Tests:
- In Section 8.5.1, Tempers H111 and H112 were added to the list of tempers that require corrosion testing for exfoliation and intergranular corrosion resistance.

- A reference to ASTM B928, Section 9.4.1 was added to UR W25, Section 8.5.2 for instruction on the preparation of photomicrographs.
- A reference to ASTM B928, Section 9.6.1 was added to UR W25, Section 8.5.3 for instruction on the preparation of the metallographic examination.
- The acceptance criteria for the corrosion tests (as set out in ASTM B928) were added to UR W25, Section 8.5.3.
- In Section 14; Documentation, "h) Corrosion Test Results" was added to the list of details to be supplied by the manufacturer.

Thickness Tolerance:

- It is understood that the thickness tolerance values were taken from an old Standard and it was noted that vessels designed with aluminium are typically done so on close margins. The thickness tolerances on extruded products in UR W25 were changed in 2004/2005 in order to bring them in line with recognized standards. This was due to the fact that most extrusions were manufactured in accordance with recognized standards with respect to thickness tolerances. We are aware that the under-thickness tolerances for rolled products differ from recognized standards, however IACS wanted to keep the somewhat stricter under-thickness tolerances compared to recognized standards.

Technical Background for UR W25 (Rev.5, June 2014)

1. Scope and objectives

To modify the Unified Requirement UR W25, following discussions at the annual meeting of the IACS EG/MW.

2. Engineering background for technical basis and rationale

At the IACS EG/MW 2012 meeting a number of members questioned the UR W25 requirement for corrosion testing of 5083, 5383, 5059, 5086 and 5456 in the H111 and H112 temper conditions.

The corrosion tests specified in UR W25 are intended to demonstrate freedom from exfoliation and intergranular corrosion. The risk of sensitisation to exfoliation and intergranular corrosion is considered to be low due to the production methods associated with manufacture of H111 and H112 temper condition products.

The corrosion testing of temper conditions H111 and H112 is considered technically unnecessary and out of step with industry practice and is therefore to be removed form UR W25.

3. Source / derivation of proposed IACS Resolution

IACS EG/MW 2012 meeting minutes.

4. Summary of changes intended for the revised Resolution

Corrosion Tests:
- In Section 8.5.1, Tempers H111 and H112 were deleted from the list of tempers that require corrosion testing for exfoliation and intergranular corrosion resistance.

5. Points of discussions or possible discussions

None

IACS UR W26 (Rev.0)

Requirements for Welding Consumables for Aluminium Alloys

Technical Backgrounds

a) **Objective / Scope**

The objective was to newly elaborate the Unified Requirement for Welding Consumables for Aliminium Alloys. The consumables specified in this draft UR are applicable to welding of the aluminium alloys for hull construction / marine structure specified in UR W25, which was formerly established.

b) **Source of Proposed Requirements**

The requirements in this draft UR were elaborated referring to UR W17 "Approval of Consumables for Welding Normal and Higher Strength Hull Structural Steels" and corresponding National / International Standards.

c) **Points of Discussion**

The discussions had been held mainly upon the following three points of view and achieved full agreement in the AHG/MW :

- Quality grades ;
  The requirements for manufacturing were decided in line with ones in UR W17. The grades of consumables were categorized based on the kinds of consumables (rod/wire) and the materials grade of base metals for which the consumables are used.
- Approval test procedures ;
  The approval test procedures (including the requirements on annual test) were decided in line with ones in UR W17, i.e; the tests required are carried out by using the test pieces taken from both deposited metals and butt-weld test assemblies.
- Required properties ;
  The requirements concerning tensile/bend tests on butt-weld assemblies were specified. The minimum tensile strength's level is basically equal to the lower limit of the ones for O-materials (annealing) of the base metals to be used in the tests.

△△

Technical Background Document
UR W26 (Rev.1 June 2005)

Requirements for Welding Consumables for Aluminium Alloys

a) Objective/Scope

The objective was to develop requirements of welding consumables for aluminium alloys 5383 and 5059.

b) Source of Proposed Requirements

The revised draft UR was developed referring to the existing requirements of the UR W26 “Requirements for Welding Consumables for Aluminium Alloys”.

c) Points of Discussion

The discussion on the following technical points for the above a) objective/Scope had been made and achieved full agreement of the members:

Base materials for test;
Aluminium alloys 5383, 5456, 5059, 6005A and 6061 are to be added as base material for the test.

Requirements for the transverse tensile and bend test;
The requirements of tensile strength of quality grade RC/WC are to be amended depending on the base material applied for the tests.

Approval range;
It is understood that a welding consumable of quality grade RC/WC can be qualified using any base materials within that quality grade.
The WP pointed out the need to specify the tensile strength of butt joint for each base material and the range of application of the different welding consumables to the base materials should be specified in matrix of IACS Recommendation 70 “Guidelines on welding procedure qualification tests of aluminium alloys for hull construction and marine structures”.
This matter should be considered under Task No.54.

Submitted by WP/MW Chair
28/12/2004

Technical Background (TB) document for UR W26 (Rev.2 Sep 2021)

1. Scope and objectives

Review and update industry standards format according to GPG instructions.

2. Engineering background for technical basis and rationale

N.A.

3. Source/derivation of the proposed IACS Resolution

ISO 4063:2009

4. Summary of Changes intended for the revised Resolution:

UR W27 – Cast Steel Propellers

Summary

This UR provides requirements for the manufacture, inspection and repair procedures of cast steel propellers, blades and bosses. This revision has the following technical change:

Paragraph 11.5: Repair of defects in zone A:
- the permissibility of a modified Zone A, is now deleted.

Opportunity was taken to carry out other minor edits and clarifications.

Updated the definitions of linear and non-linear indications to align with ISO 23277:2015

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev.3 (Sep 2023)	11 Sep 2023	1 January 2025
Corr.1 (Sep 2020)	29 Sep 2020	-
Rev.2 (July 2020)	16 July 2020	1 July 2021
Rev.1 (May 2004)	*No records*	-
NEW (May 2000)	*No records*	-

- **Revision No. 3, July 2023**

1 Origin of Change:

✓ Suggestion by IACS member

2 Main Reason for Change:

To revise paragraph 11.5 of UR W27 Rev.2 Corr.1 to exclude such a permissibility of a modified Zone A.

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

No contribution by non-IACS Member classification societies.

4 History of Decisions Made:

The previous (Rev.2 Corr.1) Resolution introduced the permissibility of modification of Zone A in case of repair by welding on an individual approach. However, the lack of criteria for the application of these modification and the inconsistency of the applied approach (with feedback from the IACS Machinery Panel) caused several IACS Members to have difficulties in implementing UR W27 Rev.2 Corr.1 in their Classification Rules.

Responding to statements of interest from a number of IACS members, EG/M&W decided that it is necessary to revise the above Unified Requirements to exclude this permissibility. Since there are no detailed requirements for the basis of a modified Zone A, it is left to the Classification Society to decide the technical basis for such a decision. Every effort should be made to rectify a discontinuity within Zone A without recourse to welding.

5 Other Resolutions Changes:

None.

6 Any hinderance to MASS, including any other new technologies:

None.

7 Dates:

Original Proposal	: 10 February 2022 Made by: EG M&W
EG/M&W Approval	: 30 June 2020 (Ref: 18149_EMWe)
GPG Approval	: 11 September 2023 (Ref: 22023_IGf)

- **Corr.1 (Sep 2020)**

1 Origin of Change:

Suggestion by an IACS member

2 Main Reason for Change:

The application statement of UR W27(Rev.2) "Cast Steel Propeller", needs to be corrected as follows:

Quote
1. Changes introduced in Rev.2 are to be uniformly implemented by IACS Societies on ships contracted for construction on or after 1 July 2021, or when the application for certification of cast copper alloy steel propellers is dated on or after 1 July 2021, or the
application for certification of manufacturer approval is dated on or after 1 July 2021.
Unquote

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None

4 History of Decisions Made:

Having noted this proposal could be regarded as minor editorial correction to the application statement, it was approved by GPG as a corrigenda without further involvement of EG/M&W.

5 Other Resolutions Changes:

None

6 Any hinderance to MASS, including any other new technologies:

None

7 Dates:

Original Proposal: 11 September 2020 (Ref: 18149_IRd)
GPG Approval: 29 Sep 2020 (Ref: 18149aIGb)

• Rev.2 (July 2020)

1 Origin of Change:

Suggestion by an IACS member

2 Main Reason for Change:

Review and harmonize non-destructive testing requirements in URW24 and URW27. Review the repair welding requirements.

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

No contribution by non-IACS Member classification societies.

4 History of Decisions Made:

Original proposal to revise IACS UR W24 and UR W27 for consistency of the definition of liquid penetrant indications and for evaluation of technical requirements was made at IACS EG/MW meeting in September 2016. Four drafts have been discussed by the group.

Discussions took place about UR W24 article 11.3 & UR W27 article 11.5- repair of defects in Zone A. Members decided to reword these articles to introduce cases where propeller designer submit technical documentation to propose a modified Zone A. Discussions took place about UR W27 article 7.1 – Mechanical properties. Members decided to make reference to recognized standard for the thickness of test coupon.

5 Other Resolutions Changes:

None

6 Any hinderance to MASS, including any other new technologies:

None

7 Dates:

IACS Unified Requirement W [27]

Cast steel propellers

Technical Backgrounds:

a) Objective / Scope
The objective was to newly elaborate the Unified requirement for cast steel propellers. This draft UR applies to Cr-Ni alloyed cast steel propellers.

b) Source of Proposed Requirements
The requirements in this draft UR were developed referring to the UR W24 "Cast copper alloy propellers", in addition to the corresponding specifications of individual Society's Rules and National/International Standards.

c) Points of Discussion

The discussion had been mainly made on the following technical points and achieved full agreement of the members:

<u>Type of alloy steels;</u>
Typical 4 types of Cr-Ni alloy steels are to be specified according to their microstructures and chemical components (major elements only).

Heat treatment required for each type is to be specified, i.e., austenitization and temper for martensitic castings and solution treatment for austenitic castings.

<u>Test procedures and required properties;</u>

Mechanical properties such as proof stress, tensile strength, elongation, reduction of area and CVN energy, tested with the integrally cast test specimens are to be specified. Basically, one set of test specimens is to be taken for each casting. CVN test is not required in the case of the use of general service and the lowest Ice class notation. Also, separately cast test specimens and/or batch testing procedures may be allowed subject to the prior approval of the individual Society.

<u>NDE and repair procedures;</u>

NDE procedures/criteria and repair procedures (include repair welding) are to be given according to the severity Zones which divide the propeller surface into Zones A to C, that is in line with the corresponding specifications of UR W24 for better use. Also, procedure qualification tests for repair weldings are to be specified in the Appendix, in the same manner as UR W24.

* * * * *

IACS Unified Requirement W27(Rev.1)
Technical Background

Cast Steel Propellers

a) Objective/Scope
The objective was to rationalize all UR Ws procedures on mechanical testing by reference to the new UR W2 (Rev.2, 2003).

b) Source of Proposed Requirements
The revised draft UR was developed referring to the existing requirements of the UR W27 “Cast Steel Propellers” and the UR W2 “Test specimens and mechanical testing procedures for materials”.

c) Points of Discussion
Nil.

* * * * *

Technical Background (TB) document for UR W27 (Rev.2, July 2020)

1. Scope and objectives

The objectives were to review:
- the definition of severity zones with regards to current propeller design established by the marine industry.
- the status of sampling and testing requirements for mechanical properties.
- the repair welding requirements.

Review and harmonize non-destructive testing requirements in URW24 and URW27.

2. Engineering background for technical basis and rationale

UR W24 "Cast copper alloy propellers" and UR W27 "Cast steel propellers" have been reviewed for consistency and for evaluation of technical requirements. It was noted that non-destructive testing requirements are to be harmonized between both URs. The conditions for the execution of welding repair procedure qualification must be revised with regards to the recognized standards and current foundries practice.

3. Source/derivation of the proposed IACS Resolution

Existing Classification Societies Rules as well as international standard ISO 11970:2016 have been considered.

The UR refers to the following international standard:
ISO 3452-1:2013 "Non-destructive testing -- Penetrant testing -- Part 1: General principles".
ISO 9934-1:2016"Non-destructive testing – Magnetic Particle Testing -- Part 1: General principles".

4. Summary of Changes intended for the revised Resolution:

The content of UR W27 has been fully reworked and revised with major changes summarised hereafter:

- Revised and update requirements for NDT,
- Revised and develop requirements for welding procedure qualification tests for repairs.

5. Points of discussions or possible discussions

UR W27 article 7.1 – Mechanical properties: testing sampling has been discussed. It was agreed to make reference to recognized standard for the thickness of test coupon.

UR W24 article 11.3 & UR W27 article 11.5- repair of defects in Zone A: Requirement has been discussed and reworded to introduce cases where propeller designer submit technical documentation to propose a modified Zone A.

6. Attachments if any

None

***

Technical Background for UR W27 (Rev.3 Sep 2023)

1. Scope and objectives

The objectives were to:
- either provide detailed requirements for the basis of a modified zone A, or;
- to exclude such permissibility of modifying the zone A

2. Engineering background for technical basis and rationale

The lack of detailed criteria for the application of a modified zone A, and the inconsistency of the applied approach (upon discussions with the IACS Machinery Panel) caused several IACS Members to have difficulties in implementing UR W27 in their Classification Rules.

Responding to statements of interest from a number of IACS members, a decision was taken by EG/M&W that it was necessary to revise UR W27 to either detail the requirements for the permissibility of modification of Zone A (and agree the chosen approach with the Machinery Panel), or to exclude such a permissibility.

2a. Specification of the data utilised in the development/revision of the proposed IACS Resolution, if any

None

3. Source/derivation of the proposed IACS Resolution

Existing Classification Societies Rules
IACS UR W24
IACS UR W27
ISO 23277:2015. Non-destructive testing of welds — Penetrant testing — Acceptance levels.

4. Summary of Changes intended for the revised Resolution:

- Referring to paragraph 11. Repair of defects, and specifically 11.5 - it was unanimously agreed to exclude such a permissibility of a modified Zone A, and it is left to the member Society to decide any technical basis for such a decision. Therefore, the text relating to this clause is deleted.

- Minor (non-technical) typographical/editorial changes were made to other paragraphs.

- Updated the definitions of linear and non-linear indications to align with ISO 23277:2015

5. Points of discussions or possible discussions

- Members unanimously agreed that it was not possible to specify detailed requirements within this UR as to how (or on what basis) a modified zone A could be achieved.

- IACS Machinery Panel were also consulted, and they agreed that no detailed requirements could be included in this UR for such a modified zone A
- It was noted amongst members that other paragraphs within the UR make some provision that upon special agreement with the Classification Society, weld repair may take place (it is left to the member Society to decide the technical basis for such a decision)
- It was further noted amongst members that the UR advises that grinding may be carried out in zone A (where possible), to rectify any defects within this zone.

Technical Background Document
UR W28 (June 2005)

Welding procedure qualification tests of steels for hull construction and marine structures

a) Objective/Scope

The objective was to develop a new UR concerning welding procedure qualification test for hull construction, referring to the existing Rec.32.

b) Source of Proposed Requirements

The revised draft UR was developed referring to the existing IACS Recommendation 32 "Guidelines on welding procedure qualification tests for hull construction", ISO 15614-1 "Specification and qualification of welding procedures for metallic materials –Welding procedure test-" and other recognized standards.

c) Points of Discussion

The discussion on the following technical points had been made and achieved full agreement of the members:

<u>Scope;</u>
The requirements are applicable to the welding procedure qualification tests for steels specified in UR W7, W8, W11 and W16.

<u>Preliminary welding procedure specification and welding procedure specification;</u>
A preliminary welding procedure specification (pWPS) is to be submitted prior to the tests. A pWPS may be approved as a welding procedure specification, upon satisfactory completion of the test.

<u>Qualification of welding procedure (Longitudinal tensile test);</u>
The test is to be carried in case where the welding consumable is not approved by the Society.

<u>Qualification of welding procedure (Impact test);</u>
1) Sampling position and notch location are to be developed depending on the thickness and the heat input.

2) The requirements(test temperature and required energy) for steels specified in UR W11 are to be specified for steels with thickness not more than 50mm and are to follow the Rec.32 which are based on the impact test requirements of welding consumable specified in UR W17.

3) The requirements for steels specified in UR W16 are to follow the requirements of base metals.

4) Test for cast and forged structural steels are to be carried out only in case where the tests are required for the base metals.

Range of approval;

1) Base metal

The Range of approval for steel grade is to be specified with the following key concepts:

- For each strength level, welding procedures are considered applicable to the same and lower toughness grades as that tested.

- For each toughness grade, welding procedures are considered applicable to the same and two lower strength levels as that tested.

- For high heat input processes above 50kJ/cm, welding procedure is applicable to that toughness grade tested and one strength level below.

2) Welding position

Test assemblies are to be welded with the highest heat input position and the lowest heat input position, i.e. two positions are usually tested for approval of all positions, and all applicable tests are to be made.

3) Welding consumable

Welding consumable having the same grade marks including all suffixes with that tested are to be included.

4) Heat input

The upper limits of heat input for high heat input welding is to be stricter than normal heat input welding.

5) Type of joint

The range of approval is to be specified with the concept that one side welding is superior to both side welding.

Test records;

The statement included in test record that the test piece was made according to the particular welding procedure is to be signed by the surveyor witnessing the test.

Permsec Note: In connection with approval of new UR W28, GPG decided to delete Recommendation No.32 from the Blue Book.

Submitted by WP/MW Chair
28/12/2004

Technical Background Document
UR W28 (Rev. 1 November 2006)

Welding procedure qualification tests of steels for hull construction and marine structures

a) Objective/Scope

Prior to the implementation of UR W28 (June 2005), which was adopted by the Council on 27 June 2005, the member societies found difficulties in the implementation of the UR based on the contracted for construction date as specified therein. As unanimously agreed upon by WP/MW, Hull Panel, GPG and Council, the contents of the requirements for welding procedure qualification tests remain unchanged. Revision 1 to the UR aims to clarify the application date of the requirements.

b) Source of Proposed Requirements

No changes are made from W28 (June 2005)

c) Points of Discussion

Issues of W28 (June 2005)

1) In the footnote 1 of the UR, it specifies that the UR is to be uniformly implemented on ships contracted for construction from 1 January 2007 as well as the manufacturing of which is commenced on or after 1 January 2007.

2) This means that all current welding procedures approved by the members' societies in the past and being used by shipyards/manufacturers for long time, are no longer valid as the qualified welding procedures and new qualification tests are required to be performed for compliance with the UR W28.

3) There should be no point for introduction of the situation as mentioned in 2 above.

Solutions by W28 (Rev. 1 October 2006)

1) In order to solve the implementation issue, the following limit statements are provided in the new paragraphs 1.3 and 1.4:

1.3 All new welding procedure qualification tests are to be carried out in accordance with this document from 1 July 2007.

1.4 This document does not invalidate welding procedure qualification tests made and accepted by the Classification Society before 1 July 2007 provided the welding procedure qualification tests are considered by the Classification Society to meet the technical intent of this UR or have been qualified in accordance with the recognized standards such as ISO, EN, AWS, JIS or ASME.

2) The above new descriptions clarify the application/scope of the UR W28 without deletion of the footnotes 1 and 2 of W28 (June 2005) as approved by Council on 27 June 2005.

3) The accepted welding procedures according to each Classification Society's rules are considered to meet the technical intent of this UR.

d) Others

A member advised of the need for them to reserve on certain technical aspects of the UR as a result of it's governance body review. Member will detail its reservations to Council as soon as possible.

Submitted by Hull Panel Chair, October 2006

Permanent Secretariat Note (November 2006):
- Item (d) added by GPG following their discussion.
- Revised W28 approved by GPG and Council, 14 November 2006 (6183_IGd)

Technical Background Document
UR W28 (Rev. 2 March 2012)

Welding procedure qualification tests of steels for hull construction and marine structures

1. Objective/Scope

To modify the range of approval depending on type of welded joint for test assemblies specified in Table 3 “Range of approval for type of welded joint”.

2. Engineering Background for Technical Basis and Rationale

Qualifying a welding procedure from one side with backing implies a technique with a designated joint geometry (root face, root opening, and groove angle), a designated backing material, and a heat input to achieve a sound weld in the root against the backing whether the backing remains in place or is removed. Utilizing this same technique within the limits of the (one side) procedure variables in a weld made from both sides may or may not provide a satisfactory root weld depending on joint geometry and heat input limits of the procedure.

3. Source/Derivation of Proposed Requirements

- Hull Panel Member
- ISO 15614-1

4. Summary of Changes Intended for the Revised Resolution

- In Table 3, item “D” was removed from the range of approval for item “A”.

5. Points of Discussion and Decision by Voting

<u>Associated International Standards</u>
Rev. 1 of UR W28 was in line with the international standard ISO 15614. There was some concern regarding the fact that the changes made in Rev. 2 made the IACS requirements stricter than the ISO requirement.

However, ISO is an international standard that is used for not only ships but also other industries, while an IACS UR is a requirement dedicated to ships. There is precedent among this UR and other URs where the requirements are stricter than their ISO equivalent.

Additionally, there appears to be a contradiction among the more important welding qualification standards used in industry (ie ISO 15614, AWS D1.1, ASME IX) in this regard.

<u>Removing “D” from the range of approval of “A”</u>
Table 3 showed that, in cases where the welding procedure specifications of “A” were approved, “C” (both side welding with gouging) and “D” could be also included in the range of approval for the welding procedure specifications.

Regarding "D", it is important not to leave any defects in the root pass for quality control of welded joints. The condition of a groove in the root pass is similar to that of "B" and the root pass is required to be a penetration bead. Accordingly, the welding condition is different from "A".

Therefore, it was suggested that it was not appropriate to include "D" in the range of approval of "A". That suggestion was accepted by the Hull Panel.

<u>Adding "A" to the range of approval of both side without gouging "D"</u>
In addition to the above, it was also proposed to add "A" to the range of approval of "D", since "A" would be technically covered by the qualifications for "D" if the qualification level required for "D" is properly achieved,.

However, some Hull Panel members commented that the qualifications for the welding procedure for "D" should not cover the procedure for "A", given that certain factors for "A" such as the type of backing strip, heat input, and weld gaps are different from those applicable to "D".

As a 2/3 majority was not achieved, the proposal was rejected.

6. Attachments, if any

None

Technical Background Document
UR W29 (June 2005)

Requirements for manufacture of anchors

a) Objective/Scope
The objective was to develop the requirements for the manufacture and certification of anchors.

b) Source of Proposed Requirements
The revised draft UR was developed referring to UR A1 “Equipment” and JIS F 3301 “Anchors”.

c) Points of Discussion
The discussion on the following technical points had been made and achieved full agreement of the members:

Scope;
The requirements are to be specified for manufacture of any types of anchors specified in UR A1.

Materials;
Cast steel, forged steel and rolled steel used for anchor are to be manufactured and tested in accordance with the UR W to be applied.

Product test programme;
The Society can require, in addition to proof load test, either of two kinds of product test programme to anchors, depending of product form i.e. cast, forged or fabricated anchor. In stead of drop test and hammering test required in Programme A, Charpy V notch impact tests for cast anchor and extended NDE are required in Programme B. In this regards, requirement of NDE for locations of anchor was specified based on UR A1.

Repair criteria
Repair is not permitted for fracture and unsoundness defected in hammering test and drop test.

Certification;
The Classification Society issues the certificate to the manufacturer, including the information of type, mass, ID No., grade of materials, proof test load, heat treatment, and marking the applied to anchor etc.

Part B. Technical Background

Annex 1. **TB for New (Feb 2013)**

See separate TB document in Annex 1.

Technical Background document for UR W30 (New, Feb 2013)

1. Scope and objectives

The Performance Standard for Alternative Means of Corrosion Protection for Cargo Oil Tanks of Crude Oil Tankers (IMO Resolution MSC.289 (87)) allows for the use of "*Corrosion Resistant Steel*". This steel is modified ship steel with micro additions of certain chemical elements that have been found to have a beneficial effect by retarding the corrosion rate in the environments found in cargo tanks of crude oil carriers.

Many issues arise because Corrosion resistant Steels are newly developed materials. It has therefore been necessary to produce a new IACS UR W30, to explain the manufacture, testing and certification of these steels.

2. Engineering background for technical basis and rationale

Several issues were highlighted that IACS needed to address:

a) The materials need to comply with strength and toughness in accordance with UR W11.

b) There is no IACS unified approach to the approval, manufacture, certification and shipyard application of these steels. Their application has no effect on fabrication in shipbuilding, but there are no requirements in the IMO resolution addressing approval, manufacture and certification and these processes need to be addressed.

c) The steel must be approved to confirm the corrosion resistance.

d) No practicable production release test is available for these steels. Although a type approval test method has been developed in the IMO PSPC it is noted that this test method allows variation in the composition of the test medium, such as concentration of H_2S. This creates uncertainty in the assessment of the corrosion resistance of the steel.

Taking the above into account a project team PT59 was asked to draft a new IACS UR W30, to explain the manufacture, testing and certification of these steels.

3. Source / derivation of the proposed IACS Resolution

The IMO Performance Standard comes into effect on 1 January 2013 for new building contracts. It was aimed to have a UI in place by 1 June 2012 to allow time for designs to be considered before contracts are signed.

4. Summary of Changes intended for the revised Resolution:

Not applicable

UR W31 "YP47 Steels and Brittle Crack Arrest Steels"

Summary

Latest revision is dealing with the approval scheme of small-scale test methods for brittle crack arrest steels. Requirements for testing and approval procedures have been revised and developed.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev.3 (Mar 2023)	07 March 2023	01 July 2024
Rev.2 (Dec 2019)	3 December 2019	01 January 2021
Rev.1 (Sept 2015)	30 September 2015	01 January 2017
New (Jan 2013)	21 January 2013	01 January 2014

• Rev.3 (Mar 2023)

1 Origin of Change:

☑ Suggestion by an IACS member

2 Main Reason for Change:

1) Stipulate the approval scheme of small-scale test methods for brittle crack arrest steels

2) Update the "Annex 3 Test Method for Brittle Crack Arrest Toughness, Kca" reflecting ISO20064: 2019.

3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

4 History of Decisions Made:

- Members agreed that small-scale test methods are approved by each manufacturer's proposed test method, not unified test method, since small-scale test methods are to be determined based on manufacturer's own technical philosophy with regard to achieving the brittle crack arrest properties of brittle crack arrest steels.
- Members agreed that the examples of small-scale test method are stipulated for manufacturer's reference and the other test methods which are not stipulated in Annex 5 are also acceptable as small-scale test method.

- Members agreed that Charpy V Notch test, if proposed as a single test method for small scale testing, is not suitable to provide robust correlation or determination of crack arrest properties
- Members agreed that the correlation in brittle crack arrest properties between the calculated values from small scale tests and the brittle crack arrest test results shall be assured by using the value of twice the standard deviation (2σ) which is obtained from at least 12 test plates.
- Members agreed that the product testing acceptance criterion of brittle crack arrest steels by the small-scale tests is to be determined so that regression equation can predict brittle crack arrest properties on safety side, considering the scatter of brittle crack arrest properties from the predicted value by the regression equation.

5 Other Resolutions Changes

None

6 Any hinderance to MASS, including any other new technologies:

None

7 Dates:

Original Proposal	: 04 February 2020	(Made by: EG M&W Member)
EG M&W Approval	: 23 January 2023	(Ref: EMW1401)
GPG Approval	: 07 March 2023	(Ref: 15198_IGl)

- **Rev.2 (Dec 2019)**

1 Origin of Change:

☑ Suggestion by an IACS member

2 Main Reason for Change:

Specify the required brittle crack arrest toughness Kca for brittle crack arrest steels (hereinafter "BCA steels") referred to in UR S33 with thickness exceeding 80mm and up to 100mm.

Specify the required Crack Arrest Temperature (CAT) for BCA steels.

Amend the unified requirements on temperature-gradient brittle crack arrest test procedure to evaluate Kca of BCA steels specified in Annex 1 of UR W31 in accordance with Japan Welding Engineering Society Standard of WES 2815:Jan 2014.

Specify unified requirements on isothermal brittle crack arrest test procedure to evaluate CAT of BCA steels.

Specify unified requirements on the manufacturing approval scheme of BCA steels.

Specify unified requirements on product inspection of BCA steels.

3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

4 History of Decisions Made:

Members agreed that the grade of BCA steels is generally only "EH" considering the past actual records of application of BCA steels of the Classification Societies.

Members agreed that the thickness range of BCA steels is over 50mm and up to 100mm considering the consistency between UR W31 and UR S33.

The majority of Hull Panel agreed to the following items in response to the EG/MW's inquiry concerned:

(a) Required Kca for BCA steels with thickness exceeding 80mm and up to 100mm are as follows:

- Upper deck: required Kca is to be 6,000N/mm$^{3/2}$ or over at -10 degree C
- Hatch side coaming: required Kca is to be 8,000N/mm$^{3/2}$ or over at -10 degree C

(b) Large-scale structural model test conditions are reasonable

(c) Requirements of YP36 BCA steels should be specified in UR W31.

Members and Hull Panel agreed that the specific required brittle crack arrest properties for each the structural member (i.e. upper deck and hatch side coaming) are to be specified in UR S33.

Members agreed that only the material specifications of brittle crack arrest properties are specified in UR W31.

Members agreed unified requirements on isothermal brittle crack arrest test procedure to evaluate CAT of BCA steels and the specific CAT criteria.

5 Other Resolutions Changes

None

6 Any hinderance to MASS, including any other new technologies:

None

7 Dates:

Original Proposal: 28 July 2016 (Made by: EG M&W Member)
Panel Approval: 11 February 2019
GPG Approval: 3 December 2019 (Ref: 15198_IGe)

- **Rev.1 (Sept 2015)**

1 Origin of Change:

☑ Suggestion by an IACS member

2 Main Reason for Change:

Amend UR W31 by removing design related content and transferring this to UR S33.
Amend UR W31 by transferring material related content from UR S33.

3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

4 History of Decisions Made:

Members concurred that annex 2 standard ESSO test in UR S33 should be transferred to UR W31. Also they agreed that the paragraph 2.1 hull structures (design) should be transferred from UR W31 to UR S33.

One member proposed to include double tension test for CAT as Annex 2 of UR W31 and to determine the required Kca value for the steel exceeding 80mm. Members agreed that this task should be transferred to EG/M&W.

Panel agreed that the crack arrest properties for brittle design should be transferred from UR S33 and defined in UR W31. Two members indicated that they would prefer the crack arrest properties for brittle design should be included in UR S33.

Panel approved that the ownership of UR W31 should be transferred to EG/M&W.

No TB is expected for the present revision.

5 Other Resolutions Changes

None.

6 Dates:

Original Proposal: 20 September 2013 made by: Panel Member
Panel Approval: *09 July 2015 (Ref: PH13026_IHy)*
GPG Approval: *30 September 2015 (Ref: 14139_IGf)*

- **New (Jan 2013)**

1 Origin of Change:

☑ Suggestion by the Japan Society of Naval Architects and Ocean Engineers (JASNAOE)

2 Main Reason for Change:

None – new document.

3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

See separate TB document in Annex 3.

Note: *There is no Technical Background (TB) document available for Rev.1 (Sept 2015).*

Technical Background (TB) document for UR W31 (New, Jan 2013)

1. Scope and objectives

An increase in the size of container ships has led to an increase in the thickness of steel materials used, thus causing problem such as making welding work difficult as well as increasing brittle fracture problem. In order to alleviate these problems, YP47 class steel plates has been developed.
YP47 is a new kind of high tensile steel plate. Various kinds of studies are necessary for the application to ship structures.
At the time of October 2010, some classification societies have their own guidelines which need to be unified. And some shipyards already applied YP47 steels in their container ships.
IACS recognized that it is necessary to develop the unified requirements (UR) on the application of YP47 steel plates, rather than amending the existing URs, covering following items;

- HT factor and material selection
- Material specification
- Manufacturing process approval
- Welding consumables
- Welding procedure qualification test(WPQT)
- Others such as welding work, etc.

2. Engineering background for technical basis and rationale

Several issues were highlighted that IACS needed to address:

a) Considering the application trend of steel thickness for ultra-large container carriers, maximum thickness of YP47 steel plate is to be up to 100mm. For steel plates exceeding 100mm, special consideration is to be given by each Classification Society.

b) YP47 steel plates are to be applied to longitudinal structural members in the upper deck region of container carriers (such as hatch side coaming, hatch coaming top and the attached longitudinals). Special consideration is to be given to the application of YP47 steels for other hull structures.

c) Supply condition of YP47 steels is to be TMCP. Other supply condition is to be each classification society's criteria.

d) The requirements for material specification and manufacturing process approval have been developed based on the UR W11. However the specified min. average impact energy should depend on the thickness of steels.

e) When YP47 steel plates are used in the longitudinal structural members in the upper deck region of container carriers, it is important that the steel plates possess brittle crack arrestability to prevent brittle crack propagation as a back up function in case a brittle crack unexpectedly occurs. So brittle crack arrest test such as standard ESSO test or CAT (Crack Arrest Temperature) should be conducted in the manufacturing approval test.

f) Fatigue property of YP47 steels need not be specified because fatigue problems are basically regarded as, not material-related matters, but design-related matters involving details such as structural discontinuities or shape, welded joint, flame cuts, etc. PT52 confirmed that the design S-N curves are applicable to YP47 steel plates as well as YP32, YP36 etc.

   Accordingly, in this material-related UR, Section 2.1.2 clarifies that fatigue assessment for structural details is the task of each society.

g) Brittle fracture initiation test in weldment is meaningless because a notch of the test specimen is placed across WM, HAZ and BM as long as V groove is applied to the actual welding procedures in shipyards and test result will be easily affected by the combination of WM, HAZ and BM on the notch.

Taking the above into account a project team PT52 was asked to draft a new IACS UR, W31, to explain the application, manufacture, testing and certification of these steels.

Based on review comments made during development, the following TB items are noted:

Section 2.5.4: the hardness requirement of 380 Hv is included in this UR. It is noted that the hardness requirement of 420 Hv used in URW28 is for quenched and tempered steel, and the quality control is different from that of hull structural steels. This section also includes the text "as defined in UR W28" which refers to the hardness test method in Annex B of UR W28.

3. Source/derivation of the proposed IACS Resolution

- Application of YP47 steel Plates prepared by PM for discussion in PT52.
- A : Guide for application of higher-strength hull structural thick steel plates in container carriers
- B : Classification notes no. 30.10, Extra high strength steel material NV47 for hull structural application in container ships
- C : Supplementary Rules for Application of Steel with Yield Strength of 460 N/mm^2
- D : Circular No. 2011-09-E, Instruction for the approval and inspection of YP47 Steel plates used for Large Container Carriers
- E : Guidelines on the Application of YP47 Steel for Hull Structures of Large Container Carriers

Technical Background (TB) document for UR W31 (Rev.2, Dec 2019)

1. Scope and objectives

In UR W31, the requirements of YP47 steels used for large container ships have been specified.
Furthermore, the specific required brittle crack arrest properties of YP47 steels has been specified in UR W31 as follows:

i) Kca≧6,000N/mm$^{3/2}$ at -10 degree C
ii) Crack Arrest Temperature (CAT)

Note 1: The specific value of the required Kca has not been specified for brittle crack arrest steels (hereinafter "BCA steels") with thickness exceeding 80mm.
Note 2: The specific required CAT has not been specified.

Apart from the above, the industry demands strongly that the specific required brittle crack arrest toughness for BCA steels with thickness up to 100mm should be specified in IACS UR due to emerging 20,000 TEU-class ultra-large container ships.

Also, the relevant material requirements on manufacturing approval scheme and product inspection of the BCA steels have not been specified in UR W31 whereas the application of the BCA steels has been required for large container ships contracted for construction on or after 1 January 2014.

In light of the above, IACS recognized that it is necessary to amend UR W31 including the following items:

(a) Specify the required crack arrest toughness Kca for BCA steels with thickness exceeding 80mm and up to 100mm
(b) Specify the required CAT for BCA steels
(c) Amend the unified requirements on temperature-gradient brittle crack arrest test procedure to evaluate Kca of BCA steels
(d) Specify unified requirements on isothermal brittle crack arrest test procedure to evaluate CAT of BCA steels
(e) Specify unified requirements on the manufacturing approval scheme of BCA steels
(f) Specify unified requirements on product inspection of BCA steels.

2. Engineering background for technical basis and rationale

(a) Based on the results of verification test using the large-scale structural model test specimens simulating the upper deck region (hatch side coaming and upper deck) of large container ships with 100mm-thick test plates submitted by the Japanese Welding Engineering Society, brittle crack arrest properties as the material specifications are specified in UR W31 as follows:

i) BCA steels with suffix BCA1: Kca is 6,000N/mm$^{3/2}$ or over at -10 degree C
ii) BCA steels with suffix BCA2: Kca is 8,000N/mm$^{3/2}$ or over at -10 degree C

(b) Industrial research was undertaken to assess the various parameters and the influence on the CAT values and compatibility with corresponding Kca value. Based on the results of research project related to isothermal brittle crack arrest test procedure to evaluate CAT and relationship between CAT and Kca, the said test procedure is specified in Annex 4 and specific CAT criteria of BCA1 is specified as -10 degree C.

It was agreed that specific CAT criteria of BCA2 is to be approved by the Classification Societies.

(c) The unified requirements on temperature-gradient brittle crack arrest test procedure to evaluate Kca of BCA steels are amended based on Japan Welding Engineering Society Standard of WES 2815:Jan 2014.

3. Source/derivation of the proposed IACS Resolution

Japan Welding Engineering Society Standard of WES 2815:Jan 2014 is referred in order to amend the unified requirements on temperature-gradient brittle crack arrest test procedure to evaluate Kca of BCA steels.

.

4. Summary of Changes intended for the revised Resolution:

(a) The required brittle crack arrest toughness Kca for BCA steels with thickness exceeding 50mm and up to 100mm are specified.
(b) The required Crack Arrest Temperature (CAT) for BCA steels corresponding to Kca = 6000 N/ $mm^{3/2}$ is specified.
(c) The chemical composition of YP47 non-BCA steels is specified.
(d) The chemical composition and brittle crack arrest properties of BCA steels (YP36, YP40 and YP47 BCA steels) are specified.
(e) Unified requirements on the manufacturing approval scheme of BCA steels are specified.
(f) The unified requirements on temperature-gradient brittle crack arrest test procedure to evaluate Kca of BCA steels are amended.
(g) Unified requirements on isothermal brittle crack arrest test procedure to evaluate CAT of BCA steels are specified.

5. Points of discussions or possible discussions

(a) In reference to 1.3.3 and Table 3, it was agreed that the thickness range of BCA steels is above 50mm and the thickness range of BCA steels with suffix BCA2 is generally above 80mm considering the ultra large structural test results and the consistency between UR W31 and UR S33.

(b) In reference to Table 3, it was agreed that brittle crack arrest properties of BCA steels are specified as the material specification in UR W31.

(c) In reference to 4.1.4, it was agreed that criteria of hardness test in Welding Procedure Qualification Test (WPQT) for YP47 non-BCA steels is changed considering the criteria of hardness test in WPQT for YP460 steels specified in UR W16 and past actual test records of the welding procedure qualification tests.

(d) In reference to 4.2.1, it was agreed that Welding Procedure Specification (WPS) for the non-BCA steels can applied to the same welding procedure of BCA steels only when heat input is 50kJ/cm or below.

(e) In reference to 4.2.2, criteria of hardness test in welding procedure qualification test for YP47 BCA steels is specified considering the deference between the specification of chemical composition of YP47 non-BCA steels and YP47 BCA steels.

(f) In reference to Table 5 and Table 6, it was agreed that criteria of impact test for welding consumables for YP47 steels is changed in order to harmonize the said criteria for welding consumables and welding procedure qualification test for YP47 steels.

6. Attachments if any

None

Technical Background (TB) document for UR W31 (Rev.3 Mar 2023)

1. Scope and objectives

In UR W31, the requirements of YP47 steels used for large container ships have been specified.

The industry is to conduct the brittle crack arrest tests for BCA steels in product testing to assure that their steels obtain the sufficient brittle crack toughness.

Corresponding the above, in UR W31, it is specified that small-scale tests approved by the Classification Society can be used for product testing (batch release testing) as the brittle crack arrest tests for BCA steels.

However, the clear approval scheme of small-scale test method for brittle crack arrest steels has not been specified.

In addition, ISO20064 was published in July 2019 based on WES2815.

In light of the above, IACS recognized that it is necessary to amend UR W31 including the following items:

1) Stipulate the approval scheme of small-scale test methods for brittle crack arrest steels

2) Update the "Annex 3 Test Method for Brittle Crack Arrest Toughness, Kca" reflecting ISO20064: 2019.

2. Engineering background for technical basis and rationale

(a) Stipulate the examples of small-scale test method which is used by representative Industries.

(b) Consideration was given to the various testing methodologies, and concluded that Charpy V Notch test, if proposed as a single test method for small scale testing, is not suitable to provide robust correlation or determination of crack arrest properties

(c) With regard to the acceptance criterion of brittle crack arrest steels by the small-scale tests and the correlation in brittle crack arrest properties between the calculated values from small scale tests and the brittle crack arrest test results, it was agreed that the industry shall be assured by using the value of twice the standard deviation (2σ).
In addition, necessary test plates (i.e. 12 test plates) which can reliably estimate brittle crack arrest properties of brittle crack arrest steels were determined considering the actual data submitted by some industries.

(d) With regard to the accuracy of correlation in brittle crack arrest properties between the calculated values from small scale tests and the brittle crack arrest test results, it was agreed that the upper limit of value of twice the standard deviation (2σ) was determined considering the actual data submitted by some industries.

3. Source/derivation of the proposed IACS Resolution

(a) IACS EG/MW Members networks with BCA steel manufacturers and academia has provided valuable research and in-depth studies into the nature and mechanisms of brittle failure, and insight into determination of crack-arrest mechanisms as applied to a variety of manufacturers.
Furthermore, determination of small-scale tests and their correlation with both large-scale testing and statistical formulae has provided a valuable basis for the detailed content within this revised UR W31.

4. Summary of Changes intended for the revised Resolution:

(a) Stipulate the approval scheme of small-scale test methods for brittle crack arrest steels

(b) Update the "Annex 3 Test Method for Brittle Crack Arrest Toughness, Kca" reflecting ISO20064: 2019.

(c) Detailed requirements are now provided for acceptable statistical correlations for small scale tests, for both CAT and K_{ca} values.

5. Points of discussions or possible discussions

(a) In reference to Table A5-1 to Table A5-3, it was agreed that these examples of small-scale test method are stipulated for manufacturer's reference and the other test methods which are not stipulated in Annex 5 are also acceptable as small-scale test method.

(b) In reference to A5.3.3.1, necessary test plates (i.e. 12 test plates) are stipulated to reliably estimate brittle crack arrest properties of brittle crack arrest steels. However, a decrease of the total of the indicated number of test plates may be accepted by the Classification Society as specified in A5.3.3.1.6.

(c) In reference to A5.3.3.1, A5.3.4.2 and A5.3.5.2, the acceptance criterion of brittle crack arrest steels by the small-scale tests and the correlation in brittle crack arrest properties between the calculated values from small scale tests and the brittle crack arrest test results shall be considered the value of twice the standard deviation (2σ).

(d) In reference to A5.3.4.2, the upper limit of value of twice the standard deviation (2σ) was determined considering the accuracy of correlation in brittle crack arrest properties between the calculated values from small scale tests and the brittle crack arrest test results. Its value when using temperature for brittle crack arrest property was determined that 2σ shall not be greater than 20℃. In other cases (e.g. K_{ca} value at -10℃), an upper limit of 2σ shall be established with the agreement of the Classification Society since it is difficult to determine the equivalent value to the upper limit of value when using temperature.

(e) In reference to A5.3.5, the acceptance criterion of brittle crack arrest steels by the small-scale tests is to be determined so that regression equation can predict brittle crack arrest properties on safety side, considering the scatter of brittle crack arrest properties from the predicted value by the regression equation as shown in A5.3.5.2. The other methods determining acceptance criterion of brittle crack arrest steels by the small-scale tests are also acceptable if it can predict brittle crack arrest properties on safety side.

(f) Discussion and considerations were given to the approval test plan (reference A5.4.), with potentially further testing requirements, depending on the results. Decisions would consider a variety of items, examples of which could be:
(i) data clustering producing a biased correlation curve;
(ii) small-scale tests providing a wide variance;
(iii) inconclusive small-scale test results.

Technical Background (TB) document for UR W31 (New, Jan 2013)

1. Scope and objectives

An increase in the size of container ships has led to an increase in the thickness of steel materials used, thus causing problem such as making welding work difficult as well as increasing brittle fracture problem. In order to alleviate these problems, YP47 class steel plates has been developed.
YP47 is a new kind of high tensile steel plate. Various kinds of studies are necessary for the application to ship structures.
At the time of October 2010, some classification societies have their own guidelines which need to be unified. And some shipyards already applied YP47 steels in their container ships.
IACS recognized that it is necessary to develop the unified requirements (UR) on the application of YP47 steel plates, rather than amending the existing URs, covering following items;

- HT factor and material selection
- Material specification
- Manufacturing process approval
- Welding consumables
- Welding procedure qualification test(WPQT)
- Others such as welding work, etc.

2. Engineering background for technical basis and rationale

Several issues were highlighted that IACS needed to address:

a) Considering the application trend of steel thickness for ultra-large container carriers, maximum thickness of YP47 steel plate is to be up to 100mm. For steel plates exceeding 100mm, special consideration is to be given by each Classification Society.

b) YP47 steel plates are to be applied to longitudinal structural members in the upper deck region of container carriers (such as hatch side coaming, hatch coaming top and the attached longitudinals). Special consideration is to be given to the application of YP47 steels for other hull structures.

c) Supply condition of YP47 steels is to be TMCP. Other supply condition is to be each classification society's criteria.

d) The requirements for material specification and manufacturing process approval have been developed based on the UR W11. However the specified min. average impact energy should depend on the thickness of steels.

e) When YP47 steel plates are used in the longitudinal structural members in the upper deck region of container carriers, it is important that the steel plates possess brittle crack arrestability to prevent brittle crack propagation as a back up function in case a brittle crack unexpectedly occurs. So brittle crack arrest test such as standard ESSO test or CAT (Crack Arrest Temperature) should be conducted in the manufacturing approval test.

f) Fatigue property of YP47 steels need not be specified because fatigue problems are basically regarded as, not material-related matters, but design-related matters involving details such as structural discontinuities or shape, welded joint, flame cuts, etc. PT52 confirmed that the design S-N curves are applicable to YP47 steel plates as well as YP32, YP36 etc.

Accordingly, in this material-related UR, Section 2.1.2 clarifies that fatigue assessment for structural details is the task of each society.

g) Brittle fracture initiation test in weldment is meaningless because a notch of the test specimen is placed across WM, HAZ and BM as long as V groove is applied to the actual welding procedures in shipyards and test result will be easily affected by the combination of WM, HAZ and BM on the notch.

Taking the above into account a project team PT52 was asked to draft a new IACS UR, W31, to explain the application, manufacture, testing and certification of these steels.

Based on review comments made during development, the following TB items are noted:

Section 2.5.4: the hardness requirement of 380 Hv is included in this UR. It is noted that the hardness requirement of 420 Hv used in URW28 is for quenched and tempered steel, and the quality control is different from that of hull structural steels. This section also includes the text "as defined in UR W28" which refers to the hardness test method in Annex B of UR W28.

Technical Background (TB) document for UR W31 (Rev.2, Dec 2019)

1. Scope and objectives

In UR W31, the requirements of YP47 steels used for large container ships have been specified. Furthermore, the specific required brittle crack arrest properties of YP47 steels has been specified in UR W31 as follows:

i) Kca≧6,000N/mm$^{3/2}$ at -10 degree C
ii) Crack Arrest Temperature (CAT)

Note 1: The specific value of the required Kca has not been specified for brittle crack arrest steels (hereinafter "BCA steels") with thickness exceeding 80mm.
Note 2: The specific required CAT has not been specified.

Apart from the above, the industry demands strongly that the specific required brittle crack arrest toughness for BCA steels with thickness up to 100mm should be specified in IACS UR due to emerging 20,000 TEU-class ultra-large container ships.

Also, the relevant material requirements on manufacturing approval scheme and product inspection of the BCA steels have not been specified in UR W31 whereas the application of the BCA steels has been required for large container ships contracted for construction on or after 1 January 2014.

In light of the above, IACS recognized that it is necessary to amend UR W31 including the following items:

(a) Specify the required crack arrest toughness Kca for BCA steels with thickness exceeding 80mm and up to 100mm
(b) Specify the required CAT for BCA steels
(c) Amend the unified requirements on temperature-gradient brittle crack arrest test procedure to evaluate Kca of BCA steels
(d) Specify unified requirements on isothermal brittle crack arrest test procedure to evaluate CAT of BCA steels
(e) Specify unified requirements on the manufacturing approval scheme of BCA steels
(f) Specify unified requirements on product inspection of BCA steels.

2. Engineering background for technical basis and rationale

(a) Based on the results of verification test using the large-scale structural model test specimens simulating the upper deck region (hatch side coaming and upper deck) of large container ships with 100mm-thick test plates submitted by the Japanese Welding Engineering Society, brittle crack arrest properties as the material specifications are specified in UR W31 as follows:

i) BCA steels with suffix BCA1: Kca is 6,000N/mm$^{3/2}$ or over at -10 degree C
ii) BCA steels with suffix BCA2: Kca is 8,000N/mm$^{3/2}$ or over at -10 degree C

(b) Industrial research was undertaken to assess the various parameters and the influence on the CAT values and compatibility with corresponding Kca value. Based on the results of research project related to isothermal brittle crack arrest test procedure to evaluate CAT and relationship between CAT and Kca, the said test procedure is specified in Annex 4 and specific CAT criteria of BCA1 is specified as -10 degree C.

It was agreed that specific CAT criteria of BCA2 is to be approved by the Classification Societies.

(c) The unified requirements on temperature-gradient brittle crack arrest test procedure to evaluate Kca of BCA steels are amended based on Japan Welding Engineering Society Standard of WES 2815:Jan 2014.

3. Source / derivation of the proposed IACS Resolution

Japan Welding Engineering Society Standard of WES 2815:Jan 2014 is referred in order to amend the unified requirements on temperature-gradient brittle crack arrest test procedure to evaluate Kca of BCA steels.

.

4. Summary of Changes intended for the revised Resolution:

(a) The required brittle crack arrest toughness Kca for BCA steels with thickness exceeding 50mm and up to 100mm are specified.
(b) The required Crack Arrest Temperature (CAT) for BCA steels corresponding to Kca = 6000 N/ $mm^{3/2}$ is specified.
(c) The chemical composition of YP47 non-BCA steels is specified.
(d) The chemical composition and brittle crack arrest properties of BCA steels (YP36, YP40 and YP47 BCA steels) are specified.
(e) Unified requirements on the manufacturing approval scheme of BCA steels are specified.
(f) The unified requirements on temperature-gradient brittle crack arrest test procedure to evaluate Kca of BCA steels are amended.
(g) Unified requirements on isothermal brittle crack arrest test procedure to evaluate CAT of BCA steels are specified.

5. Points of discussions or possible discussions

(a) In reference to 1.3.3 and Table 3, it was agreed that the thickness range of BCA steels is above 50mm and the thickness range of BCA steels with suffix BCA2 is generally above 80mm considering the ultra large structural test results and the consistency between UR W31 and UR S33.

(b) In reference to Table 3, it was agreed that brittle crack arrest properties of BCA steels are specified as the material specification in UR W31.

(c) In reference to 4.1.4, it was agreed that criteria of hardness test in Welding Procedure Qualification Test (WPQT) for YP47 non-BCA steels is changed considering the criteria of hardness test in WPQT for YP460 steels specified in UR W16 and past actual test records of the welding procedure qualification tests.

(d) In reference to 4.2.1, it was agreed that Welding Procedure Specification (WPS) for the non-BCA steels can applied to the same welding procedure of BCA steels only when heat input is 50kJ/cm or below.

(e) In reference to 4.2.2, criteria of hardness test in welding procedure qualification test for YP47 BCA steels is specified considering the deference between the specification of chemical composition of YP47 non-BCA steels and YP47 BCA steels.

(f) In reference to Table 5 and Table 6, it was agreed that criteria of impact test for welding consumables for YP47 steels is changed in order to harmonize the said criteria for welding consumables and welding procedure qualification test for YP47 steels.

6. Attachments if any

None

Technical Background (TB) document for UR W31 (Rev.3 Mar 2023)

1. Scope and objectives

In UR W31, the requirements of YP47 steels used for large container ships have been specified.

The industry is to conduct the brittle crack arrest tests for BCA steels in product testing to assure that their steels obtain the sufficient brittle crack toughness.

Corresponding the above, in UR W31, it is specified that small-scale tests approved by the Classification Society can be used for product testing (batch release testing) as the brittle crack arrest tests for BCA steels.

However, the clear approval scheme of small-scale test method for brittle crack arrest steels has not been specified.

In addition, ISO20064 was published in July 2019 based on WES2815.

In light of the above, IACS recognized that it is necessary to amend UR W31 including the following items:

1) Stipulate the approval scheme of small-scale test methods for brittle crack arrest steels

2) Update the "Annex 3 Test Method for Brittle Crack Arrest Toughness, Kca" reflecting ISO20064: 2019.

2. Engineering background for technical basis and rationale

(a) Stipulate the examples of small-scale test method which is used by representative Industries.

(b) Consideration was given to the various testing methodologies, and concluded that Charpy V Notch test, if proposed as a single test method for small scale testing, is not suitable to provide robust correlation or determination of crack arrest properties

(c) With regard to the acceptance criterion of brittle crack arrest steels by the small-scale tests and the correlation in brittle crack arrest properties between the calculated values from small scale tests and the brittle crack arrest test results, it was agreed that the industry shall be assured by using the value of twice the standard deviation (2σ).
In addition, necessary test plates (i.e. 12 test plates) which can reliably estimate brittle crack arrest properties of brittle crack arrest steels were determined considering the actual data submitted by some industries.

(d) With regard to the accuracy of correlation in brittle crack arrest properties between the calculated values from small scale tests and the brittle crack arrest test results, it was agreed that the upper limit of value of twice the standard deviation (2σ) was determined considering the actual data submitted by some industries.

3. Source/derivation of the proposed IACS Resolution

(a) IACS EG/MW Members networks with BCA steel manufacturers and academia has provided valuable research and in-depth studies into the nature and mechanisms of brittle failure, and insight into determination of crack-arrest mechanisms as applied to a variety of manufacturers.
Furthermore, determination of small-scale tests and their correlation with both large-scale testing and statistical formulae has provided a valuable basis for the detailed content within this revised UR W31.

4. Summary of Changes intended for the revised Resolution:

(a) Stipulate the approval scheme of small-scale test methods for brittle crack arrest steels

(b) Update the "Annex 3 Test Method for Brittle Crack Arrest Toughness, Kca" reflecting ISO20064: 2019.

(c) Detailed requirements are now provided for acceptable statistical correlations for small scale tests, for both CAT and K_{ca} values.

5. Points of discussions or possible discussions

(a) In reference to Table A5-1 to Table A5-3, it was agreed that these examples of small-scale test method are stipulated for manufacturer's reference and the other test methods which are not stipulated in Annex 5 are also acceptable as small-scale test method.

(b) In reference to A5.3.3.1, necessary test plates (i.e. 12 test plates) are stipulated to reliably estimate brittle crack arrest properties of brittle crack arrest steels. However, a decrease of the total of the indicated number of test plates may be accepted by the Classification Society as specified in A5.3.3.1.6.

(c) In reference to A5.3.3.1, A5.3.4.2 and A5.3.5.2, the acceptance criterion of brittle crack arrest steels by the small-scale tests and the correlation in brittle crack arrest properties between the calculated values from small scale tests and the brittle crack arrest test results shall be considered the value of twice the standard deviation (2σ).

(d) In reference to A5.3.4.2, the upper limit of value of twice the standard deviation (2σ) was determined considering the accuracy of correlation in brittle crack arrest properties between the calculated values from small scale tests and the brittle crack arrest test results. Its value when using temperature for brittle crack arrest property was determined that 2σ shall not be greater than 20℃. In other cases (e.g. K_{ca} value at -10℃), an upper limit of 2σ shall be established with the agreement of the Classification Society since it is difficult to determine the equivalent value to the upper limit of value when using temperature.

(e) In reference to A5.3.5, the acceptance criterion of brittle crack arrest steels by the small-scale tests is to be determined so that regression equation can predict brittle crack arrest properties on safety side, considering the scatter of brittle crack arrest properties from the predicted value by the regression equation as shown in A5.3.5.2. The other methods determining acceptance criterion of brittle crack arrest steels by the small-scale tests are also acceptable if it can predict brittle crack arrest properties on safety side.

(f) Discussion and considerations were given to the approval test plan (reference A5.4.), with potentially further testing requirements, depending on the results. Decisions would consider a variety of items, examples of which could be:
(i) data clustering producing a biased correlation curve;
(ii) small-scale tests providing a wide variance;
(iii) inconclusive small-scale test results.

UR W32 "Qualification scheme for welders of hull structural steels"

Summary

This revision is primarily for coping with the concern raised by a shipyards' association on the revalidation of qualification for welders.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev.1 (Sep 2020)	1 September 2020	1 January 2022
New (Sep 2016)	18 September 2016	1 January 2018

- **Rev.1 (Sep 2020)**

1 Origin of Change:

☒ Request by non-IACS entity *(KOSHIPA)*
☒ Suggestion by IACS member

2 Main Reason for Change:

Add one more option of revalidation measure of the qualification for welders apart from article 6.2.1.a) and 6.2.1.b), based on the request by KOSHIPA and the reservations made by two IACS Members as well.

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None

4 History of Decisions Made:

Since 26th Jan.,2017, Korea Offshore & Shipbuilding Association (hereinafter as referred to KOSHIPA in short) repeatedly raised their concerns about implementation of article 6.2.1 and 6.2.2 regarding to revalidation of qualification for welders.

Concerning the same issue, some of IACS Members respectively made their reservations to GPG.

The discussion also took place within EG/M&W and survey panel, GPG's concluded this matter with message 17017_IGi dated 23 August 2017, with task on EG/M&W to reconsider the inquiries of KOSHIPA's letter as a matter of urgent and identify possible solution.

Based on above-mentioned background and subsequent internal discussion within EG/M&W, revision of article 2.5 and 6.2 of UR W32 has been decided by EG/M&W.

Remarks from some Members invite the expert group to consider the wording of article 5 for possible clarification.

5 Other Resolutions Changes:

None

6 Any hinderance to MASS, including any other new technologies:

None.

7 Dates:

Original Proposal: 23rd August 2017 (Made by: IACS GPG)
Panel Approval: 28 August 2020 (Ref: 17017_EMWk)
GPG Approval: 1 September 2020 (Ref: 17017_IGv)

- **New (Sept 2016)**

1 Origin for Change:

☑ Other (Development of a new UR based on existing Rec 104)

2 Main Reason for Change:

None

3 List of non-IACS Member Classification Societies contributing through the TC Forum and/or participating in IACS Working Group:

None

4 History of Decisions Made:

See Form A EG/M&W Task No. EMW1204, minutes of EG/M&W meeting October 2013, September 2014 and September 2015, technical background.

5 Other Resolutions Changes

Rec 104 shall be withdrawn upon implementation of this new UR W32.

6 Dates:

Original Proposal: November 2013	Made by: EG/M&W Member
Panel Approval: 30 November 2015	(Ref: EMW1204)
GPG Approval: 18 September 2016	(Ref:12108_IGw)

Technical Background (TB) document for UR W32 (New Sept 2016)

1. Scope and objectives

The objective was to develop a new UR concerning Qualification Scheme for Welders based on the existing Rec.104.
This qualification scheme applies to the welders engaged in the welding processes used for the construction of steel ship hull structures, except oxy-acetylene welding and welding of pipes.

2. Engineering background for technical basis and rationale

The IACS Rec.104 has been available and used for many years by industry and classification societies. The application of welder qualifications is an accepted and developed practice in other construction industries and worldwide standards exist. It was agreed to produce an UR based on the experience of Rec 104.
Welder's skill practice is one of the important factors which influence the quality of welds. Examination of welder's skill depends on technical parameters like: welding process / base metal / welding position / type of welded joint, etc.

3. Source / derivation of the proposed IACS Resolution

The revised draft UR was developed from the existing IACS Recommendation 104 "Qualification scheme for welders of steels", and taking into consideration the standards ISO 9606-1 "Qualification testing of welders –Fusion welding – Part 1: Steels" and EN 287-1"Qualification testing of welders –Fusion welding – Part 1: Steels".

4. Summary of Changes intended for the revised Resolution:

Starting from Rec.104, there are some major amendments reviewed as shown below:

- Clarified the applicable strength range of the base metal.
- Agreed that the type of welding consumable is one of the variables for qualification of welders.
- Agreed that some welding processes may be grouped together for welder's qualification testing
- Defined the examination methods for welder engaged in tack welding only.
- Included a typical certificate format.

5. Points of discussions or possible discussions

<u>1. Scope</u>
The range of steel grades covered has been discussed and agreed. The steel grades of URW16 have not been included in the UR as the scope of the UR is steel grades for hull structure.

<u>2. General</u>
Discussion on welding processes usually used in shipyards. Needs for qualification reviewed and agreed for welders engaged in manual welding and semi-automatic welding/partly mechanized welding and operators responsible for setting up and adjustment of fully mechanized and automatic equipment.

3. Range of qualification of welders
It has been considered that the welding of structural steel grades with specified minimum yield strength lower or equal to 460 N/mm^2 needed similar welder's skill. It was agreed to group them together.

4. Qualification test
Since Rec.104 was issued, it is considered that butt welding may cover fillet welding according to the experienced practice.

A tack welding is usually fused in the structural weld joint. Tack welding may be assigned to dedicated welders in some shipyards or manufacturers. Requirements to qualify tack welders were discussed and agreed.

When used in place of bend tests, the use of ultrasonic testing to replace radiography has been reviewed and has not been considered appropriate in that case.

5. Certification
Classification societies practices about cancellation of certificates were reviewed. It was found that some societies allow the shipyard to cancel the welder's qualification directly, but some cancel the welder's qualification after being informed by the shipyard. It has been agreed to keep the practice at the discretion of the classification society.

6.2 Maintenance of the approval
The three ways to maintain the certification according to the ISO standard 9606-1 were discussed. Based on current classification societies practices, requalification has been agreed only by testing or recorded evidence of testing.

6. Attachments if any

None

Technical Background (TB) document for UR W32 (Rev.1 Sep 2020)

1. Scope and objectives

IACS UR W32 gives technical requirements and procedures for a qualification scheme for welders intended to engage in the fusion welding of steels as specified in UR W7, W8, W11 and W31 for hull structures.

This qualification scheme does not cover welders engaged in oxy-acetylene welding.

This qualification scheme does not cover welding of pipes and pressure vessels.

2. Engineering background for technical basis and rationale

According to clause 6.2.1 in the UR W32 rev.0 Sept., 2016,there are only 2 maintenance options available for industry in term of revalidation of qualification for welders. While other international standards allow industry to take other maintenance option than in UR W32, such as AWS D1.1, ISO 9606-1 etc. which give more self-control to industry based on their own welder quality management system, in place.

KOSHIPA, representing at least part of the offshore and ship builders in South Korea, raised this concern to IACS, in searching for grant of such maintenance option of revalidation of qualification for welder in IACS UR W32. Which are supported by some IACS members by making reservations.

In light of such industry inquiry and reservations made by IACS members, it is valuable to revisit UR W32, adapting to the current industry practice.

3. Source / derivation of the proposed IACS Resolution

The UR refers to the following IACS resolutions and international standards

IACS UR W2 Rev.2 July 2003 ”Test specimens and mechanical testing procedures for materials”

IACS UR W7 Rev.3 May 2004 ”Hull and machinery steel forgings”

IACS UR W8 Rev.2 May 2004 ”Hull and machinery steel castings”

IACS UR W11 Rev.9 May 2017 ”Normal and higher strength hull structural steels”

IACS UR W17 Rev.5 March 2018 “Approval of consumables for welding normal and higher strength hull structural steels”

IACS UR W31 Rev.1 Sept.2015 ”Application of YP47 steel plates”

ISO 14732:2013 “Welding personnel -Qualification testing of welding operators and weld setters for mechanized and automatic welding of metallic materials”

ISO 4063:2009 “Welding and allied processes -Nomenclature of processes and reference numbers”

ISO 5817:2014 "Fusion-welded joints in steel, nickel, titanium and their alloys (beam welding excluded)-Quality levels for imperfections"

ISO 9017:2017 "Destructive tests on welds in metallic materials-Fracture test"

4. Summary of Changes intended for the revised Resolution:

Main changes are listed as following

- Further limitation of application scope of the UR was added in clause 1.3, with qualification of welders involved in welding of pressure vessel excluded from the UR.

During the discussion of this change, the EG members' attention was drawn to one EU Directive 2014/68/EU, which doesn't allow to apply clause 9.3 c) in ISO 9606-1, which is quite similar as requested by KOSHIPA, for revalidation of qualification for welders welding pressure vessels in categories II, III and IV.

For easy reference, the extract of the correspondence between ISO 9601-1 and EU directive is put below

-Quote-

Table ZA.1 — Correspondence between this European Standard and Directive 2014/68/EU (PED) [2014 OJ L 189]

Essential Requirements of Directive 2014/68/EU (PED)	Clause(s)/sub-clause(s) of this EN	Remarks/Notes
Annex I, 3.1.2	Clauses 5, 6.2 to 6.6, 7, 8, 10, 11	Qualification testing
	Clauses 6.1, 9.1, 9.3 a), 9.3 b)	For pressure equipment in categories II, III and IV the examiner/examining body (according to 3.3 and 3.4) is a competent third party – a notified body or a recognized third party organization.
	Clause 9.3 c)	Not permitted for categories II, III and IV products.

-End quote-

- Section 6.2.1.c) and it's sub-section are newly added in the UR, in order to establish a new maintenance option in term of revalidation of qualification for welders. For the purpose of dealing with KOSHIPA concerns and IACS internal reservation from some of IACS Members, which is primary duty of this revision.

- Some editorial changes take place in Note 2, clause 2.5 , 2.5.1, 2.5.2, 5.1, 6.2.1, 6.2.1.a) for better understanding.

- Clause 1.4 is added, in order to provide a consistency throughout relevant UR's.

- The implementation dates are amended accordingly in Note.

- The amendments in clause 6.1.4 and Annex add the requirement of stating chosen maintenance option of qualification in accordance with 6.2.1.a) or b) or c) on the certificate at the time of issue. which is supported by the intent

outlined in ISO 9606-1,section 9.1(second paragraph),as quoted as below for easy reference.
-Quote-
"The validity of the certificate may be extended as specified in 9.3. The chosen method of the extension of qualification in accordance with 9.3, a) or b) or c), shall be stated on the certificate at the time of issue."
-End quote-

- All the referred industry standards are revised in format based on IACS Procedures Volume 1, C5.2.1, paragraph 8 protocol as quoted as below: "The following format is to be used for referring to industry standards: [Standard Designation], [version/revision, if applicable], [year of publication] (examples: API Spec 2F (R2015); ISO 4309, 2017), where [version/revision, if applicable] and/or [year of publication] are decided by IACS and are not necessarily to be the current/latest version."

5. Points of discussions or possible discussions

- After many discussion back and forth within EG/M&W over the newly added clause 6.2.1.c), the group finally agrees on and develops a set of requirements of welder quality management system in the UR, which is to be further consummated by the group based on industry practice.

- Some of EG member raised proposal of using qualified staff of shipyard/manufacturer to verify the welder quality management system defined in 6.2.1.c) of the UR, instead of Society's surveyor. Currently the group doesn't take this proposal, considering it is not suitable to be commonly stipulated in the UR, as this approach is at discretion of each Society. However, this proposal might be valuable to be further discussed in the future.

- How the shipyard/manufacturer to manage/control the qualification of the subcontracted welders has been discussing in the group. Which is to be further clarified in the following revision of the UR.

- How to set common criteria of evaluation on the welder performance has been raised and under discussion, it is commonly sensed uneasy to be dealt with at this moment. It is suggested that each Society needs to monitor and share experience at later stage.

- Regarding to "Identification system for welders and WPS used on welds", which is one requirements of welder quality management system set out in clause 6.2.1.c) II of the UR, there has been a discussion on if the traceability from specific welder to all welds that he/she have performed is necessary. For this revision of the UR, the group concluded that it is not compulsory due to it doesn't reflect reality in shipyard/manufacturer. However, this requirement of traceability from welder to welds does exist in some industry with high-level safety, so it might be valuable our group re-visit this issue in future.

UR W33 – Non-destructive testing of ship hull steel welds

Summary

The first Revision of the UR W33 developed to introduce the terms and definitions as used in IACS URs. The UR was slightly corrected to align the definition of welding types with the internationally used terminology.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Corr.1 (Aug 2021)	11 August 2021	-
Rev.1 (May 2020)	15 May 2020	1 July 2021
New (Dec 2019)	18 December 2019	1 July 2021

Corr.1 (Aug 2021)

1 Origin of Change:

Suggestion by IACS member

2 Main Reason for Change:

The wording "automatic (mechanized)" in paras. 5.8, 6.5.2 and 9.2 needs to be corrected to "automatic or fully mechanized".

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None

4 History of Decisions Made:

Having noted this proposal could be regarded as minor editorial correction to the used wording, it was agreed by EG/M&W without revision of the Resolution.

5 Other Resolutions Changes:

None

6 Any hinderance to MASS, including any other new technologies:

None

7 Dates:

Original Proposal: June 2021 Made by: IACS EG/M&W
EG/M&W Approval: 07 July 2021
GPG Approval: 11 August 2021 (Ref: 13202_IGzx)

Rev.1 (May 2020)

1 Origin of Change:

☒ Suggestion by IACS member

2 Main Reason for Change:

In order to keep consistency UR W33 needed to be aligned with UR Z23. In these and others IACS resolutions terms "NDT" and "NDE" (which mean the same process), applicate separately without definitions. This circumstance could potentially mislead users and holders of these URs. In order to prevent such cases, the necessary definition was introduced into the text of the UR W33.

3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

4 History of Decisions Made:

Decision was taken to harmonize the "NDT" definition text with the corresponding definition from ISO/TS 18173: 2005 Non-destructive testing — General terms and definitions.

5 Other Resolutions Changes:

UR W35

6 Any hinderance to MASS, including any other new technologies:

None.

7 Dates:

Original Proposal:	January 2020 (IACS Survey Panel)
EG/M&W Approval:	March 2020 (Ref: 13202_EMWo)
GPG Approval:	15 May 2020 (Ref: 13202_IGzs)

New (Dec 2019)

1 Origin of Change:

☒ Suggestion by IACS member

2 Main Reason for Change:

Noting the major importance of NDT in shipbuilding, it was agreed to update and revise the content of IACS Recommendation 20 to develop minimum requirements into a UR.

3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

No contribution by non-IACS Member classification societies.

4 History of Decisions Made:

Decision was taken to make reference to ISO standards for the NDT techniques used as well as the acceptance levels.
Decision was taken to require approval of the NDT plan for each construction which shall contain the extent of testing and the quality levels.

5 Other Resolutions Changes:

Withdraw IACS Recommendation 20.
Update IACS Recommendation 47 to make reference to this UR.
Update UR Z23 to make reference to this UR.

6 Any hinderance to MASS, including any other new technologies:

None.

7 Dates:

Original Proposal: January 2014 Made by: EG/M&W
EG/M&W Approval: October 2019
GPG Approval: 18 December 2019

Part B. Technical Background

List of Technical Background (TB) documents for UR W33:

Annex 1. **TB for New (Dec 2019)**

See separate TB document in Annex 1.

Annex 2. **TB for Rev.1 (May 2020)**

See separate TB document in Annex 2.

Note: There is no separate Technical Background (TB) document for Corr.1 (Aug 2021).

Technical Background (TB) document for UR W33 (New Dec 2019)

1. Scope and objectives

The scope of this UR is to give minimum requirements on the methods and quality levels that are to be adopted for the non-destructive testing (NDT) of ship hull steel welds during new building. The quality levels to be developed refer to production quality and not to fitness- for-purpose of the welds considered.

The objective of this UR is to replace the content of IACS Recommendation 20 by minimum requirements into a UR while assessing if they are sufficient for current ship building.

2. Engineering background for technical basis and rationale

The IACS Recommendation 20 has been available for use by Industry classification societies since 1988 and revised in 2007. Noting the major importance of NDT in shipbuilding, it was agreed to update and revise the content of Rec 20 to produce minimum requirements into a UR.

3. Source / derivation of the proposed IACS Resolution

The UR was developed from the existing IACS Recommendation 20 "Non-destructive testing of ship hull steel welds". Existing Classification Societies Rules as well as the set of international standards available in the field of NDT have been considered, used and referred to as relevant.
The UR refers to the following international standards:
ISO 4063:2009 "Welding and allied processes -- Nomenclature of processes and reference numbers",
ISO 3452-1:2013 "Non-destructive testing -- Penetrant testing -- Part 1: General principles",
ISO 17638:2016 "Non-destructive testing of welds -- Magnetic particle testing",
ISO 17636-1:2013 "Non-destructive testing of welds -- Radiographic testing -- Part 1: X- and gamma-ray techniques with film",
ISO 17637:2016 "Non-destructive testing of welds -- Visual testing of fusion-welded joints",
ISO 17640:2018 "Non-destructive testing of welds -- Ultrasonic testing -- Techniques, testing levels, and assessment",
ISO 23279:2017 "Non-destructive testing of welds -- Ultrasonic testing -- Characterization of discontinuities in welds",
ISO 11666:2010 "Non-destructive testing of welds -- Ultrasonic testing -- Acceptance levels",
ISO 17635:2016 "Non-destructive testing of welds -- General rules for metallic materials",
ISO 5817:2014 "Welding -- Fusion-welded joints in steel, nickel, titanium and their alloys (beam welding excluded) -- Quality levels for imperfections",
ISO 23277:2015 "Non-destructive testing of welds -- Penetrant testing -- Acceptance levels",
ISO 23278:2015 "Non-destructive testing of welds -- Magnetic particle testing -- Acceptance levels",

ISO 10675-1:2016 "Non-destructive testing of welds -- Acceptance levels for radiographic testing -- Part 1: Steel, nickel, titanium and their alloys",
ISO 9712:2012 "Non-destructive testing -- Qualification and certification of NDT personnel"
SNT-TC-1A, 2016, Recommended Practice "Personnel Qualification and Certification in Nondestructive Testing"
ASNT-CP-189, 2016 "Standard for Qualification and Certification of Nondestructive Testing Personnel"

4. Summary of Changes intended for the revised Resolution:

The content of Rec. 20 has been fully reworked and revised with major changes summarised hereafter:

- Update of the scope, base metal, welding processes and weld joints,
- Revised and develop requirements for timing of NDT,
- Update the applicable methods,
- Revised requirements for qualification of personnel,
- Revised and develop requirements for NDT plan,
- Revised and develop requirements for testing techniques,
- Revised and develop requirements for quality levels and acceptance levels for each NDT technique used. The quality levels and acceptance levels are based on recognised international standards.
- Revised and develop requirements for reporting of NDT in each NDT technique.

5. Points of discussions or possible discussions

The group progressed the work while recognizing that the task is highly complex due to the differences contained in the current Societies Rules.
The group discussed and agreed to avoid to detail the requirements for the testing techniques and agreed to refer to recognized standards.

The group discussed mainly the question of the reference to international standards for the NDT techniques used, the extent of NDTs, the rejection/acceptance criteria and the length of examined portion by UT or RT.

About rejection/acceptance criteria, the group agreed to use reference to the ISO standards using the appropriate acceptance level. About the acceptance levels, it was noted that the acceptance levels in the current Rec 20 are similar to the level C of standard ISO 5817:2014 while it was agreed that it is not possible to match exactly;

The group agreed to not use examples of formula for the number of check points and agreed that the number of checkpoints is to be on the NDT plan;
The group agreed that the survey activities are to be removed from this UR as survey activities are defined in UR Z23 as far as NDE & NDT of hull welds are concerned;
Extensive discussions took place about the UT checkpoint length. It was discussed that the UT checkpoint length cannot be regarded independently from the number of checkpoints; the group concluded that it was not possible to find a reasonable consensus to define a minimum requirement and the group defined that a checkpoint length is to be the entire weld length or a length agreed with the Class.

Apart from the UT checkpoint length, it was determined that the RT checkpoint length is 300mm based on the length of a RT film which is generally used.

Technical Background (TB) document for UR W33 (Rev.1 May 2020)

1. Scope and objectives

The objective of the first Revision of UR W33 is to keep consistency UR W33 needed to be aligned with UR Z23. In these and others IACS resolutions terms "NDT" and "NDE" (which mean the same process), applicate separately without definitions. This circumstance could potentially mislead users and holders of these URs. In order to prevent such cases, the necessary definition was introduced into the text of the UR W33.

2. Engineering background for technical basis and rationale

None

3. Source / derivation of the proposed IACS Resolution

ISO/TS 18173: 2005 Non-destructive testing — General terms and definitions

4. Summary of Changes intended for the revised Resolution:

The content of UR W33 has been supplemented by definitions of NDT and types of NDT.

5. Points of discussions or possible discussions

The group discussed on the proposed variation of definitions.

6. Attachments if any

None

UR W34 – Advanced non-destructive testing of materials and welds

Summary

This UR is a new development to provide unified requirements for the advanced non-destructive testing of materials and welds.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
New (Dec 2019)	17 December 2019	1 July 2021

- **New (Dec 2019)**

1 Origin of Change:

☒ Suggestion by IACS member

2 Main Reason for Change:

Noting that advanced non-destructive testing (NDT) techniques like Phased Array Ultrasonic Testing (PAUT) or Digital Radiography (RT-D) are more and more used by the industry, it has been agreed to develop unified requirements (UR) on the application of advanced non-destructive testing (NDT) techniques.

3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

No contribution by non-IACS Member classification societies.

4 History of Decisions Made:

Members agreed that the UR shall focus on PAUT, TOFD and RT-D.

Members agreed that Manual PAUT is not covered in the UR as there is no encoder to record the locations, noting that it is consistent with the ISO standard.

Decision was taken to make reference to ISO standards for the NDT techniques used as well as the acceptance levels.

5 Other Resolutions Changes:

None

6 Any hinderance to MASS, including any other new technologies:

None.

7 Dates:

Original Proposal:	November 2016	Made by: EG M&W
EG M&W Approval:	October 2019	
GPG Approval:	17 December 2019 (Ref: 19100_IGf)	

Part B. Technical Background

List of Technical Background (TB) documents:

Annex 1. **TB for New (Dec 2019)**

See separate TB document in Annex 1.

◄▼►

Technical Background (TB) document for UR W34 (New Dec 2019)

1 Scope and objectives

Nowadays, advanced non-destructive testing (NDT) techniques (Phased Array Ultrasonic Testing (PAUT), Time of Flight Diffraction (TOFD) and Automated Ultrasonic Testing (AUT),etc) are being more and more applied by the industry and IACS members in the day-to-day survey and inspections. There is a growing need from the industry for uniform rules and standards to be developed and applied.
All Members agreed that the application of advanced non-destructive testing technology is very important for IACS future development, and such issue was strategic and in IACS' interest, thus unanimously supported the initiatives. In the same time, IACS recognized that it is necessary to develop the unified requirements (UR) on the application of advanced non-destructive testing (NDT) techniques.
New UR covered following techniques;

- PAUT (only automated/semi-automated PAUT)
- TOFD
- Digital Radiography (RT-D)

2 Engineering background for technical basis and rationale

Several issues were highlighted that IACS needed to address:

a) More and more advanced NDT methods are used in shipbuilding, but the basic requirements are not covered in the IACS resolutions.
b) In UR S33 mentions *enhanced NDT particularly time of flight diffraction (TOFD) technique*, but the detailed requirements are not provided by IACS.
c) Using PAUT, TOFD or RT-D in lieu of RT or UT becomes a trend in development of NDT work, especially in pipeline welds testing, extremely thickness butt plate welds testing and etc.
d) When using PAUT examine austenitic stainless steels, Special probe, calibration / reference blocks and setup should be used, such as Dual Matrix Array probe with longitudinal wave. These equipment, blocks and setup should be qualified with classification society when doing Procedure Qualification.

Taking the above into account a project team PT EMW1609 was asked to draft a new IACS UR to explain the basic requirements of testing methods, procedure approval, testing requirements, acceptance levels and etc.

3 Source / derivation of the proposed IACS Resolution

The primary reference standards for new UR *Advanced non-destructive testing of materials and welds* are as following:

- ISO 4063:2009 "Welding and allied processes -- Nomenclature of processes and reference numbers"
- ISO 13588:2019 "Non-destructive testing of welds -Ultrasonic testing-Use of automated phased array technology"
- ISO 18563-1:2015 "Non-destructive testing—Characterization and verification of ultrasonic phased array equipment—Part 1"
- ISO 18563-2:2017 "Non-destructive testing -- Characterization and verification of ultrasonic phased array equipment -- Part 2: Probes"
- ISO 18563-3:2015 "Non-destructive testing—Characterization and verification of ultrasonic phased array equipment-Part 3"
- ISO 19285:2017 "Non-destructive testing of welds -- Phased Array technique (PA) -- Acceptance levels"
- ISO 10863:2011 "Non-destructive testing of welds—Ultrasonic testing—Use of time-of-fight diffraction technique (TOFD)"
- ISO 15626:2018 "Non-destructive testing of welds — time of flight diffraction technique (TOFD)—Acceptance levels"

- ISO 17636-2:2013 "Non-destructive testing of welds - Radiographic testing Part 2: X- and gamma-ray techniques with digital detectors"
- ISO 5817:2014 "Welding -- Fusion-welded joints in steel, nickel, titanium and their alloys (beam welding excluded) -- Quality levels for imperfections"
- ISO 10042:2018 "Welding -- Arc-welded joints in aluminium and its alloys -- Quality levels for imperfections"
- ISO 10675-1:2016 "Non-destructive testing of welds -- Acceptance levels for radiographic testing -- Part 1: Steel, nickel, titanium and their alloys"
- ISO 10675-2:2017 "Non-destructive testing of welds -- Acceptance levels for radiographic testing -- Part 2: Aluminium and its alloys"
- ISO 9712:2012 "Non-destructive testing -- Qualification and certification of NDT personnel"
- SNT-TC-1A, 2016, Recommended Practice "Personnel Qualification and Certification in Nondestructive Testing"
- ASNT-CP-189, 2016 "Standard for Qualification and Certification of Nondestructive Testing Personnel"

4 Summary of Changes intended for the revised Resolution

Not applicable.

5 Points of discussions or possible discussions

a) In section 2.5.1, PAUT was specified on only automated / semi-automated PAUT.
b) Applicable PAUT for testing of the different types of materials and weld joints are given in Table 2. Especially the following materials and weld joints.
   - Ferritic cruciform joints with full penetration
   - Austenitic stainless steel butt welds with full penetration
   - Austenitic stainless steel tee joints, corner joints with full penetration
   - Aluminium cruciform joints with full penetration
c) In section 7.2.2.6, Indications detected when applying testing procedure shall be evaluated either by length and height or by length and maximum amplitude.
d) Section 6.3.2 describes the requirement of angles of incidence. When testing is carried out with transverse waves and techniques that require the ultrasonic beam to be reflected from an opposite surface, care shall be taken to ensure that the angle between the beam and the normal to the opposite reflecting surface is between 35° and 70°. Where more than one probe angle is used, at least one of the angle probes used shall conform with this requirement. One of the probe angles used shall ensure that the weld fusion faces are examined at, or as near as possible to, normal incidence. When the use of two or more probe angles is specified, the difference between the nominal beam angles shall be 10° or greater.

During its meeting of September 2019, the EG M&W agreed to exclude the reference to offshore and repair from the scope of the UR. The group agreed to exclude UR W22 from the scope and to start a task on the revision of UR W22 to include a reference to UR W34 or to develop appropriate requirements for PAUT of offshore chain cable links.

Additional details may be consulted in the following documents made available to the EG M&W Members;
a) Codes and standards list (EMW1609)
b) PT EMW012016 (EMW1609) 1st MEETING MINUTES
c) PT EMW012016 (EMW1609) 2nd MEETING MINUTES
d) Revision suggestions for IACS Resolutions

UR W35 "Requirements for NDT Service Suppliers"

Summary

UR W35 provides unified requirements for NDT Service Suppliers. This latest revision (Revision 2) of IACS UR W35 addresses issues of VT qualification requirement and definition.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev.2 (Feb 2025)	09 February 2025	1 January 2027
Rev. 1 (October 2023)	20 October 2023	1 January 2025
New (June 2019)	27 June 2019	1 July 2020

- **Rev. 2 (Feb 2025)**

1 Origin of Change:

Suggestion by IACS member

2 Main Reason for Change:

Whilst Visual Testing (VT) is defined as a part of NDT in 1.3 of UR W35 and it is recognised that VT is part of the scope of ISO 9712, IACS does not require formal certification in VT.

It was decided to amend UR W35 Rev.1 to clarify that VT personnel is exempted from formal qualification and certification.

In this connection, it was decided to amend the definition of VT to be clear based on ISO 9712:2021 since it was vague.

3 Surveyability review of UR and Auditability review of PR

None.

4 Human Element issues assessment

☐ The human element checklist in internal guidelines reviewed by EG/MS and SG/HE

5 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None.

6 History of Decisions Made:

1. February 2024, one society raised the issue of VT qualification requirement.
2. In this connection, another society also raised the issue of VT definition.
3. All member agreed with resolving the above issues and addressed the issues.
4. In addition, minor amendments including typo are conducted.

7 Other Resolutions Changes:

None.

8 Any hinderance to MASS, including any other new technologies:

None.

9 Dates:

Original Proposal	: July 2024	Made by:EG/M&W
EG/M&W Approval	: 20 January 2025	(Ref: 2410_EMWn)
GPG Approval	: 09 February 2025	(Ref: 24199_IGc)

Rev. 1 (October 2023)

1 Origin of Change:

Select a relevant option and delete the rest.

- ✓ Other *(Specify: Industry best practice and feedback from industry)*

2 Main Reason for Change:

1. Provision for an alternative route for level 2 supervisor.

2. Revisions to scope, applicability, and definitions of NDT service supplier.

3. To reflect feedback from various shipyards (and industry) received by Class Societies.

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None.

4 History of Decisions Made:

1. September 2019, EG/M&W annual meeting. One Society requested that this topic should be discussed further regarding the applicability and scope of the UR.

2. Q4, 2019, the task was formally approved by IACS GPG.

3. September 2020, EG/M&W annual meeting: one Society requested that this topic should be discussed further, as industry (and Class Society) feedback suggested that some NDT companies were having practical difficulties in implementing the UR, particularly with the level 3 supervisor requirements.

4. The topic was further discussed, and the task lead changed to the Society who proposed the implementation feedback. The Form A was revised and re-issued, and GPG approved the revised Form A on 20 October 2021.

5. The task was prolonged to reach consensus amongst members, including meetings, feedback, and discussions with the IACS Survey Panel.

6. Full consensus was reached in July 2023.

7. Fourteen drafts have been discussed by the group.

8. Summary of topics that have been revised and updated during this task:

Revised scope and applicability of the UR with respect to products, shipyards, and new construction.
A decision was taken to limit the applicability of the UR to new construction (although individual Societies may also adopt the requirements for existing ships if they so wish).
UR document title change to: 'Requirements for NDT Service Suppliers'.
Updated standards reference.
Revisions to employer-based certification route for level 3 supervisor.
Revisions to terms and definitions.
Provision for an alternative route for level 2 supervisor.
Clarified (and revised) level 3 supervisor responsibilities.
Requirement upon the Class Society to verify the compliance with this UR (although the method of verification is to be decided by each Society).
Allowance for the NDT Service Supplier to also satisfy the requirements of a Type C inspection body, as per ISO/IEC 17020:2012, with the stipulation that production staff shall not be allowed to inspect their own work in the case of Type C).

9. Discussions took place during the reviews for the items as stated in the Technical Background.

5 Other Resolutions Changes:

UR W33 Rev 1 Corr.1 – Non-destructive testing of ship hull steel welds

UR W34 - Advanced non-destructive testing of materials and welds

6 Any hinderance to MASS, including any other new technologies:

None.

7 Dates:

Original Proposal	: September 2019	(Made by:EG/M&W)
Panel Approval	: 02 October 2023	(Ref: 14165_EMWg)
GPG Approval	: 20 October 2023	(Ref: 14165_IGq)

• **NEW (Jun 2019)**

1 Origin of Change:
✓ Suggestion by IACS member

2 Main Reason for Change:

Considering the importance of non-destructive testing to ensure that the required quality in manufacturing and assembling is achieved, IACS has decided to develop unified requirements to set a common way of handling the firms supplying NDT services and the qualification of their operators.

3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:
No contribution by non-IACS Member classification societies.

4 History of Decisions Made:
- Discussions took place about the need to develop additional requirements to the existing national or international schemes for qualification of NDT operators. Decision was taken to use the existing national or international schemes as basis without supplementary requirements.
- Discussions took place about the need to develop a scheme to recognise the NDT suppliers. Having consulted the IACS Survey Panel, the Members decided to develop requirements for NDT suppliers without requiring a specific certification scheme, leaving the matter to individual societies.
- Noting the final content of the UR, Members decided to develop a separate UR instead of proposing an amendment to UR Z17.
- One member considered that the document should be a recommendation while the majority of members decided to issue it as an UR.

5 Other Resolutions Changes:

None.

6 Any hinderance to MASS, including any other new technologies:

None.

7 Dates:

Original Proposal	: November 2014	(Made by:EG/M&W)
Panel Approval	: 10 May 2019	(Ref: 14165_EMWd)
GPG Approval	: 27 June 2019	(Ref: 14165_IGl)

****

Part B. Technical Background

List of Technical Background (TB) documents for UR W35:

Annex 1. **TB for New (June 2019)**

See separate TB document in Annex 1.

Annex 2. **TB for Rev.1 (Oct 2023)**

See separate TB document in Annex 2.

Annex 3. **TB for Rev.2 (Feb 2025)**

See separate TB document in Annex 3.

Technical Background (TB) document for UR W35 (NEW June 2019)

1. Scope and objectives

Suppliers providing NDT (Non-Destructive Testing) services on ship and offshore structures/components subject to classification, need to fulfil the requirements set out in this UR.
The objective of this UR is to ensure that the Supplier is using appropriate procedures, has qualified and certified personnel and has implemented written procedures for training, experience, education, examination, certification, performance, application, control, verification and reporting of NDT. In addition, the Supplier shall furnish appropriate equipment and facilities commensurate with providing a professional service.

2. Engineering background for technical basis and rationale

Considering the importance of NDT to ensure the integrity of a construction, and that in many cases NDT are carried out by companies contracted by the shipbuilders or manufacturers, the IACS members considered that it was necessary to develop IACS minimum requirements for NDT suppliers and operators.
Considering the maturity of existing schemes in Industry, these requirements are not intended to replace the recognised approval schemes used today.
The UR describes the minimum requirements for suppliers of NDT services with reference to quality management, documentation, qualification of personnel, supervision, equipment, sub-contracting, reporting, etc.

3. Source/derivation of the proposed IACS Resolution

Especially with reference to the qualification and certification of NDT personnel reference to the international standard ISO 9712:2012 is made.
Reference is also made to:
SNT-TC-1A, 2016, Recommended Practice "Personnel Qualification and Certification in Nondestructive Testing"
ASNT-CP-189, 2016 "Standard for Qualification and Certification of Nondestructive Testing Personnel"
Reference is made to international standards ISO/IEC 17020:2012, ISO/IEC 17024:2012 and ISO 9001:2015 for quality management matters.

4. Summary of Changes intended for the revised Resolution:

Not applicable – new document

5. Points of discussions or possible discussions

During the development the main discussion points were
if the resolution is going to be a separate UR or a part of UR Z17 (decision was finally to have a separate UR)

- if an approval/certification procedure will be included in the UR (after rejection of the Survey Panel it was finally decided not to include such a procedure)

6. Attachments if any

None.

***

Technical Background (TB) document for UR W35 (Rev.1 October2023)

1. Scope and objectives

The objective of this revised UR is to provide a practical way for industry to fully implement NDT services in the marine industry (with a focus on new construction activities), particularly concerning the level 3 supervisor responsibilities and duties within an NDT service supplier organisation.
Thus, the overall aim of this revision was to provide industry with a practical way forward to comply with IACS requirements, in order to deliver a professional NDT service, which shall be verified by the Classification Society.

The objectives of the task were to:

1. Review information from all Class Societies, where they have received feedback questioning the requirements of UR W35.

2. Clarify (and revise where deemed appropriate) the scope of the UR in terms of what it applies to, and clarify the definition of NDT Service Supplier (i.e. who is deemed to be a service supplier according to this UR)

3. Consider the role of level 3 supervisor, in terms of role, duties and responsibilities, certification route, and whether it is considered as a knowledge activity, an organisational role activity, or both.

4. Where necessary, consider updating other IACS Resolutions (e.g., UR W33 and UR W34).

2. Engineering background for technical basis and rationale

During the revision of this UR W33 Rev 1, it was necessary to consider the following technical points:

1. Scope and applicability of the UR.

2. Certification route of employer-based level 3 (now revised to allow certification for a full-time employed level 3 via the examination method).

3. The practical considerations (and requirements) for allowing a supervisor to be employed as a full-time level 2 (via an alternative route to be agreed with the Classification Society) – noting that some smaller organisations may not easily obtain level 3 personnel (for a variety of reasons, including geographical location, size of company, etc.)

4. Limited to new construction, and applicability within a revised scope

5. Not mandatory applicable to internal department of equipment and material manufacturers (although an individual Class Society may apply this UR to such manufacturers)

6. The requirement for a Class Society to verify the compliance with this UR (although the method of verification is to be decided by each Society).

3. Source/derivation of the proposed IACS Resolution

- ISO 9712:2021; Non-destructive testing-Qualification and certification of NDT personnel
- ISO/IEC 17020:2012; Conformity assessment-Requirements for the operation of various types of bodies performing inspection
- ISO/IEC 17024:2012; Conformity assessment-General requirements for bodies operating certification of persons
- ISO 9001:2015; Quality Management Systems-Requirements
- SNT-TC-1A: 2020; Personnel Qualification and Certification in Nondestructive Testing
- ANSI/ASNT CP-189:2020; ASNT Standard for Qualification and Certification of Nondestructive Testing Personnel

4. Summary of Changes intended for the revised Resolution:

Revised scope and applicability of the UR with respect to products, shipyards, and new construction.

A decision was taken to limit the applicability of the UR to new construction (although individual Societies may also adopt the requirements for existing ships if they so wish).

UR document title change to: 'Requirements for NDT Service Suppliers'.

Updated standards references.

Revisions to employer-based certification route for level 3 supervisor.

Revisions to terms and definitions.

Provision for an alternative route for level 2 supervisor.

Clarified (and revised) level 3 supervisor responsibilities.

Requirement upon the Class Society to verify the compliance with this UR (although the method of verification is to be decided by each Society).

Allowance for the NDT Service Supplier to also satisfy the requirements of a Type C inspection body, as per ISO/IEC 17020:2012, with the stipulation that production staff shall not be allowed to inspect their own work in the case of Type C).

5. Points of discussions or possible discussions

Members had involved discussions with the following points, which also involved IACS Survey Panel (hence there were fourteen drafts produced).

separating these requirements from UR Z17 and no inference in mandating a Class Approval Scheme for NDT companies – although there is now a requirement upon the Class Society to verify the compliance with this UR (the method of verification is to be decided by each Society).

The NDT supplier is now deemed to be an 'NDT Service Supplier', although no requirements as per UR Z17. (the title of this revised UR also reflects this change).

Whether or not to extend the scope of UR W35 to the ships in service (existing ships). It was confirmed by majority to only include new construction (although individual Societies may also adopt the requirements for existing ships if they so wish).

Qualification of level 3 NDT personnel through employer-based scheme (via examination route only, and not via an 'appointed route')

Alternative approach of taking level 2 NDT personnel as a supervisor into consideration subject to certain conditions (a new paragraph in section 2.4 of UR W35 has been added, to allow this alternative approach, subject to agreement from the Class Society)

- Revised definition of NDT
- Applicability of rudders of welded construction (majority agreed for inclusion)
- The applicability of this UR to internal departments of equipment and material manufacturers – the majority agreed to make this not applicable to such manufacturers, although an individual Class Society may apply this UR to these manufacturers should they wish to.
- Allowance for the NDT Supplier to also satisfy the requirements of a Type C inspection body, as per ISO/IEC 17020:2012, (but with the stipulation that production staff shall not be allowed to inspect their own work in the case of Type C).

Agreement on the final wording was possible following discussions and consensus between members.

6. Attachments if any

None

***

Technical Background (TB) document for UR W35 (Rev.2 Feb 2025)

1. Scope and objectives

Whilst it is recognised that VT is part of the scope of ISO 9712:2021, IACS does not require formal certification in VT. This is further endorsed by existing requirements within UR W33 Rev.1 Corr.1.

The objective of this amended UR is as follows:
a) Exemption of formal certification/qualification in VT
b) Addition of a requirement for quality management system relating to training and competency assessment programs for VT personnel
c) Clarifying the definition of VT based on ISO9712:2021
d) Revision to the requirement that employer, not supervisor authorizes NDT operator

2. Engineering background for technical basis and rationale

In an inspection for welded joints, IACS does not require the formal certification/qualification in VT as specified in IACS UR W33 Rev.1 Corr.1.
However, IACS considers NDT suppliers engaged in VT is needed to have a quality management system of training and competency assessment programs for VT personnel.
In this connection, IACS also considers it is necessary to clarify the definition of VT based on ISO9712:2021.

3. Source/derivation of the proposed IACS Resolution

- ISO9712:2021: Non-destructive testing — Qualification and certification of NDT personnel

4. Summary of Changes intended for the revised Resolution:

- Clarifying the exemption of formal certification/qualification in VT
- Addition of a requirement for quality management system relating to training and competency assessment programs for VT personnel
- Clarifying the definition of VT based on ISO9712:2021
- Revision to the requirement that employer, not supervisor authorizes NDT operator

5. Points of discussions or possible discussions

Main points of discussions are "exemption of formal certification/qualification in VT" and "the definition of VT".
However, the discussion about this amendment was smoothly proceeded in IACS since it is not an amendment that essentially changes the IACS requirements.

6. Attachments if any

- **Rev.10 (Sept 2024)**

1 Origin of Change:

☑ Other (following the publication of IMO Res. A.1186(33))

2 Main Reason for Change:

IMO Res. A.1156(32), which is incorporated in UR Z1(Rev.9), had been revoked by IMO Res. A.1186(33).

3 Surveyability review of UR and Auditability review of PR

This UR includes survey requirements only.

4 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None

[1] Title changed as 'Annual and intermediate classification survey coverage of IMO Resolution A.1186(33)' at Rev.10. Note that the title was also changed at Rev.2 to 9.

5 History of Decisions Made:

Following the publication of the IMO Res. A.1186(33), Survey Panel proceeded to review the revision 9 of UR Z1.

By making the comparisons between the IMO Res. A.1156(32) and IMO Res. A.1186(33), it was noted that only one survey item (CA) 2.2.2.32 referred to from Para. 2.3 of UR Z1 includes substantial changes to the survey requirement and that other survey items referred to in UR Z1 have no changes or only include editorial changes. Survey Panel agreed to revise UR Z1 according to Res. A.1186(33).

No TB is expected for this revision.

6 Other Resolutions Changes:

None

7 Any hinderance to MASS, including any other new technologies:

None

8 Dates:

Original Proposal	: 5 June 2024	(Proposed by Panel Chair)
Panel Approval	: 24 June 2024	(Ref: PSU24025_ISUb)
GPG Approval	: 04 Sept 2024	(Ref: 24116_IGc)

- **Rev.9 (July 2022)**

.1 Origin for Change:

☑ Other (following the publication of IMO Res. A.1156(32))

.2 Main Reason for Change:

IMO Res. A.1140(31), which is incorporated in UR Z1(Rev.8), had been revoked by IMO Res. A.1156(32).

.3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None

.4 History of Decisions Made:

Following the publication of the IMO Res. A.1156(32), Survey Panel proceeded to review the revision 8 of the UR Z1. By making the comparisons between the IMO Res. A.1140(31) and IMO Res. A.1156(32) it was noted that some items have been renumbered, and the panel agreed to revise UR Z1 according to Res.A.1156(32).

No TB is expected for this revision.

[1] Title changed from 'Annual and intermediate classification survey coverage of IMO Resolution A.1156(32)' at Rev.9. Note that the title was also changed at Rev.2 to 8.

5 Other Resolutions Changes:

None

6 Any hinderance to MASS, including any other new technologies:

None

7 Dates:

Original Proposal	: 27 June 2022	(Proposed by Panel Chair)
Panel Approval	: 08 July 2022	(Ref: PSU22037)
GPG Approval	: 28 July 2022	(Ref: 22115_IGb)

- **Rev. 8 (July 2020)**

.1 Origin for Change:

☑ Other (following the publication of IMO Res. A.1140(31))

.2 Main Reason for Change:

IMO Res. A.1120(30), which is incorporated in UR Z1(Rev.7), had been revoked by IMO Res. A.1140(31).

.3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None

.4 History of Decisions Made:

Following the publication of the IMO Res. A.1140(31), Survey Panel proceeded to review the revision 7 of the UR Z1.

By making the comparisons between the IMO Res. A.1120(30) and IMO Res. A.1140(31) it was noted that some items have been renumbered, and the panel agreed to revise UR Z1 according to Res. A.1140(31).

No TB is expected for this revision.

---

[1] Title changed from 'Annual and intermediate classification survey coverage of IMO Resolution A.1140' at Rev.8. Note that the title was also changed at Rev.2 to 7.

.5 Other Resolutions Changes:

None

.6 Any hinderance to MASS, including any other new technologies:

None

.7 Dates:

Original Proposal	: 12 December 2019	(suggested by Panel Chair)
Panel Approval	: 01 July 2020	(Ref: PSU19056)
GPG Approval	: 21 July 2020	(Ref: 20126_IGb)

- **Rev. 7 (May 2019)**

1. Origin for Change:

☑ Other (following the publication of IMO Res. A.1120(30))

2. Main Reason for Change:

IMO Res. A.1104(29), which is incorporated in UR Z1(Rev.6), had been revoked by IMO Res. A.1120(30).

3. List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

4. History of Decisions Made:

Following the publication of the IMO Res. A.1120(30), Survey Panel proceeded to review the revision 6 of the UR Z1.

By making the comparisons between the IMO Res. A.1104(29) and IMO Res. A.1120(30) it was noted that some items have been renumbered with some items newly inserted, and the panel agreed to revise UR Z1 according to Res. A.1120(30).

No TB is expected for this revision.

5. Other Resolutions Changes:

None

6. Any hinderance to MASS, including any other new technologies:

None

7. Dates:

Original Proposal:	14 March 2019 decided at Panel Spring Meeting
Panel Approval:	11 May 2019 (PSU19011)
GPG Approval:	29 May 2019 (19099_IGb)

- ## **Rev.6 (Apr 2016)**

.1 Origin for Change:

☑ Other (following the publication of IMO Res. A.1104(29))

.2 Main Reason for Change:

IMO Res.A.1053(27), amended by IMO Res. A.1078(28), which is incorporated in UR Z1(Rev.5) had been revoked by IMO Res.A.1104(29.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

According to the permanent task of the Survey Panel and following the publication of the IMO Res. A .1104(29), Members proceeded to review the revision 5 of the UR Z1.

By making the comparisons between the IMO Res.A.1053(27), amended by IMO Res. A.1078(28) and IMO Res.A.1104(29) it has noted that some items have been renumbered. The renumbering influences the references contained in the unified requirements and then the revision 6 has been agreed by the Panel.

Likewise, during the discussion Members agreed to update the resolution number referred to in the “Preamble”.

No technical background has been produced for this revision.

- ## **Rev.5 (Mar 2015)**

.1 Origin for Change:

☑ Suggestion by IACS member

.2 Main Reason for Change:

IMO Res.A.997(25), amended by IMO Res. A.1020(26), which is incorporated in UR Z1(Rev.4 Corr. 1) had been revoked by IMO Res.A.1053(27), as amended by IMO Res.A.1076(28).

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

Discussion was open by noting the Rev.4 Corr. 1 was not duly updated with the new IMO Res.A.1053(27) and subsequent Amendments contained into the IMO Res. A.1076(28).

By making the comparisons between the IMO Res.A.997(25), amended by IMO Res. A.1020(26) and IMO Res.A.1053(27), as amended by IMO Res.A.1076(28), it has noted that some items have been renumbered and new survey items have been added as detailed in the attached Technical Background. Moreover, during the discussion Members agreed the deletion of the last sentence of the "Preamble" because deemed unnecessary.

Following the first review by GPG, the Unified Requirement was returned to the Survey Panel in order to evaluate whether there are the technical grounds which may allow a modification of the items Z1.3.3 and Z1.3.4, by excluding (respectively) the items Din 1.2.3.5.and Gin 2.3.2.4 of the IMO Resolution A.1053(27) as amended by IMO resolution A. 1076(28), and so address the existing Member reservation. The qualified majority of the Panel Members concurred that spare gear is no longer an item which is commonly a class requirement.

Accordingly, Z1.3.3 and Z.1.3.4 have been modified by excluding the two items relevant to the spare parts of the ventilators.

.5 Other Resolutions Changes

None

.6 Dates:

Original Proposal: 10 March 2014 made by IACS Member
Survey Panel Approval: 16 December 2014 (Ref: PSU14005)
GPG Approval: 23 March 2015 (Ref: 14202_IGe)

- **Corr.1 (Jan 2011)**

.1 Origin of Change:

☑ Suggestion by IACS members

.2 Main Reason for Change:

To ensure that UR Z1 do not include requirements for classification surveys of items which purely fall within the scope of the statutory certification.

A number of IACS Members raised the point that the following items, which are currently required to be surveyed within the scope of classification, as per UR Z1, are in fact outside the scope of classification surveys:

Item ref. (CA) 2.2.2.29 of IMO Res.A997(25) as amended, related to the confirmation that new equipment containing asbestos was not fitted on board since last survey (SOLAS 74/00/04 reg. II-1/3-5).

Item (CA) 2.2.2.33 of IMO Res.A997(25) as amended, related to the confirmation that ship's identification number is permanently marked (SOLAS74/02, reg. XI-1/3).

Item (CA) 2.2.2.35 of IMO Res.A997(25) as amended, related to the confirmation (for ships other than CSR bulk carriers and CSR oil tankers), that the coating system in dedicated SWB tanks is maintained and that maintenance, repair and partial recoating are recorded in the coating technical file (SOLAS 74/00/06 reg. II-1/3-2).

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

The decision was made to clearly exclude the three above items, which are covered by the Safety Construction Annual Survey through IMO Res.A.997(25) as amended, from the annual survey requirements of UR Z.1.

.5 Other Resolutions Changes

None

.6 Dates:

Original Proposal: *September 2010 Made by the Survey Panel*
Panel Approval: *December 2010*
GPG Approval: *05 January 2011 (Ref: 10052aIGb)*

- **Rev.4 (May 2010)**

.1 Origin for Change:

☑ Suggestion by IACS member

.2 Main Reason for Change:

IMO Res.A.948(23) which is incorporated in UR Z1(Rev.3) had been revoked by IMO Res.A.997(25).

.3 History of Decisions Made:

KRS volunteered for drafting UR Z1(Rev. 4) taking into accounts of new requirements in IMO Res.A.997(25). During drafting, IMO Res.A.1020(26) which is the amendment to IMO Res.A.997(25) was published, therefore this was also taken into account in Rev.4.

.4 Other Resolutions Changes

None

.5 Any dissenting views

None

.6 Dates:

Original Proposal: *17 February 2010 made by Survey Panel*
Survey Panel Approval: *7 April 2010*
GPG Approval: *18 May 2010 (ref. 10052_IGb)*

- **Rev.3 (Sept 2005)**

See TB document in Part B.

The existing references to Res. A.746(18) were updated to A.948(23), including within the title.

- **Rev.2 (June 1999)**

Complete revision – see TB document in Part B.

The existing reference to IMCO Res. A.413(XI) was replaced with A.746(18).

Title changed from "*Annual survey of all cargo vessels and intermediate survey of tankers covering class matters in IMCO Resolution A.413(XI)*" to "*Annual and intermediate classification survey coverage of IMO Resolution A.746(18)*"

- **Rev.1 (1994)**

See separate TB document in Annex 3.

Annex 4. **TB for Corr.1 (Jan 2011)**

See separate TB document in Annex 4.

Annex 5. **TB for Rev.5 (Mar 2015)**

See separate TB document in Annex 5.

Note: *There are no separate Technical Background (TB) documents available for the original resolution (1982), Rev.1 (1994), Rev.6 (Mar 2016), Rev.7 (May 2019), Rev.8 (July 2020), Rev.9 (July 2022) and Rev.10 (Sept 2024).*

Technical Background Document
WP/SRC Task 1
UR Z 1 – Proposed Rev. 2

Objective and Scope:

To review existing UR Z 1 and update as required.

Source of Proposed Requirements:

WP/SRC members discussed and reviewed the requirements contained in IMO Resolution A.746(18) and UR Z 1 through correspondence and their meeting. UR Z 1 was updated to reflect the changes in IMO Res. A.746(18).

Points of Discussion:

WP/SRC unanimously agreed to the proposed draft UR Z 1.

Date of submission: 6 May 1999
By WP/SRC Chairman’s e-mail

Technical Background

UR Z1 (Rev.3) Annual and Intermediate Classification Survey coverage of IMO Resolution A.746(18)

WP/SRC Task 3 – Review of IACS URs Relating to Surveys, set as a continuous Task, discussed at the October 2004 meeting that a revision of UR Z1 was required due to the replacement of IMO Resolution A.746(18) with IMO Resolution A.948(23), which defines the annual and intermediate coverage of classification as related to IMO.

WP/SRC set a deadline to complete the Task by 31 December 2004, but was not able to complete a draft by that time. This Task was then turned over to the Survey Panel at the Panel's initial meeting in February of 2005.

Survey Panel Discussion

A draft was submitted to Survey Panel members by the Survey Panel Secretary with comments from Panel members, mainly editorial, in addition to the following:

ABS Panel member stated in PSU5011_ABa "In item 2.1 Load Line survey: ABS questions the need to have reference to paragraphs 1.2.3.1 through 1.2.3.2 of Annex 2 as these paragraphs refer to signing of the Load Line Certificate. We did not make reference to signing the Safety Construction certificate in other items. Z1 is a classification document only.
Item 2.3 Machinery and electrical systems: ABS noted that revision did not include paragraph 2.2.2.27; "examining visually the condition of any expansion joints in sea water systems". It is suggested that this item be included as a classification item as expansion joints are extremely important and usually visually examined anyway by any experienced classification surveyor during annual machinery surveys as part of the piping systems. A failure of a large expansion joint could lead to rapid engine room flooding.

RINA Panel member stated in PSU5011_RIa "As regards item 3.2 - Oil tanker additional items, it is suggested to amend the text in brackets as follows to be consistent with the contents: "(Piping systems and cargo tanks and electrical circuits in dangerous zones)".
As regards item 3.3 - Chemical tanker additional items, the last item 1.3.2.6 (which refers to noxious substances) is not to be included as similarly made for annual surveys.

Survey Panel Decision

All Panel members agreed with the attached comments, in addition to other Panel members editorial comments, and a final draft was submitted for GPG for approval by the Survey Panel Chairman.

Note:

- GPG agreed that no uniform application date for this revision was needed(4181aIGf)

Submitted by Survey Panel Chairman
17 August 2005

Technical Background for UR Z1 Rev.4 (May 2010)

1. Scope and objectives

To amend the current UR Z1 referring to IMO Res.A.948(23) which had been revoked by IMO Res.A.997(25) as amended by IMO Res.A.1020(26).

2. Engineering background for technical basis and rationale

As new amendments to the survey guidelines under the harmonized system of survey and certification, 2007, IMO Res.A.1020(26), had been published, the current UR Z 1 referring to IMO Res.A.948(23) was revised in accordance with IMO Res.A.997(25) as amended by IMO Res.A.1020(26).

3. Source/derivation of the proposed IACS Resolution

N/A

4. Summary of Changes intended for the revised Resolution:

1) To add new requirements introduced in IMO Res.A.997(25) as amended by IMO Res.A.1020(26)

2) To re-arrange items reflecting the requirement number's changes in IMO Res.A.997(25) as amended by IMO Res.A.1020(26)

3) To remove invalid requirements including the reference to Annex 1 para 1.2.3.5 in para 2.5 of UR Z1 as proposed from GPG

5. Points of discussions or possible discussions

None

6. Attachments if any

None

Technical Background for UR Z1 Corr.1, Jan 2011

1. Scope and objectives

To remove from UR Z1 items which should not be covered by classification surveys, but remain subject to statutory surveys.

2. Engineering background for technical basis and rationale

Marking of ship's identification number, the issue of asbestos, the coating of WBT according to the IMO PSPC for ships other than CSR bulk carriers and CSR oil tankers contracted for construction on or after 8th December 2006, are items which are not covered by classification.

3. Source / derivation of the proposed IACS Resolution

UR Z1 and IMO Res.A.997(25) as amended.

4. Summary of Changes intended for the revised Resolution:

The following amendment is made to the annual survey requirements in UR Z1:

"2.2 Hull items - Annex 1 Paragraphs 2.2.2.1 through 2.2.2.6 and 2.2.2.28 through <u>2.2.2.34 except for 2.2.2.29 and 2.2.2.33."</u>

5. Points of discussions or possible discussions

None

6. Attachments if any

None

Technical Background for UR Z1 Rev.5, Mar 2015

1. Scope and objectives

To remove a reservation and update UR Z1 by inserting/removing items according to the modifications introduced by IMO Res. A. 1053(27) as amended by IMO Res. A.1076(28).

2. Engineering background for technical basis and rationale

None

3. Source / derivation of the proposed IACS Resolution

UR Z1 and IMO Res. A. 1053(27) as Amended by IMO Res. 1076(28).

4. Summary of Changes intended for the revised Resolution:

The following amendment is made to the annual survey requirements in UR Z1:

Annual Survey

Loadline Items: No modifications

Hull Items : following modification have been noted

1) A new paragraph has been introduced as follows
   (CA) 2.2.2.2*bis* examining, for bulk carriers of 150 m and above, where appropriate, the ship's structure in accordance with the Ship Construction File, taking into account identified areas that need special attention (SOLAS 10 reg. II-1/3-10 and MSC.287(87));since it is numbered with a *bis* the numbering from 2.2.2.1 to 2.2.2.4 is not modified.

2) Following the renumbering of the item 2.2.2.4 bis (see Res.1020) as 2.2.2.5 the items 2.2.2.5 and 2.2.2.6 are now renumbered as 2.2.2.6 and 2.2.7 (respectively).

3) A new subparagraph has been introduced under the renamed item 2.7 as follows
   CA) 2.2.2.7.1 examining visually the drainage facilities for blockage or other damage and confirming the provision of means to prevent blockage of drainage arrangements, for closed vehicle and ro-ro spaces and special category spaces where fixed pressure water-spraying systems are used (SOLAS 08 reg.II-2/20.6.1.5);

4) Moreover the hull items 2.2.2.28 through 2.2.2.34 are now renumbered as follows 2.2.2.29 to 2.2.2.35. Consequently the two exceptions represented by paragraphs 2.2.2.29 and 2.2.2.33 are now renumbered as 2.2.2.30 and 2.2.2.34.

5) New paragraphs 2.2.2.37, 2.2.2.38 (under the already renamed 2.2.2.35) has been introduced as follows:
   5.1) (CA) 2.2.2.37 confirming, for bulk carriers constructed before 1 July 1999 with restrictions imposed with respect to the carriage of cargoes with a density of 1,780 kg/m^3 and above, that a triangle is permanently marked at midship (SOLAS 74/97/04 reg.XII/8.3);

5.2 (CA) 2.2.2.38 confirming, for bulk carriers, that the loading instrument is on board and functioning (SOLAS 74/97/04 reg.XII/11)

No further renumbering of paragraphs has been done because after paragraph 2.2.2.38 the paragraph 2.2.3 starts.

Machinery and electrical items: following modification have been noted

1) Following the renumbering of item 2.2.2.4bis the machinery items 2.2.2.7 through 2.2.2.27 have been renumbered as follow from 2.2.2.8 to 2.2.2.28. Consequently the two exceptions represented by paragraphs 2.2.2.17 and 2.2.2.26 are now renumbered as 2.2.2.18 and 2.2.2.27

2) A new paragraph has been introduced as follows
(CA) 2.2.2.24*bis* examining, where applicable, the alternative design and arrangements for machinery or electrical installations, or fire safety, in accordance with the test, inspection and maintenance requirements, if any, specified in the approved documentation (SOLAS 00/06 regs. II-1/55 and II-2/17); since it is numbered with a *bis* the numbering from NEW 2.2.2.8 to new 2.2.2.28 (see above) is not modified.

Fire fighting equipment: following modification have been noted

1) A new paragraph has been introduced as follows
(EA) 1.2.2.7 checking that fixed carbon dioxide fire-extinguishing systems for the protection of machinery spaces and cargo pump-rooms, where applicable, are provided with two separate controls, one for opening of the gas piping and one for discharging the gas from the storage container, each of them located in a release box clearly identified for the particular space (SOLAS 08 reg.II-2/10.4.1.5);

2) Following the insertion of the new paragraph the items 1.2.2.7 through 1.2.2.13 has been renamed from 1.2.2.8 to 1.2.2.14

Oil tanker additional items: following modification have been noted

1) A new paragraph has been introduced as follows:
CA) 2.2.3.15*bis* confirming that the coating system in cargo oil tanks of crude oil tankers, when appropriate, is maintained and that in-service maintenance and repair activities are recorded in the coating technical file (SOLAS 10 reg. II-1/3-11 and MSC.288(87)). Since it is numbered with a *bis* the numbering from 2.2.3.1 to 2.2.3.16 is not modified.

2) A new paragraph has been introduced as follows:
(CA) 2.2.3.17 examining, for oil tankers of 150 m in length and above, where appropriate, the ship's structure in accordance with the Ship Construction File, taking into account identified areas that need special attention (SOLAS reg. II-1/3-10 and MSC.287(87));

   No further renumbering of paragraphs has been done because after paragraph 2.2.3.16 the paragraph 2.2.4 starts.

Chemical tanker additional items following modification have been noted

1) Following the renumbering of the item 1.2.2.16 bis (see Res.1020) as 1.2.2.17, the items from 1.2.2.17 to 1.2.2.19.7 are now renumbered as 1.2.2.18 and 1.2.2.20.7. Item 1.2.2.21 has been renumbered as 1.2.2.22 (respectively).

Gas carrier additional items. No modifications

Intermediate Survey

Chemical tanker additional items following modification have been noted:

Z1.3.3. of the Unified Requirement has have been modified by removing the item relevant to the spare parts of the ventilators: excluded paragraph 1.3.2.5 of annex 4, of the IMO Res. A 1053(27) as amended.

Gas carrier additional items following modification have been noted:

Z.1.3.4 of the Unified Requirement has have been modified by removing the item relevant to the spare parts of the ventilators: excluded paragraph 2.3.2.4 of annex 4, of the IMO Res. A 1053(27) as amended.

Both items are no longer belonging into the class requirements: No modifications at all.

5. Points of discussions or possible discussions

None

6. Attachments if any

UR Z3 "Periodical Survey of the Outside of the Ship's Bottom and Related Items"

Summary

This resolution was revised for addressing the inconsistency between UR Z7 2.2.2.1 and UR Z3.1.6 relevant to the dry dock survey requirements for Liquefied Gas Carriers.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev.8 (Apr 2019)	11 April 2019	1 July 2020
Rev.7 (Jan 2018)	16 January 2018	1 January 2019
Rev.6 (Dec 2013)	21 Dec 2013	1 July 2014
Rev.5 (Apr 2011)	14 Apr 2011	1 January 2012
Rev.4 (Oct 2006)	29 Oct 2006	1 January 2008
Rev.3 (Aug 2004)	4 Aug 2004	1 July 2005
Corr.1 (Feb 2004)	11 Feb 2004	-
Rev.2 (Aug 2002)	30 Aug 2002	1 July 2003
Rev.1 (1996)	No record	1 July 1996
NEW (1984)	No record	-

• Rev.8 (Apr 2019)

.1 Origin of Change:

☑ Suggestion by IACS member

.2 Main Reason for Change:

One IACS member indicated that for Liquefied Gas Carriers the UR Z7.2 requirement, "A survey in dry dock is to be a part of the Special Survey", is not reflected in UR Z3 and Rec.133, and proposed to revise UR Z3 and Rec.133 to address this inconsistency.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None.

.4 History of Decisions Made:

Survey Panel discussed the proposed revisions to UR Z3 and Rec.133, and agreed to only revise UR Z3.1.6 for aligning with UR Z7.2 and leave Rec. 133 as it is with a view that according to the discussions during the drafting of Rec 133 it was decided by the panel that gas carriers could apply for EDD.

The implementation date of this revision was agreed to be set as 1st July 2020.

.5 Other Resolutions Changes:

None.

.6 Any hinderance to MASS, including any other new technologies:

None.

.7 Dates:

Original Proposal: 22nd February 2018 Made by: One IACS Member
Panel Approval: 27 March 2019 (ref: 19061_PYa)
GPG Approval: 11 April 2019 (ref: 19061_IGb)

- ## Rev.7 (Jan 2018)

.1 Origin of Change:

☑ Suggestion by an IACS member

.2 Main Reason for Change:

To address the FUA 11 of C73, raised by the Council of the IACS in respect to the future work directions on the implications of new technology on survey regime. A revision of UR Z3 is in order to consider the use of Remotely Operated Vehicle (ROV) and to propose the possible list of the service suppliers that need to be certified.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

Task assigned by GPG on 21th October 2016. Panel discussed and agreed to add clarification in UR Z3 for details of In-Water Survey regarding ROV and service suppliers. Accordingly, Panel agreed with the amendment to Para Z3.3.

No TB is expected for the present revision.

.5 Other Resolutions Changes

UR Z7, UR Z10.3, UR Z17

.6 Dates:

Original Proposal: 21 October 2016 assigned by GPG
Panel Approval: 08 December 2017 by Survey Panel (Ref: PSU16056)

GPG Approval: 16 January 2018 (Ref: 16151_IGq)

- **Rev.6 (Dec 2013)**

.1 Origin of Change:

☑ Suggestion by an IACS member

.2 Main Reason for Change:

A member of Survey Panel initiated this discussion with reference to a recent external audit observation that class society procedures and checklists do not address clearly details of inspection to be carried out on Directional Propulsion Systems during an IWS or Docking Survey.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

Panel discussed and agreed to add clarification in UR Z3 for details of inspection regarding other types of propulsion and manoeuvring systems such as directional propulsion systems, vertical axis propellers, water jet units etc. Accordingly, Panel agreed with the amendment to Para Z3.2.6.

.5 Other Resolutions Changes

None

.6 Dates:

Original Proposal: *05 June 2013 Made by a Member of the Survey Panel*
Panel Approval: *31 July 2013 by Survey Panel*
GPG Approval: *21 Dec 2013 (Ref: 13205_IGd)*

- **Rev.5 (April 2011)**

.1 Origin of Change:

☑ Suggestion by an IACS member

Item 1.
A member of IACS raised the point that, although the issue of IWS visibility requirements has been discussed at various times, UR Z3 states "The in-water visibility is to be good" which can lead to surveyors being put under pressure to accept marginal visibility.

Item 2.

Continuous harmonisation between IMO Res.A744(18) as amended (ESP Guidelines) and IACS survey requirements.

.2 Main Reason for Change:

1. To improve the wording of UR Z3 to resolve this issue.
2. The following proposed amendment to IMO Res.A744(18) as amended was not accepted at DE54:
"For ships of over 15 years of age ~~and over~~ , inspection of the outside.... For ships of ~~less than~~ 15 years of age or less, alternate inspections.."

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

1. The decision was made to clarify UR Z3, para. 3.3.2.
2. The decision was made to amend UR Z3, para. 3.1.3 in accordance with IMO Res. A744(18) as amended.

.5 Other Resolutions Changes

UR Z10s related to ESP ships, through a separate task.

.6 Dates:

Original Proposal: *September 2010 Made by the Survey Panel*
Panel Approval: *January 2011*
GPG Approval: *14 April 2011 (Ref: 11050_IGd)*

- **Rev.4 (Oct 2006)**

Note: *There are no separate Technical Background (TB) documents for the original resolution (1984), Rev.1 (1996), Corr.1 (Feb 2004), Rev.7 (Jan 2018) and Rev.8 (Apr 2019).*

Technical Background Document
UR Z3 Rev.2 August 2002

Revised UR Z3-Periodical Survey of the Outside of the Ship's Bottom and Related Items (WP/SRC Task 101)

Objective and Scope:

To revise the dry-docking survey requirements in UR Z10.2, 10.3, 10.4 and UR Z3 to harmonise them with those in Z10.1 (Rev.9) and reflect in UR Z3 the interim application of bottom survey requirements as introduced in MSC/Circ.1013 (Res.A746(18))

Source of Proposed Requirements:

WP/SRC developed the revised UR Z3 through correspondence and at their Spring meeting this year.
The revised UR Z3 is in accordance with the interim application of bottom survey requirements as introduced in the revised MSC/CIRC: 1013 which was approved at MSC 75 in May 2002. A new circular number will be assigned by IMO.
The dry-docking requirements in UR Z10.1(Rev 9), Z 10.2(Rev 12) and Z10.3(Rev 5) need not be further amended as a result of this revised MSC/CIRC.
UR Z10.4 para 2.2.2.1 is to be updated to correspond with the text in the same para of UR Z10.1.

Points of Discussion:

1. The revised UR Z3 was unanimously agreed by WP/SRC.

2. BV proposed to suppress for the time being the reference to UR Z10,5 as same has not been submitted to GPG for approval. (ref 1060hBVa) The chairman of WP/SRC is in agreement with BV's proposal and suggests that UR Z10.4, UR Z10.5 and UR Z10.6 should be considered in the harmonisation project. (WP/SRC-Task 102)

3. The chairmen of WP/SRC and GPG asked Mr Gil-Yong Han to verify the use of the term "special/class renewal survey, which appears in para 1.2 and 2.3.
   Mr Han suggests to use the term "special survey" throughout the document and add a note to Z3 para 1.2:
   "Some member Societies use the term "Special Periodical Survey, others use the term Class Renewal Survey". The chairman of WP/SRC agrees to inserting this note.

4. With respect to the definition of "any five period" in SOLAS 88 and Res A.746(18), the following text was approved at MSC 75.

   "Any five-year period is the five-year validity of the Cargo Ship Safety Construction Certificate(SC) or the Cargo Ship Safety Certificate."

   (See FSI 10/17/Annex 5. MSC 75/WP.11/Add.1/13.9 reads the Committee approved it.)

   The chairman of WP/SRC advises that WP/SRC found it not necessary to introduce the above interpretation into UR Z3 with change of SC to Class Certificate. Instead, WP/SRC agreed to use "during each five year special survey period".

5. The revised MSC/CIRC is applicable as from 1.July 2002.
   The chairman of WP/SRC recommends that the revised UR Z3 is given high priority and adopted from the same date.

Note by the Permanent Secretariat:
After a considerable length of discussion on Z3.1.1(The Owner is to notify…), GPG decided to keep it as it was. (GPG subject number 1060h)

Submitted by WP/SRC Chairman in July 2002

Technical Background UR Z 3 Rev.3.

This is a partial outcome of WP/SRC's Task *110 Develop an IACS resolution on the control of extensions of class beyond the special survey due date (UR Z 7, 2.1.2) and similar extensions to drydocking due dates* which was to:
a). define the "Exceptional Circumstances" under which an extension to special (renewal) survey and/or drydocking may be granted;
b). provide a specific and consistent policy and procedures for extension surveys.

The task was triggered by complaints by the Marshall Islands Administration at its meeting with its ROs in 2002 of a lack of consistency in this area.

Under 2222bNVb of 21 January 2004, WP/SRC submitted amendments to UR Z3 to clarify the drydocking aspects. They confirm that an extension may be granted in exceptional circumstances, which term is to be defined in a revision of PR1A. In addition, the requirements for an in-water survey in lieu of dry-docking are made more specific.

GPG approved the revision to UR Z3 on 1 April 2004 (2222bIGc).

In Council discussion, the definition of 'exceptional circumstances' agreed for the revision of PR1A was added as a footnote to para 3.1.2. The wording of para 3.1.2 itself was simplified.

Adopted by Council on 4 August 2004 (2222bICd).

Permanent Secretariat 13/04/04 and 09/08/04.

TECHNICAL BACKGROUND

UR Z3 (Rev. 4), Z 7 (Rev. 14), Z18 (Rev. 2) and Z21 (Rev. 2)

Survey Panel Meeting March 2006 New Business Item – Applying UR Z3, Z7, Z18 and Z21 for Military Vessels.

1. **Objective**

To add the following new paragraph to UR Z3, Z7, Z18 and Z21 to reflect that special consideration may be used for military vessels:
"Special consideration may be given in application of relevant sections of this Unified Requirement to military vessels or commercial vessels owned or chartered by Governments, which are utilized in support of military operations or service".

2. **Background**

This task was originally discussed during the Survey Panel meeting, which took place at ABS Houston on the 1st to 3rd March 2006; it was subsequently recorded under paragraph 3 "new business" of the minutes of this meeting.
This initial started as a proposal for ABS to remove their reservation (see below) for military vessels against UR Z3 and Z7s. However all of the members agreed to the proposal.
Current ABS Reservation: "ABS allows variations in survey interval in agreement with US Government for military vessels or commercial vessels owned or chartered by the Government which are utilized in support of military operations or service."

3. **Methodology of Work**

Survey Panel members through correspondence.

4. **Discussion**

Survey Panel member from ABS raised this issue at the March 2006 Survey Panel meeting and volunteered to propose amendments to the applicable URs for Panel members to review and comment on through correspondence. At the Fall meeting of the Survey Panel, it was agreed upon by all Panel members that the proposed amendments for UR Z3, Z7, Z18 and Z21, which were proposed by ABS, were acceptable.

5. Implementation

The Survey Panel is of the view that the Members need 12 months from the adoption date to implement these amendments into their class rules. Assuming that GPG and Council approve to the amendments, the Survey Panel would propose January 2008 as an

implementation date. However due to other on going revisions to UR Z21 this UR will be held abeyance until the other revisions are completed.

6. **Discussion at GPG:** GPG amended the proposal by deleting the phrase “military vessels or” on the basis that military vessels and other government ships operated for non-commercial purposes are out of the scope of IACS URs. The adopted amendment therefore reads:

“Special consideration may be given in application of relevant sections of this Unified Requirement to commercial vessels owned or chartered by Governments, which are utilized in support of military operations or service”.

Submitted by Survey Panel Chair, October 2006
Updated by GPG to reflect their discussion

Technical Background for UR Z3 Rev.5, Apr 2011

1. Scope and objectives

Item 1.
To clarify the requirements in UR Z3 with respect to the in-water visibility during an in-water survey.

Item 2.
To harmonise IMO Res.A744(18) and IACS Unified Requirements with respect to the age limit above which the bottom survey is to be carried out in dry-dock.

2. Engineering background for technical basis and rationale

Panel members agreed not to use a defined visibility distance.

3. Source / derivation of the proposed IACS Resolution

UR Z3 and IMO Res.A744(18) as amended and IMO Res.A997(25) as amended.

4. Summary of Changes intended for the revised Resolution:

1. The following amendment is made to UR Z3:

Z3.3.2 The In-water Survey is to be carried out with the ship in sheltered water and preferably with weak tidal streams and currents. The in-water visibility and the cleanliness of the hull below the waterline is to be clear enough to permit a meaningful examination which allows the surveyor and diver to determine the condition of the plating, appendages and the welding. The Classification Society is to be satisfied with the methods of orientation of the divers on the plating, which should make use where necessary of permanent markings on the plating at selected points.

2. The following amendment is made to UR Z3:

Z3.1.3 Examinations of the outside of the ship's bottom and related items of ships is normally to be carried out with the ship in drydock. However, consideration may be given to alternate examination while the ship is afloat as an In-water Survey, subject to provisions of Z3.3. Special consideration is to be given to ships of 15 years or over before being permitted to have such examinations. For ESP ships of 15 years of age and over, such examinations are to be carried out with the ship in drydock.

5. Points of discussions or possible discussions

None

6. Attachments if any

None

Technical Background (TB) document for UR Z3 (Rev.6 Dec 2013)

1. Scope and objectives

Clarify the inspection requirements in UR Z3 for Directional Propulsion Systems.

2. Engineering background for technical basis and rationale

Panel discussed and agreed to add clarification in UR Z3 for details of inspection regarding other types of propulsion and manoeuvring systems such as directional propulsion systems, vertical axis propellers, water jet units etc.

3. Source / derivation of the proposed IACS Resolution

UR Z3

4. Summary of Changes intended for the revised Resolution

The following amendment is made to UR Z3.2.6:

Z3.2.6 Visible parts of side thrusters are to be examined. Other propulsion systems which also have manoeuvring characteristics (such as directional propellers, vertical axis propellers, water jet units) are to be examined externally with focus on the condition of gear housing, propeller blades, bolt locking and other fastening arrangements. Sealing arrangement of propeller blades, propeller shaft and steering column shall be verified.

Also minor editorial corrections are done in paragraphs Z3.2.2 and Z3.2.4.

5. Points of discussions or possible discussions

Technical Background Document
WP/SRC Task 59
UR Z 6 – Proposed Rev. 3

Objective and Scope:

To remove the ambiguity of survey requirements for ballast tanks for ships on hull continuous survey.

Source of Proposed Requirements:

WP/SRC members discussed this issue and agreed that it is an administrative problem for each society to track due dates of ballast tanks survey. However, a footnote was added to UR Z 6 to clarify that ships on CHS are not exempt from other periodical surveys.

Points of Discussion:

WP/SRC unanimously agreed -to the draft UR Z 6.

Date of submission: 6 May 1999
By WP/SRC Chairman's e-mail

Technical Background

Revision (4) of UR Z6-Continuous System for Hull Special Survey

As part of its continuous review of IACS URs relating to surveys, the WP/SRC has revised the UR Z6-Continuous System for Hull Special Survey. The following draft amendments were agreed unanimously by the WP and submitted to GPG for approval.

Amendments

First sentence below the title to be amended to read: For ships other than ESP ships (Oil Tankers, Combination Tankers, Bulk Carriers and Chemical Tankers) subject to UR Z10s and ships other than General Dry Cargo Ships subject to UR Z7.1

Paragraph 6.4, the following sentence to be added at the end of the paragraph: The survey in dry-dock may be held at any time within the five-year class period.

New Note 3: General Dry Cargo Ships. For the application of the new requirements, a General Dry Cargo Ship is defined as a self-propelled ship of 500 gross tonnes or above, constructed generally with a tween deck and intended to carry solid cargoes. This excludes bulk carriers, refrigerated cargo ships, roll on-roll off ships and ships dedicated for the carriage of containers, forest products (but not log or timber carriers), woodchips or cement as well as livestock carriers and dock/deck ships. The changeover from continuous survey to special survey is to be carried out as early as possible and should be no later than the due date of the next intermediate survey, or the due date for completion of the current Continuous survey hull cycle, whichever is earlier.

In this connection:-

(i) all items credited for Continuous survey within the previous 15 months may be accepted without further survey at the Surveyor's discretion.

(ii) all other items are to be surveyed and credited at the date of conversion.

Phasing-in of UR Z7.1

The members of WP/SRC agreed unanimously that for general dry cargo ships the phasing-in period of UR Z7.1 will be latest by the first Intermediate Survey or Special Survey, whatever comes first after 1 January 2004.

GPG proposed that as 1 January 2004 had already passed, the changeover from continuous survey to special survey should be carried out as soon as possible but not later than the due date of the next Intermediate or Special Survey or the due date of the end of the five year class period, whichever comes first after 1 July 2005.

April 2004 (corr May 2004)

****

Technical Background Document
UR Z6 (Rev. 5 July 2005)

1. Objective:

Revise text of Z6 to ensure that vessels 10 years of age and over where the survey requirements are based upon Z7 and the vessel is also on a Continuous Survey of Hull in accordance with Z6 that the ballast tanks are being surveyed twice in each five year Special Survey Period.

2. Background

ABS had requested that WP/SRC review the requirements for ballast tanks in Z7 and how they should be applied under Z6 (Continuous Hull Surveys) for vessels 10 years of age and over where the survey requirements require all ballast tanks are to be internally examined at the intermediate survey and special surveys.

WP/SRC developed a draft revision to Z6 and WP/SRC Chairman submitted the revision of Z6 to GPG following the October 2004 meeting.

The revision was considered a minor amendment however at GPG several issues were raised and no consensus could be reached so GPG tasked the Survey Panel to review the matter again taking into account the GPG Correspondence.

3. Discussion

3.1 WP/SRC developed a draft revision to Z6 in October 2004.

3.2 GPG had several issues that were raised and no decision was made to amend Z6. Survey Panel, in the beginning of 2005, was tasked to review the issues again and amend Z6 as necessary.

3.3 Z6.4 was amended by the IACS Survey Panel members, which clearly defined requirements for internal examination of ballast tanks for vessels over 10 years of age as required in Z7, for vessels on Continuous Survey of Hull.

Submitted by Survey Panel Chairman
20 June 2005

UR Z7 "Hull Classification Surveys"

Summary

By this corrigendum, Para. 1.5 of this UR and its footnotes were updated due to withdrawal of UR S21A and merger of its contents into UR S21.

- **Corr.1 (May 2024)**

1 Origin of Change:

☑ Suggestion by IACS member

2 Main Reason for Change:

UR S21A was withdrawn, and its content was merged into UR S21 (with the implementation date of 1 July 2024). Accordingly, there was a need to update Para. 1.5 of UR Z7 and its footnotes.

3 Surveyability review of UR and Auditability review of PR

Survey Panel checked the correctness of this corrigendum.

4 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None

5 History of Decisions Made:

During the 39th Survey Panel meeting, the suggested correction of this UR in the form of corrigendum was unanimously agreed.

No TB is expected for the present revision.

6 Other Resolutions Changes:

None

7 Any hinderance to MASS, including any other new technologies:

None

8 Dates:

Original Proposal	:	22 January 2024	(Ref. PSU24006_ISUa)
Panel Approval	:	7 March 2024	(Ref: 39th Survey Panel meeting)
GPG Approval	:	10 May 2024	(Ref: 24057_IGb)

- **Rev.29 (May 2022)**

1 Origin of Change:

☑ Suggestion by an IACS member

2 Main Reason for Change:

To clarify the requirements for thickness measurements for ships without cargo space.

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None

4 History of Decisions Made:

A member of Survey Panel raised the issue how to apply the requirements to ships without cargo space because the thickness measurement requirements within the amidships 0.5L are stipulates only cargo space(s) in table 1. Survey panel reviewed it and agreed to revise the wording considering ships without cargo spaces.

No TB is expected for the present revision.

5 Other Resolutions Changes:

None

6 Any hinderance to MASS, including any other new technologies:

None

7 Dates:

Original Proposal	: 13 January 2021	(Made by a Survey Panel member)
Panel Approval	: 13 April 2022	(Ref: PSU21002)
GPG Approval	: 11 May 2022	(Ref: 22062_IGb)

- **Corr.1 (Dec 2020)**

1 Origin of Change:

☑ Suggestion by an IACS member

2 Main Reason for Change:

This modification is to correct a reference (change from "2.2.12" to "2.2.9") in para.2.2.2.

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group: None
4 History of Decisions Made:

A member of Survey Panel found one wrong reference in para.2.2.2. Para.2.2.2 is a requirement regarding the hull examination so it should refer to para.2.2.9, but refers to para.2.2.12 which is regarding the examination for piping systems.

5 Other Resolutions Changes:

None

6 Any hinderance to MASS, including any other new technologies:

None

7 Dates:

Original Proposal: 8 September 2020 Made by a Survey Panel member (PSU20041)
Panel Approval: 23 November 2020 (Ref: 20168_PYb)
GPG Approval: 07 December 2020 (Ref: 20168_IGd)

- **Rev.28 (May 2019)**

1 Origin of Change:

☑ Suggestion by an IACS member

2 Main Reason for Change:

2.1 This revision is to address the policy decision made by GPG using the common terminology 'Condition of Class'(CoC) instead of the terms 'Recommendation/ Condition of Class' based on the outcome of III 5. (PSU19010)

2.2 Additionally, further revision was agreed to use the harmonized terms of ballast tanks for their survey requirements. (PSU18070)

3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

4 History of Decisions Made:

4.1 Harmonization of the terms "Recommendation" and "Condition of Class" (PSU19010)

During the 29th panel meeting, the panel discussed about the comments of members, and concurred with the view to retain the present definitions of CoC in the IACS resolutions with the wording 'Recommendation' to be removed. The panel also agreed to use the term 'Statutory Condition' for the 'recommendation' of the statutory certificates in IACS resolutions and RECs, and when discussing the proposal of a member to consider the harmonization of the terms of 'recommendation' and 'condition of class' in RO Code, the panel unanimously agreed to take no action on the IMO instruments, leaving the relevant actions to be decided by the relevant IMO bodies when IACS feeds back to IMO the IACS action on the harmonization of the two terms.

Before the implementation date of 1st July 2020 for using the common terminology 'Condition of Class' only, 'Recommendations' and 'Condition of Class' are to be read as being different terms used by Societies for the same thing, i.e. requirements to the effect that specific measures, repairs, surveys etc. are to be carried out within a specific time limit in order to retain Classification.

Panel members concurred with the view that it is not necessary to develop a new procedure requirement, and agreed to set the implementation date of these IACS resolutions (other than RECs) as 1st July 2020.

4.2 Additional revision to use the harmonized terms of ballast tanks for their survey requirements (PSU18070)

Upon the discussions within Survey Panel under task No. PSU18070, the following changes were decided to be made to UR Z7, Z7.1 and Z7.2:
1. To use "ballast tanks" in lieu of "ballast spaces", "water ballast tanks", "tanks used for water ballast" or "spaces used for water ballast"; and
2. To use "double bottom ballast tanks" in lieu of "water ballast double bottom tanks".

No TB is expected for the present revision.

5 Other Resolutions Changes:

The following IACS resolutions and Recommendations (RECs) were agreed to be revised: (PSU19010)
- Procedural Requirements: PR1A, PR1B, PR1C, PR1D, PR1 Annex, PR3, PR12, PR20, PR35 and the attachment of PR16;
- Unified Requirements: Z7, Z7.1, Z7.2, Z10.1, Z10.2, Z10.3, Z10.4, Z10.5, Z15 and Z20
- Unified Interpretations: GC13
- Recommendations: Rec.41, Rec.96, Rec.98

URs Z7.1 and Z7.2 (PSU18070)

6 Any hinderance to MASS, including any other new technologies:

None

7 Dates:

Original Proposal: 14 January 2019 tasked by GPG (17044bIGm) (PSU19010)
19 December 2018 Made by: a Survey Panel member (PSU18070)
Panel Approval: 22 March 2019 (PSU19010)
3 May 2019 (PSU18070)
GPG Approval: 30 May 2019 (Ref: 17044bIGu)

- **Rev.27 (Oct 2018)**

.1 Origin of Change:

☑ Suggestion by IACS members

.2 Main Reasons for Change:

To revise UR Z7 to clarify the applicability of FP and AP tanks in UR Z7 Table 1. The relevant text in Recommendation 82 is also to be aligned with the UR Z7.

.3 List of non-IACS Member Classification Societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

A member noted that the description of current FP and AP tanks in UR Z7 Table 1 and Rec.82 are not completely accurate and recommended to be revised.

During the 27th Survey Panel Meeting, the members reviewed the UR Z7 & Rec.82 and agreed to modify the item 4) of UR Z7 table 1 as “Internals in forepeak and afterpeak ballast tanks.”

During the 28th Survey Panel Meeting, the members finalized the revisions of UR Z7 and Rec. 82 and their HFs.

No TB is expected for the present revision.

.5 Other Resolutions Changes

Rec.82

.6 Dates:

Original Proposal: 07 December 2017 Made by a Survey Panel Member
Panel Approval: 12 October 2018 (Ref: PSU17044)
GPG Approval: 28 October 2018 (Ref: 18160_IGc)

- **Rev.26 (Jan 2018)**

.1 Origin of Change:

☑ Suggestion by IACS members
☑ Others (GPG task)

.2 Main Reasons for Change:

To introduce:

- The criteria for the steel renewal which belongs under the unified requirements of series S and are related to the net scantling approach.

- The definition of Remote Inspection Technologies

- The criteria for the survey of the downflooding ducts and ventilations ducts which are integrated to the ship’s structures.

.3 List of non-IACS Member Classification Societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

(1) A member noted that some Unified Requirements of series S (Strength of Ships), such as UR S18, contain criteria addressing the steel renewal for dedicated structures such as transverse bulkheads, cargo hatch coamings and plating. These criteria (based on the net scantling approach) are applicable also to units designed with the gross scantling approach because they refers to particular structures for which it is foresaw the dimensioning (or the design verification) according to the net scantling approach.

Under the task PSU16044 the Panel analysed all URs looking for those containing any structural renewal criteria based on the net scantling approach.

Having found that UR S18 and UR S21a contain steel renewal criteria that need to be taken into account during the thickness measurements review process, the members agreed a new paragraph 1.5, "Thickness measurements Acceptance Criteria", and inserted it in the present revision of UR Z7.

(2) Members discussed under Panel task PSU 16056 the issue allocated by GPG on 21th October 2016. The subject deals with the review of the UR and Recommendation under Panel responsibility in order to determine whether a revision could need in order to consider the new technologies on Remote Inspections (RIT). The Panel Members concurred to discuss the possible revisions of the UR Z7 in order to address the issue.

A new paragraph 1.2.15 with definition of RIT and new section 1.6 "Remote Inspection Techniques (RIT)" were agreed and inserted in the present revision of UR Z7.

(3) During 25th Survey Panel Meeting, the Panel discussed the proposal made by a Member and relevant to the inspection of the downflooding ducts and ventilations ducts which are integrated to the ship's structures under task PSU17002. The qualified majority of the members agreed to modify the paragraph 2.2.5 of the UR Z7 by introducing the survey requirements for these arrangements to be applied to ship having age of 15 years or more.

No TB is expected for the present revision.

.5 Other Resolutions Changes

UR Z3, UR Z7.1, UR Z7.2, UR Z10.3, UR Z17

.6 Dates:

Original Proposal: 09 September 2016 (24th Survey Panel meeting) Made by a Survey Panel Member. 21 October 2016 assigned by GPG.

02 February 2017 Made by a Survey Panel Member.

Panel Approval: 08 February 2017 (Ref: PSU16044),
08 December 2017 by Survey Panel (Ref: PSU16056)
22 May 2017 by Survey Panel (Ref: PSU17002)

GPG Approval: 16 January 2018 (Ref: 16151_IGq)

- **Rev.25 (June 2016)**

.1 Origin of Change:

☑ Suggestion by an IACS member

.2 Main Reasons for Change:

As consequence of review of the paragraph 2.3.1 of UR Z10.2 and UR Z10.5.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

A member proposed to review paragraph 2.3.1 of UR Z10.2 and UR Z10.5 with the aim to delete the embedded table dealing with the survey requirements of Fuel Oil Tanks located in cargo length area of ESP bulk carriers.

Panel, under task PSU15059, evaluated the reasons of the request since, apparently, the requirements of the said paragraph are the same as those contained in Table 3 of the UR Z7, which is applicable to all ships.

Panel noted the following:

- The revision 17 of June 2005 (harmonisation) of the UR Z10.2 and the revision 1 of June 2005 (harmonisation) of the UR Z10.5 introduced the table into the paragraph 2.3.1. According the technical background of these revisions the matter has been dealt with by a dedicated PT on the basis of a specific task assigned by the GPG
- The requirements for overall inspection of Fuel Oil Tanks located within cargo length area of a ESP Bulk Carrier have to be applied starting from the Special/Renewal surveys no.2. This requirement has the same consistency as those contained in table 3 of the UR Z7 which are applicable to all ship.
- According to the provisions of paragraph 1.1.2 of UR Z10.2 and paragraph 1.1.3 of the UR Z10.5, the fuel oil tanks located within cargo length area are not subjected to the survey provisions of UR Z7
- According to the provisions of paragraphs 4.2.3.1 and 4.2.4.1 of the UR Z10.2 and UR Z10.5 the extent of the intermediate survey (after the ship reached ten years of age) is the same as the previous special/renewal survey. Therefore

the fuel oil tanks might be part of the compartments to be inspected (in fact the same paragraphs leave to the Surveyor the decision whether these need to be inspected).

- The requirements of both UR Z10.2 and UR Z10.5 reflect those set by the ESP Code. Hence any modification of these URs needs to be reflected in the ESP Code, but whereas the removal of these survey requirements from the URs may be supported by the existence of the same requirement in UR Z7 (to which it is always possible to make reference), this is not possible in the ESP Code since this is a self standing document.

Panel agreed that no modification to UR Z10.2 and UR Z10.5 should be applied but, at the same time, concurred that the table 3 of UR Z7 would need to be updated in order to clarify that the survey requirements for fuel oil tanks located within cargo area, are not applicable to ESP bulk carriers subject to UR Z10.2 or UR Z10.5. However, after further discussions, the majority of the Panel members agreed it was not necessary to include such clarification in table 3 since UR Z10.2 and UR Z10.5 clearly state that UR Z7 applies only to the remainder parts of the ship not covered by Z10.2 and Z10.5 which do not include fuel oil tanks.

Moreover Panel noted that the survey requirements of table 3, for fuel oil tanks, are not based on the typology of the service carried out by these but, rather, by their location on board. In fact the possible difference in number of fuel oil tanks to be inspected, for two ships having the same age, depends only on the fact whether one of the two has fuel oil tanks located in cargo area length (since in engine room there is, at least, one or two fuel oil tanks, e.g. daily and/or settling tank).

Panel members agreed to introduce a new row into the table3 of UR Z7, so that the number of fuel oil tanks, to be inspected at special survey, can assure that, regardless the ship configuration and tanks layout, the adequate number of tanks are internally examined.

During the 23rd Survey Panel Meeting, Members found a final agreement for the modification of table 3 of UR Z7 by introducing the requirements for the surveys of fuel oil tanks not located in engine room or in the cargo length area.

No TB is expected for the present revision.

.5 Other Resolutions Changes

Nil

.6 Dates:

Original Proposal: 01 December 2015 Made by Survey Panel Member
Panel Approval: 16 March 2016 (Ref: PSU15059)
GPG Approval: 20 June 2016 (Ref: 16104_IGb)

- **Rev.24 (Feb 2016)**

.1 Origin of Change:

☑ Suggestion by an IACS member

.2 Main Reasons for Change:

Review of the paragraph S11A.1.3 of UR S11A (issued in June 2015)

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

Panel evaluated, under task PSU 15036, the newly introduced requirements for the evaluation of the longitudinal strength standard for container ships with particular reference to paragraph S11A.1.3 dealing with the corrosion margin and net thickness.

Members sought the advice of Hull Panel in order to understand whether the requirements are applicable also to the existing ships and whether the thickness measurements of the longitudinal elements contributing to the longitudinal strength of the ship should be evaluated by the surveyor by using the net scantling approach (t_{net}).

The Hull Panel provided the following reply:
- The provisions of the new UR S11A are applicable only to new container ships
- The use of the net scantling approach is limited to the evaluation of the residual midship section moduli, however it would be advisable to set a simple criterion in order to allow the evaluation of the residual area of a transverse section which may be handled by the surveyor during the revision of the thickness measurement report.

Panel by acknowledging the contents of the reply wondered if the use of the net scantling approach does not require providing the surveyor with appropriate reporting forms for thickness measurements.

Moreover Members tried to consider the issue of reporting of thickness measurements in a broader way by keeping in mind that there could be Societies that may expect in their own rules for ships (i.e. those not subjected to CSR) two types of hull design verification:
- The traditional by which the calculated thickness is inclusive of the corrosion margins
- The net scantling design.

Considering that the reports of thickness measurements should be prepared every time thickness measurements are required (e.g. during special/renewal surveys), Members concurred that it would be advisable that the thickness measurement reporting forms were provided for both systems (traditional and net scantling design).

During the 22nd Survey Panel Meeting Members discussed the issue and agreed that two annexes to UR Z7 containing the thickness measurement report forms, similar to those provided for the UR Z10.2, UR Z10.4 and UR Z10.5, needed to be added. These annexes are not a mandatory requirement under UR Z7, but of recommendatory nature.

The further details of the revision 24 of UR Z7 have been agreed by correspondence.

No TB is expected for the present revision.

.5 Other Resolutions Changes

Nil

.6 Dates:

Original Proposal: 17 July *2015* Made by *Survey Panel Member*
Panel Approval: 28 December 2015 (Ref: PSU15036)
GPG Approval: 12 February 2016 (Ref: 15209_IGb)

- **Rev.23 (Jul 2015)**

.1 Origin of Change:

☑ Suggestion by an IACS member

.2 Main Reasons for Change:

Consider the possibility to have different criteria relevant to the thickness measurements for ships built with metallic material other than steel.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

Panel evaluated, under task PSU 14042, the issue relevant the consistency (amount) of the thickness measurements to be applied to ships built in metallic material different from steel, such as light alloys.

Members concurred that in the cases where the materials used for the hull construction are corrosion resistant, e.g. light alloys, aluminium, the requisite to apply the same extension of thickness measurements of a steel ship would seem excessive.

Keeping in consideration the above some Members argued that these ships should be excluded by the application thickness measurement campaign at special/renewal survey.

Other Members concurred that notwithstanding the extension of the thickness measurement campaign, expected by the actual provisions of UR Z7, might be excessive for ships built in non-steel metallic materials these ships should be anyway subjected to a tailored campaign of measurements in order to assess the whole strength of the hull.

During the 21st Survey Panel Meeting members discussed the issue and agreed that the consistency of the thickness measurement campaign, for ship's built with metallic materials different from steel, shall be left to the Societies determination in accordance with its own rules.

Panel also agreed the modification of the paragraph 1.4 of the UR Z7 in consistency with the decisions taken

No TB is expected for the present revision.

.5 Other Resolutions Changes

Nil

.6 Dates:

Original Proposal: 22 October *2014 Made* by: *Survey Panel Member*
Panel Approval: At 21st Survey Panel Meeting (18 March 2015)
GPG Approval: 08 July 2015 (Ref: 15109_IGb)

• Rev.22 (Feb 2015)

.1 Origin of Change:

☑ Suggestion by an IACS member

.2 Main Reasons for Change:

Consider appropriate text in IACS document regarding the applicability of the Thickness Measurements when the Close up survey is performed.

a) Consider appropriate text in IACS document regarding the applicability of the Thickness Measurements when the Close up survey is performed.
b) To consider the impracticability of the internal structure close up inspection of cargo hold hatch covers which have no access structurally (from the approved design) and it is possible to survey and gauge plating only.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

a) Following an ACB query an IACS member proposed to add suitable text in appropriate IACS documents regarding the application of the Thickness Measurements when the close up surveys are performed as survey requirement due at the Intermediate/ Renewal Class surveys. This Member expressed the view that the requirements to execute the Thickness Measurements of the area subject to Close Up Surveys are expected into the "MINIMUM REQUIREMENTS FOR THICKNESS MEASUREMENTS AT SPECIAL SURVEY" while the paragraph 1.4 of the document contains only the requirement that "Thickness Measurements of the areas subject to close up surveys shall be taken in conjunction with the close up survey".

Panel discussed the matter under item PSU13051 and considered that wordings of Para 1.4 of current UR Z7s/10s need to be revised in order to clarify this issue; finally Panel agreed to add additional wording to Para.1.4.

b) Panel, following the proposal submitted by a Member, concurred and agreed that in case the cargo hold hatch covers have a configuration that does not permit the ingress of the surveyor for the internal inspection (e.g. box type panel), the close up survey should be limited to external parts as well as the Thickness Measurements that should be performed only on the external plating. The technical background, on which is based the modification of the requirement, is that the internal structure of a hatch cover of box type construction are reasonably not subject to any corrosion phenomenon. Hence, unless the external plating of the box is damaged, no depletion of the internal structures is expectable.

Panel discussed the matter under item PSU13051 and considered that an additional wording to Para 2.2.10.1 and table 1, of current UR Z7, need to be added to clarify this issue.

c) With this revision the following clerical errors have been corrected:

- in table 1 (MINIMUM REQUIREMENTS FOR THICKNESS MEASUREMENTS AT SPECIAL SURVEY), row 4, column 4 has been corrected as follow: from "4) Internals in forepeak and after tanks." to "4) Internals in forepeak and afterpeak tanks".
- in paragraph 1.2.10 the definition of FAIR (related to coating condition) has been corrected by adding the missing wording "AND/OR" so that now it reads:

FAIR: condition with local breakdown at edges of stiffeners and weld connections and/or light rusting over 20% or more of areas under consideration, but less than as defined for POOR condition

.5 Other Resolutions Changes

The amendment a) affects UR Z7.1, UR Z7.2, UR Z10.1, UR Z10.2, UR Z10.3, UR Z10.4 and UR Z 10.5.

The amendment b) affects also UR Z7.1, UR Z10.2 and UR Z10.5.

.6 Dates:

Panel Approval: At 19th Survey Panel Meeting (6 March 2014)
GPG Approval: 05 February 2015 (Ref: 14193_IGc)

- **Rev.21 (Jan 2014)**

.1 Origin of Change:

☑ Suggestion by an IACS member

.2 Main Reasons for Change:

Consider appropriate text in IACS document regarding class period for lengthy conversions.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

With reference to IMO Res. A1053 (27) (5.5 Application of "special circumstances") an IACS member proposed to add suitable text in appropriate IACS document regarding class period for lengthy conversions. This Member expressed that when a renewal survey has been completed, the new 5 year class period would normally be calculated from the expiry of previous class period/class certificate and in some cases this might result in unreasonably short time from one renewal survey completion until the next renewal would be due.

Panel discussed and considered that wordings of Para 2.13 of current UR Z7s/10s (second sentence) could address this issue but finally agreed to add additional text to Para.2.1.3 in order to clarify this matter.

.5 Other Resolutions Changes

The identical amendment affects UR Z7.1, UR Z7.2, UR Z10.1, UR Z10.2, UR Z10.3, UR Z10.4 and UR Z 10.5.

.6 Dates:

Panel Approval: At 18th Survey Panel Meeting (5 September 2013)
GPG Approval: 14 January 2014 (Ref: 12011aIGd)

- **Rev.20 (May 2013)**

.1 Origin of Change:

☑ Suggestion by an IACS member

.2 Main Reason for Change:

a) An inquiry from a member whether the 'Other equivalent means' referred in Para 5.3.2 of IACS UR Z10.2 include the use of Cherry Pickers for survey of other structures. (PSU 12022)

b) A member suggested that UR Z4 and UR Z22 are no longer needed since they have been incorporated into UR Z7. (PSU12038)

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

a) Discussion of this matter initiated by a Panel member regarding the use of Cherry Pickers in Cargo Holds with reference of IACS URZ10.2. In accordance with UI SC191 and Rec 91, the Cherry Picker is allowed up to 17m height for Cargo Hold structure (ships constructed after 2006 for Alternative means of access). As per the provisions of URZ10.2, Cherry pickers are allowed for survey of side shell frames only.

   Panel discussed and considered that Para 5.3.2 of UR Z10.2 allows the use of Cherry Pickers as 'Other equivalent means'. Accordingly, Panel agreed to clarify this matter by including text "hydraulic arm vehicles such as conventional cherry pickers" to UR Z10s and UR Z7s for a ship not subject to the above 17m restriction.

b) Panel reviewed the suggestion of an IACS member to delete UR Z4 and UR Z22. In order to delete UR Z4 Panel discussed two options ,that is- last survey item from Para 4.5 of UR Z4 either to be included as new Para 2.2.10.4 in UR Z7 or there is no need to change the existing text of UR Z7 since Para 2.2.11 covers the survey requirements needed by UR Z4. During 17th Panel meeting Panel agreed to delete UR Z4 without any modification of UR Z7.

   Panel also agreed to delete IACS UR Z22 with inclusion a new "note" in Table 4, column 3 of UR Z7.

.5 Other Resolutions Changes

a) The identical amendment affects UR Z7.1, UR Z10.1, UR Z10.2, UR Z10.3, UR Z10.4 and UR Z 10.5.

.6 Dates:

Panel Approval: 7 March 2013 during Survey Panel Meeting
GPG Approval: 22 May 2013 (Ref: 9640_IGn)

- **Rev.19 (July 2011)**

.1 Origin of Change:

☑ Suggestion by an IACS member

.2 Main Reason for Change:

Following external audit a member was advised that a small temporary doubler on a cross-deck strip of a bulk carrier should have been promptly and thoroughly repaired at the time of survey. The member carried out an investigation and found that the actions of the surveyor were fully justifiable, the temporary repair and short term

Condition of Class imposed were an appropriate method of dealing with such a situation. The member advised that the current requirements for 'Prompt and Thorough Repair' stipulated under the UR 7 and UR 10 series do not give any leeway for carrying out temporary repairs (and imposing a Recommendation/Condition of Class in accordance PR 35) where the damage in question is isolated and localised, and in which the ship's structural integrity is not impaired.

The Survey Panel discussed the matter and agreed that under carefully defined circumstances a temporary repair and short term Recommendation/Condition of Class would be an appropriate course of action.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

The matter was discussed by correspondence within the Survey Panel and at the Autumn 2010 Panel Meeting. Following discussion at which the possibility of a Unified Interpretation being raised was considered, it was eventually decided to make direct amendment to the relevant Unified Requirements.

The wording of the new paragraph to be inserted as Para 1.3.3 in all relevant Unified Requirements was extensively discussed prior to agreement.

The proposal was unanimously agreed by Survey Panel Members.

.5 Other Resolutions Changes

The identical amendment affects UR Z7, UR Z7.1, UR Z7.2, UR Z10.1, UR Z10.2, UR Z10.3, UR Z10.4 and UR Z 10.5.

.6 Dates:

Original Proposal: *September 2010 Made by a Member*
Panel Approval: *March 2011*
GPG Approval: *27 July 2011 (Ref: 11118_IGb)*

- **Rev.18 (Jan 2011)**

.1 Origin of Change:

☑ Suggestion by an IACS member, further to an external audit, where the question of the applicable requirements for intermediate survey of cargo tanks of supply vessels over 10 years of age was raised.

.2 Main Reason for Change:

To include classification requirements in UR Z7, for the intermediate survey of cargo spaces of ships over 10 years of age, for ships other than ships engaged in the carriage of dry cargoes only or ships subject to Z10.1, Z10.3, Z10.4 or Z7.2.

This is in order to align UR Z7 with UR Z1: UR Z1 identifies intermediate survey requirements based on IMO Res.A.997(25) as amended by IMO Res. A.1020(26) which are, as a minimum, to be covered by classification surveys.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

The decision was made to keep the current para. 4.2.5 of UR Z7 which reflects item (CIn) 2.3.2.4 of the IMO Res. (dry cargo ships over 15 years of age, other than bulk carriers ESP or general dry cargo ships subject to Z7.1) and to add a requirement in a new para. 4.2.6 to reflect item (CIn) 2.3.2.3 of the IMO Res. Both the items are already part of UR Z1.

The Panel was also of the view that supply vessels cannot be considered as "General Dry Cargo Ships" carrying solid cargoes and thus they fall automatically outside the scope of UR Z 7.1. Consequently, no reference to “supply vessels” is needed in the exemption list in para. 1.1.1 of UR Z 7.1.

.5 Other Resolutions Changes

None

.6 Dates:

Original Proposal: *July 2010 Made by the Survey Panel*
Panel Approval: *October 2010*
GPG Approval: *04 January 2011 (Ref: 10167_IGd)*

- **Rev.17 (May 2010)**

.1 Origin for Change:

☑ Suggestion by IACS member

.2 Main Reason for Change:

To improve requirements in UR Z7 for access to structure for survey.

.3 History of Decisions Made:

The Survey Panel reviewed the AVC Chairman’s report to C59 on Quality Management Review with respect to thickness measurements in the context of PR 19, but following correspondence and discussions during the ‘10th Survey Panel meeting’, members agreed that the provisions of PR 19 were adequate though the implementation might be inconsistent.

In this context ABS pointed out possible difficulties in surveying bulkheads of general dry cargo ships protected by wooden insulation. Accordingly, this issue was discussed within the Panel.

Draft form A for Survey Panel Task 68 was submitted to GPG on 29 Dec 2009. GPG approved Form A on 29 Jan 2010 and invited the Panel to take into consideration the following issue raised by RINA: *"it is not clear to us the reason why the Panel agreed that the proposed amendments to UR Z7 would apply to "ships other than those covered by UR Z 7.1, Z 7.2 and Z 10s" (see the last sentence of the "Background" section). In fact, we are of the opinion that the proposed amendments to UR Z7 should apply also to the ships subject to UR Z7.1, Z7.2 and Z10s in the zones outside the scope of UR Z7.1, Z7.2 and Z10s (i.e. zones other than cargo area and ballast tanks)."*. At the Panel's March 2010 meeting, the RINA member explained the grounds of the above-mentioned issue and the Panel agreed to delete the proposed Note indicating that the amendments would "apply to all ships except those subject to UR Z 7.1, Z 7.2 and Z 10s".

.4 Other Resolutions Changes

None

.5 Any dissenting views

RS Survey Panel Member recommended that specific requirements about new types of insulation to be removed for examination of underlying structure be included in the UR, even if in a different way and to a different extent from other types of insulation, such as loose insulation. However, this recommendation was not supported by the majority of the panel.

Part B. Technical Background

List of Technical Background (TB) documents for UR Z7:

Annex 1. **TB for Rev.6 (Apr 1999)**

See separate TB document in Annex 1.

Annex 2. **TB for Rev.7 (Nov 2000)**

See separate TB document in Annex 2.

Annex 3. **TB for Rev.8 (Mar 2002)**

See separate TB document in Annex 3.

Annex 4. **TB for Rev.11 (Jun 2005)**

See separate TB document in Annex 4.

Annex 5. **TB for Rev.12 (Jan 2006)**

See separate TB document in Annex 5.

Annex 6. **TB for Rev.13 (Aug 2006)**

See separate TB document in Annex 6.

Annex 7. **TB for Rev.14 (Oct 2006)**

See separate TB document in Annex 7.

Annex 8. **TB for Rev.15 (Nov 2007)**

See separate TB document in Annex 8.

Annex 9. **TB for Rev.16 (Mar 2009)**

See separate TB document in Annex 9.

Annex 10. **TB for Rev.17 (May 2010)**

See separate TB document in Annex 10.

Annex 11. **TB for Rev.18 (Jan 2011)**

See separate TB document in Annex 11.

Annex 12. **TB for Rev.19 (July 2011)**

See separate TB document in Annex 12.

Annex 13. **TB for Rev.21 (Jan 2014)**

See separate TB document in Annex 13.

Note: *There are no separate Technical Background (TB) documents for the original resolution (1990), Rev.1 (1990), Rev.2 (1992), Rev.3 (1994), Rev.4 (1996), Rev.5 (Jul 1998), Rev.9 (Oct 2002), Rev.10 (Apr 2004), Rev.20 (May 2013), Rev.22 (Feb 2015), Rev.23 (Jul 2015), Rev.24 (Feb 2016), Rev.25 (June 2016), Rev.26 (Jan 2018), Rev.27 (Oct 2018), Rev.28 (May 2019) Corr.1 (Dec 2020), Rev.29 (May 2022) and Corr.1 (May 2024).*

Technical Background Document
WP/SRC Task 44 (Z 7)

Objective and Scope:

Develop requirements for examination of specific components of ship's bow, stern, side and inner weathertight doors by specialist company at annual, intermediate and special classification surveys.

Source of Proposed Requirements:

The proposed requirements were developed by WP/SRC members through their experience in the examination of the weathertight doors. IACS Guidelines No. 8, Checksheet for Surveyors of Ro-Ro Ships Shell and Inner Doors Guidelines for Surveyors was referenced for requirements.

Points of Discussion:

WP/SRC unanimously agreed to the draft UR.

Date of submission: 31/3/99
By: WP/SRC Chairman's e-mail

Technical Background Document
WP/SRC Task 1-A
UR Z 7 – Proposed Rev. 6

Objective and Scope:

To review existing UR Z 7 to which a reservation has been lodged with a view to eliminating the cause for the reservation and achieving full implementation.

Source of Proposed Requirements:

WP/SRC members discussed and reviewed the reservation lodged against the UR. A proposal based upon the member's experience with soft coatings in small tanks was agreed to and contained in the proposed draft.

Points of Discussion:

WP/SRC unanimously agreed to the proposed draft UR Z 7.

Date of submission: 6 May 1999
By WP/SRC Chairman's e-mail

Technical Background Document
WP/SRC Task 77
UR Z7 – Proposed Draft Revision 7
(Including Rev.8 of Z10.1, Rev.11 of Z10.2, Rev.4 of Z10.3)

Objective and Scope:

Extend the requirements for permanent repairs at the time of survey in UR Z 10.2 to all ships.

Source of Proposed Requirements:

The proposed requirements were developed by WP/SRC members through correspondence and discussions at the September 2000 meeting.

Points of Discussion:

UR Z7 was amended to apply "prompt and thorough" repairs to all vessels. The new wording defines a prompt and thorough repair to be a repair as a result of wastage and not an incident such as contact damage where a temporary repair or deferral of repairs could be permitted. This wording is more explicit than the wording in UR Z10.2 and should achieve a uniform application among the Members.

WP/SRC also agreed to include these requirements in Z10.1, Z10.2 and Z10.3 in order to not effect A.744(18).

WP/SRC unanimously agreed to the draft UR.

Note by Permsec

GPG 49 (11-13 Oct. 2000) agreed that the same changes be introduced to Z10's and carried out editorial review of Z 10's.

Technical Background Document
WP/SRC Task 83
Rev.8 of Z7 (para. 2.2.6 + Table 1, also see the attached)

Objective and Scope:

To introduce additional survey requirements to address machinery failures and engine room flooding problems.

Source of Proposed Requirements:

WP/SRC Chairman reported by e-mail 15 January 2002 that WP/SRC Members had discussed and reviewed the requirements contained in UR Z7 through correspondence and at their last meeting.

When dealing with this task the WP/SRC agreed not to address the issue of machinery component failures due to the fact that the necessary competence was not available within the WP. The WP members were also of the opinion that WP/MCH was more able to deal with this part of the task.

Points of Discussion:

- WP/SRC unanimously agreed to the proposed amendments to Z7.

Note by the Permanent Secretariat (0065fIGc of 19 February 2002)

- GPG agreed with ABS that in lieu of the WP's proposed additional wording to item 9 of Table 1, **an additional item 10** should be added to the table in order to provide clarification with regard to the plating of the sea chest.
- With respect to the issues of machinery component failures, GPG decided as follows:
  - AHG/CMC review the casualty report and database developed under 9168e at their March 2002 meeting with a view to assessing the additional info on machinery/equipment damages reported therein in relation to the database of machinery/equipment failures the AHG has been developing (AHG/CMC Task 01 Rev.1);
  - AHG/CMC is to provide both databases (information) to WP/MCH with their comments in time for WP/MCH to review and discuss the materials at their Fall 2002 annual meeting;
  - WP/MCH is then to assess and identify problem areas and provide recommendations for improvement (MCH Task 68).
  - WP/MCH is to provide proposals to AHG/CMC and WP/SRC(Task 83 Rev.1) for their review during 2004.

Date of submission: 5 March 2002
By the Permanent Secretariat

Technical Background Document
WP/SRC Task 1
New UR Z 18, Z21 and deletion of M20
(+ Rev.8 of Z7)

Objective and Scope:

To review existing UR M 20 and relocate it as a UR under UR Z.

Source of Proposed Requirements:

WP/SRC Chairman reported by e-mail 6 May 1999 that WP/SRC Members had discussed and reviewed the requirements contained in UR M20 through correspondence and at their last meeting and had relocated the text of M20 to a new UR Z18. A proposal for resolving ABS' existing reservations against M20 is included in the proposed UR Z18.

Points of Discussion:

WP/SRC unanimously agreed to the proposed draft UR Z 18.

<u>Note by the Permanent Secretariat</u>

GPG did not accept WP/SRC's proposal for resolving ABS' reservations since the proposal would not, in fact, lead to any greater uniformity in practice than by simply retaining ABS' existing reservations, and therefore did not approve the proposed UR Z18, pending receipt and consideration of an acceptable means of resolving ABS' reservations from the ABS GPG representative. The ABS GPG representative reported to GPG, at its 51st meeting on 2-4 October 2001 that ABS was not prepared to change its practice and that he could not identify any means of resolving ABS' reservations without significant change to other Members practices, which other Members were not prepared to accept.

Therefore, GPG expressed its preparedness to live with ABS reservation to the tail shaft survey requirements of ex M20 (now Z21), agreed to isolate it from Z18.

Outcome:

- Delete M 20;
- Create new Z18 excluding tail shaft survey requirements;
- Create new Z21 for the tail shaft survey requirements.
- Revision 8 of Z7 to have the same descriptions of special survey as those in Z10s and Z18.

  (GPG considered it prudent to keep Revision 8 of Z7 in abeyance until WP/SRC complete its Task 83 "revision of Z7".)

Date of submission: 6 May 1999
By WP/SRC Chairman's e-mail

WP/SRC Task 102
HARMONIZATION OF UR Z7s AND Z10s

Technical Background
UR Z7 (Rev. 11)
UR Z7.1 (Rev. 2)
UR Z10.1 (Rev. 12)
UR Z10.2 (Rev. 17)
UR Z10.3 (Rev. 7)
UR Z10.4 (Rev. 2)
UR Z10.5 (Rev. 1)

Contents:

1. Objective

To amend UR Z7s and Z10s in order to make the texts of the above-mentioned URs consistent eliminating all the differences both in substance and in wording (WP/SRC Task 102).

2. Background

In the process of approving UR Z10.4, GPG found it necessary to amend the other existing URs Z10.1, Z10.2, Z10.3, Z10.6 and Z7 in order to eliminate any inconsistencies existing among them.

3. Methodology of work

The WP has progressed its work through many sessions, both during the periodical meetings and dedicated meetings restricted to a Small Group of Members (BV, DNV, GL, LR, RINA) who developed the work in order to be more efficient. All the proposed amendments of the Small Group have regularly been circulated to all Members for comment and agreement.

4. Discussion

4.1 The WP/SRC has completed a comprehensive comparative review of UR Z7 and Z10s, and identified inconsistencies which existed among them. During this review, attention was given to the severity of the requirements applicable to the same spaces/structural areas on different types of ESP ships. As a result, the inconsistencies were eliminated making the URZs harmonized. However, there has been no change to the scope and extent of the survey requirements.

4.2 The starting point for each UR was the most updated version available at the time of commencement. Any revision to the URZs, which were introduced during this task, was taken into account. As for instance, the UR Z10.1 was initially amended based on Rev. 9, while the last amendments are based on Rev. 11 and the UR Z10.2 was initially amended based on Rev. 13, while the last amendments are based on Rev. 16. The proposed revisions of URs Z10.1 and Z10.4 have not been numbered, as there will be revisions to those URs before the revisions introduced by the Task 102 are adopted. In fact, GPG is currently developing a Revision 12 of Z10.1 with the view to introducing significant improvements in the survey regime for ballast tanks (including combined cargo/ballast tanks) of oil tankers and UR Z10s applicable to oil tankers will also have to be revised by incorporating the amendments to A.744(18) contained in Resolution MSC 144(77), which enter into force 1 January 2005 (see 4.3 below).

4.3 Also, in harmonizing UR Z10.1 and Z10.2 care has been taken to align the corresponding text with that of IMO Res. A.744(18). However, it has been noted that the amendments to A.744(18) contained in Resolution MSC 144(77), which enter into force 1 January 2005, have not been incorporated into the IACS UR Z10s applicable to oil tankers. It seems that the updating of the above-said UR Z10s will be done by the Perm Sec and reviewed by the WP/SRC Chairman and then circulated for adoption by GPG with concurrence of Council Members for uniform application from 1 January 2005. It is understood that the revisions of the UR Z10s affected by those amendments will not include the changes introduced by the Task 102, as the implementation date proposed for those changes is 1 January 2006 (see below **6. Implementation**).

4.4 In the course of the work the WP has been developing for more than two years, several additional Tasks were assigned to the WP by GPG which affected the development of Task 102. The additional tasks which have been taken into account are the following:

1) In the course of Council discussion on UR Z10.6 (General Cargo Ships), certain inconsistencies were identified between Z10.6 and other Z10s. WP was instructed to expedite Task 102 (1060gIAa, 12 June 2002);
2) WP was instructed to include “Survey Planning for Intermediate Survey” into harmonization work (2108_IAa, 12 July 2002);
3) GPG instructed WP to consider whether Z10.6 should be re-assigned as Z7.1, in connection with the harmonization work. 1060gIAb, 20 Sept 2002.

Z7.1 developed;

4) Partial outcome (Z7 and Z7.1) was submitted to GPG on 17 July 2003(1060g). Council decided that approval of Z7(Rev.10) and Z7.1(Rev.2) is postponed until the harmonization is completed (1060gICb, 6 April 2004);
Council Chairman instructed WP/SRC to Members' comments on the draft revision of UR Z7 and Z7.1 (collected under s/n 1060g, 1060gNKi (30/03/2004) in particular) on 6 April 2004.

5) GPG tasked WP to include the amendments to Z10.2 / Z11 (BCs with hybrid cargo hold arrangements), deleting sheets 15 and 16 for ore carriers, into the harmonized UR Z10s (2212aIGa, 19 Jan 2004);
6) GPG tasked WP to consider whether the requirements relevant to examination of Fuel Oil Tanks in the cargo area at each Special Survey should be put into Z 10s, and internal examination of FOT at Intermediate Survey after SS 2 is needed. (1060gIAf, 30 Jan 2004);
7) GPG tasked WP to harmonize tank testing requirements in Z7s and Z10s. (3006lIAa, 5 April 2004);
8) GPG tasked WP with Task 108 - Develop uniform survey requirements for air vent pipes including the welded connection to deck. Z22 developed. GPG instructed WP to incorporate Z22 into the harmonized Z10s;
9) GPG tasked WP with Task 114 - Verification and signature of TM reports. REC 77(Rev.1) developed and approved on 29 July 2004. Council approved parallel amendments to Z7.1 and Z10s (TM Forms included) and instructed WP to incorporate these into the harmonized Z10s:
    - Recommendation No.77 was revised (Rev.1, July 2004);
    - Z7.1 para.6.3.2 and Z10s para.7.3.2 so amended.
    - "Surveyor's signature" is deleted from all TM Forms in Z10s;
    - A note is added to Annex II(Z10s) declaring that Annex II is recommendatory.

   WP/SRC's investigation into Members' practice in dealing with verification and signature of TM reports is annexed for record keeping purpose. See Annex 2.

10) GPG tasked WP to consider the BV comments on "TM may be dispensed with…." and include the findings into the harmonized Z10s (2219iIAa, 7 April 2004).

5. Agreement within the WP/SRC

All Members have unanimously agreed the attached final versions of UR's.

6. Implementation

WP/SRC is of the view that the Members need 12 months from the adoption date to implement these amendments into their class rules. Assuming Council adoption in December 2004, WP/SRC would propose January 2006 as implementation date.

Annex 1: TB for UR Z10.1(Rev.12, C49 amendments, see Permsec's note 1 below)
Annex 2: WP/SRC Task 114, verification and signature of TM reports(see 9 above).
Annex 3**:** TB for revision of UR Zs concerning "anodes".

Note by the Permanent Secretariat

1. Annex 1 to this TB contains background for amendments to UR Z 10.1(Rev.12) relating to FAIR/POOR/GOOD (C49 amendments). Council at its 49th meeting (June 2004) agreed/decided that comparable changes should be added to Z10.3 and Z10.4.

2. Appendix 3 "TM sampling method" has been added to UR Z10.1 and Z10.4 to keep them consistent with IMO Res.MSC.144(77). The amendments to A.744 contained in MSC.144(77) entered into force on 1 January 2005. *(GPG s/n 4181)*

Under s/n 4072g, paragraph **2.4.6** of UR Z10.1 and **2.4.6** and of UR Z10.4 (paragraph numbering is now harmonized) were amended in order to provide a link between the main text of the UR Z10.1 and 10.4 and the new Annex III Appendix 3 containing the MSC Res.144(77).

Further, it was agreed that the requirements for evaluation of longitudinal strength of the hull girder (as written in MSC.144(77)) should not be required for Intermediate Survey unless deemed necessary by the attending Surveyor. This is covered in 4.2.3.1 and 4.2.4.1 of Z10.1 and Z10.4.

3. GPG agreed that the amended UR Zs should be implemented from 1 July 2006 altogether.

4. DNV's proposed amendments to UR Z10.1, Z10.3 and Z10.4 concerning annual survey of ballast tanks were agreed by Council (1060gICq, 27 June 2005). See Appendix 2 to Annex 1.

5. Annex 3 contains a TB for revision of UR Zs concerning "anodes".

Date: September 2004
Prepared by the WP/SRC

– – –

Annex 1 to Technical Background
UR Z 10.1 (Rev.12, C49 amendments(coating-related))

1. Objective

To introduce significant improvements in the survey regime for ballast tanks (including combined/ballast tanks) of oil tankers as matter of strategic concern and urgency to IACS, given the aging of both the single and double hull tanker fleets and the problems encountered with corrosion of ballast tanks in several shipping casualties.

2. Background

Draft amendments to UR Z10.1 were submitted to Council 47 (June 2003) and agreed in principle.

3. Discussion

There was particular concern over accelerated corrosion with age (as the thinner the material, the more rapidly the allowable diminution margin percentage disappears) especially where coatings have broken down. There is also a disincentive for any spend on maintenance of the structure of a ship within a few years of its statutory scrapping date.

Council discussion by correspondence had evolved to the position of substantive proposals – summed as follows (3095_ABa, 2 June 2003):

1. Enhance the Intermediate Survey in Z10.1, Z10.3 and 10.4 for Tankers after 2nd Special / Renewal Survey to the same level (scope of work) as the preceding Special / Renewal Survey). This corresponds to the latest revision to UR Z10.2.
2. At Annual Survey of ballast tanks with substantial corrosion, the overall survey is to be replaced by close-up survey with thickness measurements of the exposed area.
3. Proposed to task WP/SRC to re-consider the acceptance criteria for the rating FAIR further. For this, eliminate FAIR, leaving only GOOD and POOR redefined as appropriate.
4. Proposed to task WP/SRC to explicitly require close-up survey of Suspect Areas identified at the previous Special Survey.

Council 47 discussed the proposals(June 2003) as follows:

1. Definition of FAIR
   Council 47 agreed that “FAIR” would be retained as a rating and that GPG should instruct WP/SRC to redefine FAIR, so that there would be a clear differences between FAIR, POOR and GOOD. It was also agreed that for oil tankers the Intermediate Survey following Special Survey No.2 would have the same scope as Special Survey No.2(Z10.1). WP/SRC should also clarify the definition of satisfactory repair.

   Based on the strong majority, Council agreed to discuss with Industry annual surveys of ballast tanks when coating is found in LESS than GOOD condition at special survey, with the objective to encourage the owner to carry out repairs and maintenance of coating to GOOD condition.

   > *DNV and NK stated that they could not accept a requirement for annual surveys of ballast tanks when the coating condition is less*

than GOOD and proposed that GOOD be changed to FAIR (3095_IGc, 30 June 2003)

2. ABS' proposed amendments to Z10.1(annual examination of BWTs in certain conditions) were approved.
3. C 47 agreed that the BWT coating requirements (Z10.1.2.2.3) for intermediate Survey after SS 2 should be the same extent to the previous SS.
4. Given the substance of the changes, the revised Z10.1 should be shown to Industry before adoption.
5. A guidance for coating repairs needs to be developed by WP/SRC with reference to TSCF Guidelines.

Following Council 47, the draft text of Z10.1(Rev.12) was distributed to Industry and discussed at the IACS/Industry meeting on 29 August 2003. Industry indicated that UR Z10.1(Rev.12) is acceptable, provided that appropriate IACS guidelines on coating repairs are developed.

The Small Group on Coating (SG/Coating) under WP/SRC prepared draft guidelines on coating repairs and considered the definitions of GOOD / FAIR / POOR. The SG/Coating did not change the definitions and found that the Guidelines provide useful clarifications on the definitions and criteria in achieving an industry wide uniform judgement of coating conditions as well as what is needed to restore GOOD conditions.
Further, an IACS/Industry JWG/Corrosion was established and met in February 2004. The outcome is (3095_IGh, 4 June 2004):

- Draft Guidelines on Coating Repair (IACS REC 87)
- Draft UR Zxx (mandatory coating of cargo tanks on oil tankers)
- Draft UI SC 122 (Rev.2) – mandatory coating of ballast tanks

4. Others

1. Z10.11.2.2bis - Definition of "Combined Cargo/Ballast Tank. …as a routine part of the vessel's operation and will be treated as a Ballast Tank. ...". By so amending, Z10s do not need to repeat "Ballast Tanks *and Combined cargo/salt water Ballast Tanks*" in addressing the ballast tanks. Hence, all the references to "*and Combined cargo/salt water Ballast Tanks"* were deleted.
2. Z10.1.2.2.1.2: The aim of the examination is ~~to be sufficient~~ to discover substantial corrosion…
   Comparable changes are to be added to other UR Zs wherever the same sentence occurs.
3. "IACS Guidelines for Coating Maintenance & Repairs for Ballast Tanks and Combined/Ballast tanks on Oil Tankers" are referenced where relevant.
4. Comparable changes are to be added to UR Z10.3 and Z10.4, after adoption of Z10.1(Rev.12).

Attached: Memo on Coating Matters (GPG Chairman)

9 June 2004
Prepared by the Permsec

Appendix 1 to Annex 1: MEMO on Coating matters

1. Background and discussion within IACS on UR Z10.1 (draft Rev.12) between 29/01/03 and 14/08/03

In view of the survey experience with oil tankers, it was proposed that all ballast tanks should be examined, routinely and uniformly, at annual surveys on ESP tankers exceeding 15 years of age. IACS should amend UR Z10.1 to require the examination of ballast tanks on such ships at each annual survey. This is simple, clear and thorough and not subject to interpretation. (2242_ABq dated 29/1/03)

Then, ABS modified the proposal asking, for tankers subject to URs Z10.1, Z10.3 and Z10.4, exceeding 15 years of age, that the current requirement - pertaining to annual examination of Ballast Tanks adjacent to cargo tanks with any means of heating - be deleted and replaced by a simpler and more stringent requirement that all Ballast Tanks be subject to survey at each subsequent annual survey where either substantial corrosion is found within the tank or the protective coating is found to be in less than GOOD condition and the protective coating is not renewed at special survey or intermediate survey. This will ensure that all Ballast Tanks with substantial corrosion or protective coating which is not in GOOD condition at the time of special survey or intermediate survey will be examined at each subsequent annual survey on tankers exceeding 15 years of age. (2242_ABzb dated 14/3/03)
This was later expanded to include all tanks used routinely for ballast water, both ballast-only and cargo/ballast tanks (2242_ABzc dated 14/3/03).

ABS further reviewed the issue of the survey of salt water ballast spaces and combined cargo/salt water ballast spaces with ABS' governing bodies in light of recent casualties and survey findings on other tankers. Their review found an increasing amount of coating breakdown/failure and subsequent rapid wastage in key structures after Special Survey No. 2, i.e. after 10 years of age. These conditions are most prevalent in the under deck structure and the side shell structure in way of the deep loadline. In a number of cases the serious wastage has caused fracturing of the under deck longitudinals and in some cases fracturing has extended to the main deck structure. This led ABS to refine proposed amendments to URs Z10.1, Z10.3 and Z10.4 to require (2242_ABzf dated 9/5/03):

a. For Tankers exceeding 10 years of age

> Salt Water Ballast Spaces and Combined Cargo/Salt Water Ballast Spaces. For tankers exceeding 10 years of age, salt water ballast spaces and combined cargo/salt water ballast spaces are to be internally examined at each subsequent Annual Survey where substantial corrosion is found within the tank or where the protective coating is found to be less than GOOD condition and protective coating is not repaired. Internal examination to be an Overall Survey.

b. For Tankers exceeding 15 years of age:

Salt Water Ballast Spaces and Combined Cargo/Ballast Spaces. For tankers exceeding 15 years of age, salt water ballast spaces and combined cargo/ballast spaces are to be examined internally at each subsequent Annual Survey. Where substantial corrosion is found within the tank, or where the protective coating is found to be in less than GOOD condition and the protective coating is not repaired then in addition to an Overall Survey, under deck structure and the side shell structure in way of the deep loadline is to be subject to Close-up Survey.

NK and BV replied that the proposed amendments made by ABS need to be substantiated in a transparent manner with technical data that ABS may possess and put forward for further assessment and discussion. (2242_NKn dated 14/5/03 and 2242_BVz dated 16/5/03)

DNV (2242_NVn dated 2/6/03), having carefully considered the practical consequences of taking the ship off-hire for gas freeing etc. and being concerned about the difficulties to have these surveys executed in a safe manner and whether the intended safety benefits in implementing the proposed extended scope of the annual survey of Ballast tanks will be met, **proposed the following alternative measures** which would be as effective and may not have such delaying effects to the ship:

1) Enhance the Intermediate Survey in UR Z10.1, 10.3, and 10.4 for Tankers after the 2 Special / Renewal Survey to the same level (scope of work) as the preceding Special / Renewal Survey. (This will correspond to the latest revised requirements of UR Z10.2 for Bulk Carriers.)
2) At Annual Survey of ballast tanks with substantial corrosion the overall survey should be replaced by close up survey with thickness measurements of the exposed area. (An overall survey of these tanks does not give sufficient information of the development of the areas with substantial corrosion.)
3) Further we will not fail to mention that the WP/SRC has proposed to extend the close up survey in cargo and combination tanks to 30% from the 3 Special / Renewal Surveys.
4) **Experience has shown that the coating condition rating category FAIR has a tendency to be stretched too far into the POOR condition. We will therefore propose that we task the WP/SRC to reconsider the acceptance criteria for the rating FAIR further.**
5) We do also question the need for redefining the definition of combination tanks, particularly since the category I tankers which are the ships that normally are fitted with these type of tanks are to be phased out 2 to 4 years from now. However DNV will not oppose to such a redefinition.

DNV requested Members to consider the above as an alternative to the ABS proposal, bearing in mind that we ought to present this to the industry prior to deciding.

ABS (3095_Aba dated 2/6/03), having further considered its earlier proposals in light of NVn, submitted a revised proposal for consideration by Council at C47 and replied to the above 5 DNV proposals as follows:

1) ABS fully supports this proposal.
2) While ABS agrees with this proposal, it is in fact already provided for in Z7 (3.2.3) and Z10.1 (3.2.5.1)--which require that "Suspect areas (which include any area where substantial corrosion is found) identified at previous Special Survey are to be examined. Areas of substantial corrosion identified at previous special or intermediate survey are to have thickness measurements taken." To us, this implies that close-up survey of these areas is to be done at annual survey in conjunction with the thickness measurements. However, we can

agree to tasking WP/SRC to explicitly require "close-up" survey in this connection and to amend Z7, and all the Z10's, appropriately to make this explicit, if there is majority support for this.

3) We agree that this has been put forward to GPG by WP/SRC via 0237hNVb, 27 May. However, these additional CAS close-up survey requirements do not apply to salt water ballast tanks; only to cargo oil tanks and combined cargo/ballast tanks.
4) **We agree with this assessment and we propose that the only way to eliminate the subjectivity and raise the standard is to eliminate the category "FAIR" completely; leaving only "GOOD" and "POOR" redefined as follows:**
   "GOOD -- condition with no breakdown or rusting or only minor spot rusting.
   POOR -- any condition which is not GOOD condition."
5) ABS does not agree with this proposal. We are particularly concerned that we need a very thorough and robust survey regime for these tankers precisely because they are subject to mandatory phase out over the next several years. We are very concerned that without additional IACS requirements, these tanks will receive little or no inspection and maintenance by owners or others after their last special or intermediate survey, if no substantial corrosion is found at that time. Rapid, localized wastage in way of deteriorating coatings may pose significant hazard if the survey regime is not further tightened as we are proposing.

In conjunction with the above comments on DNV proposals, ABS further considered their previous proposal in ABzf and modified it as follows:

- **ABS simplified the proposal to require annual examination of all salt water Ballast Tanks and combined Cargo/salt water Ballast Tanks irrespective of age, when either substantial corrosion is found within the tank or the protective coating is found to be in less than GOOD condition and is not repaired.**
- the requirement for annual (close-up) examination of salt water ballast tanks and combined tanks is already required in Z10.1 (3.2.5.1). ABS proposed adding it to 2.2.3 for clarity and emphasis so that all the conditions which may lead to annual examination of such tanks are listed together in one place.
- Since the principal problem that we are trying to address is rapid, localized corrosion in way of breakdown or deterioration of the protective coating, we are proposing that the coating condition should be found and kept in "GOOD" condition to obviate the need for annual examination. **The attached proposal is made together with the proposals in items 3.1 (intermediate following Special survey 2 to have same scope as prior Special survey) and 3.4 (eliminating "FAIR" and redefining "POOR" as any condition other than "GOOD" condition.**

ABS requested to decide on a course of action at C47 for tightening the survey regime for tankers. They agreed that industry be informed of Council's decisions in this regard prior to IACS making the decision public, but IACS should maintain its independence and take decisive action in this matter. Debate with industry can only lead to delay and to a watering down and compromising of these important requirements.

NK agreed to task WP/SRC to reconsider the acceptance criteria of "FAIR" for clearly define the border between "FAIR" and "POOR" condition. However, **NK strongly opposed the elimination of "FAIR" coating condition from UR Zs** because this can not resolve to remove subjectivity of coating assessment. The three-categorization system of coating condition should be retained. (3095_NKa dated 5/5/03)

Outcome of C47

At **C47**, it was agreed that “Fair” would be retained as a rating and that GPG should instruct WP/SRC to redefine “Fair”, so that there would be a clear differentiation between “Fair”, “Poor” and “Good”. It was also agreed that for oil tankers the Intermediate Survey following Special Survey No.2 would have same scope as Special Survey No.2 (Z10.1). WP/SRC should also clarify the definition of satisfactory repair.

Based on strong majority support Council agreed to discuss with Industry annual surveys of ballast tanks when coating is found in LESS than GOOD condition at special survey, with the objective to encourage the owner to carry out repairs and maintenance of coating to GOOD condition.

This matter should be discussed with Industry prior to adoption of any UR by Council.

In a final summary, the Chairman proposed that a constructive dialogue with Industry should take place on the IACS proposal as set out in WP1 plus maintaining 3.2.5.2 modified to say that ballast/combined ballast/cargo tanks will be subject to annual survey when considered necessary by surveyors.

After discussion in the JWG (Industry/IACS), GPG should propose final rules for this matter to Council, including acceptable repair definition.

F**UA 17:** *To instruct WP/SRC to develop guidance on coating repairs and more precise definition of “Fair” coating condition.*

Once approved, these requirements should be incorporated into Z10.3 and Z10.4.

FUA 15

1) *To prepare a draft revision to UR Z10.1 incorporating C 47 decisions:*
   - *The definition of “FAIR” remains as it is;*
   - *ABS proposed amendments to Z10.1 (annual examination of BWTs in certain conditions) were approved;*
   - *C47 agreed that the BWT coating requirements (Z10.1.2.2.3) for Intermediate Survey after Special Survey No.2 should be the same extent to the previous Special Survey.*
   - *Given the substance of the changes, the revised UR Z10.1 should be shown to Industry (OCIMG/Intertanko first among others) before adoption for their review and comments.*
   - *A guidance for coating repairs needs to be developed by WP/SRC with reference to TSCF Guidelines.*

2) *GPG Members are to confirm the draft revision to Z10.1 in consultation with their WP/SRC members by correspondence. See 3095_IGa of 13/06/03.*

According to C47 FUA 15, GPG Chairman circulated (3095_IGa dated 13/6/03) draft amendments to UR Z10.1 as agreed in principle at C47.

Having received a number on comments, GPG Chairman (3095_IGb dated 27/6/03) informed that the Council Chairman confirmed that GPG is not to amend the principles agreed at C47, i.e. we are not empowered to change "GOOD" to "FAIR" as proposed by DNV and NK, nor to amend the definitions of "FAIR" and "POOR" as proposed by DNV.

DNV's intention to possibly lodge a reservation was noted, however the matter should be raised at Council and not be dealt with by GPG. An amended draft text incorporating the non-substantive changes proposed by Members was circulated.

DNV said that its understanding was that the draft should be circulated to the Industry (ICS, INTERTANKO, and BIMCO) prior to adoption by Council. (3095_NVc dated 30/6/03)

GPG Chairman (3095_IGc dated 30/6/03) circulated a draft amendment of UR Z10.1 for Council's agreement and use in discussions with the industry associations.
The draft was generally agreed by GPG but individual Members have requested that the following matters (which were deemed to be outside the remit of GPG in this task) be brought to Council's attention for further consideration:

1 DNV and NK stated that they can not accept a requirement for annual surveys of ballast tanks when the coating condition is less than GOOD and propose that GOOD be changed to FAIR.
2 In connection with item 1 above, DNV also propose to amend the definitions of FAIR and POOR in order to raise the standard of FAIR.

Council Chairman (3095_ICb dated 14/8/03) concluded that Council has agreed that the draft amendments to UR Z10.1 attached to IGc reflect Councils' decision taken at C47 and that they be circulated to industry associations.
Perm Sec was therefore invited to submit the draft to OCIMF and INTERTANKO in view of discussion at the IACS/ industry meeting on 29 August.

2. Discussion with Industry (29/08/2003 – 11/10/2003)

As requested by Council, the whole matter was presented to Industry during the “general matters” meeting with IACS held on 29 August 2003; comments from Industry were requested. In the following an extract from the minutes of the meeting (see message 3100aIAb dated 5 September 2003):

___________________________ from Meeting minutes _________________________________

4. & 5. Annual surveys of ballast tanks and IACS guidelines on coating repairs

M. Dogliani introduced the matter (see Items 4&5 in Appendix).

A. LinoCosta gave a presentation to show where concerns and decisions stand: too many cases when coating was considered fair at SS but problems occurred just after one/two years.

N. Mikelis commented on draft amendments to Z10.1 (Rev.11) stating that the extent of annual survey is not clear; it should be limited to the affected zones, e.g. coating breakdowns, only.
M. Guyader clarified that, in this draft amendments, it is expected an overall survey of the whole tank and a close up survey of the affected zones.
N. Mikelis noted that, in the draft amendments to Z10.1 (Rev.11), the intermediate survey at 12.5 years would have the same scope as the previous special survey and that needed a justification. See 7 a).
M. Dogliani said that Z10.1 (Rev.11) was adopted in August 2003 and will be introduced into IACS Societies’ Rules over the next year.

Conclusions:
4.1 Industry shared IACS concerns on coatings and, in general, agreed with the draft amendments to Z10.1 (Rev.11) suggesting also extending them to Z10.2 on bulk carriers

4.2 Industry agreed that a guideline for surveyor on coating would greatly improve uniform application of so-amended Z10.1 including issues such as how to consider load bearing elements when judging GOOD/FAIR/POOR status and how to consider bottom pitting in connection with GOOD conditions
4.3 Industry will more precisely comment, by the end of September, the draft Z10.1 so as for IACS to finalise the matter, as planned, for the Council's December meeting.

Item	Title	Industry recommandation	IACS/ M. Dogliani Introduction
4 & 5	Annual survey of ballast tanks IACS guidelines on coating repairs	NN	**1. IACS is considering the following:** - **amend UR Z10.1 (draft circulated to Industry) to the effect that in case at Special Survey or Intermediate Survey the coating in a ballast tank is found less than GOOD, either GOOD conditions are restored or the tank's coating is inspected at each annual survey;** - **develop IACS guideline to assist an uniform application of the so modified (if adopted) UR Z10.1; the guideline should address which repairs are necessary to restore GOOD conditions from FAIR and POOR respectively and which are the criteria for the restored (after repair) situation to be rated as GOOD.**

______________________________ End of extract from minutes ____________________________

INTERTANKO commented (see R. Leslie email to GPG dated 25 September 2003):

- expressing their concern for the draft Z10.1 and underlining

a) targeting: concerns that, if not properly dealt with, Z10.1 would target all ships and not just those which need intervention; the view was expressed that guidelines would probably solve the matter;
b) definition: indicating that the current definitions of GOOD, FAIR and POOR is not clear enough and that the matter would be even worst with GOOD and NON GOOD; again it was indicated that guidelines could solve the matter;
c) expertise: expressing doubts on IACS' surveyors expertise and ability to judge coating conditions; in this respect they (hiddenly) suggest that IACS position is unclear when we say that we are not competent to judge the coating during construction but then we are competent to judge coating during operational life. Even if not explicitly stated, the impression is that also in this case guidelines would help.

Additionaly, INTERTANKO suggested a (quite detailed) set of assessment criteria.

The matter was then finally addressed at the TRIPARTITE Meeting (held in Soul on 29/30 September 2003). There Industry agreed that the way forward was the (joint) development of IACS guidelines (see minutes attached to message 3100_RIe dated 11 October 2003, an extract of which is reproduced below).
______________________________ Extract from the TRIPARTITE minutes ________________

Industry is concerned by the definition of GOOD/NOT GOOD in relation to coating repairs and acceptance criteria. Industry agreed that new guideline on this, which IACS is already producing, was the way forward.

________________________________ End of the extract from the minutes ___________________

3. Further developments

a) from the above, it was concluded that, provided the guidelines are sound, Industry would accept the concept of Z10.1 (draft) Rev. 12, therefore an IACS team and a JWG were established in order to progress the matter of the guidelines (among other related matters).

b) the team of IACS experts on coating developed draft guidelines and provided recommendations to GPG on the way forward (attached to message 3095bNVc dated 20 November 2003).

c) the guidelines were discussed within the JWG with Industry (see draft minutes circulated within GPG with messages 3095cIGd and 3095cIGe both dated 13 March 2004)

d) further suggestions and comments (as requested at the meeting) were provided by Industry (not circulated to GPG)

e) Bulk Carrier Industry is recommending that similar guidelines are developed in due time also for bulk carriers

f) at DE47 and MSC78, IMO is asking Industry and IACS to develop (compulsory) performance standards for coating of newbuilding (double hull spaces of DSS Bulk Carriers), a matter which is, indirectly related to the above one.

1 June 2004
M. Dogliani
IACS GPG Chairman
IACS JWG/COR Chairman

Subject: FW: 1060gNVs; WP/SRC - Task 102 - Harmonization of UR Z 7 and Z 7.1

25 May 2005

To: Mr. B. Anne, Chairman of IACS Council,
cc: Council Members, IACS Perm. Sec.

Ref.: My mail NVr dated 20 May 2005

DNV have further studied the amendments to UR Z10.1, Z10.3, and Z10.4, and as a result are presenting the following as a compromise solution:

General comment:
From the comments by other Members it is obvious that there is reluctance to accept annual surveys of ballast tanks with a common plane boundary to heated cargo tanks in the case where the coating is in good condition. This is particularly unreasonable as at the same time we enhance the Intermediate survey of Tankers between 10 and 15 years to also include examination of all ballast tanks, meaning that all ballast tanks will be close up surveyed with 2-3 years intervals from the ship is 10 years old, with the possibility for the surveyor to require thickness measurements and testing of the tanks to ensure the structural integrity of the tanks if necessary.
It is also proposed for the Intermediate survey between 5 and 10 years, to increas the scope from representative to all ballast tanks, a requirement DNV find to strict, and require that we here keep the original text.
If a ballast tank is found to have coating in GOOD condition at the renewal or intermediate survey, a deterioration of the tank beyond structural reliability is very unlikely even if the tank has a common plane boundary to a heated cargo tank.

DNV finds it particularly unreasonable to have this requirement to apply to double hull tankers for the following reasons:
- these ships have double hull and the risk of pollution is here much reduced,
- the double hull is constructed with small spaces giving improved structural reliability,
- almost all double hull tankers below VLLC have heated cargo tanks, and all ballast tanks have common plane boundaries to these tanks, meaning that this requirement will apply to a major part of the tanker fleet in the future,
- the ballast tanks of double hull tankers are so designed that a general examination of these tanks will be identical to a close up survey,
- survey of ballast tanks of double hull tankers will mean either gas freeing of all cargo tanks or at least dropping the inert gas pressure of all cargo tanks in addition to proper airing of all ballast tanks.

Since the single hull tankers will be faced out in the near future, and for clear political reasons, DNV will as a compromise proposal to keep paragraph 2.2.3.1 and 4.2.2.2 in Z 10.1 as amended by Council (ref. IAo) but amend it to not include 2.2.3.1.e, 4.2.2.2.e and last paragraph of 3.2.5.1 in Z10.3 and Z10.4. In addition we request that the original text of 4.2.2.1 is kept.
If BV, ABS and other Members can accept this DNV is willing to drop our reservation presented at C49.
DNV's proposal will then be as follows:

Z10.1:

2.2.3.1: This paragraph can be accepted as is for the reasons stated above.
3.2.5.1: This paragraph is accepted as amended.
4.2.2.2: This paragraph can be accepted as is for reasons stated above.

For other comments to Z10.1 see NVo and NVp.

Z10.3:

2.2.3.1.e to be deleted.
3.2.5.1 delete last paragraph
4.2.2.1 the original text to be kept."For tanks used for water ballast ---"
4.2.2.2.e to be deleted

Z10.4

2.2.3.1e to be deleted
3.2.5.1 delete last paragraph
4.2.2.1 the original text to be kept, "For tanks used for water ballast --"
4.2.2.2.e to be deleted.

For details see attached document where the text for the requirements in Z10.3 and Z10.4 that DNV will accept is stated.

Best Regards

Arve Myklebust
on behalf of
Terje Staalstrom
DNV IACS Council Member
<<Doc1.doc>>

Annex 2 to TB (Harmonization Z10s)

WP/SRC Task 114 "Clarify the procedure of verification and signature of the thickness measurement report"

Item No.	Item	ABS	BV[1]	CCS	CRS	DNV	GL	IRS	KR	LR	NK	RINA	RS
1	**Verification onboard**	.											
1.1	Minimum extent of measuring points for direct verification by attending surveyor specified	No	No	No	No	No	No	No	Yes	No	No	Yes	No
1.2	Preliminary TM record to be signed upon completion of the measurements onboard	Yes	Yes [7]	Yes	No (copy taken)	No[3]	No[6]	Yes	Yes	Yes	Yes	No[8]	No
2	**Final TM report**												
2.1	Signature of all pages in TM record required	No	No	No	Yes	No	Yes	Yes	No	No	No[5]	Yes	Yes
2.2	Signature of 'cover' ('general particulars') page only	Yes	Yes	Yes	No	Yes	No	No	No[4]	Yes	Yes	Yes	No
2.3	Measuring points verified by attending surveyor required identified in TM record and signature of the corresponding pages required	No	No	Yes Without signature	Yes	No	No	No	Yes	No	No	No	No

2004-04-20

[1] Instructions not clear regarding signature of the thickness measurement record

[2] Signature on front and last page, stamp on all other pages, or signature on each page (IACS TM forms)

[3] Upon completion of measurements onboard a draft report in electronic format (DNV TM template, including operator's notes as relevant) to be given to attending surveyor

[4] Signature of cover page, pages of meeting record and pages of attended measuring points

[5] Each page to be signed in case of 'loose-leaf' type record

[6] Preliminary TM record has to be passed to the Surveyor, signed by the Operator

[7] The only measures which the Surveyors can certify exact are those for which that they have seen the results on the screen of the apparatus. That means in fact few points in comparison with the numbers of recorded measures.

8) The Surveyor reviews the TM record for completeness and assessment of TM readings, but no signature required.

Annex 3: **Technical Background**
(May 2005)

UR Z7s and Z10s (Corrosion Prevention System)

1. Objective:

To clarify whether the survey of anodes is a class matter, and if so, whether acceptance criteria for anode should be developed.

2. Method: GPG by correspondence (5037_)

3. Discussion

3.1 BV initiated GPG discussion as follows:

Paris La Défense, 8 Mars 05

1 - We have noticed that, in the draft UR Z's (7.1, 10.1 to 10.5) issued further to the WP/SRC Task 102, the original sentence "......the examination may be limited to a verification that the hard protective coating remains efficient......" has been replaced by ....that the corrosion prevention system remains efficient....". in a number of paragraphs (such as , for instance, Z 7.1, 4.2.3.1 a) ; Z 10.2 4.2.3.3 ;), in line with IMO Res.A744(18).

2 - However, a corrosion prevention system is defined, in the same UR Z's and in IMO Res.A744(18) , as being either a full hard protective coating or a full hard protective coating supplemented by anodes.

3 - The above would mean that the survey of the anodes is a classification matter.

4 - However, whereas coating conditions are defined as good or fair or poor, there are no criteria in the IACS URs and IMO Res. A744(18) for the anodes condition.

5 - Assessing the anodes condition to confirm that they "remain efficient" looks to BV to be a quite difficult task for the ships in service Surveyor.

6 - Member's view and interpretations on the following would consequently be appreciated:
- do Members consider that the above requirements in IACS URs imply that survey of anodes is part of the classification ?
- do Members consider that the above requirements in IMO Res. A 744 (18) imply that survey of anodes is mandatory?
- if yes, what is the acceptance criteria to conclude that the anodes" remain efficient" ?

3.2 The majority of GPG Members replied that they did not include requirements for anodes in their class rules.

LR / ABS / DNV / KR / NK / RINA / RS were of the view that the condition of any anodes fitted should be recorded for information purposes as the survey of anodes is neither a classification matter nor a mandatory requirement in IMO A.744(18) and has no impact on future surveys (5037_LRa**). [**Note; LR further clarified that “Whilst I agree that the performance of anodes is not normally a class matter LR does require that as part of Special Survey on oil tankers : "The attachment to the structure and condition of anodes in tanks are to be examined ." Therefore we cannot say that 'the survey of anodes is not a classification matter'**. 5037_LRb]**

However, GL said that "for GL, anodes are a matter of class and as such are subject to plan approval as well as surveys. In case of missing or worn-out anodes we issue a condition of class"(5037_GLa&b).

CCS advised that its rules have a general requirement relating to anode survey, which is only conducted, through sampling, during construction, docking survey or where there is a definite requirement for the survey of ballast tanks.

NK proposed that the following footnote be added to Z7s and Z10s:
"The survey of anodes is not a classification matter." No majority support was achieved.

4. Conclusion

RINA suggested to simply amend the definition of "Corrosion Prevention System" in paragraph 1.2.9 of UR Z7 (and, of course, the paragraphs in all the other UR Zs containing the definition of "Corrosion Prevention System") in order to eliminate any reference to anodes. This proposal would leave room for Societies willing to include additional class requirements for anodes to do so in their Rules.

GPG agreed.

RINA proposed amendments to paragraph 1.2.9 of UR Z7 and corresponding paragraphs in all other UR Zs (5037_RIb, 6 April 2005)

1.2.9 Corrosion Prevention System

A corrosion prevention system is normally considered ~~either:~~ a full hard protective coating.
~~.1 a full hard protective coating, or~~
~~.2 a full hard protective coating supplemented by anodes.~~
Hard protective coating is usually to be epoxy coating or equivalent. Other coating systems may be considered acceptable as alternatives provided that they are applied and maintained in compliance with the manufacturer's specifications.
Where soft coatings have been applied, safe access is to be provided for the surveyor to verify the effectiveness of the coating and to carry out an assessment of the conditions of internal structures which may include spot removal of the coating. When safe access cannot be provided, the soft coating is to be removed.

Annex: Council Chair's conclusive message.

6 May 2005
Permsec

Annex. (5037_ICb, 15 May 2005)

To : All IACS Council Members
c.c : Mr. R. Leslie, IACS Permanent Secretariat

Ref. Mr G-Y. Han's message IAa dated 6 May 05
Message ICa dated 6 May 05
Admiral R.E. Kramek's message ABb dated 13 May 05

Paris La Défense, 15 May 05

1 - All Members have agreed with the texts attached to Mr Han's message.

2 - Further to ABS comments the reference to anodes is to be deleted in Annex I and in tables IX (IV) and IX(II).

3 - further to ABS questions regarding what IACS plan to do regarding IMO and A.744(18) further to IACS deletion of reference to anodes from the UR Z7's and UR Z10's it is to noted that:

The Item 1.2.9 in UR Z1O.1 and relative items in these URs states
1.2.9 10 Corrosion Prevention System: A corrosion prevention system is normally considered either:
.1 a full hard protective coating, or
.2 a full hard protective coating supplemented by anodes.
Hard Pprotective Ccoating is to usually to be epoxy coating or equivalent. Other coating systems may be considered acceptable as alternatives provided that they are applied and maintained in compliance with the manufacturer's specification.
Where Soft Coatings have been applied, safe access is to be provided for the surveyor to verify the effectiveness of the coating and to carry out an assessment of the conditions of internal structures which may include spot removal of the coating. When safe access cannot be provided, the soft coating is to be removed.

- therefore the anodes are not considered as the main means of protection against the corrosion It is only a supplement;

- there is no provision in UR Z7's and Z10's to evaluate the level efficiency of the anodes;

- there is no specific requirements in case of lack of efficiency of the anodes.

The experience has shown that ballast tanks only protected by anodes are subject to corrosion when the anodes are becoming less efficient.

The anodes are active only when immersed by sea water. Therefore the upper part of the ballast tanks are not protected when the ballast is full of water and the ballast is not protected when it is empty..

The ships operators are reluctant to replace the anodes especially in upper part which request fitting of scaffolding fo welding the anode supports to the structure.

The above arguments justify the reasons why IACS consider that the anodes are not class item.

4 - These arguments can be used by IACS Members attending the WG bulk carriers at MSC 80 to try to obtain deletion of the reference to anodes in A. 744(18).

Best regards,

Bernard Anne
IACS Council Chairman.

Survey Panel Task 22 – Amend applicable URZ7s and Z10s to align Close-Up Survey and Thickness measurements to be carried out at the same time and location allowing for a more structured control of the thickness measurement process.

Technical Background

Z7(Rev.12)
Z7.1(Rev.3)
Z10.1(Rev.13, para.1.4 & 7.1.3)
Z10.2(Rev.18, para. 1.4 & 7.1.3)
Z10.3(Rev.8, para. 1.4 & 7.1.3)
Z10.4(Rev.3, para. 1.4 & 7.1.3)
Z10.5(Rev.2, para. 1.4 & 7.1.3)

1. **Objective**

To amend the applicable URZ7s and Z10s to align Close-Up Survey and Thickness measurements to be carried out at the same time and location allowing for a more structured control of the thickness measurement process.

2. **Background**

IACS QC findings, through audits of numerous Societies, which indicated concerns over Surveyor attendance and control of thickness measurement processes.

3. **Methodology of Work**

Survey Panel members through correspondence.

4. **Discussion**

To align Close-up survey requirements and thickness measurements in the applicable URZ7s and URZ10s, in accordance with PR19, all Panel members agreed through correspondence and a final vote at the fall Survey Panel meeting, that URZ7, Z7.1, Z10.1, Z10.2, Z10.3, Z10.4 and Z10.5 should include in the applicable sections of the noted URs as proposed by the Survey Panel the wording “ In any kind of survey, i.e. special, intermediate, annual, or other surveys having the scope of the foregoing ones, thickness measurements of structures in areas where close-up surveys are required, shall be carried out simultaneously with close-ups surveys.”

5. Implementation

The Survey Panel is of the view that the Members need 12 months from the adoption date to implement these amendments into their class rules. Assuming that GPG and Council approve to the amendments, the Survey Panel would propose January 2007 as an implementation date.

TECHNICAL BACKGROUND

UR Z7.1 (REV. 4) AND UR Z7 (REV.13)

SURVEY PANEL TASK 39 – Amend URZ7.1 to align with the requirements of URZ10.2 and URZ10.5 in accordance with SOLAS reg. II-I/23-3 and II-1/25 regarding Water level detectors on single hold cargo ships other than bulk carriers, and to propose to IMO that these requirements be included in relevant sections of IMO resolution A.948(23).

1. **Objective**

To amend UR Z7.1 Section 2.6 and 3.3 to include survey requirements related to SOLAS reg. II-I/23-3 and II-I/25 and to propose to IMO that these requirements be included in relevant sections of IMO resolution A.948(23).

2. **Background**

GPG member from LR requested that URZ7.1 should be amended to meet SOLAS regulations II-I/23-3(entry into force :1 January 2007) and II-I/25 (entry into force: 1 January 2009)

3. **Methodology of Work**

Survey Panel

4. **Discussion**

Survey Panel members at the spring 2006 meeting discussed how to address these changes in a similar manner as were carried out in Survey Panel Task 11 for URZ10.2 and Z10.5, for URZ7.1. During the discussion, the member from RINA proposed that URZ7 also be amended to refer to the applicable changes in URZ7.1.
All members agreed and made necessary amendments to URZ7 section 1.1.5 and added note 5 as far as the implementation date.
For URZ7.1 it was agreed that sections 2.6 and 3.3 be added to add these additional requirements.

5. Implementation

The Survey Panel is of the view that the Members need 12 months from the adoption date to implement these amendments into their class rules. Assuming that GPG and Council approve to the amendments, the Survey Panel would propose July 2007 as an implementation date.

Submitted by Survey Panel Chair,
13 July 2006

Permanent Secretariat note:

- Council approved URZ7.1 Rev.4 and URZ7 Rev.13 on 17 August 2006 (5031fICb).
- In addition to the proposed changes a typographical error was corrected in Table 4 of UR Z7.

TECHNICAL BACKGROUND

UR Z3 (Rev. 4), Z 7 (Rev. 14), Z18 (Rev. 2) and Z21 (Rev. 2)

Survey Panel Meeting March 2006 New Business Item – Applying UR Z3, Z7, Z18 and Z21 for Military Vessels.

1. **Objective**

To add the following new paragraph to UR Z3, Z7, Z18 and Z21 to reflect that special consideration may be used for military vessels:
"Special consideration may be given in application of relevant sections of this Unified Requirement to military vessels or commercial vessels owned or chartered by Governments, which are utilized in support of military operations or service".

2. **Background**

This task was originally discussed during the Survey Panel meeting, which took place at ABS Houston on the 1st to 3rd March 2006; it was subsequently recorded under paragraph 3 "new business" of the minutes of this meeting.
This initial started as a proposal for ABS to remove their reservation (see below) for military vessels against UR Z3 and Z7s. However all of the members agreed to the proposal.
Current ABS Reservation: "ABS allows variations in survey interval in agreement with US Government for military vessels or commercial vessels owned or chartered by the Government which are utilized in support of military operations or service."

3. **Methodology of Work**

Survey Panel members through correspondence.

4. **Discussion**

Survey Panel member from ABS raised this issue at the March 2006 Survey Panel meeting and volunteered to propose amendments to the applicable URs for Panel members to review and comment on through correspondence. At the Fall meeting of the Survey Panel, it was agreed upon by all Panel members that the proposed amendments for UR Z3, Z7, Z18 and Z21, which were proposed by ABS, were acceptable.

5. Implementation

The Survey Panel is of the view that the Members need 12 months from the adoption date to implement these amendments into their class rules. Assuming that GPG and Council approve to the amendments, the Survey Panel would propose January 2008 as an

implementation date.   However due to other on going revisions to UR Z21 this UR will be held abeyance until the other revisions are completed.

6. **Discussion at GPG:** GPG amended the proposal by deleting the phrase "military vessels or" on the basis that military vessels and other government ships operated for non-commercial purposes are out of the scope of IACS URs. The adopted amendment therefore reads:

"Special consideration may be given in application of relevant sections of this Unified Requirement to commercial vessels owned or chartered by Governments, which are utilized in support of military operations or service".

Submitted by Survey Panel Chair, October 2006
Updated by GPG to reflect their discussion

Technical Background

URs Z7(Rev.15), Z7.1(Rev.5), Z7.2(Rev.1), Z10.1(Rev.15), Z10.2(Rev.26), Z10.3(Rev. 9), Z10.4(Rev.6), Z10.5(Rev.8) – November 2007

Survey Panel Task 1 – Annual Review of Implementation of IACS Resolutions

1. Objective

To review IACS Resolutions annually and discuss or propose amendments as deemed necessary.

2. Background

This proposed amendment to all URZ7s and URZ 10s was raised by the Panel member from DNV due to Owners crediting tanks concurrently under intermediate and special survey.

3. Methodology of Work

Survey Panel members through correspondence.

4. Discussion

The Panel member from DNV raised the issue of Owners having the ability of crediting spaces and thickness measurements only once in a 54 month interval, due to the availability of concurrent crediting of spaces and thickness measurements due to the flexible time window that is currently allowed between the intermediate survey and the special survey.
After a presentation and discussion lead by the DNV Panel member, all Survey Panel members agreed to the argument given by DNV, and further agreed to make the necessary changes in all URZ7s and URZ10s where Owners are not allowed to concurrently credit surveys and thickness measurements of spaces.

5. Implementation

The Survey Panel is of the view that the Members need 12 months from the adoption date to implement these amendments into their class rules. Assuming that GPG approve to the amendments, the Survey Panel would propose January 2009 as an implementation date.

Submitted by Survey Panel Chairman
22 October 2007

Permanent Secretariat note (December 2007):

During GPG discussion DNV proposed that *"since this matter will be discussed between Owner and Class mainly in connection with the forthcoming Special Survey, DNV would prefer to locate this text, not only as part of Intermediate Survey, but also as a new text for the Special Survey."* This was supported by BV, ABS, RINA and KR.

The revised documents were approved, with DNV's proposal and an implementation date of 1 January 2009, on 15 November 2007 (ref. 7690_IGb).

Technical Background

URs Z7(Rev.16), Z7.1(Rev.6), Z7.2(Rev.2), Z10.1(Rev.16), Z10.2(Rev.27), Z10.3(Rev.11), Z10.4(Rev.7) and Z10.5(Rev.9) - March 2009

Survey Panel Task 62:

A) Harmonization of UR Z10.1, Z10.2, Z10.4 and Z10.5 with UR Z10.3 with respect to items 5.5.4.4 and 5.6.2.

B) Harmonization of UR Z7, Z7.1, Z10.1, Z10.2, Z10.3, Z10.4 and Z10.5 with UR Z7.2 with respect to the definition of the corrosion prevention system and with respect to the footnote 1 related to semi-hard coatings.

C) Harmonization of the definition of Ballast Tank in UR Z7(Rev.14)

1. Objective

A) Amend the texts of items 5.5.4.4 and 5.6.2 in Unified Requirements Z10.1, Z10.2, Z10.4 and Z10.5 in order to align them with those in UR Z10.3, in which they were changed while performing Task 55, whereas in the other UR Z10s they were kept unchanged on the grounds that this change was out of the scope of Task 55.

B) Amend the definition of “Corrosion Prevention System” and include a Footnote 1 related to semi-hard coatings in Unified Requirements Z7, Z7.1, Z10.1, Z10.2, Z10.3, Z10.4 and Z10.5 in order to align them with those adopted in UR Z7.2, when this new UR was issued.

C) Amend UR Z7 (Rev. 14) in all items where the term “Ballast Tank” is used in order to get them harmonized with the definition itself.

2. Background

The task, as regards item A), was triggered by a Member Society, while performing Task 55, on the grounds that this part was out of the scope of the task and then should have been dealt with in a separate task.
The task, as regards item B), was triggered as a consequence of the “New Business action item 2” of the Minutes of the September 2008 Survey Panel meting, for sake of harmonization of the various URZs.
The task, as regards item C), was triggered as a consequence of the “Task 54-Examination of Double Bottom Ballast Tanks at annual surveys” of the Minutes of March 2008 Survey Panel meeting, for sake of harmonization of the definition of Ballast Tank in UR Z7(Rev.14).

3. Discussion

The task was carried out by correspondence. All the amended texts for the affected URs were prepared by the Survey Panel Member who had chaired the PT on Task 55, in accordance with the Form A approved by GPG. In addition to the objectives outlined in the Form A, an amendment was added to item 1.3.1 of UR Z10.2 and UR Z10.5 in which the reference 3.2.3.6 in the last item of the list was replaced by 3.2.3.10 as can be correctly verified in the text.
The amended URs were circulated to all Survey Panel Members for review, comments and agreement. The texts of the URs were unanimously agreed by all Members.

4. Implementation

The Survey Panel is of the view that the Member Societies need at least 12 months from the adoption date to implement these amendments into their class rules/procedures. Therefore, in the first version of all amended URs the following implementation sentence should be proposed:

Changes introduced in Rev .xx are to be uniformly applied by Member Societies and Associates for surveys commenced on or after [not less than 12 months after the adoption by GPG/Council].

Since it is common practice and convenience to have implementation dates either on 1st January or on 1st July of the year, the Survey Panel proposes the 1st July 2010 as implementation date, if GPG/Council approve the URs not later than 30 June 2009.

Submitted by Survey Panel Chairman
28 February 2009

Permanent Secretariat notes (April 2009):

1. The amended URs were approved by GPG on 18 March 2009 (ref. 7718bIGd).
2. During the typesetting process it was noted that para 5.1.5 of UR 7.2 was inconsistent with the amended URs and so following consultation with the Survey Panel this was also amended at this time.
3. Regarding the implementation date, GPG agreed to use 1st July 2010 provided that it was consistently used for the amended URs.

Technical Background for UR Z7 Rev.17 (May 2010)*

1. Scope and objectives

Amend UR Z7 to include requirements for partial removal of casings, ceilings or linings, and loose insulation.

2. Engineering background for technical basis and rationale

To improve requirements in UR Z7 for access to structure for survey.

3. Source / derivation of the proposed IACS Resolution

- C59 Follow - up Action Item 29 – AVC Chairman's report
- UR Z7

4. Summary of Changes intended for the revised Resolution:

To allow partial removal of casings, ceilings or linings, and loose insulation, where fitted, to the satisfaction of the attending Surveyor upon findings (such as indents, scratches, etc.) detected during surveys of shell plating from the outside.

5. Points of discussions or possible discussions

N/A

6. Attachments if any

None

* Survey Panel Task 68 - *To make amendments to UR Z7 to allow only partial removal of casings, ceilings or linings, and loose insulation, where fitted, to the satisfaction of the attending Surveyor, for examination of plating and framing and to allow for TMs'*

Technical Background for UR Z7 Rev.18, Jan 2011

1. Scope and objectives

Starting from the example of supply vessels, to align UR Z7, Z7.1, Z1 and IMO Res. A997(25) as amended consistently.

2. Engineering background for technical basis and rationale

Supply vessels may carry different types of cargo which do not fall into category of dry cargo, such as brine, mud etc. and therefore this type of ship is subject to the intermediate survey requirements of item (CIn) 2.3.2.3 of IMO Res.A.997(25) as amended, through UR Z1. This requirement is to be added to UR Z7 as well.

3. Source / derivation of the proposed IACS Resolution

UR Z1 and IMO Res.A.997(25) as amended.

4. Summary of Changes intended for the revised Resolution:

The following requirement is included in UR Z7, for intermediate surveys:

"4.2.6 In the case of ships over 10 years of age, other than ships engaged in the carriage of dry cargoes only or ships subject to Z10.1, Z10.3, Z10.4 or Z7.2, an internal examination of selected cargo spaces is to be carried out."

5. Points of discussions or possible discussions

The Panel agreed that the above requirement was intended to cover the internal examination of selected cargo spaces intended for carriage of liquid cargo.

6. Attachments if any

None

Technical Background for UR Z7 Rev.19, July 2011

1. Scope and objectives

Review the requirement for repairs within IACS UR 7 and UR 10 series, in particular the requirement for Prompt and Thorough Repair, with a view to developing wording that would permit a temporary repair and the imposition of a Recommendation/ Condition of Class under specific and controlled circumstances, and in accordance with PR35.

2. Engineering background for technical basis and rationale

There are instances, for example a localised, isolated and very minor hole in a cross-deck strip, at which a suitable temporary repair, for example by welding or doubling, and the imposition of a suitable short term Recommendation/ Condition of Class for permanent repair at a later date, are considered very adequate methodology for dealing with the defect.

Current IACS Requirements in the UR Z7 and Z10 series, for Prompt and Thorough repair, would not permit this to be an option, the defect would have to be permanently Promptly and Thoroughly repaired, which might require removing cargo, moving to a repair berth and staging inner spaces.

Under the Requirements of IACS Procedural Requirement PR 35 the methodology of Temporary Repair and imposition of a suitable short term Recommendation/ Condition of Class for permanent repair at a later date is fully permissible.

3. Source / derivation of the proposed IACS Resolution

Based upon discussion within the IACS Survey Panel.

4. Summary of Changes intended for the revised Resolution:

Following the definition of Prompt and Thorough Repair in the Unified Requirement, a new paragraph is proposed to be added:-

"1.3.3 Where the damage found on structure mentioned in Para. 1.3.1 is isolated and of a localised nature which does not affect the ship's structural integrity, consideration may be given by the surveyor to allow an appropriate temporary repair to restore watertight or weather tight integrity and impose a Recommendation/Condition of Class in accordance with IACS PR 35, with a specific time limit."

5. Points of discussions or possible discussions

a) The points of discussion are as indicated in Sections 2 and 4 above.

b) Discussion took place on whether to prepare this amendment as a Unified Interpretation of IMO Resolution A.744(18)/UR Z7 and Z10 series, finally it was agreed to make direct amendment to the relevant URs.

c) It is proposed that this amendment be submitted directly to the IMO DE/MSC Committees for consideration of amending directly IMO Res. A744(18)

6. Attachments if any

None

Technical Background for UR Z7 Rev.21, Jan 2014

1. Scope and objectives

Consider appropriate text in IACS document regarding class period for lengthy conversions.

2. Engineering background for technical basis and rationale

As per the IMO Res. A1053 (27), lengthy conversions (not necessarily of major character) or other major repair work can be assigned for a 5 year period from the date of completion of conversion/repairs/surveys.

3. Source / derivation of the proposed IACS Resolution

None

4. Summary of Changes intended for the revised Resolution

Following additional text was included to section 2.1.3 to clarify the class period for lengthy conversions

"In cases where the vessel has been laid up or has been out of service for a considerable period because of a major repair or modification and the owner elects to only carry out the overdue surveys, the next period of class will start from the expiry date of the special survey. If the owner elects to carry out the next due special survey, the period of class will start from the survey completion date."

5. Points of discussions or possible discussions

Additional text to Para.2.1.3 was discussed in order to clarify class period.

6. Attachments if any

- **Corr.1 (May 2024)**

1 Origin of Change:

☑ Suggestion by IACS member

2 Main Reason for Change:

UR S21A was withdrawn, and its content was merged into UR S21 (with the implementation date of 1 July 2024). Accordingly, there was a need to update Para. 1.6 of UR Z7.1 and its footnotes.

3 Surveyability review of UR and Auditability review of PR

Survey Panel checked the correctness of this corrigendum.

4 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None

5 History of Decisions Made:

During the 39th Survey Panel meeting, the suggested correction of this UR in the form of corrigendum was unanimously agreed.

No TB is expected for the present revision.

6 Other Resolutions Changes:

None

7 Any hinderance to MASS, including any other new technologies:

None

8 Dates:

Original Proposal	:	22 January 2024	(Ref. PSU24006_ISUa)
Panel Approval	:	7 March 2024	(Ref: 39th Survey Panel meeting)
GPG Approval	:	10 May 2024	(Ref: 24057_IGb)

- **Rev. 15 (June 2019)**

1 Origin of Change:

☑ Suggestion by an IACS member

2 Main Reason for Change:

2.1 This revision is to address the policy decision made by GPG using the common terminology 'Condition of Class'(CoC) instead of the terms 'Recommendation/ Condition of Class' based on the outcome of III 5. (PSU19010)

2.2 Additionally, further revision was agreed to enable special consideration of classification societies in the assessment of cargo hold designs containing only short single side skin area in forward/aft cargo hold. (PSU18040)

2.3 Additionally, further revision was agreed to use the harmonized terms of ballast tanks for their survey requirements. (PSU18070)

2.4 Furthermore, in view of that in accordance with Res. MSC.194(80) the SOLAS regulation II-1/23-3 in the annex 1 was completely replaced by regulation II-1/25 in the annex 2 since 1 January 2009, regarding the additional requirements for single hold cargo ships, the references to SOLAS II-1/23-3 in this UR was agreed to be removed from Paragraphs 2.6 and 3.3.

3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

4 History of Decisions Made:

4.1 Harmonization of the terms “Recommendation” and “Condition of Class” (PSU19010)

During the 29th panel meeting, the panel discussed about the comments of members, and concurred with the view to retain the present definitions of CoC in the IACS resolutions with the wording ‘Recommendation’ to be removed. The panel also agreed to use the term ‘Statutory Condition’ for the ‘recommendation’ of the statutory certificates in IACS resolutions and RECs, and when discussing the proposal of a member to consider the harmonization of the terms of ‘recommendation’ and ‘condition of class’ in RO Code, the panel unanimously agreed to take no action on the IMO instruments, leaving the relevant actions to be decided by the relevant IMO bodies when IACS feeds back to IMO the IACS action on the harmonization of the two terms.

Panel members concurred with the view that it is not necessary to develop a new procedure requirement, and agreed to set the implementation date of these IACS resolutions (other than RECs) as 1st July 2020.

Before the implementation date of 1st July 2020 for using the common terminology 'Condition of Class' only, 'Recommendations' and 'Condition of Class' are to be read as being different terms used by Societies for the same thing, i.e. requirements to the effect that specific measures, repairs, surveys etc. are to be carried out within a specific time limit in order to retain Classification.

4.2 Additional revision to Paragraph 1.1.1 (PSU18040)

Survey Panel members concurred with the view that the application of UR Z7.1 was inappropriate and did not improve level of safety for general dry cargo ships that were of double side-skin construction, but with single skin in way of several frame spaces e.g. in way of a cargo hold entrance or at the forward end of the forward cargo hold in way of forebody hull form.

The panel agreed to modify paragraph 1.1.1 of UR Z7.1 with a belonging note being additionally developed, which enabled the classification society an assessment of respective cargo hold designs with special consideration.

4.3 Additional revision to use the harmonized terms of ballast tanks for their survey requirements (PSU18070)

Upon the discussions within Survey Panel under task No. PSU18070, the following changes were decided to be made to UR Z7, Z7.1 and Z7.2:

1) To use “ballast tanks” in lieu of “ballast spaces”, “water ballast tanks”, “tanks used for water ballast” or “spaces used for water ballast”; and
2) To use “double bottom ballast tanks” in lieu of “water ballast double bottom tanks”.

4.4 Additional revision to Paragraphs 2.6 and 3.3 (PSU19028)

Upon the discussions within Survey Panel under task No. PSU19028, in view of that in accordance with Res. MSC.194(80) the SOLAS regulation II-1/23-3 in the annex 1 was completely replaced by regulation II-1/25 in the annex 2 since 1 January 2009, regarding the additional requirements for single hold cargo ships, the references to SOLAS II-1/23-3 in this UR was agreed to be removed from Paragraphs 2.6 and 3.3.

No TB is expected for the present revision.

5 Other Resolutions Changes:

PSU19010;
The following IACS resolutions and Recommendations (RECs) were agreed to be revised:

- Procedural Requirements: PR1A, PR1B, PR1C, PR1D, PR1 Annex, PR3, PR12, PR20, PR35 and the attachment of PR16;
- Unified Requirements: Z7, Z7.1, Z7.2, Z10.1, Z10.2, Z10.3, Z10.4, Z10.5, Z15 and Z20
- Unified Interpretations: GC13
- Recommendations: Rec.41, Rec.96, Rec.98

PSU18070;
URs Z7 and Z7.2

6 Any hinderance to MASS, including any other new technologies:

None.

	31 May 2019 (PSU19028)
GPG Approval:	15 June 2019 (17044bIGy)

- **Rev.14 (Jan 2018)**

.1 Origin of Change:

☑ Suggestion by IACS members

.2 Main Reasons for Change:

To address the FUA 11 of C73, raised by the Council of the IACS in respect to the future work directions on the implications of new technology on survey regime. A revision of UR Z7.1 is in order to consider the new technologies on Remote Inspections (RIT).

.3 List of non-IACS Member Classification Societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

Members discussed under Panel task PSU 16056 the issue allocated by GPG on 21th October 2016. The subject deals with the review of the UR and Recommendation under Panel responsibility in order to determine whether a revision could need in order to consider the new technologies on Remote Inspections (RIT). The Panel Members concurred to discuss the possible revision of the UR Z7.1 in order to address the issue.

Panel agreed the revised paragraph 1.4, 1.5 and 5.2.3. In addition, a new paragraph 1.2.15 with definition of RIT was agreed and inserted in the present revision of UR Z7.1.

No TB is expected for the present revision.

.5 Other Resolutions Changes

UR Z7, UR Z7.2, UR Z10.3

.6 Dates:

Original Proposal: 21 October 2016 assigned by GPG
Panel Approval: 08 December 2017 by Survey Panel (Ref: PSU16056)
GPG Approval: 16 January 2018 (Ref: 16151_IGp)

- **Rev.13 (Aug 2017)**

.1 Origin of Change:

☑ Suggestion by an IACS member

.2 Main Reasons for Change:

2.1 To introduce the criteria for the steel renewal which belongs under the unified requirements of series S and are related to the net scantling approach, discussed under the task No. PSU16044;

2.2 To clarify the applicability of hybrid cargo hold arrangements by adding paragraph 1.1.2, discussed under the task No. PSU17005.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

4.1 Criteria for the steel renewal which belongs under the unified requirements of series S and are related to the net scantling approach

4.1.1 A member noted that some Unified Requirements of series S (Strength of Ships), such as UR S18, contain criteria addressing the steel renewal for dedicated structures such as transverse bulkheads, cargo hatch coamings and plating. These criteria (based on the net scantling approach) are applicable also to units designed with the gross scantling approach because they refer to particular structures for which it is foreseen that the dimensioning (or the design verification) according to the net scantling approach is applicable.

4.1.2 During the 24th Survey Panel Meeting the members agreed to review all UR of the S series in order to identify those containing any steel renewal criteria with the scope to review them.

4.1.3 Having found that UR S18 and UR S21a contain steel renewal criteria that need to be taken in to account during the thickness measurements review process, the members agreed that a new paragraph dealing with this issue needed to be added under the general section of the UR Z7.1.

4.1.4 The paragraph 1.5, "Thickness measurements Acceptance Criteria", has been agreed and inserted in the present revision of UR Z7.1.

4.2 Applicability of hybrid cargo hold arrangements

4.2.1 A member noted that the clarification of current UR Z7.1 is not clear for the situation of hybrid cargo hold arrangements and proposed to add new paragraph 1.1.2 into UR Z7.1.

4.2.2 During the 25th Survey Panel Meeting, the members reviewed the UR Z7.1 and agreed to add the new paragraph 1.1.2 into UR Z7.1.

No TB is expected for the present revision.

.5 Other Resolutions Changes

UR Z7, UR Z10.2, UR Z10.5

.6 Dates:

Original Proposal:	09 September 2016 (24th Survey Panel meeting) Made by a Survey Panel Member 15 February 2017 Made by a Survey Panel Member.
Panel Approval:	08 February 2017 (Ref: PSU16044) 22 May 2017 (Ref: PSU17005)
GPG Approval:	23 August 2017 (Ref: 17017_IGb)

- **Rev.12 (June 2016)**

.1 Origin of Change:

☑ Suggestion by an IACS members

.2 Main Reasons for Change:

To consider appropriate text of paragraph 2.4.2 in order to replace the vague wording "dispensed" and provide a definition of the sentence *"hard protective coating where applied remains efficient".*

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

Following an ACB query an IACS member sought the Members opinion to clarify the meaning of the sentence *"The thickness measurements may be dispensed with provided the surveyor is satisfied by the close-up examination, that there is no structural diminution, and the hard protective coating where applied remains efficient*", in particular if the thickness measurements might be totally avoided when the pre-requisites are fulfilled.

Panel Members offered their interpretation to this sentence and the common view of the majority is that the thickness measurements should not be totally avoided since surveyor shall demonstrate: *"that is no structural diminution"*. Panel agreed to remove the word "*dispensed*" from the last sentence of paragraph 2.4.2 and insert the new wording "specially considered".

A margin of the discussion Panel examined the pre-requisite relevant to the condition of the coating; in fact the wording "*hard protective coating where applied remains efficient"* does not provide clarity when compared with the definitions under paragraph 1.2.11 of the unified requirement.

The common view of the Members is that the coating condition of the structural area under examination shall be in "GOOD" condition to be considered "efficient", whilst the overall coating condition of the compartment/space under examination might be "FAIR". Panel agreed to add in the text a footnote which explains the meaning of "efficient".

According to a latest proposal made by a Member, the paragraph 2.4.2 has been further modified to clarify better the structures to be subjected to examination. The Panel agreed that for the "water ballast tanks" the wording *"transverse webs of"* has to be added before and for the transverse bulkhead the wording *"and framing"* has to be inserted after "bulkhead plating".

During the 23rd Survey Panel meeting, the modifications to paragraph 2.4.2 have been re-examined by the Members. The review has been performed by taking in account the whole history files of the UR Z7.1. Members concurred that the paragraph 2.4.2

(both the original and the revised versions) might be misleading if it is read in association to paragraph 2.4.4.

Therefore Members agreed:
- to include the cargo holds in paragraph 2.4.4 so that the special considerations can be applied also to these compartments.
- the deletion of paragraph 2.4.2 and the consequent renumbering of the subsequent paragraph.

The Panel common view on the "Minimum quantity of thickness measurements to be taken in case special considerations have been applied" has been developed and agreed.

No TB is expected for this revision.

.5 Other Resolutions Changes

None

.6 Dates:

Original Proposal 02 September 2015 made by IACS Member
Panel Approval: At 20th Survey Panel Meeting (Ref: PSU15045)
GPG Approval: 06 June 2016 (Ref: 16093_IGb)

- **Rev.11 (Feb 2015)**

.1 Origin of Change:

☑ Suggestion by an IACS members

.2 Main Reasons for Change:

a) To consider appropriate text in IACS document regarding the applicability of the Thickness Measurements when the Close up survey is performed.

b) To consider the impracticability of the internal structure close up inspection of cargo hold hatch covers which have no access structurally (from the approved design) and it is possible to survey and gauge plating only..

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

a) Following an ACB query an IACS member proposed to add suitable text in appropriate IACS documents regarding the application of the Thickness Measurements when the close up surveys are performed as survey requirement due at the Intermediate/ Renewal Class surveys. This Member expressed the view that the requirements to execute the Thickness Measurements of the area subject to Close Up Surveys are expected into the table relevant to "MINIMUM REQUIREMENTS FOR THICKNESS MEASUREMENTS AT SPECIAL SURVEY ………" while the paragraph 1.4 of the document contains only the requirement that "Thickness Measurements of the areas subject to close up surveys shall be taken in conjunction with the close up survey".

Panel discussed and considered that wordings of Para 1.4 of current UR Z7s/10s need to be revised in order to clarify this issue; finally Panel agreed to add additional wording to Para.1.4.

b) Panel, following the proposal submitted by a Member, concurred and agreed that in case the cargo hold hatch covers have a configuration that does not permit the ingress of the surveyor for the internal inspection (e.g. box type panel), the close up survey should be limited to external parts as well as the Thickness Measurements that should be performed only on the external plating. The technical background, on which is based the modification of the requirement, is that the internal structure of a hatch cover of box type construction are reasonably not subject to any corrosion phenomenon. Hence, unless the external plating of the box is damaged, no depletion of the internal structures is expectable.

Panel discussed the matter under item PSU13051 and considered that an explanation note to Para 2.2.4.1 and to Table 1 of current UR Z7.1 need to be added to clarify this issue.

.5 Other Resolutions Changes

The amendment a) affects UR Z7, UR Z7.1, UR Z7.2, UR Z10.1, UR Z10.3, UR Z10.4 and UR Z 10.5.

The amendment b) affects also UR Z 10.2 and UR Z 10.5.

.6 Dates:

Panel Approval: At 20th Survey Panel Meeting (5 September 2014)
GPG Approval: 05 February 2015 (14193_IGc)

- **Rev.10 (Jan 2014)**

.1 Origin of Change:

☑ Suggestion by an IACS member

.2 Main Reason for Change:

Consider appropriate text in IACS document regarding class period for lengthy conversions.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

With reference to IMO Res. A1053 (27) (5.5 Application of "special circumstances") an IACS member proposed to add suitable text in appropriate IACS document regarding class period for lengthy conversions. This Member expressed that when a renewal survey has been completed, the new 5 year class period would normally be calculated from the expiry of previous class period/class certificate and in some cases this might result in unreasonably short time from one renewal survey completion until the next renewal would be due.

Panel discussed the matter under item PSU13051 and considered that wordings of Para 2.13 of current UR Z7s/10s (second sentence) could address this issue but finally agreed to add additional text to Para.2.1.3 in order to clarify this matter.

.5 Other Resolutions Changes

The identical amendment affects UR Z7, UR Z7.2, UR Z10.1, UR Z10.2, UR Z10.3, UR Z10.4 and UR Z 10.5.

.6 Dates:

Panel Approval: At 18th Survey Panel Meeting (5 September 2013)
GPG Approval: 14 January 2014 (Ref: 12011aIGd)

- **Rev.9 (May 2013)**

.1 Origin of Change:

☑ Suggestion by IACS members

.2 Main Reason for Change:

a) An inquiry from a member whether the 'Other equivalent means' referred in Para 5.3.2 of IACS UR Z10.2 include the use of Cherry Pickers for survey of other structures. (PSU 12022)
b) A Panel member raised a query about the definition of “dedicated forest product carrier” and how does it differ from a timber or log carrier. (PSU12040)

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

a) Discussion of this matter initiated by a Panel member regarding the use of Cherry Pickers in Cargo Holds with reference of IACS URZ10.2. In accordance with UI SC191 and Rec 91, the Cherry Picker is allowed up to 17m height for Cargo Hold structure (ships constructed after 2006 for Alternative means of access). As per the provisions of URZ10.2, Cherry pickers are allowed for survey of side shell frames only.

Panel discussed and considered that Para 5.3.2 of UR Z10.2 allows the use of Cherry Pickers as 'Other equivalent means'. Accordingly, Panel agreed to clarify this matter by including text "hydraulic arm vehicles such as conventional cherry pickers" to UR Z10s and UR Z7s for a ship not subject to the above 17m restriction.

b) Panel discussed to define "dedicated forest product carrier" under PSU 12040. However, Panel was unable to define this type of ship in terms of the "dedicated forest product". Panel agreed to delete this type of ship from URZ7.1 considering that this type of ship might also be a general dry cargo ship and could be surveyed accordingly.

.5 Other Resolutions Changes

a) The identical amendment affects UR Z7, UR Z10.1, UR Z10.2, UR Z10.3, UR Z10.4 and UR Z 10.5.

.6 Dates:

Panel Approval: 7 March 2013 during Survey Panel Meeting
GPG Approval: 22 May 2013 (Ref: 9640_IGn)

- **Rev.8 (Oct 2011)**

.1 Origin of Change:

☑ Suggestion by an IACS member

.2 Main Reason for Change:

The design of General Dry Cargo Ships has evolved significantly in recent years. Many of these modern multi-purpose ships are now with a double-side skin extending for the entire length and height of the cargo-carrying area, with in-built container-carrying capability.
The traditional general dry cargo ship was of single-side skin construction with tween decks, as indicated in Figures 1 and 2 of UR Z7.1, and it is for this structural configuration that the need was perceived to enhance surveys to include Close-Up Surveys.
IMO Resolution MSC 277(85) Para 1.6.1 also makes the distinction that double-side skin general dry cargo ships are of significantly different construction from conventional general dry cargo ships.
The double-side skin construction ship is afforded significantly more protection to cargo spaces than the traditional single-side skin design, and is akin to a container ship in configuration. For these reasons it was considered correct to exclude double-side skin general cargo ships, with the double-side skin extending over the entire length and height (to the upper deck) of the cargo carrying area from the requirements of IACS UR Z7.1.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

The matter was raised by a member and agreed by the majority of panel members under job PSU 10051. Some detail discussion ensued on wording, implementation dates and definitions, both by correspondence and at the Spring Meeting of the Panel 2011.

One member did not agree with the proposal, citing concerns with specific types of damages, including grab damages and other aspects associated with the carriage of bulk cargoes on double-side skin general dry cargo ships, and most particularly river/sea navigation type ships.

.5 Other Resolutions Changes

None

.6 Dates:

Original Proposal: *17 November 2010 Made by a Member*
Panel Approval: *02 March 2011*
GPG Approval: *19 October 2011 (Ref: 11153_IGb)*

- **Rev.7 (July 2011)**

.1 Origin of Change:

☑ Suggestion by an IACS member

.2 Main Reason for Change:

Following external audit a member was advised that a small temporary doubler on a cross-deck strip of a bulk carrier should have been promptly and thoroughly repaired at the time of survey. The member carried out an investigation and found that the actions of the surveyor were fully justifiable, the temporary repair and short term Condition of Class imposed were an appropriate method of dealing with such a situation. The member advised that the current requirements for 'Prompt and Thorough Repair' stipulated under the UR 7 and UR 10 series do not give any leeway for carrying out temporary repairs (and imposing a Recommendation/Condition of Class in accordance PR 35) where the damage in question is isolated and localised, and in which the ship's structural integrity is not impaired.

The Survey Panel discussed the matter and agreed that under carefully defined circumstances a temporary repair and short term Recommendation/Condition of Class would be an appropriate course of action.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

The matter was discussed by correspondence within the Survey Panel and at the Autumn 2010 Panel Meeting. Following discussion at which the possibility of a Unified Interpretation being raised was considered, it was eventually decided to make direct amendment to the relevant Unified Requirements.

The wording of the new paragraph to be inserted as Para 1.3.3 in all relevant Unified Requirements was extensively discussed prior to agreement.

The proposal was unanimously agreed by Survey Panel Members.

.5 Other Resolutions Changes

The identical amendment affects UR Z7, UR Z7.1, UR Z7.2, UR Z10.1, UR Z10.2, UR Z10.3, UR Z10.4 and UR Z 10.5.

.6 Dates:

UR Z7.1 (Rev.1)

(Re-categorization of Z10.6 as Z7.1, June 2003)

Technical background

1. Objective

WP/SRC in its Progress Report to GPG 54 reported that under their Task "Harmonization of UR Z10s" WP agreed that Z10.6 should be re-categorized as Z7.1 since it did not contain the whole of essential ESP requirements such as survey planning document and executive hull summary.

GPG agreed.

2. Points of discussion

At GPG 53 meeting, DNV raised a concern that ships whose tonnage is in excess of 500 GRT but exempted from SOLAS requirements may fall under the scope of application of UR ex-Z10.6. DNV suggested to change the application scheme in Z7.1.1.1 from "500 grt" to "ships having SOLAS SC certificate".

DnV further clarified that IACS Members are not always the organizations issuing the SAFCON certificate and therefore the issue on whether or not a ship is issued with a SAFCON is not evident. Finally, the application scheme remains unchanged.

BV suggested that livestock carriers and deck/dock ships be excluded from the application of UR Z7.1. Agreed. See 1.1.1 and a footnote of the UR 7.1.

submitted by the Permanent Secretariat

30 June 2003

WP/SRC Task 102
HARMONIZATION OF UR Z7s AND Z10s

Technical Background
UR Z7 (Rev. 11)
UR Z7.1 (Rev. 2)
UR Z10.1 (Rev. 12)
UR Z10.2 (Rev. 17)
UR Z10.3 (Rev. 7)
UR Z10.4 (Rev. 2)
UR Z10.5 (Rev. 1)

Contents:

1. Objective

To amend UR Z7s and Z10s in order to make the texts of the above-mentioned URs consistent eliminating all the differences both in substance and in wording (WP/SRC Task 102).

2. Background

In the process of approving UR Z10.4, GPG found it necessary to amend the other existing URs Z10.1, Z10.2, Z10.3, Z10.6 and Z7 in order to eliminate any inconsistencies existing among them.

3. Methodology of work

The WP has progressed its work through many sessions, both during the periodical meetings and dedicated meetings restricted to a Small Group of Members (BV, DNV, GL, LR, RINA) who developed the work in order to be more efficient. All the proposed amendments of the Small Group have regularly been circulated to all Members for comment and agreement.

4. Discussion

4.1 The WP/SRC has completed a comprehensive comparative review of UR Z7 and Z10s, and identified inconsistencies which existed among them. During this review, attention was given to the severity of the requirements applicable to the same spaces/structural areas on different types of ESP ships. As a result, the inconsistencies were eliminated making the URZs harmonized. However, there has been no change to the scope and extent of the survey requirements.

4.2 The starting point for each UR was the most updated version available at the time of commencement. Any revision to the URZs, which were introduced during this task, was taken into account. As for instance, the UR Z10.1 was initially amended based on Rev. 9, while the last amendments are based on Rev. 11 and the UR Z10.2 was initially amended based on Rev. 13, while the last amendments are based on Rev. 16. The proposed revisions of URs Z10.1 and Z10.4 have not been numbered, as there will be revisions to those URs before the revisions introduced by the Task 102 are adopted. In fact, GPG is currently developing a Revision 12 of Z10.1 with the view to introducing significant improvements in the survey regime for ballast tanks (including combined cargo/ballast tanks) of oil tankers and UR Z10s applicable to oil tankers will also have to be revised by incorporating the amendments to A.744(18) contained in Resolution MSC 144(77), which enter into force 1 January 2005 (see 4.3 below).

4.3 Also, in harmonizing UR Z10.1 and Z10.2 care has been taken to align the corresponding text with that of IMO Res. A.744(18). However, it has been noted that the amendments to A.744(18) contained in Resolution MSC 144(77), which enter into force 1 January 2005, have not been incorporated into the IACS UR Z10s applicable to oil tankers. It seems that the updating of the above-said UR Z10s will be done by the Perm Sec and reviewed by the WP/SRC Chairman and then circulated for adoption by GPG with concurrence of Council Members for uniform application from 1 January 2005. It is understood that the revisions of the UR Z10s affected by those amendments will not include the changes introduced by the Task 102, as the implementation date proposed for those changes is 1 January 2006 (see below **6. Implementation**).

4.4 In the course of the work the WP has been developing for more than two years, several additional Tasks were assigned to the WP by GPG which affected the development of Task 102. The additional tasks which have been taken into account are the following:

1) In the course of Council discussion on UR Z10.6 (General Cargo Ships), certain inconsistencies were identified between Z10.6 and other Z10s. WP was instructed to expedite Task 102 (1060gIAa, 12 June 2002);
2) WP was instructed to include “Survey Planning for Intermediate Survey” into harmonization work (2108_IAa, 12 July 2002);
3) GPG instructed WP to consider whether Z10.6 should be re-assigned as Z7.1, in connection with the harmonization work. 1060gIAb, 20 Sept 2002.

Z7.1 developed;

4) Partial outcome (Z7 and Z7.1) was submitted to GPG on 17 July 2003(1060g). Council decided that approval of Z7(Rev.10) and Z7.1(Rev.2) is postponed until the harmonization is completed (1060gICb, 6 April 2004);
Council Chairman instructed WP/SRC to Members' comments on the draft revision of UR Z7 and Z7.1 (collected under s/n 1060g, 1060gNKi (30/03/2004) in particular) on 6 April 2004.

5) GPG tasked WP to include the amendments to Z10.2 / Z11 (BCs with hybrid cargo hold arrangements), deleting sheets 15 and 16 for ore carriers, into the harmonized UR Z10s (2212aIGa, 19 Jan 2004);
6) GPG tasked WP to consider whether the requirements relevant to examination of Fuel Oil Tanks in the cargo area at each Special Survey should be put into Z 10s, and internal examination of FOT at Intermediate Survey after SS 2 is needed. (1060gIAf, 30 Jan 2004);
7) GPG tasked WP to harmonize tank testing requirements in Z7s and Z10s. (3006lIAa, 5 April 2004);
8) GPG tasked WP with Task 108 - Develop uniform survey requirements for air vent pipes including the welded connection to deck. Z22 developed. GPG instructed WP to incorporate Z22 into the harmonized Z10s;
9) GPG tasked WP with Task 114 - Verification and signature of TM reports. REC 77(Rev.1) developed and approved on 29 July 2004. Council approved parallel amendments to Z7.1 and Z10s (TM Forms included) and instructed WP to incorporate these into the harmonized Z10s:
    - Recommendation No.77 was revised (Rev.1, July 2004);
    - Z7.1 para.6.3.2 and Z10s para.7.3.2 so amended.
    - "Surveyor's signature" is deleted from all TM Forms in Z10s;
    - A note is added to Annex II(Z10s) declaring that Annex II is recommendatory.

   WP/SRC's investigation into Members' practice in dealing with verification and signature of TM reports is annexed for record keeping purpose. See Annex 2.

10) GPG tasked WP to consider the BV comments on "TM may be dispensed with…." and include the findings into the harmonized Z10s (2219iIAa, 7 April 2004).

5. Agreement within the WP/SRC

All Members have unanimously agreed the attached final versions of UR's.

6. Implementation

WP/SRC is of the view that the Members need 12 months from the adoption date to implement these amendments into their class rules. Assuming Council adoption in December 2004, WP/SRC would propose January 2006 as implementation date.

Annex 1: TB for UR Z10.1(Rev.12, C49 amendments, see Permsec's note 1 below)
Annex 2: WP/SRC Task 114, verification and signature of TM reports(see 9 above).
Annex 3**:** TB for revision of UR Zs concerning "anodes".

Note by the Permanent Secretariat

1. Annex 1 to this TB contains background for amendments to UR Z 10.1(Rev.12) relating to FAIR/POOR/GOOD (C49 amendments). Council at its 49th meeting (June 2004) agreed/decided that comparable changes should be added to Z10.3 and Z10.4.

2. Appendix 3 "TM sampling method" has been added to UR Z10.1 and Z10.4 to keep them consistent with IMO Res.MSC.144(77). The amendments to A.744 contained in MSC.144(77) entered into force on 1 January 2005. *(GPG s/n 4181)*

Under s/n 4072g, paragraph **2.4.6** of UR Z10.1 and **2.4.6** and of UR Z10.4 (paragraph numbering is now harmonized) were amended in order to provide a link between the main text of the UR Z10.1 and 10.4 and the new Annex III Appendix 3 containing the MSC Res.144(77).

Further, it was agreed that the requirements for evaluation of longitudinal strength of the hull girder (as written in MSC.144(77)) should not be required for Intermediate Survey unless deemed necessary by the attending Surveyor. This is covered in 4.2.3.1 and 4.2.4.1 of Z10.1 and Z10.4.

3. GPG agreed that the amended UR Zs should be implemented from 1 July 2006 altogether.

4. DNV's proposed amendments to UR Z10.1, Z10.3 and Z10.4 concerning annual survey of ballast tanks were agreed by Council (1060gICq, 27 June 2005). See Appendix 2 to Annex 1.

5. Annex 3 contains a TB for revision of UR Zs concerning "anodes".

Date: September 2004
Prepared by the WP/SRC

– – –

Annex 1 to Technical Background
UR Z 10.1 (Rev.12, C49 amendments(coating-related))

1. Objective

To introduce significant improvements in the survey regime for ballast tanks (including combined/ballast tanks) of oil tankers as matter of strategic concern and urgency to IACS, given the aging of both the single and double hull tanker fleets and the problems encountered with corrosion of ballast tanks in several shipping casualties.

2. Background

Draft amendments to UR Z10.1 were submitted to Council 47 (June 2003) and agreed in principle.

3. Discussion

There was particular concern over accelerated corrosion with age (as the thinner the material, the more rapidly the allowable diminution margin percentage disappears) especially where coatings have broken down. There is also a disincentive for any spend on maintenance of the structure of a ship within a few years of its statutory scrapping date.

Council discussion by correspondence had evolved to the position of substantive proposals – summed as follows (3095_ABa, 2 June 2003):

1. Enhance the Intermediate Survey in Z10.1, Z10.3 and 10.4 for Tankers after 2nd Special / Renewal Survey to the same level (scope of work) as the preceding Special / Renewal Survey). This corresponds to the latest revision to UR Z10.2.
2. At Annual Survey of ballast tanks with substantial corrosion, the overall survey is to be replaced by close-up survey with thickness measurements of the exposed area.
3. Proposed to task WP/SRC to re-consider the acceptance criteria for the rating FAIR further. For this, eliminate FAIR, leaving only GOOD and POOR redefined as appropriate.
4. Proposed to task WP/SRC to explicitly require close-up survey of Suspect Areas identified at the previous Special Survey.

Council 47 discussed the proposals(June 2003) as follows:

1. Definition of FAIR
   Council 47 agreed that "FAIR" would be retained as a rating and that GPG should instruct WP/SRC to redefine FAIR, so that there would be a clear differences between FAIR, POOR and GOOD. It was also agreed that for oil tankers the Intermediate Survey following Special Survey No.2 would have the same scope as Special Survey No.2(Z10.1). WP/SRC should also clarify the definition of satisfactory repair.

   Based on the strong majority, Council agreed to discuss with Industry annual surveys of ballast tanks when coating is found in LESS than GOOD condition at special survey, with the objective to encourage the owner to carry out repairs and maintenance of coating to GOOD condition.

   > *DNV and NK stated that they could not accept a requirement for annual surveys of ballast tanks when the coating condition is less*

than GOOD and proposed that GOOD be changed to FAIR (3095_IGc, 30 June 2003)

2. ABS' proposed amendments to Z10.1(annual examination of BWTs in certain conditions) were approved.
3. C 47 agreed that the BWT coating requirements (Z10.1.2.2.3) for intermediate Survey after SS 2 should be the same extent to the previous SS.
4. Given the substance of the changes, the revised Z10.1 should be shown to Industry before adoption.
5. A guidance for coating repairs needs to be developed by WP/SRC with reference to TSCF Guidelines.

Following Council 47, the draft text of Z10.1(Rev.12) was distributed to Industry and discussed at the IACS/Industry meeting on 29 August 2003. Industry indicated that UR Z10.1(Rev.12) is acceptable, provided that appropriate IACS guidelines on coating repairs are developed.

The Small Group on Coating (SG/Coating) under WP/SRC prepared draft guidelines on coating repairs and considered the definitions of GOOD / FAIR / POOR. The SG/Coating did not change the definitions and found that the Guidelines provide useful clarifications on the definitions and criteria in achieving an industry wide uniform judgement of coating conditions as well as what is needed to restore GOOD conditions.
Further, an IACS/Industry JWG/Corrosion was established and met in February 2004. The outcome is (3095_IGh, 4 June 2004):

- Draft Guidelines on Coating Repair (IACS REC 87)
- Draft UR Zxx (mandatory coating of cargo tanks on oil tankers)
- Draft UI SC 122 (Rev.2) – mandatory coating of ballast tanks

4. Others

1. Z10.11.2.2bis - Definition of "Combined Cargo/Ballast Tank. …as a routine part of the vessel's operation and will be treated as a Ballast Tank. ...". By so amending, Z10s do not need to repeat "Ballast Tanks *and Combined cargo/salt water Ballast Tanks*" in addressing the ballast tanks. Hence, all the references to "*and Combined cargo/salt water Ballast Tanks"* were deleted.
2. Z10.1.2.2.1.2: The aim of the examination is ~~to be sufficient~~ to discover substantial corrosion…
   Comparable changes are to be added to other UR Zs wherever the same sentence occurs.
3. "IACS Guidelines for Coating Maintenance & Repairs for Ballast Tanks and Combined/Ballast tanks on Oil Tankers" are referenced where relevant.
4. Comparable changes are to be added to UR Z10.3 and Z10.4, after adoption of Z10.1(Rev.12).

Attached: Memo on Coating Matters (GPG Chairman)

9 June 2004
Prepared by the Permsec

Appendix 1 to Annex 1: MEMO on Coating matters

1. Background and discussion within IACS on UR Z10.1 (draft Rev.12) between 29/01/03 and 14/08/03

In view of the survey experience with oil tankers, it was proposed that all ballast tanks should be examined, routinely and uniformly, at annual surveys on ESP tankers exceeding 15 years of age. IACS should amend UR Z10.1 to require the examination of ballast tanks on such ships at each annual survey. This is simple, clear and thorough and not subject to interpretation. (2242_ABq dated 29/1/03)

Then, ABS modified the proposal asking, for tankers subject to URs Z10.1, Z10.3 and Z10.4, exceeding 15 years of age, that the current requirement - pertaining to annual examination of Ballast Tanks adjacent to cargo tanks with any means of heating - be deleted and replaced by a simpler and more stringent requirement that all Ballast Tanks be subject to survey at each subsequent annual survey where either substantial corrosion is found within the tank or the protective coating is found to be in less than GOOD condition and the protective coating is not renewed at special survey or intermediate survey. This will ensure that all Ballast Tanks with substantial corrosion or protective coating which is not in GOOD condition at the time of special survey or intermediate survey will be examined at each subsequent annual survey on tankers exceeding 15 years of age. (2242_ABzb dated 14/3/03)
This was later expanded to include all tanks used routinely for ballast water, both ballast-only and cargo/ballast tanks (2242_ABzc dated 14/3/03).

ABS further reviewed the issue of the survey of salt water ballast spaces and combined cargo/salt water ballast spaces with ABS' governing bodies in light of recent casualties and survey findings on other tankers. Their review found an increasing amount of coating breakdown/failure and subsequent rapid wastage in key structures after Special Survey No. 2, i.e. after 10 years of age. These conditions are most prevalent in the under deck structure and the side shell structure in way of the deep loadline. In a number of cases the serious wastage has caused fracturing of the under deck longitudinals and in some cases fracturing has extended to the main deck structure. This led ABS to refine proposed amendments to URs Z10.1, Z10.3 and Z10.4 to require (2242_ABzf dated 9/5/03):

a. For Tankers exceeding 10 years of age

> Salt Water Ballast Spaces and Combined Cargo/Salt Water Ballast Spaces. For tankers exceeding 10 years of age, salt water ballast spaces and combined cargo/salt water ballast spaces are to be internally examined at each subsequent Annual Survey where substantial corrosion is found within the tank or where the protective coating is found to be less than GOOD condition and protective coating is not repaired. Internal examination to be an Overall Survey.

b. For Tankers exceeding 15 years of age:

Salt Water Ballast Spaces and Combined Cargo/Ballast Spaces. For tankers exceeding 15 years of age, salt water ballast spaces and combined cargo/ballast spaces are to be examined internally at each subsequent Annual Survey. Where substantial corrosion is found within the tank, or where the protective coating is found to be in less than GOOD condition and the protective coating is not repaired then in addition to an Overall Survey, under deck structure and the side shell structure in way of the deep loadline is to be subject to Close-up Survey.

NK and BV replied that the proposed amendments made by ABS need to be substantiated in a transparent manner with technical data that ABS may possess and put forward for further assessment and discussion. (2242_NKn dated 14/5/03 and 2242_BVz dated 16/5/03)

DNV (2242_NVn dated 2/6/03), having carefully considered the practical consequences of taking the ship off-hire for gas freeing etc. and being concerned about the difficulties to have these surveys executed in a safe manner and whether the intended safety benefits in implementing the proposed extended scope of the annual survey of Ballast tanks will be met, **proposed the following alternative measures** which would be as effective and may not have such delaying effects to the ship:

1) Enhance the Intermediate Survey in UR Z10.1, 10.3, and 10.4 for Tankers after the 2 Special / Renewal Survey to the same level (scope of work) as the preceding Special / Renewal Survey. (This will correspond to the latest revised requirements of UR Z10.2 for Bulk Carriers.)
2) At Annual Survey of ballast tanks with substantial corrosion the overall survey should be replaced by close up survey with thickness measurements of the exposed area. (An overall survey of these tanks does not give sufficient information of the development of the areas with substantial corrosion.)
3) Further we will not fail to mention that the WP/SRC has proposed to extend the close up survey in cargo and combination tanks to 30% from the 3 Special / Renewal Surveys.
4) **Experience has shown that the coating condition rating category FAIR has a tendency to be stretched too far into the POOR condition. We will therefore propose that we task the WP/SRC to reconsider the acceptance criteria for the rating FAIR further.**
5) We do also question the need for redefining the definition of combination tanks, particularly since the category I tankers which are the ships that normally are fitted with these type of tanks are to be phased out 2 to 4 years from now. However DNV will not oppose to such a redefinition.

DNV requested Members to consider the above as an alternative to the ABS proposal, bearing in mind that we ought to present this to the industry prior to deciding.

ABS (3095_Aba dated 2/6/03), having further considered its earlier proposals in light of NVn, submitted a revised proposal for consideration by Council at C47 and replied to the above 5 DNV proposals as follows:

1) ABS fully supports this proposal.
2) While ABS agrees with this proposal, it is in fact already provided for in Z7 (3.2.3) and Z10.1 (3.2.5.1)--which require that "Suspect areas (which include any area where substantial corrosion is found) identified at previous Special Survey are to be examined. Areas of substantial corrosion identified at previous special or intermediate survey are to have thickness measurements taken." To us, this implies that close-up survey of these areas is to be done at annual survey in conjunction with the thickness measurements. However, we can

agree to tasking WP/SRC to explicitly require "close-up" survey in this connection and to amend Z7, and all the Z10's, appropriately to make this explicit, if there is majority support for this.

3) We agree that this has been put forward to GPG by WP/SRC via 0237hNVb, 27 May. However, these additional CAS close-up survey requirements do not apply to salt water ballast tanks; only to cargo oil tanks and combined cargo/ballast tanks.
4) **We agree with this assessment and we propose that the only way to eliminate the subjectivity and raise the standard is to eliminate the category "FAIR" completely; leaving only "GOOD" and "POOR" redefined as follows:**
   "GOOD -- condition with no breakdown or rusting or only minor spot rusting.
   POOR -- any condition which is not GOOD condition."
5) ABS does not agree with this proposal. We are particularly concerned that we need a very thorough and robust survey regime for these tankers precisely because they are subject to mandatory phase out over the next several years. We are very concerned that without additional IACS requirements, these tanks will receive little or no inspection and maintenance by owners or others after their last special or intermediate survey, if no substantial corrosion is found at that time. Rapid, localized wastage in way of deteriorating coatings may pose significant hazard if the survey regime is not further tightened as we are proposing.

In conjunction with the above comments on DNV proposals, ABS further considered their previous proposal in ABzf and modified it as follows:

- **ABS simplified the proposal to require annual examination of all salt water Ballast Tanks and combined Cargo/salt water Ballast Tanks irrespective of age, when either substantial corrosion is found within the tank or the protective coating is found to be in less than GOOD condition and is not repaired.**
- the requirement for annual (close-up) examination of salt water ballast tanks and combined tanks is already required in Z10.1 (3.2.5.1). ABS proposed adding it to 2.2.3 for clarity and emphasis so that all the conditions which may lead to annual examination of such tanks are listed together in one place.
- Since the principal problem that we are trying to address is rapid, localized corrosion in way of breakdown or deterioration of the protective coating, we are proposing that the coating condition should be found and kept in "GOOD" condition to obviate the need for annual examination. **The attached proposal is made together with the proposals in items 3.1 (intermediate following Special survey 2 to have same scope as prior Special survey) and 3.4 (eliminating "FAIR" and redefining "POOR" as any condition other than "GOOD" condition.**

ABS requested to decide on a course of action at C47 for tightening the survey regime for tankers. They agreed that industry be informed of Council's decisions in this regard prior to IACS making the decision public, but IACS should maintain its independence and take decisive action in this matter. Debate with industry can only lead to delay and to a watering down and compromising of these important requirements.

NK agreed to task WP/SRC to reconsider the acceptance criteria of "FAIR" for clearly define the border between "FAIR" and "POOR" condition. However, **NK strongly opposed the elimination of "FAIR" coating condition from UR Zs** because this can not resolve to remove subjectivity of coating assessment. The three-categorization system of coating condition should be retained. (3095_NKa dated 5/5/03)

<u>Outcome of C47</u>

At **C47**, it was agreed that "Fair" would be retained as a rating and that GPG should instruct WP/SRC to redefine "Fair", so that there would be a clear differentiation between "Fair", "Poor" and "Good". It was also agreed that for oil tankers the Intermediate Survey following Special Survey No.2 would have same scope as Special Survey No.2 (Z10.1). WP/SRC should also clarify the definition of satisfactory repair.

Based on strong majority support Council agreed to discuss with Industry annual surveys of ballast tanks when coating is found in LESS than GOOD condition at special survey, with the objective to encourage the owner to carry out repairs and maintenance of coating to GOOD condition.

This matter should be discussed with Industry prior to adoption of any UR by Council.

In a final summary, the Chairman proposed that a constructive dialogue with Industry should take place on the IACS proposal as set out in WP1 plus maintaining 3.2.5.2 modified to say that ballast/combined ballast/cargo tanks will be subject to annual survey when considered necessary by surveyors.

After discussion in the JWG (Industry/IACS), GPG should propose final rules for this matter to Council, including acceptable repair definition.

F**UA 17:** *To instruct WP/SRC to develop guidance on coating repairs and more precise definition of "Fair" coating condition.*

Once approved, these requirements should be incorporated into Z10.3 and Z10.4.

FUA 15

1) *To prepare a draft revision to UR Z10.1 incorporating C 47 decisions:*
    - *The definition of "FAIR" remains as it is;*
    - *ABS proposed amendments to Z10.1 (annual examination of BWTs in certain conditions) were approved;*
    - *C47 agreed that the BWT coating requirements (Z10.1.2.2.3) for Intermediate Survey after Special Survey No.2 should be the same extent to the previous Special Survey.*
    - *Given the substance of the changes, the revised UR Z10.1 should be shown to Industry (OCIMG/Intertanko first among others) before adoption for their review and comments.*
    - *A guidance for coating repairs needs to be developed by WP/SRC with reference to TSCF Guidelines.*

2) *GPG Members are to confirm the draft revision to Z10.1 in consultation with their WP/SRC members by correspondence. See 3095_IGa of 13/06/03.*

According to C47 FUA 15, GPG Chairman circulated (3095_IGa dated 13/6/03) draft amendments to UR Z10.1 as agreed in principle at C47.

Having received a number on comments, GPG Chairman (3095_IGb dated 27/6/03) informed that the Council Chairman confirmed that GPG is not to amend the principles agreed at C47, i.e. we are not empowered to change "GOOD" to "FAIR" as proposed by DNV and NK, nor to amend the definitions of "FAIR" and "POOR" as proposed by DNV.

DNV's intention to possibly lodge a reservation was noted, however the matter should be raised at Council and not be dealt with by GPG. An amended draft text incorporating the non-substantive changes proposed by Members was circulated.

DNV said that its understanding was that the draft should be circulated to the Industry (ICS, INTERTANKO, and BIMCO) prior to adoption by Council. (3095_NVc dated 30/6/03)

GPG Chairman (3095_IGc dated 30/6/03) circulated a draft amendment of UR Z10.1 for Council's agreement and use in discussions with the industry associations.
The draft was generally agreed by GPG but individual Members have requested that the following matters (which were deemed to be outside the remit of GPG in this task) be brought to Council's attention for further consideration:

1 DNV and NK stated that they can not accept a requirement for annual surveys of ballast tanks when the coating condition is less than GOOD and propose that GOOD be changed to FAIR.
2 In connection with item 1 above, DNV also propose to amend the definitions of FAIR and POOR in order to raise the standard of FAIR.

Council Chairman (3095_ICb dated 14/8/03) concluded that Council has agreed that the draft amendments to UR Z10.1 attached to IGc reflect Councils' decision taken at C47 and that they be circulated to industry associations.
Perm Sec was therefore invited to submit the draft to OCIMF and INTERTANKO in view of discussion at the IACS/ industry meeting on 29 August.

2. Discussion with Industry (29/08/2003 – 11/10/2003)

As requested by Council, the whole matter was presented to Industry during the “general matters” meeting with IACS held on 29 August 2003; comments from Industry were requested. In the following an extract from the minutes of the meeting (see message 3100aIAb dated 5 September 2003):

____________________ from Meeting minutes ____________________

4. & 5. Annual surveys of ballast tanks and IACS guidelines on coating repairs

M. Dogliani introduced the matter (see Items 4&5 in Appendix).

A. LinoCosta gave a presentation to show where concerns and decisions stand: too many cases when coating was considered fair at SS but problems occurred just after one/two years.

N. Mikelis commented on draft amendments to Z10.1 (Rev.11) stating that the extent of annual survey is not clear; it should be limited to the affected zones, e.g. coating breakdowns, only.
M. Guyader clarified that, in this draft amendments, it is expected an overall survey of the whole tank and a close up survey of the affected zones.
N. Mikelis noted that, in the draft amendments to Z10.1 (Rev.11), the intermediate survey at 12.5 years would have the same scope as the previous special survey and that needed a justification. See 7 a).
M. Dogliani said that Z10.1 (Rev.11) was adopted in August 2003 and will be introduced into IACS Societies’ Rules over the next year.

Conclusions:
4.1 Industry shared IACS concerns on coatings and, in general, agreed with the draft amendments to Z10.1 (Rev.11) suggesting also extending them to Z10.2 on bulk carriers

4.2 Industry agreed that a guideline for surveyor on coating would greatly improve uniform application of so-amended Z10.1 including issues such as how to consider load bearing elements when judging GOOD/FAIR/POOR status and how to consider bottom pitting in connection with GOOD conditions
4.3 Industry will more precisely comment, by the end of September, the draft Z10.1 so as for IACS to finalise the matter, as planned, for the Council's December meeting.

Item	Title	Industry recommandation	IACS/ M. Dogliani Introduction
4 & 5	Annual survey of ballast tanks IACS guidelines on coating repairs	NN	**1. IACS is considering the following:** - **amend UR Z10.1 (draft circulated to Industry) to the effect that in case at Special Survey or Intermediate Survey the coating in a ballast tank is found less than GOOD, either GOOD conditions are restored or the tank's coating is inspected at each annual survey;** - **develop IACS guideline to assist an uniform application of the so modified (if adopted) UR Z10.1; the guideline should address which repairs are necessary to restore GOOD conditions from FAIR and POOR respectively and which are the criteria for the restored (after repair) situation to be rated as GOOD.**

______________________________ End of extract from minutes ___________________________

INTERTANKO commented (see R. Leslie email to GPG dated 25 September 2003):

- expressing their concern for the draft Z10.1 and underlining

  a) targeting: concerns that, if not properly dealt with, Z10.1 would target all ships and not just those which need intervention; the view was expressed that guidelines would probably solve the matter;

  b) definition: indicating that the current definitions of GOOD, FAIR and POOR is not clear enough and that the matter would be even worst with GOOD and NON GOOD; again it was indicated that guidelines could solve the matter;

  c) expertise: expressing doubts on IACS' surveyors expertise and ability to judge coating conditions; in this respect they (hiddenly) suggest that IACS position is unclear when we say that we are not competent to judge the coating during construction but then we are competent to judge coating during operational life. Even if not explicitly stated, the impression is that also in this case guidelines would help.

Additionaly, INTERTANKO suggested a (quite detailed) set of assessment criteria.

The matter was then finally addressed at the TRIPARTITE Meeting (held in Soul on 29/30 September 2003). There Industry agreed that the way forward was the (joint) development of IACS guidelines (see minutes attached to message 3100_RIe dated 11 October 2003, an extract of which is reproduced below).

______________________________ Extract from the TRIPARTITE minutes ________________

Industry is concerned by the definition of GOOD/NOT GOOD in relation to coating repairs and acceptance criteria. Industry agreed that new guideline on this, which IACS is already producing, was the way forward.

_______________________________ End of the extract from the minutes __________________

3. Further developments

a) from the above, it was concluded that, provided the guidelines are sound, Industry would accept the concept of Z10.1 (draft) Rev. 12, therefore an IACS team and a JWG were established in order to progress the matter of the guidelines (among other related matters).

b) the team of IACS experts on coating developed draft guidelines and provided recommendations to GPG on the way forward (attached to message 3095bNVc dated 20 November 2003).

c) the guidelines were discussed within the JWG with Industry (see draft minutes circulated within GPG with messages 3095cIGd and 3095cIGe both dated 13 March 2004)

d) further suggestions and comments (as requested at the meeting) were provided by Industry (not circulated to GPG)

e) Bulk Carrier Industry is recommending that similar guidelines are developed in due time also for bulk carriers

f) at DE47 and MSC78, IMO is asking Industry and IACS to develop (compulsory) performance standards for coating of newbuilding (double hull spaces of DSS Bulk Carriers), a matter which is, indirectly related to the above one.

25 May 2005

To: Mr. B. Anne, Chairman of IACS Council,
cc: Council Members, IACS Perm. Sec.

Ref.: My mail NVr dated 20 May 2005

DNV have further studied the amendments to UR Z10.1, Z10.3, and Z10.4, and as a result are presenting the following as a compromise solution:

General comment:
From the comments by other Members it is obvious that there is reluctance to accept annual surveys of ballast tanks with a common plane boundary to heated cargo tanks in the case where the coating is in good condition. This is particularly unreasonable as at the same time we enhance the Intermediate survey of Tankers between 10 and 15 years to also include examination of all ballast tanks, meaning that all ballast tanks will be close up surveyed with 2-3 years intervals from the ship is 10 years old, with the possibility for the surveyor to require thickness measurements and testing of the tanks to ensure the structural integrity of the tanks if necessary.
It is also proposed for the Intermediate survey between 5 and 10 years, to increas the scope from representative to all ballast tanks, a requirement DNV find to strict, and require that we here keep the original text.
If a ballast tank is found to have coating in GOOD condition at the renewal or intermediate survey, a deterioration of the tank beyond structural reliability is very unlikely even if the tank has a common plane boundary to a heated cargo tank.

DNV finds it particularly unreasonable to have this requirement to apply to double hull tankers for the following reasons:
- these ships have double hull and the risk of pollution is here much reduced,
- the double hull is constructed with small spaces giving improved structural reliability,
- almost all double hull tankers below VLLC have heated cargo tanks, and all ballast tanks have common plane boundaries to these tanks, meaning that this requirement will apply to a major part of the tanker fleet in the future,
- the ballast tanks of double hull tankers are so designed that a general examination of these tanks will be identical to a close up survey,
- survey of ballast tanks of double hull tankers will mean either gas freeing of all cargo tanks or at least dropping the inert gas pressure of all cargo tanks in addition to proper airing of all ballast tanks.

Since the single hull tankers will be faced out in the near future, and for clear political reasons, DNV will as a compromise proposal to keep paragraph 2.2.3.1 and 4.2.2.2 in Z 10.1 as amended by Council (ref. IAo) but amend it to not include 2.2.3.1.e, 4.2.2.2.e and last paragraph of 3.2.5.1 in Z10.3 and Z10.4. In addition we request that the original text of 4.2.2.1 is kept.
If BV, ABS and other Members can accept this DNV is willing to drop our reservation presented at C49.
DNV's proposal will then be as follows:

Z10.1:

2.2.3.1: This paragraph can be accepted as is for the reasons stated above.
3.2.5.1: This paragraph is accepted as amended.
4.2.2.2: This paragraph can be accepted as is for reasons stated above.

For other comments to Z10.1 see NVo and NVp.

Z10.3:

2.2.3.1.e to be deleted.
3.2.5.1 delete last paragraph
4.2.2.1 the original text to be kept."For tanks used for water ballast ---"
4.2.2.2.e to be deleted

Z10.4

2.2.3.1e to be deleted
3.2.5.1 delete last paragraph
4.2.2.1 the original text to be kept, "For tanks used for water ballast --"
4.2.2.2.e to be deleted.

For details see attached document where the text for the requirements in Z10.3 and Z10.4 that DNV will accept is stated.

Best Regards

Arve Myklebust
on behalf of
Terje Staalstrom
DNV IACS Council Member
<<Doc1.doc>>

Annex 2 to TB (Harmonization Z10s)

WP/SRC Task 114 "Clarify the procedure of verification and signature of the thickness measurement report"

Item No.	Item	ABS	BV[1]	CCS	CRS	DNV	GL	IRS	KR	LR	NK	RINA	RS
1	**Verification onboard**	.											
1.1	Minimum extent of measuring points for direct verification by attending surveyor specified	No	No	No	No	No	No	No	Yes	No	No	Yes	No
1.2	Preliminary TM record to be signed upon completion of the measurements onboard	Yes	Yes [7]	Yes	No (copy taken)	No[3]	No[6]	Yes	Yes	Yes	Yes	No[8]	No
2	**Final TM report**												
2.1	Signature of all pages in TM record required	No	No	No	Yes	No	Yes	Yes	No	No	No[5]	Yes	Yes
2.2	Signature of 'cover' ('general particulars') page only	Yes	Yes	Yes	No	Yes	No	No	No[4]	Yes	Yes	Yes	No
2.3	Measuring points verified by attending surveyor required identified in TM record and signature of the corresponding pages required	No	No	Yes Without signature	Yes	No	No	No	Yes	No	No	No	No

2004-04-20

[1] Instructions not clear regarding signature of the thickness measurement record

[2] Signature on front and last page, stamp on all other pages, or signature on each page (IACS TM forms)

[3] Upon completion of measurements onboard a draft report in electronic format (DNV TM template, including operator's notes as relevant) to be given to attending surveyor

[4] Signature of cover page, pages of meeting record and pages of attended measuring points

[5] Each page to be signed in case of 'loose-leaf' type record

[6] Preliminary TM record has to be passed to the Surveyor, signed by the Operator

[7] The only measures which the Surveyors can certify exact are those for which that they have seen the results on the screen of the apparatus. That means in fact few points in comparison with the numbers of recorded measures.

8) The Surveyor reviews the TM record for completeness and assessment of TM readings, but no signature required.

Annex 3: **Technical Background**
(May 2005)

UR Z7s and Z10s (Corrosion Prevention System)

1. Objective:

To clarify whether the survey of anodes is a class matter, and if so, whether acceptance criteria for anode should be developed.

2. Method: GPG by correspondence (5037_)

3. Discussion

3.1 BV initiated GPG discussion as follows:

Paris La Défense, 8 Mars 05

1 - We have noticed that, in the draft UR Z's (7.1, 10.1 to 10.5) issued further to the WP/SRC Task 102, the original sentence "......the examination may be limited to a verification that the hard protective coating remains efficient......" has been replaced by ....that the corrosion prevention system remains efficient....". in a number of paragraphs (such as , for instance, Z 7.1, 4.2.3.1 a) ; Z 10.2 4.2.3.3 ;), in line with IMO Res.A744(18).

2 - However, a corrosion prevention system is defined, in the same UR Z's and in IMO Res.A744(18) , as being either a full hard protective coating or a full hard protective coating supplemented by anodes.

3 - The above would mean that the survey of the anodes is a classification matter.

4 - However, whereas coating conditions are defined as good or fair or poor, there are no criteria in the IACS URs and IMO Res. A744(18) for the anodes condition.

5 - Assessing the anodes condition to confirm that they "remain efficient" looks to BV to be a quite difficult task for the ships in service Surveyor.

6 - Member's view and interpretations on the following would consequently be appreciated:
- do Members consider that the above requirements in IACS URs imply that survey of anodes is part of the classification ?
- do Members consider that the above requirements in IMO Res. A 744 (18) imply that survey of anodes is mandatory?
- if yes, what is the acceptance criteria to conclude that the anodes" remain efficient" ?

3.2 The majority of GPG Members replied that they did not include requirements for anodes in their class rules.

LR / ABS / DNV / KR / NK / RINA / RS were of the view that the condition of any anodes fitted should be recorded for information purposes as the survey of anodes is neither a classification matter nor a mandatory requirement in IMO A.744(18) and has no impact on future surveys (5037_LRa**). [**Note; LR further clarified that “Whilst I agree that the performance of anodes is not normally a class matter LR does require that as part of Special Survey on oil tankers : "The attachment to the structure and condition of anodes in tanks are to be examined ." Therefore we cannot say that 'the survey of anodes is not a classification matter'**. 5037_LRb]**

However, GL said that “for GL, anodes are a matter of class and as such are subject to plan approval as well as surveys. In case of missing or worn-out anodes we issue a condition of class”(5037_GLa&b).

CCS advised that its rules have a general requirement relating to anode survey, which is only conducted, through sampling, during construction, docking survey or where there is a definite requirement for the survey of ballast tanks.

NK proposed that the following footnote be added to Z7s and Z10s:
“The survey of anodes is not a classification matter.” No majority support was achieved.

4. Conclusion

RINA suggested to simply amend the definition of "Corrosion Prevention System" in paragraph 1.2.9 of UR Z7 (and, of course, the paragraphs in all the other UR Zs containing the definition of "Corrosion Prevention System") in order to eliminate any reference to anodes. This proposal would leave room for Societies willing to include additional class requirements for anodes to do so in their Rules.

GPG agreed.

RINA proposed amendments to paragraph 1.2.9 of UR Z7
and corresponding paragraphs in all other UR Zs
(5037_RIb, 6 April 2005)

1.2.9 Corrosion Prevention System

A corrosion prevention system is normally considered ~~either:~~ a full hard protective coating.
~~.1 a full hard protective coating, or~~
~~.2 a full hard protective coating supplemented by anodes.~~
Hard protective coating is usually to be epoxy coating or equivalent. Other coating systems may be considered acceptable as alternatives provided that they are applied and maintained in compliance with the manufacturer’s specifications.
Where soft coatings have been applied, safe access is to be provided for the surveyor to verify the effectiveness of the coating and to carry out an assessment of the conditions of internal structures which may include spot removal of the coating. When safe access cannot be provided, the soft coating is to be removed.

Annex: Council Chair’s conclusive message.

6 May 2005
Permsec

Annex. (5037_ICb, 15 May 2005)

To : All IACS Council Members
c.c : Mr. R. Leslie, IACS Permanent Secretariat

Ref. Mr G-Y. Han's message IAa dated 6 May 05
Message ICa dated 6 May 05
Admiral R.E. Kramek's message ABb dated 13 May 05

Paris La Défense, 15 May 05

1 - All Members have agreed with the texts attached to Mr Han's message.

2 - Further to ABS comments the reference to anodes is to be deleted in Annex I and in tables IX (IV) and IX(II).

3 - further to ABS questions regarding what IACS plan to do regarding IMO and A.744(18) further to IACS deletion of reference to anodes from the UR Z7's and UR Z10's it is to noted that:

The Item 1.2.9 in UR Z1O.1 and relative items in these URs states
1.2.9 10 Corrosion Prevention System: A corrosion prevention system is normally considered either:
.1 a full hard protective coating, or
.2 a full hard protective coating supplemented by anodes.
Hard Pprotective Ccoating is to usually to be epoxy coating or equivalent. Other coating systems may be considered acceptable as alternatives provided that they are applied and maintained in compliance with the manufacturer's specification.
Where Soft Coatings have been applied, safe access is to be provided for the surveyor to verify the effectiveness of the coating and to carry out an assessment of the conditions of internal structures which may include spot removal of the coating. When safe access cannot be provided, the soft coating is to be removed.

- therefore the anodes are not considered as the main means of protection against the corrosion It is only a supplement;

- there is no provision in UR Z7's and Z10's to evaluate the level efficiency of the anodes;

- there is no specific requirements in case of lack of efficiency of the anodes.

The experience has shown that ballast tanks only protected by anodes are subject to corrosion when the anodes are becoming less efficient.

The anodes are active only when immersed by sea water. Therefore the upper part of the ballast tanks are not protected when the ballast is full of water and the ballast is not protected when it is empty..

The ships operators are reluctant to replace the anodes especially in upper part which request fitting of scaffolding fo welding the anode supports to the structure.

The above arguments justify the reasons why IACS consider that the anodes are not class item.

4 - These arguments can be used by IACS Members attending the WG bulk carriers at MSC 80 to try to obtain deletion of the reference to anodes in A. 744(18).

Best regards,

Bernard Anne
IACS Council Chairman.

Survey Panel Task 22 – Amend applicable URZ7s and Z10s to align Close-Up Survey and Thickness measurements to be carried out at the same time and location allowing for a more structured control of the thickness measurement process.

Technical Background

Z7(Rev.12)
Z7.1(Rev.3)
Z10.1(Rev.13, para.1.4 & 7.1.3)
Z10.2(Rev.18, para. 1.4 & 7.1.3)
Z10.3(Rev.8, para. 1.4 & 7.1.3)
Z10.4(Rev.3, para. 1.4 & 7.1.3)
Z10.5(Rev.2, para. 1.4 & 7.1.3)

1. **Objective**

To amend the applicable URZ7s and Z10s to align Close-Up Survey and Thickness measurements to be carried out at the same time and location allowing for a more structured control of the thickness measurement process.

2. **Background**

IACS QC findings, through audits of numerous Societies, which indicated concerns over Surveyor attendance and control of thickness measurement processes.

3. **Methodology of Work**

Survey Panel members through correspondence.

4. **Discussion**

To align Close-up survey requirements and thickness measurements in the applicable URZ7s and URZ10s, in accordance with PR19, all Panel members agreed through correspondence and a final vote at the fall Survey Panel meeting, that URZ7, Z7.1, Z10.1, Z10.2, Z10.3, Z10.4 and Z10.5 should include in the applicable sections of the noted URs as proposed by the Survey Panel the wording " In any kind of survey, i.e. special, intermediate, annual, or other surveys having the scope of the foregoing ones, thickness measurements of structures in areas where close-up surveys are required, shall be carried out simultaneously with close-ups surveys."

5. Implementation

The Survey Panel is of the view that the Members need 12 months from the adoption date to implement these amendments into their class rules. Assuming that GPG and Council approve to the amendments, the Survey Panel would propose January 2007 as an implementation date.

TECHNICAL BACKGROUND

UR Z7.1 (REV. 4) AND UR Z7 (REV.13)

SURVEY PANEL TASK 39 – Amend URZ7.1 to align with the requirements of URZ10.2 and URZ10.5 in accordance with SOLAS reg. II-I/23-3 and II-1/25 regarding Water level detectors on single hold cargo ships other than bulk carriers, and to propose to IMO that these requirements be included in relevant sections of IMO resolution A.948(23).

1. **Objective**

To amend UR Z7.1 Section 2.6 and 3.3 to include survey requirements related to SOLAS reg. II-I/23-3 and II-I/25 and to propose to IMO that these requirements be included in relevant sections of IMO resolution A.948(23).

2. **Background**

GPG member from LR requested that URZ7.1 should be amended to meet SOLAS regulations II-I/23-3(entry into force :1 January 2007) and II-I/25 (entry into force: 1 January 2009)

3. **Methodology of Work**

Survey Panel

4. **Discussion**

Survey Panel members at the spring 2006 meeting discussed how to address these changes in a similar manner as were carried out in Survey Panel Task 11 for URZ10.2 and Z10.5, for URZ7.1. During the discussion, the member from RINA proposed that URZ7 also be amended to refer to the applicable changes in URZ7.1.
All members agreed and made necessary amendments to URZ7 section 1.1.5 and added note 5 as far as the implementation date.
For URZ7.1 it was agreed that sections 2.6 and 3.3 be added to add these additional requirements.

5. Implementation

The Survey Panel is of the view that the Members need 12 months from the adoption date to implement these amendments into their class rules. Assuming that GPG and Council approve to the amendments, the Survey Panel would propose July 2007 as an implementation date.

Submitted by Survey Panel Chair,
13 July 2006

Permanent Secretariat note:

- Council approved URZ7.1 Rev.4 and URZ7 Rev.13 on 17 August 2006 (5031fICb).
- In addition to the proposed changes a typographical error was corrected in Table 4 of UR Z7.

Technical Background

URs Z7(Rev.15), Z7.1(Rev.5), Z7.2(Rev.1), Z10.1(Rev.15), Z10.2(Rev.26), Z10.3(Rev. 9), Z10.4(Rev.6), Z10.5(Rev.8) – November 2007

Survey Panel Task 1 – Annual Review of Implementation of IACS Resolutions

1. Objective

To review IACS Resolutions annually and discuss or propose amendments as deemed necessary.

2. Background

This proposed amendment to all URZ7s and URZ 10s was raised by the Panel member from DNV due to Owners crediting tanks concurrently under intermediate and special survey.

3. Methodology of Work

Survey Panel members through correspondence.

4. Discussion

The Panel member from DNV raised the issue of Owners having the ability of crediting spaces and thickness measurements only once in a 54 month interval, due to the availability of concurrent crediting of spaces and thickness measurements due to the flexible time window that is currently allowed between the intermediate survey and the special survey.
After a presentation and discussion lead by the DNV Panel member, all Survey Panel members agreed to the argument given by DNV, and further agreed to make the necessary changes in all URZ7s and URZ10s where Owners are not allowed to concurrently credit surveys and thickness measurements of spaces.

5. Implementation

The Survey Panel is of the view that the Members need 12 months from the adoption date to implement these amendments into their class rules. Assuming that GPG approve to the amendments, the Survey Panel would propose January 2009 as an implementation date.

Submitted by Survey Panel Chairman
22 October 2007

Permanent Secretariat note (December 2007):

During GPG discussion DNV proposed that *"since this matter will be discussed between Owner and Class mainly in connection with the forthcoming Special Survey, DNV would prefer to locate this text, not only as part of Intermediate Survey, but also as a new text for the Special Survey."* This was supported by BV, ABS, RINA and KR.

The revised documents were approved, with DNV's proposal and an implementation date of 1 January 2009, on 15 November 2007 (ref. 7690_IGb).

Technical Background

URs Z7(Rev.16), Z7.1(Rev.6), Z7.2(Rev.2), Z10.1(Rev.16), Z10.2(Rev.27), Z10.3(Rev.11), Z10.4(Rev.7) and Z10.5(Rev.9) - March 2009

Survey Panel Task 62:

A) ***Harmonization of UR Z10.1, Z10.2, Z10.4 and Z10.5 with UR Z10.3 with respect to items 5.5.4.4 and 5.6.2.***

B) ***Harmonization of UR Z7, Z7.1, Z10.1, Z10.2, Z10.3, Z10.4 and Z10.5 with UR Z7.2 with respect to the definition of the corrosion prevention system and with respect to the footnote 1 related to semi-hard coatings.***

C) ***Harmonization of the definition of Ballast Tank in UR Z7(Rev.14)***

1. Objective

A) Amend the texts of items 5.5.4.4 and 5.6.2 in Unified Requirements Z10.1, Z10.2, Z10.4 and Z10.5 in order to align them with those in UR Z10.3, in which they were changed while performing Task 55, whereas in the other UR Z10s they were kept unchanged on the grounds that this change was out of the scope of Task 55.

B) Amend the definition of “Corrosion Prevention System” and include a Footnote 1 related to semi-hard coatings in Unified Requirements Z7, Z7.1, Z10.1, Z10.2, Z10.3, Z10.4 and Z10.5 in order to align them with those adopted in UR Z7.2, when this new UR was issued.

C) Amend UR Z7 (Rev. 14) in all items where the term “Ballast Tank” is used in order to get them harmonized with the definition itself.

2. Background

The task, as regards item A), was triggered by a Member Society, while performing Task 55, on the grounds that this part was out of the scope of the task and then should have been dealt with in a separate task.
The task, as regards item B), was triggered as a consequence of the “New Business action item 2” of the Minutes of the September 2008 Survey Panel meting, for sake of harmonization of the various URZs.
The task, as regards item C), was triggered as a consequence of the “Task 54-Examination of Double Bottom Ballast Tanks at annual surveys” of the Minutes of March 2008 Survey Panel meeting, for sake of harmonization of the definition of Ballast Tank in UR Z7(Rev.14).

3. Discussion

The task was carried out by correspondence. All the amended texts for the affected URs were prepared by the Survey Panel Member who had chaired the PT on Task 55, in accordance with the Form A approved by GPG. In addition to the objectives outlined in the Form A, an amendment was added to item 1.3.1 of UR Z10.2 and UR Z10.5 in which the reference 3.2.3.6 in the last item of the list was replaced by 3.2.3.10 as can be correctly verified in the text.
The amended URs were circulated to all Survey Panel Members for review, comments and agreement. The texts of the URs were unanimously agreed by all Members.

4. Implementation

The Survey Panel is of the view that the Member Societies need at least 12 months from the adoption date to implement these amendments into their class rules/procedures. Therefore, in the first version of all amended URs the following implementation sentence should be proposed:

Changes introduced in Rev .xx are to be uniformly applied by Member Societies and Associates for surveys commenced on or after [not less than 12 months after the adoption by GPG/Council].

Since it is common practice and convenience to have implementation dates either on 1st January or on 1st July of the year, the Survey Panel proposes the 1st July 2010 as implementation date, if GPG/Council approve the URs not later than 30 June 2009.

Submitted by Survey Panel Chairman
28 February 2009

Permanent Secretariat notes (April 2009):

1. The amended URs were approved by GPG on 18 March 2009 (ref. 7718bIGd).
2. During the typesetting process it was noted that para 5.1.5 of UR 7.2 was inconsistent with the amended URs and so following consultation with the Survey Panel this was also amended at this time.
3. Regarding the implementation date, GPG agreed to use 1st July 2010 provided that it was consistently used for the amended URs.

Technical Background for UR Z7.1 Rev.7, July 2011

1. Scope and objectives

Review the requirement for repairs within IACS UR 7 and UR 10 series, in particular the requirement for Prompt and Thorough Repair, with a view to developing wording that would permit a temporary repair and the imposition of a Recommendation/ Condition of Class under specific and controlled circumstances, and in accordance with PR35.

2. Engineering background for technical basis and rationale

There are instances, for example a localised, isolated and very minor hole in a cross-deck strip, at which a suitable temporary repair, for example by welding or doubling, and the imposition of a suitable short term Recommendation/ Condition of Class for permanent repair at a later date, are considered very adequate methodology for dealing with the defect.

Current IACS Requirements in the UR Z7 and Z10 series, for Prompt and Thorough repair, would not permit this to be an option, the defect would have to be permanently Promptly and Thoroughly repaired, which might require removing cargo, moving to a repair berth and staging inner spaces.

Under the Requirements of IACS Procedural Requirement PR 35 the methodology of Temporary Repair and imposition of a suitable short term Recommendation/ Condition of Class for permanent repair at a later date is fully permissible.

3. Source / derivation of the proposed IACS Resolution

Based upon discussion within the IACS Survey Panel.

4. Summary of Changes intended for the revised Resolution:

Following the definition of Prompt and Thorough Repair in the Unified Requirement, a new paragraph is proposed to be added:-

"1.3.3 Where the damage found on structure mentioned in Para. 1.3.1 is isolated and of a localised nature which does not affect the ship's structural integrity, consideration may be given by the surveyor to allow an appropriate temporary repair to restore watertight or weather tight integrity and impose a Recommendation/Condition of Class in accordance with IACS PR 35, with a specific time limit."

5. Points of discussions or possible discussions

a) The points of discussion are as indicated in Sections 2 and 4 above.

b) Discussion took place on whether to prepare this amendment as a Unified Interpretation of IMO Resolution A.744(18)/UR Z7 and Z10 series, finally it was agreed to make direct amendment to the relevant URs.

c) It is proposed that this amendment be submitted directly to the IMO DE/MSC Committees for consideration of amending directly IMO Res. A744(18)

6. Attachments if any

None

Technical Background for UR Z7.1 Rev.8, Oct 2011

1. Scope and objectives

Double Skin General Dry Cargo Ships are increasingly common and are of a completely different structural configuration to the conventional single skin General Dry Cargo Ship.

The scope and objective was to review and examine UR Z7.1 with a view to adding Double Skin General Dry Cargo Ships to the list of exempted ship types under Para 1.1.1. on the basis that their double skin configuration afforded significantly enhanced protection to the cargo holds.

2. Engineering background for technical basis and rationale

The design of General Dry Cargo Ships has been evolving over the last 20 years. Modern multipurpose general cargo ships are designed around containers configuration, ie with double skin. They are primarily intended to carry other cargoes and only occasionally carry containers. However, because of the double skin configuration the risks associated with carriage of other cargoes are significantly lower than for an older single skin general cargo ship (the side shell and frames are protected from the impact of cargo handling by the double skin).
UR Z7.1 was introduced in June 2002 (as Z10.6) and focussed on traditional General Cargo Ship Construction, with tween-decks and single skin. The drawings (Figs 1 and 2) of Z7.1 indicate this structural configuration.
IMO Resolution MSC 277(85) Para 1.6.1 also makes the distinction that double-skin general dry cargo ships are of significantly different construction from conventional general dry cargo ships.
The Survey Panel is of the view that the traditional risks associated with the single skin configuration of General Cargo Ship are mitigated in the double-skin design, and as such, they should be exempted from the requirements of UR Z7.1, given their strong similarity to Container Ship design.

3. Source/derivation of the proposed IACS Resolution

IACS UR Z7.1

4. Summary of Changes intended for the revised Resolution:

In IACS UR Z7.1, para 1.1.1, the existing list of ship types exempted from the requirements of UR Z7.1 is to be augmented by the addition of:-

- general dry cargo ships of double side-skin construction, with double side-skin extending for the entire length of the cargo area, and for the entire height of the cargo hold to the upper deck.

5. Points of discussions or possible discussions

Discussion was held on the following aspects:-

a) The extent of double skin required – it was agreed that this would apply only to General Cargo Ships with complete double-skin for the entire length and height of the cargo area.
b) River-Sea Navigation ships – it was agreed that these ship types did not form a specific sub-type of the General Cargo Ship group and that all General Cargo Ships have some river-sea capability. Pure river navigation general cargo ships were considered outside the remit of IACS.
c) The carriage of bulk cargoes aboard such ships was considered in view of the propensity for grab and other damages associated with these cargoes, however, general opinion was that the double skin arrangements mitigated this.

6. Attachments if any

None

Technical Background for UR Z7.1 Rev.10, Jan 2014

1. Scope and objectives

Consider appropriate text in IACS document regarding class period for lengthy conversions.

2. Engineering background for technical basis and rationale

As per the IMO Res. A1053 (27), lengthy conversions (not necessarily of major character) or other major repair work can be assigned for a 5 year period from the date of completion of conversion/repairs/surveys.

3. Source/derivation of the proposed IACS Resolution

None

4. Summary of Changes intended for the revised Resolution

Following additional text was included to section 2.1.3 to clarify the class period for lengthy conversions

"In cases where the vessel has been laid up or has been out of service for a considerable period because of a major repair or modification and the owner elects to only carry out the overdue surveys, the next period of class will start from the expiry date of the special survey. If the owner elects to carry out the next due special survey, the period of class will start from the survey completion date."

5. Points of discussions or possible discussions

Additional text to Para.2.1.3 was discussed in order to clarify class period.

6. Attachments if any

None

UR Z7.2 "Hull Surveys for Liquefied Gas Carriers"

Summary

1. This revision is to harmonize the terms of 'recommendation' and 'condition of class' with only the term 'condition of class' being retained.

2. Additionally, this UR was revised to use the harmonized terms of ballast tanks for their survey requirements.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev.8 (May 2019)	30 May 2019	1 July 2020
Rev.7 (Jan 2018)	16 January 2018	1 January 2019
Rev.6 (Feb 2015)	05 February 2015	1 July 2016
Rev.5 (Jan 2014)	14 Jan 2014	1 January 2015
Rev.4 (May 2013)	22 May 2013	1 July 2014
Rev.3 (July 2011)	27 July 2011	1 July 2012
Rev.2 (Mar 2009)	18 March 2009	1 July 2010
Rev.1 (Nov 2007)	15 November 2007	1 January 2009
New (May 2007)	08 May 2007	1 July 2008

- **Rev. 8 (May 2019)**

1 Origin of Change:

☑ Suggestion by an IACS member

2 Main Reason for Change:

2.1 This revision is to address the policy decision made by GPG using the common terminology 'Condition of Class'(CoC) instead of the terms 'Recommendation/ Condition of Class' based on the outcome of III 5. (PSU19010)

2.2 Additionally, further revision was agreed to use the harmonized terms of ballast tanks for their survey requirements. (PSU18070)

3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

4 History of Decisions Made:

4.1 Harmonization of the terms "Recommendation" and "Condition of Class" (PSU19010)

During the 29th panel meeting, the panel discussed about the comments of members, and concurred with the view to retain the present definitions of CoC in the IACS resolutions with the wording 'Recommendation' to be removed. The panel also agreed to use the term 'Statutory Condition' for the 'recommendation' of the statutory certificates in IACS resolutions and RECs, and when discussing the proposal of a member to consider the harmonization of the terms of 'recommendation' and 'condition of class' in RO Code, the panel unanimously agreed to take no action on the IMO instruments, leaving the relevant actions to be decided by the relevant IMO bodies when IACS feeds back to IMO the IACS action on the harmonization of the two terms.

Panel members concurred with the view that it is not necessary to develop a new procedure requirement, and agreed to set the implementation date of these IACS resolutions (other than RECs) as 1st July 2020.

Before the implementation date of 1st July 2020 for using the common terminology 'Condition of Class' only, 'Recommendations' and 'Condition of Class' are to be read as being different terms used by Societies for the same thing, i.e. requirements to the effect that specific measures, repairs, surveys etc. are to be carried out within a specific time limit in order to retain Classification.

4.2 Additional revision to use the harmonized terms of ballast tanks for their survey requirements (PSU18070)

Upon the discussions within Survey Panel under task No. PSU18070, the following changes were decided to be made to UR Z7, Z7.1 and Z7.2:

1. To use "ballast tanks" in lieu of "ballast spaces", "water ballast tanks", "tanks used for water ballast" or "spaces used for water ballast"; and
2. To use "double bottom ballast tanks" in lieu of "water ballast double bottom tanks".

Furthermore, Definition "Ballast tank" in UR Z7.2-para.1.2.1 was agreed to be revised in consistence with UR Z7- para. 1.2.1.

No TB is expected for the present revision.

5 Other Resolutions Changes:

The following IACS resolutions and Recommendations (RECs) were agreed to be revised: (PSU19010)

- Procedural Requirements: PR1A, PR1B, PR1C, PR1D, PR1 Annex, PR3, PR12, PR20, PR35 and the attachment of PR16;
- Unified Requirements: Z7, Z7.1, Z7.2, Z10.1, Z10.2, Z10.3, Z10.4, Z10.5, Z15 and Z20
- Unified Interpretations: GC13
- Recommendations: Rec.41, Rec.96, Rec.98

URs Z7 and Z7.1 (PSU18070)

6 Any hinderance to MASS, including any other new technologies:

None.

7 Dates:
Original Proposal: 14 January 2019 tasked by GPG (17044bIGm) (PSU19010)
19 December 2018 Made by: a Survey Panel member (PSU18070)
Panel Approval: 22 March 2019 (PSU19010)
3 May 2019 (PSU18070)
GPG Approval: 30 May 2019 (Ref: 17044bIGu)

- **Rev.7 (Jan 2018)**

.1 Origin of Change:

☑ Suggestion by IACS members

.2 Main Reasons for Change:

To address the FUA 11 of C73, raised by the Council of the IACS in respect to the future work directions on the implications of new technology on survey regime. A revision of UR Z7.2 is in order to consider the new technologies on Remote Inspections (RIT).

.3 List of non-IACS Member Classification Societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

Members discussed under Panel task PSU 16056 the issue allocated by GPG on 21th October 2016. The subject deals with the review of the UR and Recommendation under Panel responsibility in order to determine whether a revision could need in order to consider the new technologies on Remote Inspections (RIT). The Panel Members concurred to discuss the possible revision of the UR Z7.2 in order to address the issue.

Panel agreed the revised paragraph 1.4, 1.5 and 5.2.3. In addition, a new paragraph 1.2.14 with definition of RIT was agreed and inserted in the present revision of UR Z7.2.

No TB is expected for the present revision.

.5 Other Resolutions Changes

UR Z7, UR Z7.1, UR Z10.3

.6 Dates:

Original Proposal: 21 October 2016 assigned by GPG
Panel Approval: 08 December 2017 by Survey Panel (Ref: PSU16056)

GPG Approval: 16 January 2018 (Ref: 16151_IGq)

- **Rev.6 (Feb 2015)**

.1 Origin of Change:

☑ Suggestion by an IACS member

.2 Main Reasons for Change:

Consider appropriate text in IACS document regarding the applicability of the Thickness Measurements when the Close up survey is performed.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

Following an ACB query an IACS member proposed to add suitable text in appropriate IACS documents regarding the application of the Thickness Measurements when the close up surveys are performed as survey requirement due at the Intermediate/ Renewal Class surveys. This Member expressed the view that the requirements to execute the Thickness Measurements of the area subject to Close Up Surveys are expected into the table relevant to "MINIMUM REQUIREMENTS FOR THICKNESS MEASUREMENTS AT SPECIAL SURVEY ………" while the paragraph 1.4 of the document contains only the requirement that "Thickness Measurements of the areas subject to close up surveys shall be taken in conjunction with the close up survey".

Panel discussed and considered that wordings of Para 1.4 of current UR Z7s/10s need to be revised in order to clarify this issue; finally Panel agreed to add additional wording to Para.1.4.

.5 Other Resolutions Changes

The identical amendment affects UR Z7, UR Z7.1, UR Z10.1, UR Z10.2, UR Z10.3, UR Z10.4 and UR Z 10.5.

.6 Dates:

Panel Approval: At 19th Survey Panel Meeting (6 March 2014)
GPG Approval: 05 February 2015 (Ref: 14193_IGc)

- **Rev.5 (Jan 2014)**

.1 Origin of Change:

☑ Suggestion by an IACS member

.2 Main Reason for Change:

Consider appropriate text in IACS document regarding class period for lengthy conversions.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

With reference to IMO Res. A1053(27) (5.5 Application of "special circumstances") an IACS member proposed to add suitable text in appropriate IACS document regarding class period for lengthy conversions. This Member expressed that when a renewal survey has been completed, the new 5 year class period would normally be calculated from the expiry of previous class period/class certificate and in some cases this might result in unreasonably short time from one renewal survey completion until the next renewal would be due.

Panel discussed the matter under item PSU13051 and considered that wordings of Para 2.13 of current UR Z7s/10s (second sentence) could address this issue but finally agreed to add additional text to Para.2.1.3 in order to clarify this matter.

.5 Other Resolutions Changes

The identical amendment affects UR Z7, UR Z7.1, UR Z10.1, UR Z10.2, UR Z10.3, UR Z10.4 and UR Z 10.5.

.6 Dates:

Original Proposal: At 18th Survey Panel Meeting (5 September 2013)
GPG Approval: 14 January 2014 (Ref: 12011aIGd)

- **Rev.4 (May 2013)**

.1 Origin of Change:

☑ Suggestion by an IACS member

.2 Main Reason for Change:

A Member suggested clarifying the paragraph 6.2.1 of UR Z7.2 regarding the approval of thickness measurement firms in respect of thickness measurements of ships less than 500 gross tonnage (PSU 13005).

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

This matter was discussed by correspondence within the Survey Panel and at the Survey Panel meeting. Members expressed that clarification is not necessary since UR Z17 has been referenced which states firms carrying out thickness measurements on non-ESP vessels under 500 GT do not require certification. However the member who proposed to discuss this issue referred that other UR 7s and 10s are synchronized with UR Z17 for propelled ships of "....of 500gt and above...." and only UR Z7.2 needs some clarification.

Panel during 17th Panel agreed to clarify the paragraph 6.2.1 of UR Z7.2.

.5 Other Resolutions Changes

None

.6 Dates:

Original Proposal: 4 February 2013 Made by a Member
Panel Approval: 7 March 2013 during 17th Survey Panel meeting
GPG Approval: 22 May 2013 (Ref: 9640_IGn)

- **Rev.3 (July 2011)**

.1 Origin of Change:

☑ Suggestion by an IACS member

.2 Main Reason for Change:

Following external audit a member was advised that a small temporary doubler on a cross-deck strip of a bulk carrier should have been promptly and thoroughly repaired at the time of survey. The member carried out an investigation and found that the actions of the surveyor were fully justifiable, the temporary repair and short term Condition of Class imposed were an appropriate method of dealing with such a situation. The member advised that the current requirements for 'Prompt and Thorough Repair' stipulated under the UR 7 and UR 10 series do not give any leeway for carrying out temporary repairs (and imposing a Recommendation/Condition of Class in accordance PR 35) where the damage in question is isolated and localised, and in which the ship's structural integrity is not impaired.

The Survey Panel discussed the matter and agreed that under carefully defined circumstances a temporary repair and short term Recommendation/Condition of Class would be an appropriate course of action.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

The matter was discussed by correspondence within the Survey Panel and at the Autumn 2010 Panel Meeting. Following discussion at which the possibility of a Unified Interpretation being raised was considered, it was eventually decided to make direct amendment to the relevant Unified Requirements.

The wording of the new paragraph to be inserted as Para 1.3.3 in all relevant Unified Requirements was extensively discussed prior to agreement.

The proposal was unanimously agreed by Survey Panel Members.

.5 Other Resolutions Changes

The identical amendment affects UR Z7, UR Z7.1, UR Z7.2, UR Z10.1, UR Z10.2, UR Z10.3, UR Z10.4 and UR Z 10.5.

.6 Dates:

Original Proposal: *September 2010 Made by a Member*
Panel Approval: *March 2011*
GPG Approval: *27 July 2011 (Ref: 11118_IGb)*

See separate TB document in Annex 5.

◄▼►

Note: There is no separate Technical Background (TB) document available for Rev.4 (May 2013), Rev.6(Feb 2015), Rev.7 (Jan 2018) and Rev.8 (May 2019).

Technical Background Document

UR Z7.2 (NEW May 2007)

(Survey Panel Task 9 – Develop survey requirements for Gas Tanker Ballast Spaces)

1. Objective:
Develop survey requirements for ballast spaces of gas tankers.

2. Background
DNV requested at WP/SRC Annual meeting October 2004 to develop survey requirements for ballast spaces of gas tankers.

3. Discussion
The task has been carried out by a Project Team chaired by DNV Survey Panel member and with Survey Panel members from BV, LR, NK and RINA.

The Project Team drafted a new Unified Requirement UR Z7.2 « Hull Surveys for Liquefied Gas Carriers » applicable to surveys of hull structure and piping systems, except piping covered by Z16, in way of pump rooms, compressor rooms, cofferdams, pipe tunnels, void spaces and fuel oil tanks within the cargo area and all ballast tanks.

The requirements are additional to the classification requirements applicable to the remainder of the ship, for which Z7 is to be referred.

Z16 is to be referred to for periodical surveys of cargo installations on ships carrying liquefied gases in bulk.

The draft UR Z 7.2 was presented to the Survey Panel members on the 13th-15th September 2006 meeting at ABS Headquarters in Houston and was agreed upon in principle by the Panel members.

Further comments by members were considered by the Project Team which proposed an updated version of the UR Z7.2 including some optional items. This version was submitted to the Panel for final decisions at the Spring meeting in February 2007.

4. Implementation
The Survey Panel is of the view that the Members need 12 months from the adoption date to implement these amendments into their class rules/procedures. Assuming that GPG and Council approve the amendments during the first half of 2007, the Survey Panel would propose **July 2008** as implementation date.

Submitted by Survey Panel Chairman
18 April 2007

Permsec note (June 2007):
New UR Z7.2 adopted by GPG 8 May 2007 (5031hIGi) with an implementation date of 1 July 2008.

Technical Background

URs Z7(Rev.15), Z7.1(Rev.5), Z7.2(Rev.1), Z10.1(Rev.15), Z10.2(Rev.26), Z10.3(Rev. 9), Z10.4(Rev.6), Z10.5(Rev.8) – November 2007

Survey Panel Task 1 – Annual Review of Implementation of IACS Resolutions

1. Objective

To review IACS Resolutions annually and discuss or propose amendments as deemed necessary.

2. Background

This proposed amendment to all URZ7s and URZ 10s was raised by the Panel member from DNV due to Owners crediting tanks concurrently under intermediate and special survey.

3. Methodology of Work

Survey Panel members through correspondence.

4. Discussion

The Panel member from DNV raised the issue of Owners having the ability of crediting spaces and thickness measurements only once in a 54 month interval, due to the availability of concurrent crediting of spaces and thickness measurements due to the flexible time window that is currently allowed between the intermediate survey and the special survey.
After a presentation and discussion lead by the DNV Panel member, all Survey Panel members agreed to the argument given by DNV, and further agreed to make the necessary changes in all URZ7s and URZ10s where Owners are not allowed to concurrently credit surveys and thickness measurements of spaces.

5. Implementation

The Survey Panel is of the view that the Members need 12 months from the adoption date to implement these amendments into their class rules. Assuming that GPG approve to the amendments, the Survey Panel would propose January 2009 as an implementation date.

Submitted by Survey Panel Chairman
22 October 2007

Permanent Secretariat note (December 2007):

During GPG discussion DNV proposed that *"since this matter will be discussed between Owner and Class mainly in connection with the forthcoming Special Survey, DNV would prefer to locate this text, not only as part of Intermediate Survey, but also as a new text for the Special Survey."* This was supported by BV, ABS, RINA and KR.

The revised documents were approved, with DNV's proposal and an implementation date of 1 January 2009, on 15 November 2007 (ref. 7690_IGb).

Technical Background

URs Z7(Rev.16), Z7.1(Rev.6), Z7.2(Rev.2), Z10.1(Rev.16), Z10.2(Rev.27), Z10.3(Rev.11), Z10.4(Rev.7) and Z10.5(Rev.9) - March 2009

Survey Panel Task 62:

A) Harmonization of UR Z10.1, Z10.2, Z10.4 and Z10.5 with UR Z10.3 with respect to items 5.5.4.4 and 5.6.2.

B) Harmonization of UR Z7, Z7.1, Z10.1, Z10.2, Z10.3, Z10.4 and Z10.5 with UR Z7.2 with respect to the definition of the corrosion prevention system and with respect to the footnote 1 related to semi-hard coatings.

C) Harmonization of the definition of Ballast Tank in UR Z7(Rev.14)

1. Objective

A) Amend the texts of items 5.5.4.4 and 5.6.2 in Unified Requirements Z10.1, Z10.2, Z10.4 and Z10.5 in order to align them with those in UR Z10.3, in which they were changed while performing Task 55, whereas in the other UR Z10s they were kept unchanged on the grounds that this change was out of the scope of Task 55.

B) Amend the definition of “Corrosion Prevention System” and include a Footnote 1 related to semi-hard coatings in Unified Requirements Z7, Z7.1, Z10.1, Z10.2, Z10.3, Z10.4 and Z10.5 in order to align them with those adopted in UR Z7.2, when this new UR was issued.

C) Amend UR Z7 (Rev. 14) in all items where the term “Ballast Tank” is used in order to get them harmonized with the definition itself.

2. Background

The task, as regards item A), was triggered by a Member Society, while performing Task 55, on the grounds that this part was out of the scope of the task and then should have been dealt with in a separate task.
The task, as regards item B), was triggered as a consequence of the “New Business action item 2” of the Minutes of the September 2008 Survey Panel meting, for sake of harmonization of the various URZs.
The task, as regards item C), was triggered as a consequence of the “Task 54-Examination of Double Bottom Ballast Tanks at annual surveys” of the Minutes of March 2008 Survey Panel meeting, for sake of harmonization of the definition of Ballast Tank in UR Z7(Rev.14).

3. Discussion

The task was carried out by correspondence. All the amended texts for the affected URs were prepared by the Survey Panel Member who had chaired the PT on Task 55, in accordance with the Form A approved by GPG. In addition to the objectives outlined in the Form A, an amendment was added to item 1.3.1 of UR Z10.2 and UR Z10.5 in which the reference 3.2.3.6 in the last item of the list was replaced by 3.2.3.10 as can be correctly verified in the text.
The amended URs were circulated to all Survey Panel Members for review, comments and agreement. The texts of the URs were unanimously agreed by all Members.

4. Implementation

The Survey Panel is of the view that the Member Societies need at least 12 months from the adoption date to implement these amendments into their class rules/procedures. Therefore, in the first version of all amended URs the following implementation sentence should be proposed:

Changes introduced in Rev .xx are to be uniformly applied by Member Societies and Associates for surveys commenced on or after [not less than 12 months after the adoption by GPG/Council].

Since it is common practice and convenience to have implementation dates either on 1st January or on 1st July of the year, the Survey Panel proposes the 1st July 2010 as implementation date, if GPG/Council approve the URs not later than 30 June 2009.

Submitted by Survey Panel Chairman
28 February 2009

Permanent Secretariat notes (April 2009):

1. The amended URs were approved by GPG on 18 March 2009 (ref. 7718bIGd).
2. During the typesetting process it was noted that para 5.1.5 of UR 7.2 was inconsistent with the amended URs and so following consultation with the Survey Panel this was also amended at this time.
3. Regarding the implementation date, GPG agreed to use 1st July 2010 provided that it was consistently used for the amended URs.

Technical Background for UR Z7.2 Rev.3, July 2011

1. Scope and objectives

Review the requirement for repairs within IACS UR 7 and UR 10 series, in particular the requirement for Prompt and Thorough Repair, with a view to developing wording that would permit a temporary repair and the imposition of a Recommendation/ Condition of Class under specific and controlled circumstances, and in accordance with PR35.

2. Engineering background for technical basis and rationale

There are instances, for example a localised, isolated and very minor hole in a cross-deck strip, at which a suitable temporary repair, for example by welding or doubling, and the imposition of a suitable short term Recommendation/ Condition of Class for permanent repair at a later date, are considered very adequate methodology for dealing with the defect.

Current IACS Requirements in the UR Z7 and Z10 series, for Prompt and Thorough repair, would not permit this to be an option, the defect would have to be permanently Promptly and Thoroughly repaired, which might require removing cargo, moving to a repair berth and staging inner spaces.

Under the Requirements of IACS Procedural Requirement PR 35 the methodology of Temporary Repair and imposition of a suitable short term Recommendation/ Condition of Class for permanent repair at a later date is fully permissible.

3. Source/derivation of the proposed IACS Resolution

Based upon discussion within the IACS Survey Panel.

4. Summary of Changes intended for the revised Resolution:

Following the definition of Prompt and Thorough Repair in the Unified Requirement, a new paragraph is proposed to be added:-

"1.3.3 Where the damage found on structure mentioned in Para. 1.3.1 is isolated and of a localised nature which does not affect the ship's structural integrity, consideration may be given by the surveyor to allow an appropriate temporary repair to restore watertight or weather tight integrity and impose a Recommendation/Condition of Class in accordance with IACS PR 35, with a specific time limit."

5. Points of discussions or possible discussions

a) The points of discussion are as indicated in Sections 2 and 4 above.

b) Discussion took place on whether to prepare this amendment as a Unified Interpretation of IMO Resolution A.744(18)/UR Z7 and Z10 series, finally it was agreed to make direct amendment to the relevant URs.

c) It is proposed that this amendment be submitted directly to the IMO DE/MSC Committees for consideration of amending directly IMO Res. A744(18)

6. Attachments if any

None

Technical Background for UR Z7.2 Rev.5, Jan 2014

1. Scope and objectives

Consider appropriate text in IACS document regarding class period for lengthy conversions.

2. Engineering background for technical basis and rationale

As per the IMO Res. A1053 (27), lengthy conversions (not necessarily of major character) or other major repair work can be assigned for a 5 year period from the date of completion of conversion/repairs/surveys.

3. Source / derivation of the proposed IACS Resolution

None

4. Summary of Changes intended for the revised Resolution

Following additional text was included to section 2.1.3 to clarify the class period for lengthy conversions

"In cases where the vessel has been laid up or has been out of service for a considerable period because of a major repair or modification and the owner elects to only carry out the overdue surveys, the next period of class will start from the expiry date of the special survey. If the owner elects to carry out the next due special survey, the period of class will start from the survey completion date."

5. Points of discussions or possible discussions

Additional text to Para.2.1.3 was discussed in order to clarify class period.

6. Attachments if any

None

UR Z10.1 "Hull Surveys of Oil Tankers"

Summary

This revision is to harmonize the revised requirements in line with the amendments made to ESP Code vide Res.MSC.525(106)

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev.25 (Feb 2023)	08 February 2023	1 July 2024

NEW (1992)	*No record*	

**** Notes:***

1. *Changes introduced in Rev.14 are to be uniformly implemented for surveys commenced on or after 1 January 2008, whereas statutory requirements of IMO Res. MSC 197(80) apply on 1 January 2007.*

2. *Changes introduced in Rev.9 to UR Z10.1, which come from Res. MSC.105(73) and MSC.108(73) are to be applied by all Member Societies and Associates from 1 July 2002.*
   Changes introduced in Rev.9 to UR Z10.1, other than the above, are to be implemented by all Member Societies and Associates within one year of the adoption by Council.

- **Rev.25 (Feb 2023)**

.1 Origin of Change:

   - Suggestion by an IACS member
   - Based on IMO Regulation

.2 Main Reason for Change:

To revise the definition of Oil Tanker to exclude ships carrying oil in independent tanks not part of the ship's hull such as asphalt carriers in line with the amendments made to ESP Code vide Res.MSC.525(106).

To revise the definition of Ballast tank from use of 'solely' carriage of salt water to 'primarily' use in line with other IACS URs and ESP Code.

To refine the wording of tank testing requirements in line with the amendments made to ESP Code vide Res.MSC.525(106).

To refine the wording of ballast tanks examination requirements at annual surveys in line with the amendments made to ESP Code vide Res.MSC.525(106).

To delete a reference, IACS UR Z10.1, in line with other IACS URs and the amendments made to ESP Code vide Res.MSC.525(106).

.3 List of non-IACS Member classification societies contributing and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

- One survey panel member raised a question whether oil tankers having independent tanks like asphalt carriers are applicable to the ESP Code because the current definition of oil tankers includes those tankers. Survey panel unanimously agreed to the view that those ships carrying oil in independent tanks not part of the ship's hull such as asphalt carriers are not subject to the ESP Code and decided to modify the definition in UR 10s and the ESP Code. It was accepted in SDC8 and published as Res.MSC.525(106). (PSU19047)

- One survey panel member pointed out the definition of ballast tank in UR 10s are different from other URs like UR7/7.1/7.2 and the ESP Code, so panel decided to modify the wording 'solely' to 'primarily'. (PSU20004)

- One survey panel member proposed to accept tank testing carried out by crew under the direction of the Master like oil tankers and decided to insert the requirements for oil tankers after minor modification of wording. However, at SDC8, the proposal for bulk carriers was rejected but the minor modification of wording for oil tankers was accepted. Survey panel considered to resubmit this issue to next SDC but decided not to do because it was disagreed by Ship owners/operators associations like INTERCARGO and ICS. (PSU17030/17039)

- One survey panel member suggested to refine the wording 'extended annual/intermediate survey' to 'examination of ballast tanks at annual surveys' in Executive Hull Summary and panel decided to modify it in the ESP Code first. It was submitted to SDC8 and included in Res.MSC.525(106). (PSU18056)

- One survey panel member pointed out that the references in UR Z10s need to be deleted to be in line with other UR Z10s. And panel decided to delete the reference of itself in UR Z10.1 in line with the amendments made to ESP Code vide Res.MSC.525(106). (PSU19057)

No TB is expected for the present revision.

.5 Other Resolutions Changes:

Unified Requirements: Z10.2, Z10.4 and Z10.5

.6 Any hinderance to MASS, including any other new technologies:

None

.7 Dates:

Original Proposal:	19 September 2019	(PSU19047)
	28 January 2020	(PSU20004)
	19 September 2017	(PSU17030)
	17 November 2017	(PSU17039)
	24 October 2017	(PSU18056)
	18 December 2019	(PSU19057)
Panel Approval:	12 October 2021	(PSU21026_ISUf)
GPG Approval:	08 February 2023	(22198_IGd)

- **Rev.24 (May 2019)**

.1 Origin of Change:

  - o Suggestion by an IACS member

.2 Main Reason for Change:

This revision is to address the policy decision made by GPG using the common terminology 'Condition of Class'(CoC) instead of the terms 'Recommendation/ Condition of Class' based on the outcome of III 5.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

During the 29th panel meeting, the panel discussed about the comments of members, and concurred with the view to retain the present definitions of CoC in the IACS resolutions with the wording 'Recommendation' to be removed. The panel also agreed to use the term 'Statutory Condition' for the 'recommendation' of the statutory certificates in IACS resolutions and RECs, and when discussing the proposal of a member to consider the harmonization of the terms of 'recommendation' and 'condition of class' in RO Code, the panel unanimously agreed to take no action on the IMO instruments, leaving the relevant actions to be decided by the relevant IMO bodies when IACS feeds back to IMO the IACS action on the harmonization of the two terms.

Panel members concurred with the view that it is not necessary to develop a new procedure requirement, and agreed to set the implementation date of these IACS resolutions (other than RECs) as 1st July 2020.

Before the implementation date of 1st July 2020 for using the common terminology 'Condition of Class' only, 'Recommendations' and 'Condition of Class' are to be read as being different terms used by Societies for the same thing, i.e. requirements to the effect that specific measures, repairs, surveys etc. are to be carried out within a specific time limit in order to retain Classification.

No TB is expected for the present revision.

.5 Other Resolutions Changes:

The following IACS resolutions and Recommendations (RECs) were agreed to be revised:

- Procedural Requirements: PR1A, PR1B, PR1C, PR1D, PR1 Annex, PR3, PR12, PR20, PR35 and the attachment of PR16;
- Unified Requirements: Z7, Z7.1, Z7.2, Z10.1, Z10.2, Z10.3, Z10.4, Z10.5, Z15 and Z20
- Unified Interpretations: GC13
- Recommendations: Rec.41, Rec.75, Rec.96, Rec.98

.6 Any hinderance to MASS, including any other new technologies:

None

.7 Dates:

Original Proposal: 14 January 2019 tasked by GPG (17044bIGm)
Panel Approval: 22 March 2019 (PSU19010)
GPG Approval: 30 May 2019 (17044bIGu)

- **Rev.23 (Jan 2018)**

.1 Origin of Change:

☑ Suggestion by IACS members

.2 Main Reason for Change:

In order to introduce new provisions into the ESP Code which were found among the ESP Code and relevant UR Z10s, a series of items of UR Z10s shall be amended accordingly with ESP Code.

.3 List of non-IACS Member Classification Societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

Panel members discussed this issue under PSU17018: "Thickness measurement company" was replaced with "Thickness measurement firm" throughout the UR; some paragraphs were to be revised for consisting with ESP Code; etc.

During the 26th Survey Panel Meeting, the Panel discussed the divergence and reached the agreements with the revisions.

No TB is expected for the present revision.

.5 Other Resolutions Changes

UR Z10.2, UR Z10.3, UR Z10.4, UR Z10.5

.6 Dates:

Original Proposal: 22 October 2016 by a Survey Panel Member
Panel Approval: 24 December 2017 by Survey Panel (Ref: PSU17018)
GPG Approval: 15 January 2018 (Ref: 17189_IGc)

- **Rev.22 (Feb 2015)**

.1 Origin of Change:

☑ Suggestion by an IACS member

.2 Main Reasons for Change:

a) To consider appropriate text in IACS document regarding the applicability of the Thickness Measurements when the Close up survey is performed.
b) To specify the minimum content of the Tank Testing guideline cited at paragraph 2.5.1.bullet a).

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

a) Following an ACB query an IACS member proposed to add suitable text in appropriate IACS documents regarding the application of the Thickness Measurements when the close up surveys are performed as survey requirement due at the Intermediate/ Renewal Class surveys. This Member expressed the view that the requirements to execute the Thickness Measurements of the area subject to Close Up Surveys are expected into the table relevant to "MINIMUM REQUIREMENTS FOR THICKNESS MEASUREMENTS AT SPECIAL SURVEY ………" while the paragraph 1.4 of the document contains only the requirement that "Thickness Measurements of the areas subject to close up surveys shall be taken in conjunction with the close up survey".

   Panel discussed the matter under item PSU13051 and considered that wordings of Para 1.4 of current UR Z7s/10s need to be revised in order to clarify this issue; finally Panel agreed to add additional wording to Para.1.4.

b) An IACS Member following the discussion of PSU 14017 (relevant to the drafting of a Guidelines for Master tank testing) proposed to improve the content of the bullet a) of paragraph 2.5.1 of the UR by inserting the description of the minimum requirements that need to be specified inside the "Cargo Tank Testing Procedure" to be used when Master of a Tanker is allowed to perform the cargo tank testing. Panel concurred with the proposal (ref, message PSU14017…ISUc), the sentence has been modified as follow
   "a tank testing procedure, <u>specifying fill heights, tanks being filled and bulkheads being tested,</u> has been submitted by the owner and reviewed by the Society prior to the testing being carried out";

.5 Other Resolutions Changes

i) The identical amendment affects UR Z7, UR Z7.1, UR Z7.2, UR Z10.2, UR Z10.3, UR Z10.4 and UR Z 10.5.
ii) The amendment b) affects also UR Z10.3, UR Z10.4.

.6 Dates:

Panel Approval: Amendment a) at 19th Survey Panel Meeting (6 March 2014)
Amendment B) on 29 July 2014 by correspondence under PSU14017.

GPG Approval: 05 February 2015 (Ref: 14193_IGc)

• Rev.21 (Jan 2014)

.1 Origin of Change:

☑ Suggestion by IACS members
☑ Suggestion by GPG

.2 Main Reason for Change:

a) To consider appropriate text in IACS document regarding class period for lengthy conversions.

b) To align the difference between PR37 and URZ's regarding safe entry to confined spaces.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

a) With reference to IMO Res. A1053 (27) (5.5 Application of "special circumstances") an IACS member proposed to add suitable text in appropriate IACS document regarding class period for lengthy conversions. This Member expressed that when a renewal survey has been completed, the new 5 year class period would normally be calculated from the expiry of previous class period/class certificate and in some cases this might result in unreasonably short time from one renewal survey completion until the next renewal would be due.

Panel discussed and considered that wordings of Para 2.1.3 of current UR Z7s/10s (second sentence) could address this issue but finally agreed to add additional text to Para 2.1.3 in order to clarify this matter. (PSU13024)

b) Panel discussed to clarify the survey requirements in PR37 and URZ's regarding safe entry to confined spaces. Panel considered that the safety issues of surveyor should be dealt by PR37. At 18th Panel meeting, Panel concluded to delete requirements from UR Z10s which were already covered by the PR37. (PSU13032)

.5 Other Resolutions Changes

a) The identical amendment affects UR Z7, UR Z7.1, UR Z7.2, UR Z10.2, UR Z10.3, UR Z10.4 and UR Z 10.5.

b) The identical amendment affects UR Z10.2, UR Z10.3, UR Z10.4 and UR Z 10.5.

.6 Dates:

Panel Approval: 7 November 2013 by Survey Panel
GPG Approval: 14 January 2014 (Ref: 12011aIGd)

- **Rev.20 (May 2013)**

.1 Origin of Change:

☑ Suggestion by IACS members
☑ Suggestion by GPG in response to the request of EG/SoS

.2 Main Reason for Change:

a) To establish a consistent practice among Members through amendments to the requirements related to pressure testing of cargo tanks with the correct level of safety for accepting Master's statement that the pressure testing has been carried out according to requirements. (PSU 9014, GPG 9640)
b) To introduce provision in UR Z10s that Rescue and emergency response equipment must be suitable for the configuration of the space being surveyed including the size of the access points.(PSU 12032, GPG 12138_)
c) An inquiry from an IACS member whether the 'Other equivalent means' referred in Para 5.3.2 of IACS UR Z10.2 include the use of Cherry Pickers for survey of other structures. (PSU 12022)

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

a) Panel considered revising the requirements in UR Z10.1 and Z10.4 for pressure testing of cargo tank bulkheads which are not adjacent to non-cargo tanks/space for oil tankers in order to accept Master's statement at class renewal survey.

Survey Panel reported this issue to GPG and asked further instruction, and accordingly, GPG instructed Survey Panel to consider this issue based on two major opinions from GPG members (i. e. the 1st view was that IACS should expand UR Z10.1 and UR Z10.4 item 2.5.1 with a text similar to the one accepted for Chemical Carriers in UR Z10.3 item 2.5.1 while the 2nd view was that external boundaries of all cargo tank bulkheads adjacent to non-cargo tanks/spaces (e.g. facing ballast tanks, void spaces, pipe tunnels, fuel oil tanks, pump rooms or cofferdams) shall still be required to be tested in the presence of a Surveyor.

Panel discussed and agreed to amend the requirement of para 2.5.1 of UR Z10.1 and UR Z10.4 in order to accept master's statement for cargo tank testing.

b) GPG Chairman requested to consider the suggestion of EG/SoS to clarify the wording in UR Z 10.1 – 10.5 to make it compliance with draft PR37 submitted by EG/SoS.

The Survey Panel discussed this matter and introduced a new (sub-)section 5.5 “Rescue and emergency response equipment” in line with the suggestion of EG/SOS.

c) Discussion of this matter initiated by a Panel member regarding the use of Cherry Pickers in Cargo Holds with reference of IACS URZ10.2. In accordance with UI SC191 and Rec 91, the Cherry Picker is allowed up to 17m height for Cargo Hold structure (ships constructed after 2006 for Alternative means of access). As per the provisions of URZ10.2, Cherry pickers are allowed for survey of side shell frames only.

Panel discussed and considered that Para 5.3.2 of UR Z10.2 allows the use of Cherry Pickers as 'Other equivalent means'. Accordingly, Panel agreed to clarify this matter by including text “hydraulic arm vehicles such as conventional cherry pickers” to UR Z10s and UR Z7s for a ship not subject to the above 17m restriction.

.5 Other Resolutions Changes

a) The identical amendment affects UR Z10.4
b) The identical amendment affects UR Z10.2, UR Z10.3, UR Z10.4 and UR Z 10.5.
c) The identical amendment affects UR Z7, UR Z7.1, UR Z10.2, UR Z10.3, UR Z10.4 and UR Z 10.5.

.6 Dates:

Survey Panel Approval: 7 March 2013 during 17th Survey Panel Meeting
GPG Approval: 22 May 2013 (Ref: 9640_IGn)

- **Rev.19 (July 2011)**

.1 Origin of Change:

☑ Suggestion by an IACS member

.2 Main Reason for Change:

Following external audit a member was advised that a small temporary doubler on a cross-deck strip of a bulk carrier should have been promptly and thoroughly repaired at the time of survey. The member carried out an investigation and found that the actions of the surveyor were fully justifiable, the temporary repair and short term Condition of Class imposed were an appropriate method of dealing with such a situation. The member advised that the current requirements for ‘Prompt and Thorough Repair’ stipulated under the UR 7 and UR 10 series do not give any leeway for carrying out temporary repairs (and imposing a Recommendation/Condition of Class in accordance PR 35) where the damage in question is isolated and localised, and in which the ship’s structural integrity is not impaired.

The Survey Panel discussed the matter and agreed that under carefully defined circumstances a temporary repair and short term Recommendation/Condition of Class would be an appropriate course of action.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

The matter was discussed by correspondence within the Survey Panel and at the Autumn 2010 Panel Meeting. Following discussion at which the possibility of a Unified Interpretation being raised was considered, it was eventually decided to make direct amendment to the relevant Unified Requirements.

The wording of the new paragraph to be inserted as Para 1.3.3 in all relevant Unified Requirements was extensively discussed prior to agreement.

The proposal was unanimously agreed by Survey Panel Members.

.5 Other Resolutions Changes

The identical amendment affects UR Z7, UR Z7.1, UR Z7.2, UR Z10.1, UR Z10.2, UR Z10.3, UR Z10.4 and UR Z 10.5.

.6 Dates:

Original Proposal: *September 2010 Made by a Member*
Panel Approval: *March 2011*
GPG Approval: *27 July 2011 (Ref: 11118_IGb)*

- **Rev.18 (Mar 2011)**

.1 Origin for Change:

☑ Suggestion by IACS member

.2 Main Reason for Change:

1) Inconsistency of the definition of transverse section of the ship given in URZ7 and URZ10s.

2) Update of references in the Executive Hull Summary Table IX.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None.

.4 History of Decisions Made:

Item 1) was proposed by RS and item 2) was proposed by GL. Both amendments were agreed by the Panel.

.5 Other Resolutions Changes

UR Z10.2, Z10.3, Z10.4 and Z10.5.

.6 Dates:

Original Proposal: *January 2010, made by Survey Panel*
Survey Panel Approval: *July/November 2010*
GPG Approval: *24 March 2011 (Ref: 10170_IGe)*

- **Rev.17 (Feb 2010)**

.1 Origin for Change:

☑ Suggestion by IACS member

.2 Main Reason for Change:

As MARPOL I was revised, the reference to MARPOL I/13 (3) in paragraph 1.2.2bis should be changed.

.3 History of Decisions Made:

GL proposed the change and it was agreed by the panel.

.4 Other Resolutions Changes

Technical Background Document
WP/SRC – Trilateral Discussions
UR Z 10.1 – Proposed Rev. 6

Objective and Scope:

WP/SRC was tasked to consider OCIMF/INTERTANKO proposals to amend the Enhanced Survey Program.

Source of Proposed Requirements:

WP/SRC members discussed and reviewed the proposals extensively through correspondence and their meeting.

Points of Discussion:

WP/SRC unanimously agreed to the proposed draft UR Z 10.1. Consensus could not be achieved on any of the other OCIMF/INTERTANKO proposals. Refer to the Chairman's letters to GPG dated 4 February 1999 and 11 March 1999.

Date of submission: 6 May 1999
By WP/SRC Chairman's e-mail

Technical Background for Rev. 6.1, Z10.1

1. Scope of objectives

Revise the paragraph 2.2.1.3 to clarify that piping on deck is to be examined.

2. Points of discussions or possible discussions

- Before the ESP tripartite group meeting in October 1999, it was agreed to change the para. 2.2.1.3 by inserting "Cargo piping on deck, and" at the beginning of the sentence.

  The change from ".....under working CONDITIONS" to "....under working pressure" was made in the last set of amendments of Z10.1--and was considered to have the same meaning as OCIMF's proposed "...to working pressure." We are agreeable to changing "under" to "to".

- However, after the ESP technical working group meeting in October 1999, it was agreed to change the para:
  Cargo piping ondeck, including COW piping, all piping systems within.....

3. Source/deviation of proposed requirements

The final minutes of the ESP Working Group meeting reads:

> The agreement already reached on piping in tanks was reaffirmed. It was reported by the Chairman of the Working Group, Mr. Bourneuf, that the IACS Council agreed to include cargo piping on deck as per UR Z10.1 para. 2.2.1.3 herein after attached. It was confirmed by IACS, at the request of the Working Group that cargo piping does include COW piping.

Prepared by the IACS Permanent Secretariat

Technical Background Document

UR Z10.1 – Revision 7
For ExCM decisions

Objective and Scope:

Revise UR Z10.1 to introduce ExCM (Extraordinary Council Meeting in Feb 2000) decision to UR Z10's

- ExCM FUA 2-1: All ballast tanks adjacent to cargo tanks with heating coils shall be examined internally on an annual basis after the ship has reached 15 years of age.

- ExCM FUA 2-2: Intermediate surveys of ships subject to ESP, which are over 15 years of age, will be enhanced to the scope of the preceding special survey with dry docking or under water survey as applicable.

Source of Proposed Requirements:

The proposed requirements were developed by WP/SRC Chairman, shortly after GPG 48th meeting:

- The para. 3.2.5.2 for ExCM FUA 2-1:
- The para. 4.2.2, 4.2.3 & 4.2.4 for ExCM FUA 2-2.
- The para. 7.1.1 for compatibility with the PR 19 (ABS GPG suggested).

Points of Discussion:

-

Unresolved Comments:

-

Discussions:

WP/SRC Chairman, when submitting draft revision to GPG, raised the following concerns:

- What tanks are required by the term "ADJACENT" ?

  WP/SRC Chairman said that tanks with a common line boundary have not been a problem since there is very little transfer of heat and should not be included.

  GPG exchanged views on this point and agreed to delete the wording "or line" from the para. 3.2.5.2 which reads: Oil Tankers exceeding 15 years of Age: All Ballast Tanks adjacent to (i.e., with a common plane ~~or line~~ boundary) a cargo tank with heating coils is to be examined internally.

- Ships using heating coils in cargo tanks

  Most existing single hull crude oil carriers only use heating coils in the slop tanks which usually do not have ballast tanks as boundaries. White oil product carriers do not need heating and therefore they should not be included in additional annual survey requirements for ballast tanks. Majority of GPG Members agreed.

Submitted by the Permsec
On 18 Sept 2000

Technical Background Document
WP/SRC Task 77
UR Z7 – Proposed Draft Revision 7
(Including Rev.8 of Z10.1, Rev.11 of Z10.2, Rev.4 of Z10.3)

Objective and Scope:

Extend the requirements for permanent repairs at the time of survey in UR Z 10.2 to all ships.

Source of Proposed Requirements:

The proposed requirements were developed by WP/SRC members through correspondence and discussions at the September 2000 meeting.

Points of Discussion:

UR Z7 was amended to apply "prompt and thorough" repairs to all vessels. The new wording defines a prompt and thorough repair to be a repair as a result of wastage and not an incident such as contact damage where a temporary repair or deferral of repairs could be permitted. This wording is more explicit than the wording in UR Z10.2 and should achieve a uniform application among the Members.

WP/SRC also agreed to include these requirements in Z10.1, Z10.2 and Z10.3 in order to not effect A.744(18).

WP/SRC unanimously agreed to the draft UR.

Note by Permsec

GPG 49 (11-13 Oct. 2000) agreed that the same changes be introduced to Z10's and carried out editorial review of Z 10's.

Technical Background Document
WP/SRC Task 75
UR Z10.1 – Proposed Draft Revision 8
&
Z10.3 – revision 4

Objective and Scope:

Develop a definition of 'related piping' as contained in UR Z10.1 and requirements for survey.

Source of Proposed Requirements:

The proposed requirements were developed by WP/SRC members through correspondence.

Points of Discussion:

The proposal limits the definition of "related piping" to the piping systems which require testing. This will not include hydraulic oil piping for remote control valves or anchor/mooring equipment which OCIMF may have wanted included. WP/SRC feels that related piping systems are those that are unique to an oil carrier and was the original intent of the wording.

WP/SRC unanimously agreed to the draft UR.

Note by the Permsec:

LR GPG proposed to change Z10.1 as follows:

> "piping systems for the handling of cargo / cargo residues and water ballast and additionally bilge systems in combination carriers. 8220iLRa, 30/8/2000"

GPG Chairman asked WP/SRC to discuss LR's proposal to include "bilge piping systems" in Z10.1 at their 2000 September meeting.

WP/SRC Chairman reported back to GPG on 22 September 2000 as follows:

> 1. "Cargo piping" adequately covers and is understood by all members to include cargo stripping piping, just as "Ballast piping" includes ballast stripping piping.
>
> 2. WP/SRC is of the opinion that bilge piping on combination carriers should not be added to the proposed revision due to the fact that it is a separate system which usually run through a pipe tunnel and is not hydro tested at new construction. The system also operates on a vacuum and is blanked off when oil is carried.
>
> Therefore, WP/SRC maintains its agreement that the previously submitted text is the preferred by all members.

GPG agreed that a similar amendment be made to Z10.3.

Based on the above discussion at GPG level, the revised of Z10.1 and Z10.3 was finally approved at GPG 49.

Submitted by WP/SRC Chairman

On 27 July 2000

(This view was shared by the majority of GPG Members, however, it has not been codified in Z 10.1 because no need was identified to prescribe it as a Unified Requirement.)

- Identify tanks with heating coils

  WP/SRC Chair said that the vessel's survey status does not tell us tanks fitted with heating coils.

- Coating Condition and Substantial Corrosion Survey Requiremnets

  Ballast tanks with poor coating, no coating or substantial corrosion identified at a previous survey already requires annual survey. With enhanced intermediate survey, all ballast/cargo tanks will be examined and gauged at special/intermediate survey and coating condition & substantial corrosion should be identified at that time. If coating condition is reported good or fair, it may be adequate to only verify the coating condition at annual survey of ballast tanks adjacent to cargo tanks fitted with heating coils.

In addition, DNV and LR (GPG) proposed the following additions:

- The 3rd sentence in para. 3.2.5.2 (DNV):

  "Tanks or areas where coating was found to be in GOOD condition at the previous intermediate or special ~~internal examination are to~~ survey may (ABS' comment) be specially considered by the Classification Society."

  The majority GPG agreed.

- The second half of the para. 4.2.4.1(LR)

  "except that testing of cargo and ballast tanks is not required unless deemed necessary by the attending surveyor."

  The majority GPG agreed.

- The paragraph 7.1.1 of Z10.1 and Z10.3, paragraph 8.1.1 of Z10.2 were revised for their compatibility with the PR 19 "PR for Thickness Measurement".

Submitted by the Permsec
On 18 Sept 2000

Technical Background for

Rev.8.1, Z10.1

Rev.11.1, Z10.2

Rev.4.1, Z10.3

(21 June 2001)

1. Scope of objectives

Revise section 2.3.1 for clarity.

2. Points of discussions or possible discussions

- BV GPG member proposed to revise section 2.3.1 of Z10s on 12 June 2001 (0065j)

- IACS Council considered the ambiguity of the sentence in Special Survey section 2.3.1 "For Fuel Oil Tanks the necessity for the Overall Survey is to be determined based on the ship's age" in the context of its application at intermediate surveys on ships over 15 years. Council agreed that the overall survey of low corrosion risk tanks such as fuel oil, lube oil and fresh water tanks could be subject to special consideration as already addressed in section 2.2.5 of UR Z7 and therefore amended the first sentence of 2.3.1, accordingly, and deleted the last sentence of 2.3.1.

- Adopted on 21 June 2001.

* * * * *

Technical Background Document
WP/SRC Task 87
Amend Z10.1&10.2 to reflect changes introduced to Res A.744 by MSC 73
(Z10.1, Rev.9) + (Z10.2, Rev.12) + (Z10.3, Rev.5)

Objective and Scope:

To harmonise IACS UR Z10.1 and Z10.2 with IMO Res A744(18), as previously amended and as amended by IMO MSC105(73) and MSC 108(73).
These amendments enter into force 1 July 2002.
It was assumed by WP/SRC that the intention of GPG has been to revise UR Z10.3 (chemical tankers) as well with respect to the intermediate dry-docking requirement, but not to include the requirement to evaluation of longitudinal strength.
In addition, the relevant changes to UR Z10.1 based on the changes introduced in IMO Res A744(18) as reported in MSC 74/24/Add1-Annex 17 have been included. These were based on IACS submission DE 44/13/1. These amendments will enter into force 1 January 2004 subject to IMO tacit acceptance procedures.

POINTS OF DISCUSSION:

The Chairman of WP/SRC would further draw GPG's attention to paragraph 4.2.4.3, which contains the requirement to intermediate dry-docking for oil tankers exceeding 15 years of age. The corresponding Res.A 744(18) requirement (paragraph 2.2.2) does not link the dry-docking to the intermediate survey. This issue was discussed extensively by correspondence and during three WP meetings this year. A consensus decision was achieved without reservations from any members. This process was time consuming, hence the delay in submitting this document to GPG for approval. However, at the annual meeting of the WP in October 2001 all members agreed that we should not accept the wording of Res. A 744(18) paragraph 2.2.2, but instead require that the intermediate dry-docking is to be linked to the intermediate survey and include a requirement to carry out surveys and thickness measurements of the lower portions of the tanks for oil tankers. (similarly, cargo holds/water ballast tanks for bulk carriers)

GPG is advised to note that the proposed requirement in paragraph 4.2.4.3 may result in a third dry-docking within the 5-year period of the classification certificate in case that a dry-docking is carried out prior to the window for intermediate survey.

The Chairman of WP/SRC suggests that GPG approves UR Z10.1 with high priority and allows PermSec in the meantime to start the work to amend and typeset UR Z10.2 and URZ10.3 with respect to the intermediate dry-docking requirement, as well as introducing the appropriate changes to UR Z10.2 and UR Z10.3 with respect to MSC 74/24/Add 1-Annex 17.

Note:

1. GPG tasked WP/SRC to review dry-docking survey requirements in Z10.2-4 and Z3 to harmonize them with those in Z10.1 (Rev.9) and reflect in Z3 the interim application of bottom survey requirements as introduced in MSC/Circ. 1013 (Res A.746(18)).

   Task 101, Target 2Q-2002

2. GPG confirmed (s/n 1060c) that 7.1.3 of A.744(MSC 74/12/Add.1/Annex 17/page 6), as quoted below, should not be included in Z10s.

   "7.1.3 Thickness measurements are to be carried out within 12 months prior to completion of the periodical survey or of the intermediate survey."

   Reason: The above sentence will restrict the 15 month and 18 month survey window for TM during the intermediate and special surveys respectively.

3. GPG confirmed that 7.1.4 of A.744(MSC 74/12/Add.1/Annex 17/page 6), as quoted below, should not be included in Z10s:

   "7.1.4 In all cases the extend of the thickness measurements should be sufficient as to represent the actual average condition."

   Reason: No compelling need, in view of MSC 74/12/Add.1 being adopted by MSC 75(May 02). IACS will live with this not harmonized sentence.

4. For IACS Council decisions to improve bulk carrier safety, see the TB for Revision 12 of Z10.2.

Submitted by WP/SRC Chairman

UR Z10.1(Rev.11) and Z10.2(Rev.14)

(July 2003)

Technical background

Part A: Survey Reporting Principles

1. Objective

WP/SRC Task 80 – Survey Reporting Principles

2. Points of discussion

The WP/SRC carried out this task according to the work specification of Form A (Rev.1) and reported the outcome on 18 December 2002 as follows:

- Review of NMD's report on "Sinking of Leros Strength", dated 6 July 2000 and the recommendations in section 5.3
- Review of IACS Council's reply, dated 22 August 2000 to those recommendations
- For recommendations 1.1, 1.2, 1.3 ,3, 4.2, 5 and 6, best practices have been identified by information exchange amongst Members and discussions at three WP-meetings.
- Harmonised survey reporting practices fulfilling, in so far as practicable, the recommendations of NMD have been included in the revised tables attached.
- Standard survey reporting terminology (recommendation 2) is in the process of being prepared and will be submitted to GPG for approval as an IACS Recommendation with the title "Surveyor's Glossary". The completion of the glossary has been delayed somewhat due to pending illustrations of typical hull structures.

Council approved on 14 July 2003 (2249_).

***

Part B: Incorporation of CAS related requirements into UR Z10s

2. Objective

WP/SRC Task 106 – Incorporation of CAS related requirements into A.744

2. Points of discussion

The WP/SRC carried out this task according to the work specification of Form A and reported the outcome on 27 May 2003.

- Since CAS was developed for tankers only, WP/SRC considered whether there is any need to further develop/modify requirements in CAS with respect to bulk carriers. Hence, amendments to Z10.15.5.5(rafting), 5.6(survey planning), 8.2.2(different survey stations) and Table 1(close-up survey).
- IACS will submit its proposed amendments to Res A.744 as a result of this revision.
- NK GPG suggested that the word "alone" be inserted after "rafting" in Z7 and Z10.1(5.5.5)~10.5.
    - WP/SRC had considered this and felt that the insertion of the word "alone" will create a loophole as the text "Rafting alone will only be allowed..." could be interpreted that other means of access have to be used. Besides this wording would impede the use of rafting for survey of side and bottom structures of the spaces.
    - GPG considered that rafts/boats should be accepted as a means to move about within a tank to gain access to any temporary platforms that may be erected. Consequently, the wording of 5.5.5 was re-drafted and split into three parts (5.5.5~5.5.7) beginning with "*Rafts or boats alone may be allowed for inspection of the under deck areas…*"

      The same wording will be introduced into Z10.3, Z10.4, Z10.5, Z7 and Z7.1.

Approved on 08/08/2003 (0237h)

***

Prepared by the Permanent Secretariat

22 July 2003

WP/SRC Task 102
HARMONIZATION OF UR Z7s AND Z10s

Technical Background
UR Z7 (Rev. 11)
UR Z7.1 (Rev. 2)
UR Z10.1 (Rev. 12)
UR Z10.2 (Rev. 17)
UR Z10.3 (Rev. 7)
UR Z10.4 (Rev. 2)
UR Z10.5 (Rev. 1)

Contents:

1. Objective

To amend UR Z7s and Z10s in order to make the texts of the above-mentioned URs consistent eliminating all the differences both in substance and in wording (WP/SRC Task 102).

2. Background

In the process of approving UR Z10.4, GPG found it necessary to amend the other existing URs Z10.1, Z10.2, Z10.3, Z10.6 and Z7 in order to eliminate any inconsistencies existing among them.

3. Methodology of work

The WP has progressed its work through many sessions, both during the periodical meetings and dedicated meetings restricted to a Small Group of Members (BV, DNV, GL, LR, RINA) who developed the work in order to be more efficient. All the proposed amendments of the Small Group have regularly been circulated to all Members for comment and agreement.

4. Discussion

4.1 The WP/SRC has completed a comprehensive comparative review of UR Z7 and Z10s, and identified inconsistencies which existed among them. During this review, attention was given to the severity of the requirements applicable to the same spaces/structural areas on different types of ESP ships. As a result, the inconsistencies were eliminated making the URZs harmonized. However, there has been no change to the scope and extent of the survey requirements.

4.2 The starting point for each UR was the most updated version available at the time of commencement. Any revision to the URZs, which were introduced during this task, was taken into account. As for instance, the UR Z10.1 was initially amended based on Rev. 9, while the last amendments are based on Rev. 11 and the UR Z10.2 was initially amended based on Rev. 13, while the last amendments are based on Rev. 16. The proposed revisions of URs Z10.1 and Z10.4 have not been numbered, as there will be revisions to those URs before the revisions introduced by the Task 102 are adopted. In fact, GPG is currently developing a Revision 12 of Z10.1 with the view to introducing significant improvements in the survey regime for ballast tanks (including combined cargo/ballast tanks) of oil tankers and UR Z10s applicable to oil tankers will also have to be revised by incorporating the amendments to A.744(18) contained in Resolution MSC 144(77), which enter into force 1 January 2005 (see 4.3 below).

4.3 Also, in harmonizing UR Z10.1 and Z10.2 care has been taken to align the corresponding text with that of IMO Res. A.744(18). However, it has been noted that the amendments to A.744(18) contained in Resolution MSC 144(77), which enter into force 1 January 2005, have not been incorporated into the IACS UR Z10s applicable to oil tankers. It seems that the updating of the above-said UR Z10s will be done by the Perm Sec and reviewed by the WP/SRC Chairman and then circulated for adoption by GPG with concurrence of Council Members for uniform application from 1 January 2005. It is understood that the revisions of the UR Z10s affected by those amendments will not include the changes introduced by the Task 102, as the implementation date proposed for those changes is 1 January 2006 (see below **6. Implementation**).

4.4 In the course of the work the WP has been developing for more than two years, several additional Tasks were assigned to the WP by GPG which affected the development of Task 102. The additional tasks which have been taken into account are the following:

1) In the course of Council discussion on UR Z10.6 (General Cargo Ships), certain inconsistencies were identified between Z10.6 and other Z10s. WP was instructed to expedite Task 102 (1060gIAa, 12 June 2002);
2) WP was instructed to include “Survey Planning for Intermediate Survey” into harmonization work (2108_IAa, 12 July 2002);
3) GPG instructed WP to consider whether Z10.6 should be re-assigned as Z7.1, in connection with the harmonization work. 1060gIAb, 20 Sept 2002.

Z7.1 developed;

4) Partial outcome (Z7 and Z7.1) was submitted to GPG on 17 July 2003(1060g). Council decided that approval of Z7(Rev.10) and Z7.1(Rev.2) is postponed until the harmonization is completed (1060gICb, 6 April 2004); Council Chairman instructed WP/SRC to Members' comments on the draft revision of UR Z7 and Z7.1 (collected under s/n 1060g, 1060gNKi (30/03/2004) in particular) on 6 April 2004.

5) GPG tasked WP to include the amendments to Z10.2 / Z11 (BCs with hybrid cargo hold arrangements), deleting sheets 15 and 16 for ore carriers, into the harmonized UR Z10s (2212aIGa, 19 Jan 2004);
6) GPG tasked WP to consider whether the requirements relevant to examination of Fuel Oil Tanks in the cargo area at each Special Survey should be put into Z 10s, and internal examination of FOT at Intermediate Survey after SS 2 is needed. (1060gIAf, 30 Jan 2004);
7) GPG tasked WP to harmonize tank testing requirements in Z7s and Z10s. (3006lIAa, 5 April 2004);
8) GPG tasked WP with Task 108 - Develop uniform survey requirements for air vent pipes including the welded connection to deck. Z22 developed. GPG instructed WP to incorporate Z22 into the harmonized Z10s;
9) GPG tasked WP with Task 114 - Verification and signature of TM reports. REC 77(Rev.1) developed and approved on 29 July 2004. Council approved parallel amendments to Z7.1 and Z10s (TM Forms included) and instructed WP to incorporate these into the harmonized Z10s:
    - Recommendation No.77 was revised (Rev.1, July 2004);
    - Z7.1 para.6.3.2 and Z10s para.7.3.2 so amended.
    - "Surveyor's signature" is deleted from all TM Forms in Z10s;
    - A note is added to Annex II(Z10s) declaring that Annex II is recommendatory.

   WP/SRC's investigation into Members' practice in dealing with verification and signature of TM reports is annexed for record keeping purpose. See Annex 2.

10) GPG tasked WP to consider the BV comments on "TM may be dispensed with…." and include the findings into the harmonized Z10s (2219iIAa, 7 April 2004).

5. Agreement within the WP/SRC

All Members have unanimously agreed the attached final versions of UR's.

6. Implementation

WP/SRC is of the view that the Members need 12 months from the adoption date to implement these amendments into their class rules. Assuming Council adoption in December 2004, WP/SRC would propose January 2006 as implementation date.

Annex 1: TB for UR Z10.1(Rev.12, C49 amendments, see Permsec's note 1 below)
Annex 2: WP/SRC Task 114, verification and signature of TM reports(see 9 above).
Annex 3**:** TB for revision of UR Zs concerning "anodes".

Note by the Permanent Secretariat

1. Annex 1 to this TB contains background for amendments to UR Z 10.1(Rev.12) relating to FAIR/POOR/GOOD (C49 amendments). Council at its 49th meeting (June 2004) agreed/decided that comparable changes should be added to Z10.3 and Z10.4.

2. Appendix 3 "TM sampling method" has been added to UR Z10.1 and Z10.4 to keep them consistent with IMO Res.MSC.144(77). The amendments to A.744 contained in MSC.144(77) entered into force on 1 January 2005. *(GPG s/n 4181)*

Under s/n 4072g, paragraph **2.4.6** of UR Z10.1 and **2.4.6** and of UR Z10.4 (paragraph numbering is now harmonized) were amended in order to provide a link between the main text of the UR Z10.1 and 10.4 and the new Annex III Appendix 3 containing the MSC Res.144(77).

Further, it was agreed that the requirements for evaluation of longitudinal strength of the hull girder (as written in MSC.144(77)) should not be required for Intermediate Survey unless deemed necessary by the attending Surveyor. This is covered in 4.2.3.1 and 4.2.4.1 of Z10.1 and Z10.4.

3. GPG agreed that the amended UR Zs should be implemented from 1 July 2006 altogether.

4. DNV's proposed amendments to UR Z10.1, Z10.3 and Z10.4 concerning annual survey of ballast tanks were agreed by Council (1060gICq, 27 June 2005). See Appendix 2 to Annex 1.

5. Annex 3 contains a TB for revision of UR Zs concerning "anodes".

Date: September 2004
Prepared by the WP/SRC

– – –

Annex 1 to Technical Background
UR Z 10.1 (Rev.12, C49 amendments(coating-related))

1. Objective

To introduce significant improvements in the survey regime for ballast tanks (including combined/ballast tanks) of oil tankers as matter of strategic concern and urgency to IACS, given the aging of both the single and double hull tanker fleets and the problems encountered with corrosion of ballast tanks in several shipping casualties.

2. Background

Draft amendments to UR Z10.1 were submitted to Council 47 (June 2003) and agreed in principle.

3. Discussion

There was particular concern over accelerated corrosion with age (as the thinner the material, the more rapidly the allowable diminution margin percentage disappears) especially where coatings have broken down. There is also a disincentive for any spend on maintenance of the structure of a ship within a few years of its statutory scrapping date.

Council discussion by correspondence had evolved to the position of substantive proposals – summed as follows (3095_ABa, 2 June 2003):

1. Enhance the Intermediate Survey in Z10.1, Z10.3 and 10.4 for Tankers after 2nd Special / Renewal Survey to the same level (scope of work) as the preceding Special / Renewal Survey). This corresponds to the latest revision to UR Z10.2.
2. At Annual Survey of ballast tanks with substantial corrosion, the overall survey is to be replaced by close-up survey with thickness measurements of the exposed area.
3. Proposed to task WP/SRC to re-consider the acceptance criteria for the rating FAIR further. For this, eliminate FAIR, leaving only GOOD and POOR redefined as appropriate.
4. Proposed to task WP/SRC to explicitly require close-up survey of Suspect Areas identified at the previous Special Survey.

Council 47 discussed the proposals(June 2003) as follows:

1. Definition of FAIR
   Council 47 agreed that “FAIR” would be retained as a rating and that GPG should instruct WP/SRC to redefine FAIR, so that there would be a clear differences between FAIR, POOR and GOOD. It was also agreed that for oil tankers the Intermediate Survey following Special Survey No.2 would have the same scope as Special Survey No.2(Z10.1). WP/SRC should also clarify the definition of satisfactory repair.

   Based on the strong majority, Council agreed to discuss with Industry annual surveys of ballast tanks when coating is found in LESS than GOOD condition at special survey, with the objective to encourage the owner to carry out repairs and maintenance of coating to GOOD condition.

   > *DNV and NK stated that they could not accept a requirement for annual surveys of ballast tanks when the coating condition is less*

than GOOD and proposed that GOOD be changed to FAIR (3095_IGc, 30 June 2003)

2. ABS' proposed amendments to Z10.1(annual examination of BWTs in certain conditions) were approved.
3. C 47 agreed that the BWT coating requirements (Z10.1.2.2.3) for intermediate Survey after SS 2 should be the same extent to the previous SS.
4. Given the substance of the changes, the revised Z10.1 should be shown to Industry before adoption.
5. A guidance for coating repairs needs to be developed by WP/SRC with reference to TSCF Guidelines.

Following Council 47, the draft text of Z10.1(Rev.12) was distributed to Industry and discussed at the IACS/Industry meeting on 29 August 2003. Industry indicated that UR Z10.1(Rev.12) is acceptable, provided that appropriate IACS guidelines on coating repairs are developed.

The Small Group on Coating (SG/Coating) under WP/SRC prepared draft guidelines on coating repairs and considered the definitions of GOOD / FAIR / POOR. The SG/Coating did not change the definitions and found that the Guidelines provide useful clarifications on the definitions and criteria in achieving an industry wide uniform judgement of coating conditions as well as what is needed to restore GOOD conditions.
Further, an IACS/Industry JWG/Corrosion was established and met in February 2004. The outcome is (3095_IGh, 4 June 2004):

- Draft Guidelines on Coating Repair (IACS REC 87)
- Draft UR Zxx (mandatory coating of cargo tanks on oil tankers)
- Draft UI SC 122 (Rev.2) – mandatory coating of ballast tanks

4. Others

1. Z10.11.2.2bis - Definition of "Combined Cargo/Ballast Tank. …as a routine part of the vessel's operation and will be treated as a Ballast Tank. ...". By so amending, Z10s do not need to repeat "Ballast Tanks *and Combined cargo/salt water Ballast Tanks*" in addressing the ballast tanks. Hence, all the references to "*and Combined cargo/salt water Ballast Tanks"* were deleted.
2. Z10.1.2.2.1.2: The aim of the examination is ~~to be sufficient~~ to discover substantial corrosion…
   Comparable changes are to be added to other UR Zs wherever the same sentence occurs.
3. "IACS Guidelines for Coating Maintenance & Repairs for Ballast Tanks and Combined/Ballast tanks on Oil Tankers" are referenced where relevant.
4. Comparable changes are to be added to UR Z10.3 and Z10.4, after adoption of Z10.1(Rev.12).

Attached: Memo on Coating Matters (GPG Chairman)

9 June 2004
Prepared by the Permsec

Appendix 1 to Annex 1: MEMO on Coating matters

1. Background and discussion within IACS on UR Z10.1 (draft Rev.12) between 29/01/03 and 14/08/03

In view of the survey experience with oil tankers, it was proposed that all ballast tanks should be examined, routinely and uniformly, at annual surveys on ESP tankers exceeding 15 years of age. IACS should amend UR Z10.1 to require the examination of ballast tanks on such ships at each annual survey. This is simple, clear and thorough and not subject to interpretation. (2242_ABq dated 29/1/03)

Then, ABS modified the proposal asking, for tankers subject to URs Z10.1, Z10.3 and Z10.4, exceeding 15 years of age, that the current requirement - pertaining to annual examination of Ballast Tanks adjacent to cargo tanks with any means of heating - be deleted and replaced by a simpler and more stringent requirement that all Ballast Tanks be subject to survey at each subsequent annual survey where either substantial corrosion is found within the tank or the protective coating is found to be in less than GOOD condition and the protective coating is not renewed at special survey or intermediate survey. This will ensure that all Ballast Tanks with substantial corrosion or protective coating which is not in GOOD condition at the time of special survey or intermediate survey will be examined at each subsequent annual survey on tankers exceeding 15 years of age. (2242_ABzb dated 14/3/03)
This was later expanded to include all tanks used routinely for ballast water, both ballast-only and cargo/ballast tanks (2242_ABzc dated 14/3/03).

ABS further reviewed the issue of the survey of salt water ballast spaces and combined cargo/salt water ballast spaces with ABS' governing bodies in light of recent casualties and survey findings on other tankers. Their review found an increasing amount of coating breakdown/failure and subsequent rapid wastage in key structures after Special Survey No. 2, i.e. after 10 years of age. These conditions are most prevalent in the under deck structure and the side shell structure in way of the deep loadline. In a number of cases the serious wastage has caused fracturing of the under deck longitudinals and in some cases fracturing has extended to the main deck structure. This led ABS to refine proposed amendments to URs Z10.1, Z10.3 and Z10.4 to require (2242_ABzf dated 9/5/03):

a. For Tankers exceeding 10 years of age

> Salt Water Ballast Spaces and Combined Cargo/Salt Water Ballast Spaces. For tankers exceeding 10 years of age, salt water ballast spaces and combined cargo/salt water ballast spaces are to be internally examined at each subsequent Annual Survey where substantial corrosion is found within the tank or where the protective coating is found to be less than GOOD condition and protective coating is not repaired. Internal examination to be an Overall Survey.

b. For Tankers exceeding 15 years of age:

Salt Water Ballast Spaces and Combined Cargo/Ballast Spaces. For tankers exceeding 15 years of age, salt water ballast spaces and combined cargo/ballast spaces are to be examined internally at each subsequent Annual Survey. Where substantial corrosion is found within the tank, or where the protective coating is found to be in less than GOOD condition and the protective coating is not repaired then in addition to an Overall Survey, under deck structure and the side shell structure in way of the deep loadline is to be subject to Close-up Survey.

NK and BV replied that the proposed amendments made by ABS need to be substantiated in a transparent manner with technical data that ABS may possess and put forward for further assessment and discussion. (2242_NKn dated 14/5/03 and 2242_BVz dated 16/5/03)

DNV (2242_NVn dated 2/6/03), having carefully considered the practical consequences of taking the ship off-hire for gas freeing etc. and being concerned about the difficulties to have these surveys executed in a safe manner and whether the intended safety benefits in implementing the proposed extended scope of the annual survey of Ballast tanks will be met, **proposed the following alternative measures** which would be as effective and may not have such delaying effects to the ship:

1) Enhance the Intermediate Survey in UR Z10.1, 10.3, and 10.4 for Tankers after the 2 Special / Renewal Survey to the same level (scope of work) as the preceding Special / Renewal Survey. (This will correspond to the latest revised requirements of UR Z10.2 for Bulk Carriers.)
2) At Annual Survey of ballast tanks with substantial corrosion the overall survey should be replaced by close up survey with thickness measurements of the exposed area. (An overall survey of these tanks does not give sufficient information of the development of the areas with substantial corrosion.)
3) Further we will not fail to mention that the WP/SRC has proposed to extend the close up survey in cargo and combination tanks to 30% from the 3 Special / Renewal Surveys.
4) **Experience has shown that the coating condition rating category FAIR has a tendency to be stretched too far into the POOR condition. We will therefore propose that we task the WP/SRC to reconsider the acceptance criteria for the rating FAIR further.**
5) We do also question the need for redefining the definition of combination tanks, particularly since the category I tankers which are the ships that normally are fitted with these type of tanks are to be phased out 2 to 4 years from now. However DNV will not oppose to such a redefinition.

DNV requested Members to consider the above as an alternative to the ABS proposal, bearing in mind that we ought to present this to the industry prior to deciding.

ABS (3095_Aba dated 2/6/03), having further considered its earlier proposals in light of NVn, submitted a revised proposal for consideration by Council at C47 and replied to the above 5 DNV proposals as follows:

1) ABS fully supports this proposal.
2) While ABS agrees with this proposal, it is in fact already provided for in Z7 (3.2.3) and Z10.1 (3.2.5.1)--which require that "Suspect areas (which include any area where substantial corrosion is found) identified at previous Special Survey are to be examined. Areas of substantial corrosion identified at previous special or intermediate survey are to have thickness measurements taken." To us, this implies that close-up survey of these areas is to be done at annual survey in conjunction with the thickness measurements. However, we can

agree to tasking WP/SRC to explicitly require "close-up" survey in this connection and to amend Z7, and all the Z10's, appropriately to make this explicit, if there is majority support for this.

3) We agree that this has been put forward to GPG by WP/SRC via 0237hNVb, 27 May. However, these additional CAS close-up survey requirements do not apply to salt water ballast tanks; only to cargo oil tanks and combined cargo/ballast tanks.
4) **We agree with this assessment and we propose that the only way to eliminate the subjectivity and raise the standard is to eliminate the category "FAIR" completely; leaving only "GOOD" and "POOR" redefined as follows:**
   "GOOD -- condition with no breakdown or rusting or only minor spot rusting.
   POOR -- any condition which is not GOOD condition."
5) ABS does not agree with this proposal. We are particularly concerned that we need a very thorough and robust survey regime for these tankers precisely because they are subject to mandatory phase out over the next several years. We are very concerned that without additional IACS requirements, these tanks will receive little or no inspection and maintenance by owners or others after their last special or intermediate survey, if no substantial corrosion is found at that time. Rapid, localized wastage in way of deteriorating coatings may pose significant hazard if the survey regime is not further tightened as we are proposing.

In conjunction with the above comments on DNV proposals, ABS further considered their previous proposal in ABzf and modified it as follows:

- **ABS simplified the proposal to require annual examination of all salt water Ballast Tanks and combined Cargo/salt water Ballast Tanks irrespective of age, when either substantial corrosion is found within the tank or the protective coating is found to be in less than GOOD condition and is not repaired.**
- the requirement for annual (close-up) examination of salt water ballast tanks and combined tanks is already required in Z10.1 (3.2.5.1). ABS proposed adding it to 2.2.3 for clarity and emphasis so that all the conditions which may lead to annual examination of such tanks are listed together in one place.
- Since the principal problem that we are trying to address is rapid, localized corrosion in way of breakdown or deterioration of the protective coating, we are proposing that the coating condition should be found and kept in "GOOD" condition to obviate the need for annual examination. **The attached proposal is made together with the proposals in items 3.1 (intermediate following Special survey 2 to have same scope as prior Special survey) and 3.4 (eliminating "FAIR" and redefining "POOR" as any condition other than "GOOD" condition.**

ABS requested to decide on a course of action at C47 for tightening the survey regime for tankers. They agreed that industry be informed of Council's decisions in this regard prior to IACS making the decision public, but IACS should maintain its independence and take decisive action in this matter. Debate with industry can only lead to delay and to a watering down and compromising of these important requirements.

NK agreed to task WP/SRC to reconsider the acceptance criteria of "FAIR" for clearly define the border between "FAIR" and "POOR" condition. However, **NK strongly opposed the elimination of "FAIR" coating condition from UR Zs** because this can not resolve to remove subjectivity of coating assessment. The three-categorization system of coating condition should be retained. (3095_NKa dated 5/5/03)

<u>Outcome of C47</u>

At **C47**, it was agreed that "Fair" would be retained as a rating and that GPG should instruct WP/SRC to redefine "Fair", so that there would be a clear differentiation between "Fair", "Poor" and "Good". It was also agreed that for oil tankers the Intermediate Survey following Special Survey No.2 would have same scope as Special Survey No.2 (Z10.1). WP/SRC should also clarify the definition of satisfactory repair.

Based on strong majority support Council agreed to discuss with Industry annual surveys of ballast tanks when coating is found in LESS than GOOD condition at special survey, with the objective to encourage the owner to carry out repairs and maintenance of coating to GOOD condition.

This matter should be discussed with Industry prior to adoption of any UR by Council.

In a final summary, the Chairman proposed that a constructive dialogue with Industry should take place on the IACS proposal as set out in WP1 plus maintaining 3.2.5.2 modified to say that ballast/combined ballast/cargo tanks will be subject to annual survey when considered necessary by surveyors.

After discussion in the JWG (Industry/IACS), GPG should propose final rules for this matter to Council, including acceptable repair definition.

F**UA 17:** *To instruct WP/SRC to develop guidance on coating repairs and more precise definition of "Fair" coating condition.*

Once approved, these requirements should be incorporated into Z10.3 and Z10.4.

FUA 15

1) *To prepare a draft revision to UR Z10.1 incorporating C 47 decisions:*
   - *The definition of "FAIR" remains as it is;*
   - *ABS proposed amendments to Z10.1 (annual examination of BWTs in certain conditions) were approved;*
   - *C47 agreed that the BWT coating requirements (Z10.1.2.2.3) for Intermediate Survey after Special Survey No.2 should be the same extent to the previous Special Survey.*
   - *Given the substance of the changes, the revised UR Z10.1 should be shown to Industry (OCIMG/Intertanko first among others) before adoption for their review and comments.*
   - *A guidance for coating repairs needs to be developed by WP/SRC with reference to TSCF Guidelines.*

2) *GPG Members are to confirm the draft revision to Z10.1 in consultation with their WP/SRC members by correspondence. See 3095_IGa of 13/06/03.*

According to C47 FUA 15, GPG Chairman circulated (3095_IGa dated 13/6/03) draft amendments to UR Z10.1 as agreed in principle at C47.

Having received a number on comments, GPG Chairman (3095_IGb dated 27/6/03) informed that the Council Chairman confirmed that GPG is not to amend the principles agreed at C47, i.e. we are not empowered to change "GOOD" to "FAIR" as proposed by DNV and NK, nor to amend the definitions of "FAIR" and "POOR" as proposed by DNV.

DNV's intention to possibly lodge a reservation was noted, however the matter should be raised at Council and not be dealt with by GPG. An amended draft text incorporating the non-substantive changes proposed by Members was circulated.

DNV said that its understanding was that the draft should be circulated to the Industry (ICS, INTERTANKO, and BIMCO) prior to adoption by Council. (3095_NVc dated 30/6/03)

GPG Chairman (3095_IGc dated 30/6/03) circulated a draft amendment of UR Z10.1 for Council's agreement and use in discussions with the industry associations.
The draft was generally agreed by GPG but individual Members have requested that the following matters (which were deemed to be outside the remit of GPG in this task) be brought to Council's attention for further consideration:

1 DNV and NK stated that they can not accept a requirement for annual surveys of ballast tanks when the coating condition is less than GOOD and propose that GOOD be changed to FAIR.
2 In connection with item 1 above, DNV also propose to amend the definitions of FAIR and POOR in order to raise the standard of FAIR.

Council Chairman (3095_ICb dated 14/8/03) concluded that Council has agreed that the draft amendments to UR Z10.1 attached to IGc reflect Councils' decision taken at C47 and that they be circulated to industry associations.
Perm Sec was therefore invited to submit the draft to OCIMF and INTERTANKO in view of discussion at the IACS/ industry meeting on 29 August.

2. Discussion with Industry (29/08/2003 – 11/10/2003)

As requested by Council, the whole matter was presented to Industry during the "general matters" meeting with IACS held on 29 August 2003; comments from Industry were requested. In the following an extract from the minutes of the meeting (see message 3100aIAb dated 5 September 2003):

____________________ from Meeting minutes ____________________

4. & 5. Annual surveys of ballast tanks and IACS guidelines on coating repairs

M. Dogliani introduced the matter (see Items 4&5 in Appendix).

A. LinoCosta gave a presentation to show where concerns and decisions stand: too many cases when coating was considered fair at SS but problems occurred just after one/two years.

N. Mikelis commented on draft amendments to Z10.1 (Rev.11) stating that the extent of annual survey is not clear; it should be limited to the affected zones, e.g. coating breakdowns, only.
M. Guyader clarified that, in this draft amendments, it is expected an overall survey of the whole tank and a close up survey of the affected zones.
N. Mikelis noted that, in the draft amendments to Z10.1 (Rev.11), the intermediate survey at 12.5 years would have the same scope as the previous special survey and that needed a justification. See 7 a).
M. Dogliani said that Z10.1 (Rev.11) was adopted in August 2003 and will be introduced into IACS Societies' Rules over the next year.

Conclusions:
4.1 Industry shared IACS concerns on coatings and, in general, agreed with the draft amendments to Z10.1 (Rev.11) suggesting also extending them to Z10.2 on bulk carriers

4.2 Industry agreed that a guideline for surveyor on coating would greatly improve uniform application of so-amended Z10.1 including issues such as how to consider load bearing elements when judging GOOD/FAIR/POOR status and how to consider bottom pitting in connection with GOOD conditions
4.3 Industry will more precisely comment, by the end of September, the draft Z10.1 so as for IACS to finalise the matter, as planned, for the Council's December meeting.

Item	Title	Industry recommandation	IACS/ M. Dogliani Introduction
4 & 5	Annual survey of ballast tanks IACS guidelines on coating repairs	NN	**1. IACS is considering the following:** - **amend UR Z10.1 (draft circulated to Industry) to the effect that in case at Special Survey or Intermediate Survey the coating in a ballast tank is found less than GOOD, either GOOD conditions are restored or the tank's coating is inspected at each annual survey;** - **develop IACS guideline to assist an uniform application of the so modified (if adopted) UR Z10.1; the guideline should address which repairs are necessary to restore GOOD conditions from FAIR and POOR respectively and which are the criteria for the restored (after repair) situation to be rated as GOOD.**

______________________________ End of extract from minutes ___________________________

INTERTANKO commented (see R. Leslie email to GPG dated 25 September 2003):

- expressing their concern for the draft Z10.1 and underlining

a) targeting: concerns that, if not properly dealt with, Z10.1 would target all ships and not just those which need intervention; the view was expressed that guidelines would probably solve the matter;

b) definition: indicating that the current definitions of GOOD, FAIR and POOR is not clear enough and that the matter would be even worst with GOOD and NON GOOD; again it was indicated that guidelines could solve the matter;

c) expertise: expressing doubts on IACS' surveyors expertise and ability to judge coating conditions; in this respect they (hiddenly) suggest that IACS position is unclear when we say that we are not competent to judge the coating during construction but then we are competent to judge coating during operational life. Even if not explicitly stated, the impression is that also in this case guidelines would help.

Additionaly, INTERTANKO suggested a (quite detailed) set of assessment criteria.

The matter was then finally addressed at the TRIPARTITE Meeting (held in Soul on 29/30 September 2003). There Industry agreed that the way forward was the (joint) development of IACS guidelines (see minutes attached to message 3100_RIe dated 11 October 2003, an extract of which is reproduced below).

______________________________ Extract from the TRIPARTITE minutes ________________

Industry is concerned by the definition of GOOD/NOT GOOD in relation to coating repairs and acceptance criteria. Industry agreed that new guideline on this, which IACS is already producing, was the way forward.

______________________________ End of the extract from the minutes __________________

3. Further developments

a) from the above, it was concluded that, provided the guidelines are sound, Industry would accept the concept of Z10.1 (draft) Rev. 12, therefore an IACS team and a JWG were established in order to progress the matter of the guidelines (among other related matters).
b) the team of IACS experts on coating developed draft guidelines and provided recommendations to GPG on the way forward (attached to message 3095bNVc dated 20 November 2003).
c) the guidelines were discussed within the JWG with Industry (see draft minutes circulated within GPG with messages 3095cIGd and 3095cIGe both dated 13 March 2004)
d) further suggestions and comments (as requested at the meeting) were provided by Industry (not circulated to GPG)
e) Bulk Carrier Industry is recommending that similar guidelines are developed in due time also for bulk carriers
f) at DE47 and MSC78, IMO is asking Industry and IACS to develop (compulsory) performance standards for coating of newbuilding (double hull spaces of DSS Bulk Carriers), a matter which is, indirectly related to the above one.

1 June 2004
M. Dogliani
IACS GPG Chairman
IACS JWG/COR Chairman

Appendix 2 to Annex 1: DNV proposal to Z10.1, Z10.3 and z10.4

Subject: FW: 1060gNVs; WP/SRC - Task 102 - Harmonization of UR Z 7 and Z 7.1

25 May 2005

To: Mr. B. Anne, Chairman of IACS Council,
cc: Council Members, IACS Perm. Sec.

Ref.: My mail NVr dated 20 May 2005

DNV have further studied the amendments to UR Z10.1, Z10.3, and Z10.4, and as a result are presenting the following as a compromise solution:

General comment:
From the comments by other Members it is obvious that there is reluctance to accept annual surveys of ballast tanks with a common plane boundary to heated cargo tanks in the case where the coating is in good condition. This is particularly unreasonable as at the same time we enhance the Intermediate survey of Tankers between 10 and 15 years to also include examination of all ballast tanks, meaning that all ballast tanks will be close up surveyed with 2-3 years intervals from the ship is 10 years old, with the possibility for the surveyor to require thickness measurements and testing of the tanks to ensure the structural integrity of the tanks if necessary.
It is also proposed for the Intermediate survey between 5 and 10 years, to increas the scope from representative to all ballast tanks, a requirement DNV find to strict, and require that we here keep the original text.
If a ballast tank is found to have coating in GOOD condition at the renewal or intermediate survey, a deterioration of the tank beyond structural reliability is very unlikely even if the tank has a common plane boundary to a heated cargo tank.

DNV finds it particularly unreasonable to have this requirement to apply to double hull tankers for the following reasons:
- these ships have double hull and the risk of pollution is here much reduced,
- the double hull is constructed with small spaces giving improved structural reliability,
- almost all double hull tankers below VLLC have heated cargo tanks, and all ballast tanks have common plane boundaries to these tanks, meaning that this requirement will apply to a major part of the tanker fleet in the future,
- the ballast tanks of double hull tankers are so designed that a general examination of these tanks will be identical to a close up survey,
- survey of ballast tanks of double hull tankers will mean either gas freeing of all cargo tanks or at least dropping the inert gas pressure of all cargo tanks in addition to proper airing of all ballast tanks.

Since the single hull tankers will be faced out in the near future, and for clear political reasons, DNV will as a compromise proposal to keep paragraph 2.2.3.1 and 4.2.2.2 in Z 10.1 as amended by Council (ref. IAo) but amend it to not include 2.2.3.1.e, 4.2.2.2.e and last paragraph of 3.2.5.1 in Z10.3 and Z10.4. In addition we request that the original text of 4.2.2.1 is kept.
If BV, ABS and other Members can accept this DNV is willing to drop our reservation presented at C49.
DNV's proposal will then be as follows:

Z10.1:

2.2.3.1: This paragraph can be accepted as is for the reasons stated above.
3.2.5.1: This paragraph is accepted as amended.
4.2.2.2: This paragraph can be accepted as is for reasons stated above.

For other comments to Z10.1 see NVo and NVp.

Z10.3:

2.2.3.1.e to be deleted.
3.2.5.1 delete last paragraph
4.2.2.1 the original text to be kept."For tanks used for water ballast ---"
4.2.2.2.e to be deleted

Z10.4

2.2.3.1e to be deleted
3.2.5.1 delete last paragraph
4.2.2.1 the original text to be kept, "For tanks used for water ballast --"
4.2.2.2.e to be deleted.

For details see attached document where the text for the requirements in Z10.3 and Z10.4 that DNV will accept is stated.

Best Regards

Arve Myklebust
on behalf of
Terje Staalstrom
DNV IACS Council Member
<<Doc1.doc>>

Annex 2 to TB (Harmonization Z10s)

WP/SRC Task 114 "Clarify the procedure of verification and signature of the thickness measurement report"

Item No.	Item	ABS	BV[1]	CCS	CRS	DNV	GL	IRS	KR	LR	NK	RINA	RS
1	**Verification onboard**	**.**											
1.1	Minimum extent of measuring points for direct verification by attending surveyor specified	No	No	No	No	No	No	No	Yes	No	No	Yes	No
1.2	Preliminary TM record to be signed upon completion of the measurements onboard	Yes	Yes [7]	Yes	No (copy taken)	No[3]	No[6]	Yes	Yes	Yes	Yes	No[8]	No
2	**Final TM report**												
2.1	Signature of all pages in TM record required	No	No	No	Yes	No	Yes	Yes	No	No	No[5]	Yes	Yes
2.2	Signature of 'cover' ('general particulars') page only	Yes	Yes	Yes	No	Yes	No	No	No[4]	Yes	Yes	Yes	No
2.3	Measuring points verified by attending surveyor required identified in TM record and signature of the corresponding pages required	No	No	Yes Without signature	Yes	No	No	No	Yes	No	No	No	No

2004-04-20

[1] Instructions not clear regarding signature of the thickness measurement record

[2] Signature on front and last page, stamp on all other pages, or signature on each page (IACS TM forms)

[3] Upon completion of measurements onboard a draft report in electronic format (DNV TM template, including operator's notes as relevant) to be given to attending surveyor

[4] Signature of cover page, pages of meeting record and pages of attended measuring points

[5] Each page to be signed in case of 'loose-leaf' type record

[6] Preliminary TM record has to be passed to the Surveyor, signed by the Operator

[7] The only measures which the Surveyors can certify exact are those for which that they have seen the results on the screen of the apparatus. That means in fact few points in comparison with the numbers of recorded measures.

8) The Surveyor reviews the TM record for completeness and assessment of TM readings, but no signature required.

Annex 3: **Technical Background (May 2005)**

UR Z7s and Z10s (Corrosion Prevention System)

1. Objective:

To clarify whether the survey of anodes is a class matter, and if so, whether acceptance criteria for anode should be developed.

2. Method: GPG by correspondence (5037_)

3. Discussion

3.1 BV initiated GPG discussion as follows:

Paris La Défense, 8 Mars 05

1 - We have noticed that, in the draft UR Z's (7.1, 10.1 to 10.5) issued further to the WP/SRC Task 102, the original sentence "......the examination may be limited to a verification that the hard protective coating remains efficient......" has been replaced by ....that the corrosion prevention system remains efficient....". in a number of paragraphs (such as , for instance, Z 7.1, 4.2.3.1 a) ; Z 10.2 4.2.3.3 ;), in line with IMO Res.A744(18).

2 - However, a corrosion prevention system is defined, in the same UR Z's and in IMO Res.A744(18) , as being either a full hard protective coating or a full hard protective coating supplemented by anodes.

3 - The above would mean that the survey of the anodes is a classification matter.

4 - However, whereas coating conditions are defined as good or fair or poor, there are no criteria in the IACS URs and IMO Res. A744(18) for the anodes condition.

5 - Assessing the anodes condition to confirm that they "remain efficient" looks to BV to be a quite difficult task for the ships in service Surveyor.

6 - Member's view and interpretations on the following would consequently be appreciated:
- do Members consider that the above requirements in IACS URs imply that survey of anodes is part of the classification ?
- do Members consider that the above requirements in IMO Res. A 744 (18) imply that survey of anodes is mandatory?
- if yes, what is the acceptance criteria to conclude that the anodes" remain efficient" ?

3.2 The majority of GPG Members replied that they did not include requirements for anodes in their class rules.

LR / ABS / DNV / KR / NK / RINA / RS were of the view that the condition of any anodes fitted should be recorded for information purposes as the survey of anodes is neither a classification matter nor a mandatory requirement in IMO A.744(18) and has no impact on future surveys (5037_LRa**). [**Note; LR further clarified that “Whilst I agree that the performance of anodes is not normally a class matter LR does require that as part of Special Survey on oil tankers : "The attachment to the structure and condition of anodes in tanks are to be examined ." Therefore we cannot say that 'the survey of anodes is not a classification matter'**. 5037_LRb]**

However, GL said that “for GL, anodes are a matter of class and as such are subject to plan approval as well as surveys. In case of missing or worn-out anodes we issue a condition of class”(5037_GLa&b).

CCS advised that its rules have a general requirement relating to anode survey, which is only conducted, through sampling, during construction, docking survey or where there is a definite requirement for the survey of ballast tanks.

NK proposed that the following footnote be added to Z7s and Z10s:
“The survey of anodes is not a classification matter.” No majority support was achieved.

4. Conclusion

RINA suggested to simply amend the definition of "Corrosion Prevention System" in paragraph 1.2.9 of UR Z7 (and, of course, the paragraphs in all the other UR Zs containing the definition of "Corrosion Prevention System") in order to eliminate any reference to anodes. This proposal would leave room for Societies willing to include additional class requirements for anodes to do so in their Rules.

GPG agreed.

RINA proposed amendments to paragraph 1.2.9 of UR Z7 and corresponding paragraphs in all other UR Zs (5037_RIb, 6 April 2005)

1.2.9 Corrosion Prevention System

A corrosion prevention system is normally considered ~~either:~~ a full hard protective coating.
~~.1 a full hard protective coating, or~~
~~.2 a full hard protective coating supplemented by anodes.~~
Hard protective coating is usually to be epoxy coating or equivalent. Other coating systems may be considered acceptable as alternatives provided that they are applied and maintained in compliance with the manufacturer’s specifications.
Where soft coatings have been applied, safe access is to be provided for the surveyor to verify the effectiveness of the coating and to carry out an assessment of the conditions of internal structures which may include spot removal of the coating. When safe access cannot be provided, the soft coating is to be removed.

Annex: Council Chair’s conclusive message.

6 May 2005
Permsec

Annex. (5037_ICb, 15 May 2005)

To : All IACS Council Members
c.c : Mr. R. Leslie, IACS Permanent Secretariat

Ref. Mr G-Y. Han's message IAa dated 6 May 05
Message ICa dated 6 May 05
Admiral R.E. Kramek's message ABb dated 13 May 05

Paris La Défense, 15 May 05

1 - All Members have agreed with the texts attached to Mr Han's message.

2 - Further to ABS comments the reference to anodes is to be deleted in Annex I and in tables IX (IV) and IX(II).

3 - further to ABS questions regarding what IACS plan to do regarding IMO and A.744(18) further to IACS deletion of reference to anodes from the UR Z7's and UR Z10's it is to noted that:

The Item 1.2.9 in UR Z1O.1 and relative items in these URs states
1.2.9 10 Corrosion Prevention System: A corrosion prevention system is normally considered either:
.1 a full hard protective coating, or
.2 a full hard protective coating supplemented by anodes.
Hard Pprotective Ccoating is to usually to be epoxy coating or equivalent. Other coating systems may be considered acceptable as alternatives provided that they are applied and maintained in compliance with the manufacturer's specification.
Where Soft Coatings have been applied, safe access is to be provided for the surveyor to verify the effectiveness of the coating and to carry out an assessment of the conditions of internal structures which may include spot removal of the coating. When safe access cannot be provided, the soft coating is to be removed.

- therefore the anodes are not considered as the main means of protection against the corrosion It is only a supplement;

- there is no provision in UR Z7's and Z10's to evaluate the level efficiency of the anodes;

- there is no specific requirements in case of lack of efficiency of the anodes.

The experience has shown that ballast tanks only protected by anodes are subject to corrosion when the anodes are becoming less efficient.

The anodes are active only when immersed by sea water. Therefore the upper part of the ballast tanks are not protected when the ballast is full of water and the ballast is not protected when it is empty..

The ships operators are reluctant to replace the anodes especially in upper part which request fitting of scaffolding fo welding the anode supports to the structure.

The above arguments justify the reasons why IACS consider that the anodes are not class item.

4 - These arguments can be used by IACS Members attending the WG bulk carriers at MSC 80 to try to obtain deletion of the reference to anodes in A. 744(18).

Best regards,

Bernard Anne
IACS Council Chairman.

Technical Background

UR Z10.1(Rev.13, Jan 2006)
UR Z10.2(Rev.18, Jan 2006)-separate TB
UR Z10.3(Rev.8, Jan 2006)
UR Z10.4(Rev.3, Jan 2006)
UR Z10.5(Rev.2, Jan 2006)

Part 1. Z10s – para. 1.4 and 7.1.3

Part 2. Z10s – para. 5.5.4 and 5.5.6

Survey Panel Task 22 – Amend applicable URZ7s and Z10s to align Close-Up Survey and Thickness measurements to be carried out at the same time and location allowing for a more structured control of the thickness measurement process.

Technical Background

Z7(Rev.12)
Z7.1(Rev.3)
Z10.1(Rev.13, para.1.4 & 7.1.3)
Z10.2(Rev.18, para. 1.4 & 7.1.3)
Z10.3(Rev.8, para. 1.4 & 7.1.3)
Z10.4(Rev.3, para. 1.4 & 7.1.3)
Z10.5(Rev.2, para. 1.4 & 7.1.3)

1. **Objective**

To amend the applicable URZ7s and Z10s to align Close-Up Survey and Thickness measurements to be carried out at the same time and location allowing for a more structured control of the thickness measurement process.

2. **Background**

IACS QC findings, through audits of numerous Societies, which indicated concerns over Surveyor attendance and control of thickness measurement processes.

3. **Methodology of Work**

Survey Panel members through correspondence.

4. **Discussion**

To align Close-up survey requirements and thickness measurements in the applicable URZ7s and URZ10s, in accordance with PR19, all Panel members agreed through correspondence and a final vote at the fall Survey Panel meeting, that URZ7, Z7.1, Z10.1, Z10.2, Z10.3, Z10.4 and Z10.5 should include in the applicable sections of the noted URs as proposed by the Survey Panel the wording " In any kind of survey, i.e. special, intermediate, annual, or other surveys having the scope of the foregoing ones, thickness measurements of structures in areas where close-up surveys are required, shall be carried out simultaneously with close-ups surveys."

5. Implementation

The Survey Panel is of the view that the Members need 12 months from the adoption date to implement these amendments into their class rules. Assuming that GPG and Council approve to the amendments, the Survey Panel would propose January 2007 as an implementation date.

Technical Background

UI SC 191 (Rev.2, Oct 2005)

&

UR Z10.1 (Rev.13, para.5.5.4 and 5.5.6, Jan 2006)
UR Z10.2 (Rev.18, para. 5.5.4 and 5.5.6, Jan 2006)
UR Z10.3 (Rev.8, para.5.5.4 and 5.5.6, Jan 2006)
UR Z10.4 (Rev.3, para.5.5.4 and 5.5.6, Jan 2006)
UR Z10.5 (Rev.2, para.5.5.4 and 5.5.6, Jan 2006)

1. Objective

- to confirm whether the guidelines for approval/acceptance of alternative means of access (now REC91, ex Annex to UI SC191) is mandatory or non-mandatory.
- to consider other safety related proposals.

2. Background

The DNV proposal to submit the UI SC191(Rev.1, May 2005, Annex 1) to IMO DE49 triggered a number of discussion points that led to amendments to the following resolutions:

UI SC191(Rev.2)
New REC 91
REC 39(Rev.2)
UR Z10s

Points of Discussion

3. Is the Annex to UI SC191(Rev.1, May ’05, guidelines for approval / acceptance of alternative means of access) mandatory or non-mandatory ?

   Answer: Non-mandatory. Hence, re-categorized as new REC 91.

4. Limitation of use of rafts in bulk carrier holds

   DNV proposed that conditions for rafting should be limited to areas, such as anchorage or harbour, where swell conditions are limited to 0.5m. After discussion, GPG approved the ABS’ alternative proposal to use the swell condition as a basis to determine the appropriateness of rafting, instead of geographic areas(harbours or anchorage). 5.5.4 of Z10.2 refers.

RINa proposed that para 5.5.4 should be included in all the Z10s. NK's objection is recorded as follows (3037hNKq, 29/08/2005):

> 1. With regard to RIm of 26 August 2005, NK considers that the proposed amendment to 5.5.4 should be limited to UR Z10.2.
>
> 2. Rafting survey for tankers are actually carried out on the open sea from a discharge port to a loading port and in such situation the rise of water within the tanks would always exceed 0.25m. It is different situation from rafting survey for hold frames of bulk carriers normally conducted in a harbour or at an anchorage.
>
> 3. If the same requirement applies to tankers, any rafting survey for cargo oil tanks and ballast tanks of tankers would be prohibited. This is not practicable under present survey procedure for tankers.
>
> 4. Therefore, NK can not support Laura's proposal that the proposed amendment to 5.5.4 of UR Z10.2 is introduced into the other URs and new Recommendation.

For compatibility with the IMO's mandatory requirements*, GPG decided to add the same amendment to all the UR Z10s.

*

- Appendix 4 to MEPC.99(48) ' Mandatory requirements for the Safe Conduct of CAS Surveys'
- MSC.197(80) – amendments to A.744918), Annex A for DSS and SSS bulk carriers and Annex B for single and double hull oil tankers.

As a consequence, 5.5.1 of REC 91(ex Annex to UI SC191) was also amended:

-to remove the reference to dynamic /sloshing (as the 0.25m rise was considered negligible);

-to refer to the rafting conditions contained for cargo holds in Z10.2 and Z10.5 and for oil cargo tanks in Z10.1 and Z10.4.

5. Means of access from longitudinal permanent means of access within each bay to rafts

GPG reviewed the proposal that the following text be added to Z10s:

A means of access to the longitudinal permanent platform from rafts or boats is to be fitted in each bay.

(Technical Background: for the safety of surveyors)

There may be ships which are arranged in accordance with para b, page 8 of the Annex to the current SC 191 (i.e., no means of access from the LPMA in each bay to a raft is required) and therefore could not be rafted if the sentence proposed by RINA("A means of access to the longitudinal permanent platform from rafts or boats is to be fitted in each bay") is included in the Z10's.
GPG therefore agreed not to include this sentence in Z10s.

For the same reason, the same sentence was not added to Rec.39.

Finally, GPG added the following sentence to UI SC191(interpretation for II-1/3-6):

> *A permanent means of access from the longitudinal platform to the water level indicated above is to be fitted in each bay (e.g permanent rungs on one of the deck webs inboard of the longitudinal permanent platform).*

6. Implementation

It was agreed that the revised UI SC191 be implemented to ships contracted for construction 6 months after adoption by Council.

UI SC191 was also edited in line with IMO MSC/Circular. 1176, leaving its mandatory language (is/are to, shall) unchanged.

(Note: UI SC191(Rev.2) makes references to the following new Recommendations:
- REC 90: Ship Structure Access Manual
- REC 91: Guidelines for approval/acceptance of Alternative Means of Access)

23 September 2005
Permanent Secretariat
Updated on 13 Oct 2005.

Technical Background

UR Z10.1 (Rev.14), UR Z10.2 (Rev.23), UR Z10.4 (Rev.5) & UR Z10.5 (Rev.5)

Survey Panel Task 3 – Maintenance of Alignment/ Compatibility of IACS URs and IMO survey requirements

1. **Objective**

Maintenance of alignment/compatibility of IACS URs and IMO survey requirements regarding resolution MSC 197(80) – amendments to A744(18)

2. **Background**

IMO survey requirements to ESP vessels as amended in A744(18) as noted in MSC 197(80), with an implementation date of 1 January 2007.

3. **Methodology of Work**

Survey Panel members through correspondence.

4. **Discussion**

Survey Panel members, at the fall 2006 Survey Panel meeting, finalized the amendments to the applicable URs due to changes adopted at MSC(80).
Additionally, Members noted that URZ10.4 paragraphs 2.2.3.1 and 4.2.2.2 does not require examination of ballast tanks adjacent to heated fuel tanks, as required by MSC197(80). The survey panel agreed that if this is the position that IACS would like to take regarding double hull tankers, then it should be brought to the attention of IMO at the next IMO meeting, DE50 in March 2007.

5. Implementation

The Survey Panel is of the view that the Members need 12 months from the adoption date to implement these amendments into their class rules. Assuming that GPG and Council approve the amendments, the Survey Panel would propose January 2008 as an implementation date, although the IMO implementation date is January 2007.

Submitted by Survey Panel Chairman
9 January 2007

GPG discussion

All members agreed to omit the requirement of examination of ballast tanks adjacent to heated fuel tanks, as required by MSC197(80), from URZ10.4 for double hull tankers and

that it should be brought to the attention of IMO at DE50. In addition ABS proposed that paragraphs relating to similar requirements in URZ10.1 should also be deleted for consistency and this was agreed by members.

Members also made a number of minor/editorial corrections to the text prior to their approval of the revised documents.

Added by Permanent Secretariat
23 April 2007

Technical Background

URs Z7(Rev.15), Z7.1(Rev.5), Z7.2(Rev.1), Z10.1(Rev.15), Z10.2(Rev.26), Z10.3(Rev. 9), Z10.4(Rev.6), Z10.5(Rev.8) – November 2007

Survey Panel Task 1 – Annual Review of Implementation of IACS Resolutions

1. Objective

To review IACS Resolutions annually and discuss or propose amendments as deemed necessary.

2. Background

This proposed amendment to all URZ7s and URZ 10s was raised by the Panel member from DNV due to Owners crediting tanks concurrently under intermediate and special survey.

3. Methodology of Work

Survey Panel members through correspondence.

4. Discussion

The Panel member from DNV raised the issue of Owners having the ability of crediting spaces and thickness measurements only once in a 54 month interval, due to the availability of concurrent crediting of spaces and thickness measurements due to the flexible time window that is currently allowed between the intermediate survey and the special survey.
After a presentation and discussion lead by the DNV Panel member, all Survey Panel members agreed to the argument given by DNV, and further agreed to make the necessary changes in all URZ7s and URZ10s where Owners are not allowed to concurrently credit surveys and thickness measurements of spaces.

5. Implementation

The Survey Panel is of the view that the Members need 12 months from the adoption date to implement these amendments into their class rules. Assuming that GPG approve to the amendments, the Survey Panel would propose January 2009 as an implementation date.

Submitted by Survey Panel Chairman
22 October 2007

Permanent Secretariat note (December 2007):

During GPG discussion DNV proposed that *"since this matter will be discussed between Owner and Class mainly in connection with the forthcoming Special Survey, DNV would prefer to locate this text, not only as part of Intermediate Survey, but also as a new text for the Special Survey."* This was supported by BV, ABS, RINA and KR.

The revised documents were approved, with DNV's proposal and an implementation date of 1 January 2009, on 15 November 2007 (ref. 7690_IGb).

Technical Background

URs Z7(Rev.16), Z7.1(Rev.6), Z7.2(Rev.2), Z10.1(Rev.16), Z10.2(Rev.27), Z10.3(Rev.11), Z10.4(Rev.7) and Z10.5(Rev.9) - March 2009

Survey Panel Task 62:

A) ***Harmonization of UR Z10.1, Z10.2, Z10.4 and Z10.5 with UR Z10.3 with respect to items 5.5.4.4 and 5.6.2.***
B) ***Harmonization of UR Z7, Z7.1, Z10.1, Z10.2, Z10.3, Z10.4 and Z10.5 with UR Z7.2 with respect to the definition of the corrosion prevention system and with respect to the footnote 1 related to semi-hard coatings.***
C) ***Harmonization of the definition of Ballast Tank in UR Z7(Rev.14)***

1. Objective

A) Amend the texts of items 5.5.4.4 and 5.6.2 in Unified Requirements Z10.1, Z10.2, Z10.4 and Z10.5 in order to align them with those in UR Z10.3, in which they were changed while performing Task 55, whereas in the other UR Z10s they were kept unchanged on the grounds that this change was out of the scope of Task 55.
B) Amend the definition of “Corrosion Prevention System” and include a Footnote 1 related to semi-hard coatings in Unified Requirements Z7, Z7.1, Z10.1, Z10.2, Z10.3, Z10.4 and Z10.5 in order to align them with those adopted in UR Z7.2, when this new UR was issued.
C) Amend UR Z7 (Rev. 14) in all items where the term “Ballast Tank” is used in order to get them harmonized with the definition itself.

2. Background

The task, as regards item A), was triggered by a Member Society, while performing Task 55, on the grounds that this part was out of the scope of the task and then should have been dealt with in a separate task.
The task, as regards item B), was triggered as a consequence of the “New Business action item 2” of the Minutes of the September 2008 Survey Panel meting, for sake of harmonization of the various URZs.
The task, as regards item C), was triggered as a consequence of the “Task 54-Examination of Double Bottom Ballast Tanks at annual surveys” of the Minutes of March 2008 Survey Panel meeting, for sake of harmonization of the definition of Ballast Tank in UR Z7(Rev.14).

3. Discussion

The task was carried out by correspondence. All the amended texts for the affected URs were prepared by the Survey Panel Member who had chaired the PT on Task 55, in accordance with the Form A approved by GPG. In addition to the objectives outlined in the Form A, an amendment was added to item 1.3.1 of UR Z10.2 and UR Z10.5 in which the reference 3.2.3.6 in the last item of the list was replaced by 3.2.3.10 as can be correctly verified in the text.
The amended URs were circulated to all Survey Panel Members for review, comments and agreement. The texts of the URs were unanimously agreed by all Members.

4. Implementation

The Survey Panel is of the view that the Member Societies need at least 12 months from the adoption date to implement these amendments into their class rules/procedures. Therefore, in the first version of all amended URs the following implementation sentence should be proposed:

Changes introduced in Rev .xx are to be uniformly applied by Member Societies and Associates for surveys commenced on or after [not less than 12 months after the adoption by GPG/Council].

Since it is common practice and convenience to have implementation dates either on 1st January or on 1st July of the year, the Survey Panel proposes the 1st July 2010 as implementation date, if GPG/Council approve the URs not later than 30 June 2009.

Submitted by Survey Panel Chairman
28 February 2009

Permanent Secretariat notes (April 2009):

1. The amended URs were approved by GPG on 18 March 2009 (ref. 7718bIGd).
2. During the typesetting process it was noted that para 5.1.5 of UR 7.2 was inconsistent with the amended URs and so following consultation with the Survey Panel this was also amended at this time.
3. Regarding the implementation date, GPG agreed to use 1st July 2010 provided that it was consistently used for the amended URs.

Technical Background document for UR Z10.1 Rev.17 (Feb 2010)

1. Scope and objectives
To amend UR Z10.1 (Rev.16) for the harmonization with currently revised MARPOL Annex I.

2. Engineering background for technical basis and rationale
-

3. Source / derivation of the proposed IACS Resolution
- MARPOL 73/78
- IACS UR Z10.1 (Rev.16)

4. Summary of Changes intended for the revised Resolution:
As MARPOL I was revised, the reference to MARPOL I/13 (3) in paragraph 1.2.2bis should read MARPOL I/18(3).

5. Points of discussions or possible discussions
None

6. Attachments if any
N/A

Technical Background for UR Z10.1 Rev.18 (Mar 2011)

1. Scope and objectives

1) To amend UR Z10.1 to harmonize the definition of transverse section.

2) Update of references in the Executive Hull Summary Table IX.

2. Engineering background for technical basis and rationale

1) Based on that fact that bulk carriers and oil tankers have a transverse framing system applied for example on ship's sides etc. and that UR Z7 is applied to all types of ships and includes an extended definition of transverse section it is necessary to unify this definition in UR Z10s.

2) Update of references in the Executive Hull Summary Table IX such that the introduction of extended annual surveys is noted in the 'Memoranda' section rather than under 'Conditions of Class'.

3. Source/derivation of the proposed IACS Resolution

IACS UR Z7.

4. Summary of Changes intended for the revised Resolution:

1) The following additional text is added to the definition of transverse section in para 1.2.5:

"For transversely framed vessels, a transverse section includes adjacent frames and their end connections in way of transverse sections."

2) In the Executive Hull Summary Table IX (iv) the reference to part H) is updated to part I) as per Table IX (ii).

5. Points of discussions or possible discussions

None.

6. Attachments if any

None.

Technical Background for UR Z10.1 Rev.19, July 2011

1. Scope and objectives

Review the requirement for repairs within IACS UR 7 and UR 10 series, in particular the requirement for Prompt and Thorough Repair, with a view to developing wording that would permit a temporary repair and the imposition of a Recommendation/ Condition of Class under specific and controlled circumstances, and in accordance with PR35.

2. Engineering background for technical basis and rationale

There are instances, for example a localised, isolated and very minor hole in a cross-deck strip, at which a suitable temporary repair, for example by welding or doubling, and the imposition of a suitable short term Recommendation/ Condition of Class for permanent repair at a later date, are considered very adequate methodology for dealing with the defect.

Current IACS Requirements in the UR Z7 and Z10 series, for Prompt and Thorough repair, would not permit this to be an option, the defect would have to be permanently Promptly and Thoroughly repaired, which might require removing cargo, moving to a repair berth and staging inner spaces.

Under the Requirements of IACS Procedural Requirement PR 35 the methodology of Temporary Repair and imposition of a suitable short term Recommendation/ Condition of Class for permanent repair at a later date is fully permissible.

3. Source / derivation of the proposed IACS Resolution

Based upon discussion within the IACS Survey Panel.

4. Summary of Changes intended for the revised Resolution:

Following the definition of Prompt and Thorough Repair in the Unified Requirement, a new paragraph is proposed to be added:-

"1.3.3 Where the damage found on structure mentioned in Para. 1.3.1 is isolated and of a localised nature which does not affect the ship's structural integrity, consideration may be given by the surveyor to allow an appropriate temporary repair to restore watertight or weather tight integrity and impose a Recommendation/Condition of Class in accordance with IACS PR 35, with a specific time limit."

5. Points of discussions or possible discussions

a) The points of discussion are as indicated in Sections 2 and 4 above.

b) Discussion took place on whether to prepare this amendment as a Unified Interpretation of IMO Resolution A.744(18)/UR Z7 and Z10 series, finally it was agreed to make direct amendment to the relevant URs.

c) It is proposed that this amendment be submitted directly to the IMO DE/MSC Committees for consideration of amending directly IMO Res. A744(18)

6. Attachments if any

None

Technical Background for UR Z10.1 Rev.21, Jan 2014

1. Scope and objectives

a) To consider appropriate text in IACS document regarding class period for lengthy conversions.
b) To align the requirements in PR37 and UR Z10s regarding safe entry to confined spaces.

2. Engineering background for technical basis and rationale

a) As per the IMO Res. A1053 (27), lengthy conversions (not necessarily of major character) or other major repair work can be assigned for a 5 year period from the date of completion of conversion/repairs/surveys.
b) Safety requirements in IACS PR37 can be applied to carry out survey in safe way for all kind of ships. When there are no indications about the safety of surveyor in UR Z10s then the requirements in PR37 shall be applied.

3. Source/derivation of the proposed IACS Resolution

None

4. Summary of Changes intended for the revised Resolution

a) Following additional text was included to section 2.1.3 to clarify the class period for lengthy conversions

"In cases where the vessel has been laid up or has been out of service for a considerable period because of a major repair or modification and the owner elects to only carry out the overdue surveys, the next period of class will start from the expiry date of the special survey. If the owner elects to carry out the next due special survey, the period of class will start from the survey completion date."

b) Existing Section 5.2.6 and 5.2.7 were deleted from UR Z10s since provisions of these sections were covered by PR37. Reference of PR37 was included in Section 5.2.1.1.

5. Points of discussions or possible discussions

i) Additional text to Para.2.1.3was discussed in order to clarify class period.
ii) Panel considered that safety of surveyors should be dealt by PR37.

Technical Background Document
WP/SRC – Trilateral Discussions
UR Z 10.1 – Proposed Rev. 6

Objective and Scope:

WP/SRC was tasked to consider OCIMF/INTERTANKO proposals to amend the Enhanced Survey Program.

Source of Proposed Requirements:

WP/SRC members discussed and reviewed the proposals extensively through correspondence and their meeting.

Points of Discussion:

WP/SRC unanimously agreed to the proposed draft UR Z 10.1. Consensus could not be achieved on any of the other OCIMF/INTERTANKO proposals. Refer to the Chairman's letters to GPG dated 4 February 1999 and 11 March 1999.

Date of submission: 6 May 1999
By WP/SRC Chairman's e-mail

Technical Background for Rev. 6.1, Z10.1

1. Scope of objectives

Revise the paragraph 2.2.1.3 to clarify that piping on deck is to be examined.

2. Points of discussions or possible discussions

- Before the ESP tripartite group meeting in October 1999, it was agreed to change the para. 2.2.1.3 by inserting "Cargo piping on deck, and" at the beginning of the sentence.

  The change from ".....under working CONDITIONS" to "....under working pressure" was made in the last set of amendments of Z10.1--and was considered to have the same meaning as OCIMF's proposed "...to working pressure." We are agreeable to changing "under" to "to".

- However, after the ESP technical working group meeting in October 1999, it was agreed to change the para:
  Cargo piping ondeck, including COW piping, all piping systems within.....

3. Source/deviation of proposed requirements

The final minutes of the ESP Working Group meeting reads:

The agreement already reached on piping in tanks was reaffirmed. It was reported by the Chairman of the Working Group, Mr. Bourneuf, that the IACS Council agreed to include cargo piping on deck as per UR Z10.1 para. 2.2.1.3 herein after attached. It was confirmed by IACS, at the request of the Working Group that cargo piping does include COW piping.

Prepared by the IACS Permanent Secretariat

Technical Background Document

UR Z10.1 – Revision 7
For ExCM decisions

Objective and Scope:

Revise UR Z10.1 to introduce ExCM (Extraordinary Council Meeting in Feb 2000) decision to UR Z10's

- ExCM FUA 2-1: All ballast tanks adjacent to cargo tanks with heating coils shall be examined internally on an annual basis after the ship has reached 15 years of age.

- ExCM FUA 2-2: Intermediate surveys of ships subject to ESP, which are over 15 years of age, will be enhanced to the scope of the preceding special survey with dry docking or under water survey as applicable.

Source of Proposed Requirements:

The proposed requirements were developed by WP/SRC Chairman, shortly after GPG 48th meeting:

- The para. 3.2.5.2 for ExCM FUA 2-1:
- The para. 4.2.2, 4.2.3 & 4.2.4 for ExCM FUA 2-2.
- The para. 7.1.1 for compatibility with the PR 19 (ABS GPG suggested).

Points of Discussion:

-

Unresolved Comments:

-

Discussions:

WP/SRC Chairman, when submitting draft revision to GPG, raised the following concerns:

- What tanks are required by the term "ADJACENT" ?

  WP/SRC Chairman said that tanks with a common line boundary have not been a problem since there is very little transfer of heat and should not be included.

  GPG exchanged views on this point and agreed to delete the wording "or line" from the para. 3.2.5.2 which reads: Oil Tankers exceeding 15 years of Age: All Ballast Tanks adjacent to (i.e., with a common plane ~~or line~~ boundary) a cargo tank with heating coils is to be examined internally.

- Ships using heating coils in cargo tanks
