UR A3	Anchor Windlass Design and Testing	Rev.1 June 2019	HF

UR A1 "Anchoring Equipment"

Summary

This revision introduces clarifications and updates to requirements regarding:
- purpose of anchoring equipment
- application of UR A1
- alternative method for calculations of anchoring equipment
- anchoring equipment for tugs
- use of wire rope in place of chain cable

Part A. Revision History

1 Origin of Change:

☑ Suggestion by IACS member

2 Main Reason for Change:

The present text of UR A1 contains general requirements for all types of ships. For fishing vessels and smaller ships with EN lower than 205 but greater than 50 operating in unrestricted service, UR A1 has been reviewed and updated to ensure a common standard for anchoring equipment requirements to reduce the number of reservations of IACS member societies against parts of UR A1.

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None

4 History of Decisions Made:

The present text of UR A1 contains general requirements for all types of ships. For fishing vessels and smaller ships with EN lower than 205 but greater than 50 operating in unrestricted service, UR A1 has been reviewed and updated to ensure a common standard for anchoring equipment requirements to reduce the number of reservations of IACS member societies against parts of UR A1.

- **Corr.1 (Sep 2021)**

1 Origin of Change:

☑ Suggestion by IACS member

2 Main Reason for Change:

In Rev.7 the definition of parameter "*a*" was changed unintentionally which is now corrected and clarified.

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None

4 History of Decisions Made:

Definition of parameter "*a*" within the definition of the effective height was discussed in Hull Panel, especially, if the deck camber should be included in parameter "*a*" or not. The inclusion of deck camber would increase the equipment number in general. As this was not supported by the Panel and the HF and TB to Rev.7 does not include information about changing this important parameter by adding the camber it was decided to correct the definition of parameter "*a*" by replacing "distance" by "vertical distance at hull side" and removing "at centreline". This is also in line with the definition of the same parameter in the previous revisions of UR A1 (before Rev.7). Figure 1 has been updated accordingly by removing "*a*". The upper deck as indicated in Figure 1 has been clarified to be measured at centreline to be consistent with the description given in the definition of 'h_i'.

5 Other Resolutions Changes:

None

6 Any hinderance to MASS, including any other new technologies:

- **Rev.7 (Sep 2020)**

.1 Origin for Change:

☒ Suggestion by IACS member

.2 Main Reason for Change:

In the recent years, the installation of equipment in the funnel such as scrubber resulted in the increase of funnel breadth. An IACS Member raised a question about how to treat the funnel whose breadth exceeds B/4 in the Equipment Number (EN) calculation specified in UR A1.2.1.

Additionally, an IACS Member highlighted differences in the approaches adopted in the UR A1 and A2.

In UR A1.7.3, the stresses of hull supporting structure of anchor windlass and chain stopper are to be computed using a gross thickness approach while in UR A2.1.5 and A2.2.5 a net thickness approach is requested for the calculation of hull supporting structure.

.3 List of non-IACS Member Classification Societies contributing or participating in IACS Working Group:

None

.4 History of Decisions Made:

The Hull Panel discussed about the increase in funnels size and decided to update the UR A1. Funnels with breadth exceeding B/4 shall be considered in the Equipment Number (EN) calculation specified in UR A1.2.1.

A separate TB has been developed detailing the scope for the consideration of funnels as summarized hereafter:

- The breadth of the funnel is considered in the front shape area
- The part of the funnel with a total breadth less than B/4 is disregarded in the front

shape area and in the side projected area.

- The effective area of accommodation deck considered in the calculation of the parameter h is considered as a shield in front of the funnel and is so deduced from the front shape area of the funnels.

The case where several funnels are fitted in the ship are also contemplated in this revision. In this case the Hull Panel decided to consider the sum of the breadth of each funnel having breadth bigger than B/4.

Additionally, as suggested by one Member, the Hull Panel decided to align the approaches utilized in UR A1 and A2. In line with UR A2, the permissible stress acting on the supporting hull structures of windlass and chain stoppers from UR A1 were modified to adopt a net thickness approach. Consequently, a new paragraph for corrosion addition was introduced in UR A1.

The guidance of meshing size for strength assessment by means of finite element analysis is newly introduced in line with the coarse mesh criteria as commonly adopted in FEA.

As a result from the Hull Panel review, the permissible stress in A1.7.3 was modified to the net thickness basis in line with A2.1.5 & A2.2.5. The guidance for finite element modelling for strength assessment by means of finite element analysis was provided in A1.7.3 also in line with A2.1.5 & A2.2.5. The new section A1.7.4 for the corrosion addition has been included in line with A2.4.

.1 Origin for Change:

☒ Request by non-IACS entity
☒ Suggestion by IACS member

.2 Main Reason for Change:

Due to concerns raised by the industry in view of an increasing number of incidents, such as anchor losses, IACS decided to review and update UR A1 and Recommendation No. 10 "Anchoring, Mooring, and Towing Equipment". Operational practices being adopted by many owners, in particular, anchoring in unsheltered waters, have been considered for the review of the existing criteria for anchoring to reflect current practice.

.3 List of non-IACS Member Classification Societies contributing through the TC Forum and/or participating in IACS Working Group:

None.

.4 History of Decisions Made:

GPG approved the initial Form A for the review of UR A1, UR A2, and Rec. No. 10 on 6 November 2009 (9633_IGc) and a revised Form A on 8 November 2010 (10035_IGg). The task was extended to allow for more extensive investigations and the associated Form A was approved by GPG on 23 August 2012 (12106_IGd).

The final draft revision of UR A1 and the associated technical background document were approved by Hull Panel on 6 January 2016.

.5 Other Resolutions Changes:

Recommendation No. 10 "Anchoring, Mooring, and Towing Equipment" was revised in parallel to and aligned with UR A1. A new Unified Requirement A3 "Anchor Windlass Design and Testing" has been set up. UR A3 is to refer to UR A1 in terms of required anchor and chain as well as requirements to hull supporting structures of anchor windlass and chain stopper.

Technical Background Document
UR A1 (Rev.5, June 2005)

Requirements for Equipment

1. Background- Review of UR A1

WP/MW Chairman reported in his final report to GPG that:

In relation to development of requirement for anchor (Task No.46), the draft amendment to UR A1 which is to be handled by the CG/MA was proposed for consideration and action by the GPG. The GPG is requested to convey the draft to the Hull Panel and appropriate Project Team on M/A for their technical consideration.

2. GPG undertook the review and approval of UR A1(Rev.5)

GPG agreed that section 1.1.2.3 of REC 10 be deleted to avoid any conflict between UR A1 and REC 10 in relation to the anchor proof testing.

Technical Background (TB) document for UR A1 (Rev.6 Oct 2016)

1. Scope and objectives

Due to concerns raised by the industry in view of an increasing number of incidents like anchor losses UR A1 has been reviewed and updated. Operational practices being adopted by many owners, in particular, anchoring in unsheltered waters have been considered for the review of the existing criteria for anchoring to reflect current practice. Extensive numerical calculations have been carried out to verify the existing environment conditions and to establish alternative environment conditions for the required anchoring equipment for anchoring in unsheltered waters including wave loads.

For further information see Attachment 1.

2. Engineering background for technical basis and rationale

See Attachment 1.

3. Source/derivation of the proposed IACS Resolution

See Attachment 1.

4. Summary of Changes intended for the revised Resolution

UR A1 has been reviewed and updated with respect to environmental criteria for the required anchoring equipment. Based on extensive numerical calculations the existing environment conditions were verified. To reflect current anchoring practice, alternative environment conditions for the required anchoring equipment have been specified for anchoring in unsheltered waters including wave loads.

Provisions have been added for wire ropes for anchors, similar to those in Recommendation No. 10, to reduce the number of reservations of IACS member societies against parts of UR A1.

Furthermore, requirements for hull supporting structures of anchor windlass and chain stopper have been introduced.

With this revision also several editorial changes have been introduced.

See Attachment 1 for more detailed information.

5. Points of discussions or possible discussions

None.

6. Attachments if any

See Attachment 1.

Technical background to UR A1 (Rev.6 Oct 2016) 'Anchoring Equipment'

A1.1. Design of the anchoring equipment

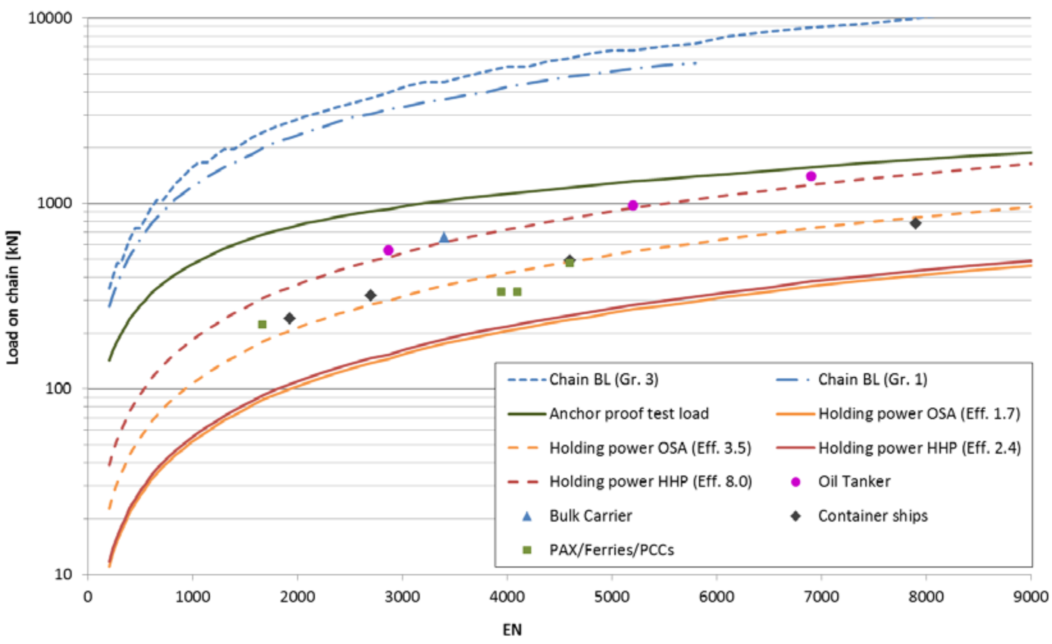
The required anchoring equipment given by UR A1 was reviewed with respect to the given environmental conditions. Furthermore, for the required anchoring equipment, alternative environmental conditions, including waves, were determined to serve as guidance for the limitations of the anchoring equipment used in semi-sheltered or unsheltered anchorages. For this, numerical anchoring calculations were performed for ships of different types and sizes under the following conditions:

a) Wind speed 25m/s, current speed 2.5 m/s, no waves, for:
   i. maximum possible water depth maintaining a scope of six
   ii. shallow water depth with maximum possible scope

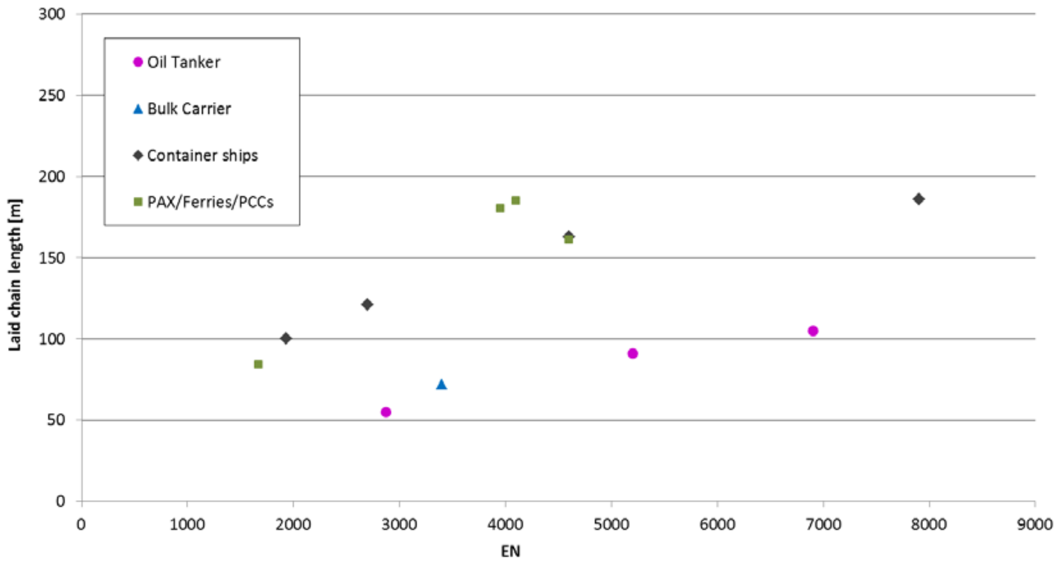
b) Wind speed 11m/s, current speed 1.54 m/s and significant wave height 2 m, for maximum possible water depth maintaining a scope of six

The results for the maximum calculated chain cable tensions for a), i) are shown below over the Equipment Number EN and are compared to:

- Holding power of ordinary stockless anchors (OSA) with a weight as required by UR A1 for anchor efficiencies of 1.7 and 3.5, representing sea bed consisting of soft mud and shingle/sand, respectively, according to OCIMF 'Anchoring Systems and Procedures'
- Holding power of high holding power anchors (HHP) with a weight as required by UR A1 for anchor efficiencies of 2.4 and 8.0, representing sea bed consisting of rock with thin mud layer and shingle/sand, respectively, according to OCIMF 'Anchoring Systems and Procedures'
- Proof test load for anchors with a weight as required by UR A1
- Breaking strength of chain cable of grades 1 and 3 as required by UR A1.



The laid length of the chain cable is important for the holding power of the anchor, which drastically reduces when the shank lifts from the sea bed. The results for the calculated minimum laid length of the chain cable for a), i) are shown below over the Equipment Number EN.



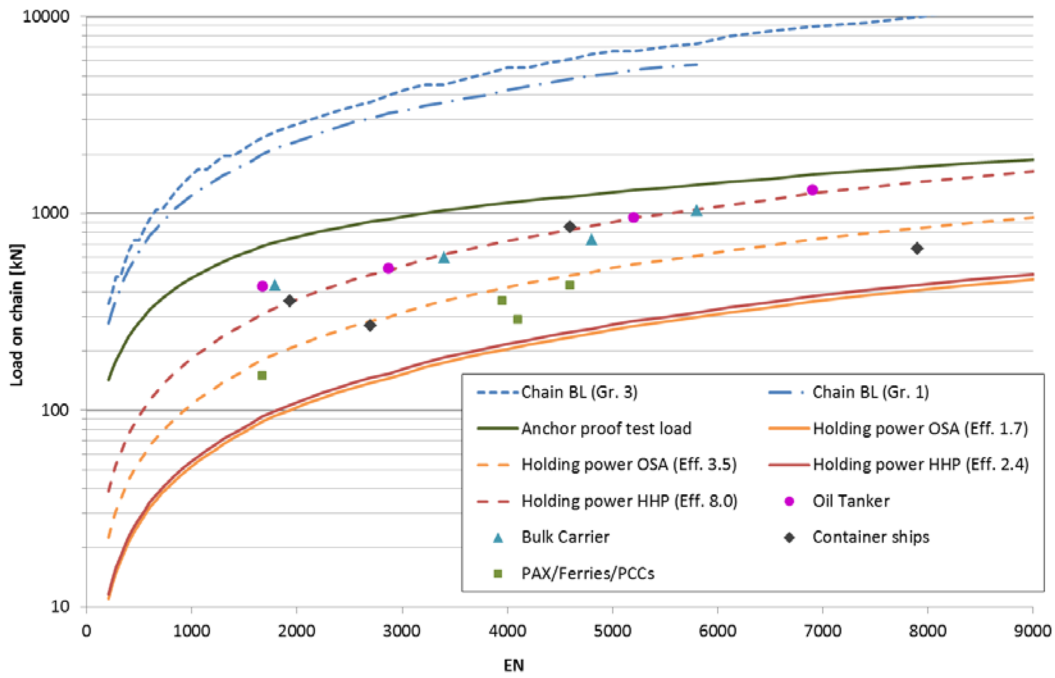
From the results it can be concluded that

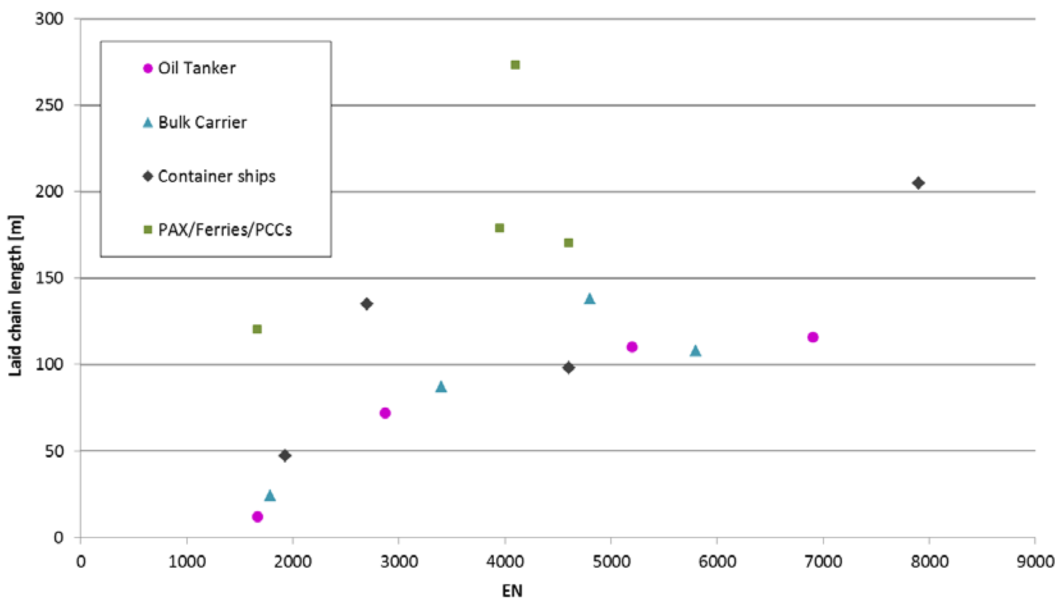
- the required breaking strength of the chain cable is sufficient,
- the laid length is sufficient (> 0m),
- the holding power of HHP anchors is sufficient in good holding ground,
- the holding power of OSA is sufficient for slender ships like the assessed container ships, PAX, Ferries, and PCCs,
- the holding power of OSA even in good holding ground is insufficient for the blunt vessels, i.e., tankers and bulk carriers.

It needs to be observed that the chain cable tension at the anchor can be up to 30% less than the maximum chain cable tension, however, for blunt ships using OSA, anchor dragging may need to be expected for more benign environmental conditions than given in A1.1.4., i.e. already for combinations of wind speeds beyond 20m/s and current speeds beyond 2 m/s. Thus, it is recommended to choose HHP anchors for ships with high block coefficients, as e.g. oil tankers and bulk carriers.

Similar results were found for shallow water according to case a), ii).

The results for the maximum calculated chain cable tensions and minimum laid length for b) are shown below over the Equipment Number EN. The results for the chosen environmental conditions, compared to the limit curves of the anchor holding power and proof test load are similar to those for case a). Irrespective of the reduced chain cable tensions at the anchor, for the blunt ships but also for two of the assessed container ships, OSA do not provide sufficient holding power and dragging may be expected for more benign conditions than stated. Thus, it is recommended to choose HHP anchors for ships intended to be anchored under the given environmental conditions including wave loads.





According to the performed anchoring calculations, the required anchoring equipment is subject to the following limitations:

- Wind, current, and waves from ahead and in the same direction.
- No strong yaw and sway motions of more than ±10 degrees, even of low frequency.
- Water depth to draught ratio not less than 1.5.

For water depth to draught ratios between 1.5 and 3, the maximum possible scope of chain cable should be provided. Disregarding these limitations may increase the loads on the anchoring equipment, and anchor dragging is to be expected under more benign environmental conditions than assumed.

If the anchoring equipment should be applicable for higher wind or current speed, the following means may be taken:

- Use HHP anchor with a weight as required for an OSA according to UR A1
- Provide longer chain cable
- Provide heavier chain cable for the shot of cable connected to the anchor

A1.2. Equipment number and anchoring equipment table

The required number of bower anchors as given in Table 1 was changed to two instead of three because the requirement for a third anchor was already left to the discretion of the individual class society in A1.4.2 of UR A1 Rev. 5.

A1.5. Chain cables for bower anchors

Chain cable may be replaced by wire ropes for both bower anchors for ships below 40 m in length instead of only for one of the two bower anchors for ships between 30 m and 40 m in length. An additional condition was added to UR A1, requesting all surfaces being in contact with the wire to be rounded with a radius of not less than 10 times the wire rope diameter, including the stem, to reduce the risk of damage to the ropes. This change was performed to align IACS member class requirements with respect to wire ropes for anchors and avoid reservations to this provision.

A1.7. Hull supporting structure of anchor windlass and chain stopper

This section was included as hull supporting structure of anchor windlass and chain stopper was not regulated by IACS but considered as gap with respect to UR A2 that imposes requirements for substructures of towing and mooring fittings and mooring winches.
The given requirements are aligned with requirements in IACS Common Structural Rules for Bulk Carriers and Oil Tankers.

Technical Background (TB) document for UR A1 (Rev.7 Sep 2020)

1. Scope and objectives

The increase of the funnel size due to the installation of equipment such as SOx scrubbers has been noticed on recent constructions. Funnels whose breadth exceeds B/4 is also more frequent. One Hull Panel Member raised this topic and proposed to study this issue. UR A1 had been reviewed and updated to treat those funnels in calculation of the Equipment Number (EN) specified in UR A1.2.1.

2. Numerical Calculation examples and comparison based on real cases

Ship Type	L x B x D (m)	EN present	EN modified	Differential	Efficient
Feeder	170.0 x 28.00 x 14.00	2,800	2,839	39	No change
Post- Panamax CNC	300.0 x 46.00 x 25.00	6,600	6,664	64	No change
Post Panamax CNC	350.0 x 50.00 x 30.00	7,350	7,420	70	Up grade
Panamax BC	220.0 x 32.20 x 20.00	3,500	3,545	45	No change
VLOC	300.0 x 55.00 x 25.00	6,070	6,147	77	Up grade
Oil/Chemical	140.0 x 25.00 x 13.00	1,400	1,475	75	No change
VLCC	325.0 x 65.00 x 29.00	7,390	7,481	91	Up grade

3. Summary of Changes intended for the revised requirements

UR A1 has been reviewed and updated with respect to the calculation of EN with the funnels whose breadth is exceeding B/4 in the transverse section of the ship.
The following principles have been agreed by the Hull Panel:

- When the breadth of the funnel exceeds B/4, its front and side projected areas are considered in the EN calculation.
- In case of several funnels, the total breadth of the funnels is considered.

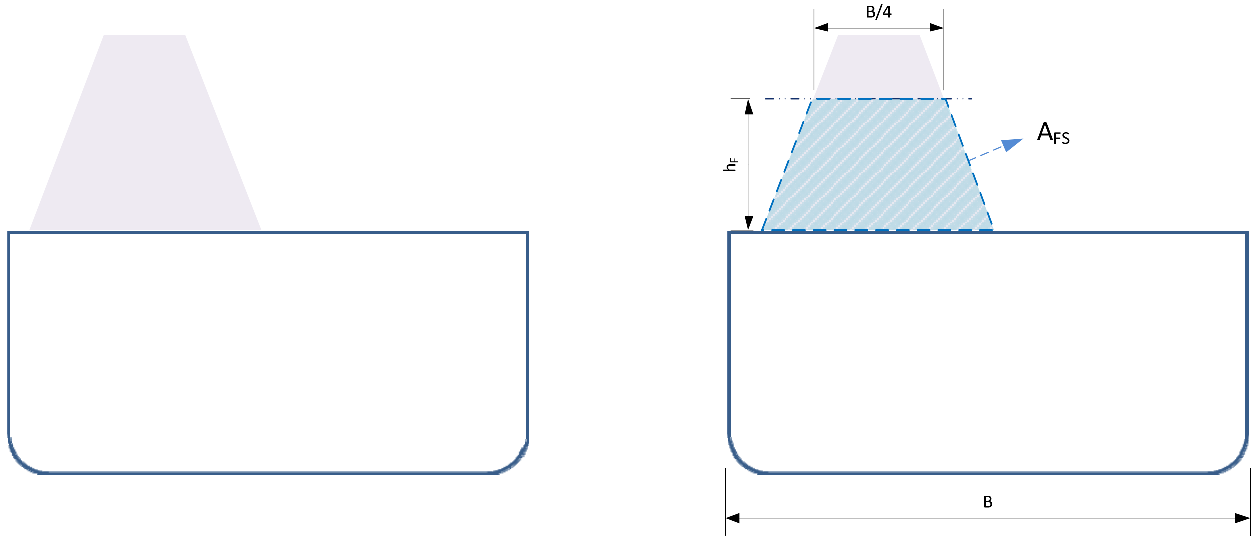
Front Area:

The funnel is usually located at the aft part of the ship, behind the accommodation. The same area shall not be accounted twice in the total front area, in the accommodation deck surface on one hand and in the funnel's areas on the other hand.

The shielded area of the accommodation S_{shield} is removed from the funnel area, A_{FS}, for obtaining the effective funnel area, S_{fun}: $S_{fun} = A_{FS} - S_{shield}$
S_{fun} is not to be taken less than zero.

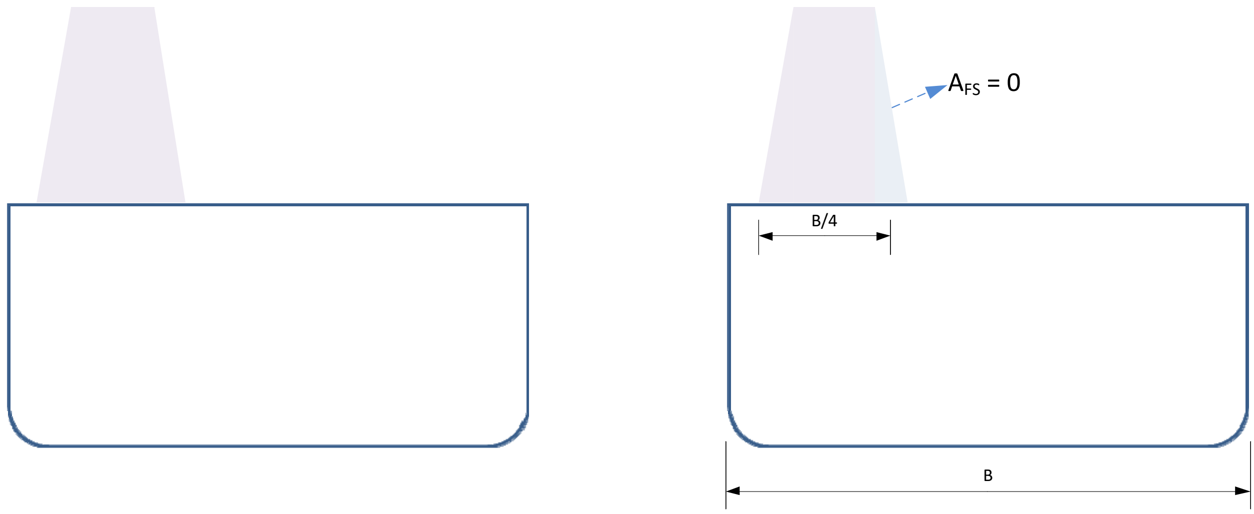
Funnel area A_{FS}:

For single funnel, A_{FS} is estimated up to the h_F level obtained when the funnel breadth reaches B/4.



Funnels arrangement on ship ⇨ Funnels consideration for A_{FS} determination

Figure 1: AFS determination for a single funnel



Funnels arrangement on ship ⇨ Funnels consideration for A_{FS} determination

Figure 2: Funnel with breadth less than B/4

The following figure provides an example with the tiers no. 1 and 3 larger than B/4 but the tier no.2 less than B/4. The shield areas are only considered for the tiers 1 and 3. There is no shield area for the tier 2. For tiers 1 and 3, the shields areas are calculated considering the tier breadth equivalent to B

The effective height is limited when the funnel breadth reaches B/4.

The effective funnel area in green is obtained by the $S_{shield1}$ and $S_{shield2}$ from A_{FS} in blue:

$$S_{fun} = A_{FS} - S_{shield} = A_{FS} - (S_{shield1} + S_{shield2})$$

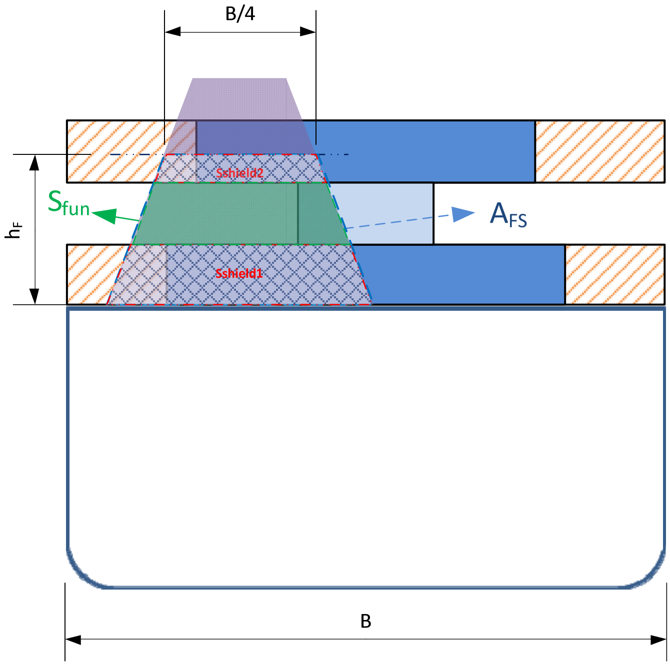


Figure 3: Example of A_{FS} and S_{fun} determination

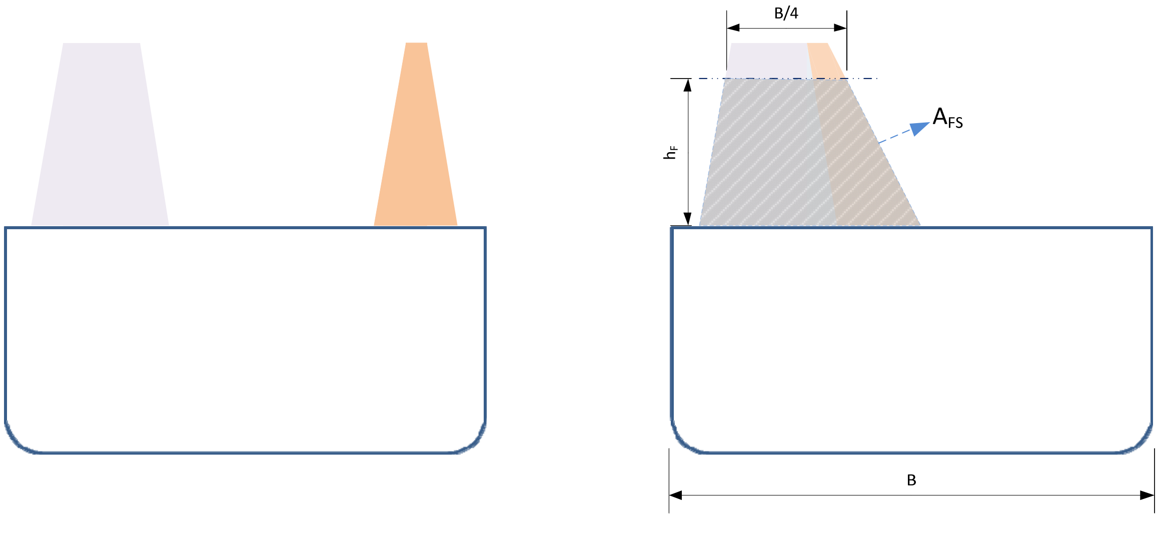
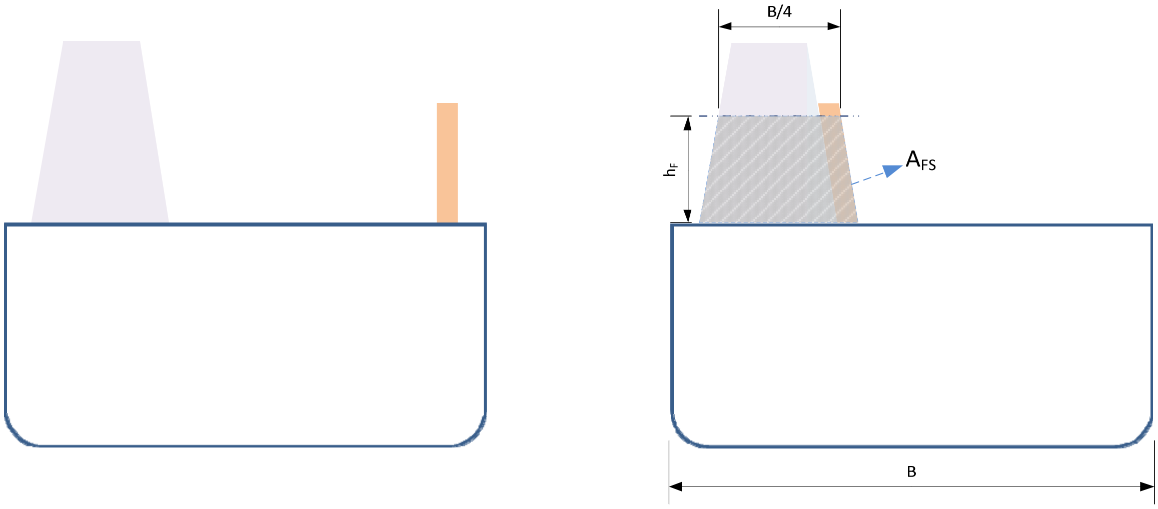
When several funnels are arranged on the ship, the funnel area is estimated from the total breadth of all funnels fitted on the ship.
The resulting front shape area of the funnels, A_{FS}, may be limited below the level of the effective height of the funnels, i.e. the height where the total breadth of the funnels reaches B/4 as shown in the following figures.



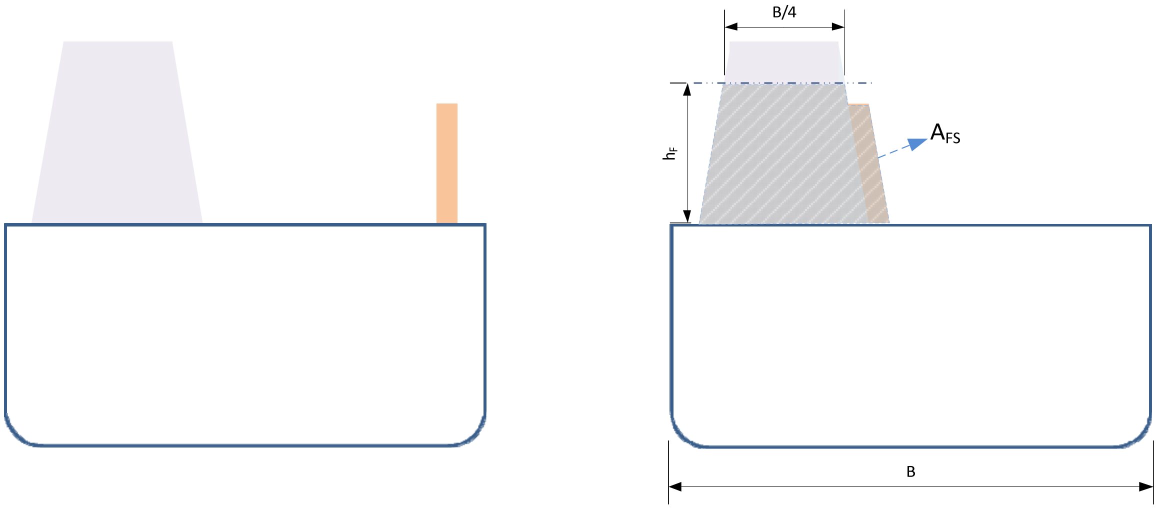
Funnels arrangement on ship ⇨ Funnels consideration for A_{FS} determination

Figure 4: Two funnels case: same height - different breadths



Funnels arrangement on ship ⇨ Funnels consideration for A_{FS} determination

Figure 5: Two funnels case: B/4 breadth below the top of the smaller funnel



Funnels arrangement on ship ⇨ Funnels consideration for A_{FS} determination

Figure 6: Two funnels case: B/4 above the top of the smaller funnel

When the total breadth of the resulting front shape of the funnels is less than or equal to B/4, the area of the funnels may be disregarded (A_{FS} = 0).

<u>Shield area S_{shield}:</u>

The total shield area S_{shield} is the sum of all shielded areas $S_{shield\ i}$ of the accommodation deck "i" having a breadth greater than B/4 and overlapping the front shape area of the funnels, A_{FS}.

The shield area, $S_{shield\ i}$ of the accommodation deck "i" having a breadth greater than B/4, is the common area between the h_i.B and the front funnels area as shown in UR A1 Figure 2.

Accommodation decks having a breadth less than or equal to B/4 are not considered in

S_{shield}.

Effective funnel area S_{fun}:

The effective funnel area, S_{fun}, is obtained by deducing the shielded area of all the accommodation decks "i" considered in the h calculation (i.e. having a breadth less than or equal to B/4) from the front shape area of the funnel, A_{FS}:

S_{fun} is defined as:

$$S_{fun} = A_{FS} - \sum_i S_{shield\ i} \text{ without being less than zero}$$

Side projected area

The funnel whose breadth is exceeding the B/4 is incorporated in "A", the ship side projected area calculation.

The funnel which reaches a breadth smaller than B/4 is disregarded in the ship side projected area. The funnel part above the effective height of the funnel, h_F, may be disregarded in the determination of "A".

When the ship is fitted with 2 or more funnels, the resulting global side projected area of the funnels is to be included in the side projected area calculation of the ship when A_{FS} is greater than zero.

The shielding effect of funnels is to be considered for the side projected area. A funnel may shield another one which is not to be accounted in this side area. If 2 funnels are fitted symmetrically as per the ship centerline axis, the side projected area corresponds to one funnel only and is considered if $h_F > 0$. For instance, when two funnels of the same dimensions are fitted symmetrically as per the ship centreline axis, the global side projected area of these 2 funnels may be taken as the area of one single funnel only.

The resulting side projected area of the funnels may be accounted if the funnels are not fitted symmetrically as per the ship centerline axis.

Technical Background (TB) document for UR A1 (Rev.8 June 2023)

1. Scope and objectives

The present text of UR A1 contains general requirements for all types of ships. For fishing vessels and smaller ships with EN lower than 205 but greater than 50 operating in unrestricted service, the anchoring equipment is not covered by UR A1 but may be defined by IACS recommendation No. 10. UR A1 has been reviewed and updated to clarify the application for smaller ships and to deal with reservations of IACS member society against parts of UR A1.

5. Points of discussions or possible discussions

See Attachment 1.

6. Attachments if any

See Attachment 1.

Attachment 1 to Technical Background for UR A1
(Rev.8 June 2023)

A1.1 Design of the anchoring equipment

A 1.1.7

The requirements given in UR A1 regarding the strength of anchoring equipment are based on normal anchoring conditions, i.e., temporary anchoring of a ship within a harbour or sheltered area when the ship is awaiting berth. But ship safety also depends on anchoring equipment, especially in emergencies. Therefore, anchoring equipment shall be installed onboard and ready for use for ships that are not intended for regular anchoring operations.

A1.1.8

This paragraph clarifies the application of UR A1, which depends on the ship size and type. The application is based on general IACS's scope (IACS GENERAL PROCEDURES, vol.1, A2) and IACS members' practices.

A1.1.9

This paragraph clarifies the requirements given in UR A1 applicable for vessels with restricted service areas:

- A1.4.3 The bower anchors are to be connected to their cables and positioned on board ready for use.
- A1.4.4 Proof testing of anchors,
- A1.4.5 SHHP anchor material selection and toughness,
- A1.4.6 Fabricated anchors,
- A1.5.2 Grades of chain cables,
- A1.5.3 Proof and breaking loads of stud link chain cables,
- A1.6 Permissible wear down of stud link chain cable for bower anchors,
- A1.7 Supporting hull structures of anchor windlass and chain stopper

A1.1.10

The definition of "unrestricted service" is based on IACS Rec.99. If the anchoring equipment is not designed for unrestricted service, the service restrictions shall be reflected in the vessel class notation.

A1.2 Equipment number and anchoring equipment table

A 1.2.4

This change was performed to align with IACS member class requirements.
According to IACS UR A1, anchoring equipment is selected based on equipment number calculation. An alternative methodology based on forces of current and wind on the ship is introduced for ships with length less than 90m. This alternative methodology is described in Appendix B of IACS Recommendation 10.

A1.3 Anchoring equipment for tugs and dredgers

A1.3.1 Equipment for tugs

The changes to IACS UR A1 are intended to provide unified anchoring requirements for towing vessels for unrestricted service and eliminate IACS member reservation on anchoring requirements for towing vessels for unrestricted service.

The revised requirements consider the feedback from ship owners and operators based on the satisfactory long service history of towing vessels fitted with a set of one anchor and chain.

Considering the unique operational profile for tugs constructed for towing service where the towing vessels are designed for unrestricted service, the typical towing vessels operate near a harbour or coastal area for the intended towing service. If there is damage to the temporary anchoring system, the towing vessel will be able to return to the home port to replace it promptly.

A1.3.2 Equipment for dredgers

Dredgers with an unusual design of the underwater part of the hull are to be covered by EN number equipment calculation. Consequently, direct force calculations for anchoring equipment described in appendix B of Rec. 10 are not applicable for such ships.

A1.5 Chain cables for bower anchors

This change was performed to align IACS member class requirements. Wire rope may replace chain cable for both bower anchors for ships below 90 m in length, which are not intended for regular anchoring. No length limitation is given to vessels with the anchoring equipment used for positioning with a minimum of 4 points anchoring, e.g., for cable or pipe laying. The requirements apply to bower anchors only.

An additional condition was added, requiring the anchor weight to be increased by 25% compared to anchors associated with chain cable, according to Table 1. The increased weight of the anchor (25%) and the wire cable length (50%) provide equivalent anchoring capabilities concerning horizontal pull force. The weight of the wire cable is 4-8 times lower than a chain cable of equal strength. It requires wire length to be approximately 2-3 times the chain cable to obtain equilibrium in static force analysis (catenary equations in anchor cable extending between the ship's hawse pipe and the anchor shank). In the same conditions, a shorter wire cable (1.5 times the chain cable) increases the angle between the cable and the seabed, resulting in a drop of anchor holding power. The increase in anchor weight compensates for that loss.

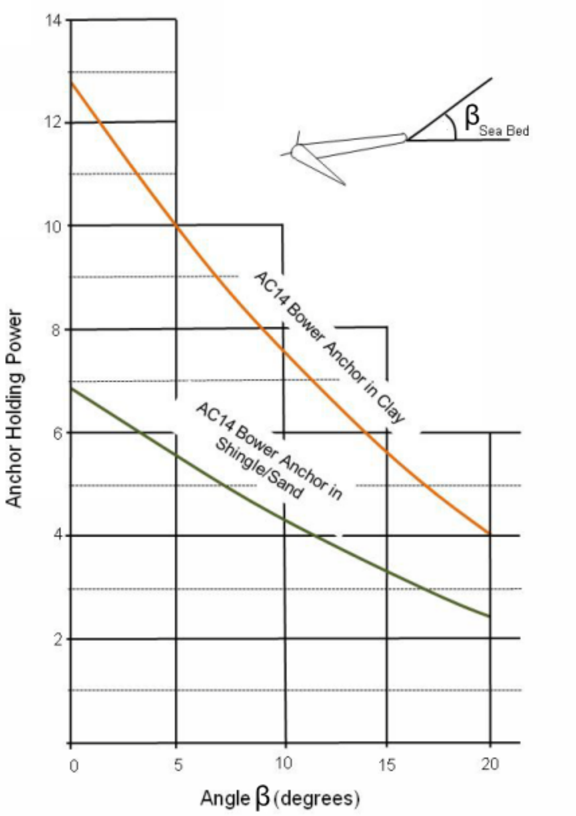

Figure 1: Relationship between anchor holding power and chain cable angle with seabed, β

UR A2 “Shipboard fittings and supporting hull structures associated with towing and mooring on conventional ships”

Summary

This revision clarifies the determination of deck cargoes side projected area and introduces the guidance of meshing size for strength assessment by means of finite element analysis in line with coarse mesh criteria as commonly adopted in FEA.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev. 5 (Sep 2020)	25 September 2020	1 January 2022

- **Rev.5 (Sep 2020)**

.1 Origin for Change:

☒ Request by non-IACS entity
☒ Suggestion by IACS Member

.2 Main Reason for Change:

IACS Member and Industry identified the necessity to clarify the determination of deck cargoes side projected area in note 1 of paragraphs UR A.2.1.3 and A.2.2.3.

Additionally, an IACS Member highlighted the differences in the approaches adopted in the UR A1 and A2.

In UR A1.7.3, the stresses of hull supporting structure of anchor windlass and chain stopper are to be computed using a gross thickness approach including its corresponding loads and criteria while in UR A2.1.5 and A2.2.5 a net thickness approach using its corresponding loads and criteria is requested.

Also, changes were made to align the text of UR with draft MSC.1/Circ.1175/Rev.1 (refer Annex 2 of SDC 6/13) approved by MSC 101 (refer para 12.9 of MSC 101/24).

.3 List of non-IACS Member Classification Societies contributing or participating in IACS Working Group:

None

.4 History of Decisions Made

The determination of the deck cargoes side projected area in note 1 of paragraphs A.2.1.3 and A.2.2.3 have been clarified through the definition of the loading condition to be considered. The side projected area of deck cargoes should be taken as given by the ship nominal capacity condition. See separate TB.

The guidance of meshing size for strength assessment with finite element analysis is provided in A2.1.5 and A2.2.5. The modified sentence "…a mesh size equal to the stiffener spacing is generally acceptable, and the mesh is to be fine enough to represent the geometry as realistically as possible." is referred from 1-7-2/2.4.2 (e) and 1-7-2/2.4.2 (f) of CSR-H.

.5 Other Resolutions Changes

UR A1 & Rec 10.

.6 Any hinderance to MASS, including any other new technologies:

None

.7 Dates:

Original Proposal:	17 May 2018 by Hull Panel
Panel Approval:	27 August 2020 (Ref: 12106_PHI)
GPG Approval:	25 September 2020 (Ref: 12106_IGzd)

- **Corr.2 (Mar 2017)**

.1 Origin for Change:

☑ Suggestion by IACS member

.2 Main Reason for Change:

To modify the effective date of the UR A1, UR A2 from 1 January 2018 to 1 July 2018 in order to have a consistent effective date of a planned RCN/URCN which is to incorporate the updates made to UR A1, UR A2 and Rec. 10.

.3 List of non-IACS Member Classification Societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made

None.

.5 Other Resolutions Changes

None

.6 Dates:

Original Proposal: 03 February 2017 by Hull Panel
Panel Approval: 10 February 2017 (Ref: PH17002).
GPG Approval: 15 March 2017 (Ref: 17022_IGb)

- **Corr.1 (Dec 2016)**

.1 Origin for Change:

☑ Other (Editorial correction identified by Hull Panel)

.2 Main Reason for Change:

Editorial correction identified by Hull Panel.

.3 List of non-IACS Member Classification Societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made

None.

.5 Other Resolutions Changes

None

.6 Dates:

Original Proposal: 07 November 2016 by Hull Panel
Panel Approval: 09 December 2016 (Ref: PH7011_IHcg).
GPG Approval: N.A.

- **Rev.4 (Oct 2016)**

.1 Origin for Change:

☒ Request by non-IACS entity
☒ Suggestion by IACS member

.2 Main Reason for Change:

Due to recurrent incidents during mooring and towing, IACS decided to review and update Unified Requirement A2 and Recommendation No. 10 "Anchoring, Mooring, and Towing Equipment". Furthermore, IACS member comments to UR A2, Rev. 3 were addressed.

.3 List of non-IACS Member Classification Societies contributing through the TC Forum and/or participating in IACS Working Group:

None.

.4 History of Decisions Made:

GPG approved the initial Form A for the review of UR A1, UR A2, and Rec. No. 10 on 6 November 2009 (9633_IGc) and a revised Form A on 8 November 2010 (10035_IGg). The task was extended to allow for more extensive investigations and the associated Form A was approved by GPG on 23 August 2012 (12106_IGd).

The final draft revision of UR A1 and the associated technical background document were approved by Hull Panel on 6 January 2016.

.5 Other Resolutions Changes:

Recommendation No. 10 "Anchoring, Mooring, and Towing Equipment" was revised in parallel to UR A2, providing recommended strengths of mooring and tow lines, being the basis for design loads of fittings for mooring and other towing.

.6 Dates:

Original Proposal: 18 September 2007 made by GPG (6111cIGb)
Panel Approval: 03 October 2016 (Ref: PH7011)
GPG Approval: 31 October 2016 (12106_IGs)

- **Corr.1 (Sept 2014)**

.1 Origin for Change:

☒ Suggestion by an IACS member.

.2 Main Reason for Change:

To correct the reference of ISO 3913 in IACS UR A2. ISO 3913 is now withdrawn and replaced by ISO 13795.

.3 List of non-IACS Member Classification Societies contributing through the TC Forum and/or participating in IACS Working Group:

None.

.4 History of Decisions Made:

A GPG Member proposed the correction and approved by GPG. Permsec corrected the file and prepared a history file to record the correction.

.5 Other Resolutions Changes:

None

.6 Dates:

Original Proposal: 26 August 2014 Made by a Member
GPG Approval: 09 September 2014 (Ref: 14141_IGc)

- **Rev.3 (July 2007)**

  Refer to the TB document in Part B.

- **Rev.2 (Sept 2006)**

  Refer to the TB document in Part B.

- **Rev.1 (July 2004)**

  "Contracted for Construction" statement added.
  No history files or TB document available.

- **Corr.1 (Feb 2004)**

  No history files or TB document available.

- **New (Jan 2004)**

  Refer to the TB document in Part B.

Part B. Technical Background

List of Technical Background (TB) documents for UR A2:

Annex 1. **TB for New (Jan 2004)**

See separate TB document in Annex 1.

Annex 2. **TB for Rev.2 (Sept 2006)**

See separate TB document in Annex 2.

Annex 3. **Rev.3 (July 2007)**

Note: There are no separate Technical Background (TB) documents available for Corr.1 (Feb 2004), Rev.1 (July 2004), Corr.1 (Sept 2014), Corr.1 (Dec 2016) and Corr.2 (Mar 2017).

UR A2 Technical Background

As a result of investigations regarding the damage caused to deck fittings by towing, IACS members have confirmed that their Rules and the regulatory bodies' standards (ISO) only provide the strength criteria for ropes, wires, fairleads, bollards, strong points, etc for anchoring and mooring. The ETA standard for emergency towing use with tankers has already been included in the Rules of members. Similarly the OCIMF has recommended towing arrangements for tankers over 20,000dwt.

In order to respond in a proper manner to the damage caused, it is necessary to analyse examples of the types of actual damage. However, owing to the time constraint and unavailability of information sources, the members were unable to look into an example of damage in depth.

Notwithstanding the above, if we accept the reasons for damage described in the Australian proposal, the following observations are made:

- Mooring fittings generally also serve as towing fittings.

- The strength of shipboard fittings for mooring is related to the required strength of the ship's mooring lines as per the regulatory bodies' standards (ISO). In the past there was no trouble because mooring force was typically higher than towing force. Now modern high-power tugs are capable of exerting towline forces that are well in excess of those exerted by tugs in services few years ago.
Also tugboat operators may use their own towing lines, which have greater strength than mooring lines. Then it becomes difficult to predetermine working loads.

Shipbuilders have been executing reinforcement to the foundation structures that are loaded with towing forces. However these local reinforcements and strength investigations have been carried out their own way, individually, as seen in the existence of various types of foundations / construction. There are no unified standards for reinforcing the foundation of mooring fittings.

It should be noted that the Rules of some member Societies do actually prescribe local reinforcement, such as scantling-up of the foundation plate thickness for steering gear installation as well as reinforcement of foundation structure for cargo gear post

In order to increase attention to this matter by the shipping industry, we propose herewith requirements for the strength of deck fittings and tie-down structure reinforcement, for shipboard deck fittings used with tugs. Considering issues related to the safety of hull construction, it is considered better to specify a "Safe Working Load" for fittings rather than increasing scantlings specifically.

****

1027IIGh ~~21~~/10/2003.

Technical Background

UR A2 (Rev.2, September 2006)

"Shipboard fittings and supporting hull structures associated with towing and mooring on conventional vessels"

1. Scope and objective

Since the original UR A2 was withdrawn in 2005 reflecting the industry feedback, IACS have been receiving further industry inputs with respect to how shipboard fittings were to be designed, used and maintained for ship's safe operation. These feedbacks were sent by shipbuilders, ship operators, tug operators and port authorities. In the meantime, MSC80 (18 to 27 May 2005) adopted MSC/Circ.1175, "Guidance on Shipboard Towing and Mooring Equipment". The revised UR A2 was developed in line with the requirements in the MSC/Circ. 1175. The valuable comments from industry, approximately 20 organisations, are also considered and incorporated into the revision.

2. Points of discussions or possible discussions

The following summarize the changes made in the revision:

1. In view of the concerns of industry about the corrosion, the revision provides the specific corrosion additions to the net thickness, on which basis all strength criteria as specified in the revision are satisfactorily complied with. The general requirements for survey after construction are also provided in order to maintain a sound structural condition under the supervision of the class. (see A2.0, A2.4 and A2.5).
2. The design loads for both towing and mooring are revised in accordance with the MSC/Circ. 1175. In addition to the specified minimum design load requirements, the revision covers a greater design load, which may be specially requested by the applicant, e.g., ship owner or ship operator. (see A2.1.3 and A2.2.3)
3. In selection of towing lines/mooring lines, it is also addressed that side projected area including maximum stacks of deck cargo is to be taken into account, of which concerns were raised by the Port of Rotterdam based on their own feasible study of mooring forces induced by the wind forces due to full stacks of deck cargoes. (see Note to A2.1.3.2 and A2.2.3.1).
4. To ensure safe towing and mooring operations, a preparation of the drawings, "towing and mooring arrangement plan" and "pilot card" for information of the operation for ship's master and pilot respectively. (see A2.3)

3. Source/ derivation of proposed requirement

Hull Panel

4. Decision by voting

N.A.

5. GPG Discussion

The following issues were discussed at GPG and decided upon by vote:

1. The draft UR was received from the Hull Panel without a proposed uniform application statement or date. A majority of Members agreed to the uniform application statement proposed by ABS ("contracted for construction from 1 January 2007", with RS preferring the uniform application statement proposed by GPG Chairman ("contracted for construction after 1 July 2007").
2. LR pointed out that there would be a gap between the contract for construction date associated with the amended UR A2 and the 1 January 2007 keel-laying date associated with the entry into force of -the revised SOLAS Reg. II-1/3-8. In order to bridge this gap, all Members agreed to task the Perm Sec to draft a simple UI of SOLAS Reg. II-1/3-8 stating that the requirements in UR A2 (Rev.2) are to be

applied for ships with a keel laying date on or after 1 January 2007. This will require Members to apply the requirements in UR A2 when acting on behalf of an Administration, unless otherwise instructed by the Administration, but provide Members additional time to implement the UR in their Rules.

Permanent Secretariat Note [7 September 2006]:
Following initial GPG approval, LR raised concerns that paragraph 2.2.3.1 of UR A2 refers to Recommendation 10, thus making it mandatory, and that Table 5 of Recommendation 10 specifies the number of mooring lines, whereas when it was copied into MSC/Circ.1175 the number of lines was omitted. This would mean that UR A2 could be considered as more restrictive than the Circular and thus an IACS member may be disadvantaged in comparison to a non-IACS member.

Further discussion was held by GPG members and it was agreed by all members to add a new footnote to A2.2.3.1 (and A2.1.3(2) which also refers to Recommendation 10) to clarify that Recommendation 10 is not a mandatory requirement. In addition the GPG Chairman has opened a new subject number to discuss the method of making reference to the mandatory/non-mandatory IACS and IMO Instruments in IACS mandatory Resolutions, i.e. footnote and Annex (GPG Small Group on Reference to Mandatory Resolutions, 6158).

LR was also concerned about a lack of harmonisation between UR A2 and CSR for both oil tankers and bulk carriers. Nine members (BV, KR, DNV, ABS, NK, RS, CCS, RINA and LR) agreed that this should be dealt with separately from the adoption of the draft UR A2 and that it should be considered and dealt with as rule change by PT1 and PT2 under the instruction of Hull Panel.

TECHNICAL BACKGROUND – Revised June 2007 (ref. 6111_IGm)

UR A2 (Rev.2, September 2006)

"Shipboard fittings and supporting hull structures associated with towing and mooring on conventional vessels"

1. Scope and objective

Since the original UR A2 was withdrawn in 2005 reflecting the industry feedback, IACS have been receiving further industry inputs with respect to how shipboard fittings were to be designed, used and maintained for ship's safe operation. These feedbacks were sent by shipbuilders, ship operators, tug operators and port authorities. In the meantime, MSC80 (18 to 27 May 2005) adopted MSC/Circ.1175, "Guidance on Shipboard Towing and Mooring Equipment". The revised UR A2 was developed in line with the requirements in the MSC/Circ. 1175. The valuable comments from industry, approximately 20 organisations, are also considered and incorporated into the revision.

2. Points of discussions or possible discussions

The following summarize the changes made in the revision:

1. In view of the concerns of industry about the corrosion, the revision provides the specific corrosion additions to the net thickness, on which basis all strength criteria as specified in the revision are satisfactorily complied with. The general requirements for survey after construction are also provided in order to maintain a sound structural condition under the supervision of the class. (see A2.0, A2.4 and A2.5).
2. The design loads for both towing and mooring are revised in accordance with the MSC/Circ. 1175. In addition to the specified minimum design load requirements, the revision covers a greater design load, which may be specially requested by the applicant, e.g., ship owner or ship operator. (see A2.1.3 and A2.2.3)
3. In selection of towing lines/mooring lines, it is also addressed that side projected area including maximum stacks of deck cargo is to be taken into account, of which concerns were raised by the Port of Rotterdam based on their own feasible study of mooring forces induced by the wind forces due to full stacks of deck cargoes. (see Note to A2.1.3.2 and A2.2.3.1).
4. To ensure safe towing and mooring operations, a preparation of the drawings, "towing and mooring arrangement plan" and "pilot card" for information of the operation for ship's master and pilot respectively is specified. This plan used for review/survey of shipboard fittings and supporting hull structures by classification society can be used as appropriate operation guidance for proper mooring of the vessel in line with the intent of design of deck fittings. (see A2.3)
5. To reflect the design conditions, especially for the vessel, of which deck fittings are designed based on the reduced breaking strength of mooring lines and the increased numbers of the mooring lines as permitted by the footnote of Table 5 of IACS Recommendation No. 10, the following information are to be clearly indicated on the plan:
   .1 the arrangement of mooring lines showing number of the lines (N), together with
   .2 the specified breaking strength of each mooring lines intended to be used (BS). (see A2.3.3)

3. Source/ derivation of proposed requirement

Hull Panel

4. Decision by voting

N.A.

5. GPG Discussion

The following issues were discussed at GPG and decided upon by vote:

1. The draft UR was received from the Hull Panel without a proposed uniform application statement or date. A majority of Members agreed to the uniform application statement proposed by ABS ("contracted for construction from 1 January 2007", with RS preferring the uniform application statement proposed by GPG Chairman ("contracted for construction after 1 July 2007").
2. LR pointed out that there would be a gap between the contract for construction date associated with the amended UR A2 and the 1 January 2007 keel-laying date associated with the entry into force of -the revised SOLAS Reg. II-1/3-8. In order to bridge this gap, all Members agreed to task the Perm Sec to draft a simple UI of SOLAS Reg. II-1/3-8 stating that the requirements in UR A2 (Rev.2) are to be applied for ships with a keel laying date on or after 1 January 2007. This will require Members to apply the requirements in UR A2 when acting on behalf of an Administration, unless otherwise instructed by the Administration, but provide Members additional time to implement the UR in their Rules.

Permanent Secretariat Note [7 September 2006]:

Following initial GPG approval, LR raised concerns that paragraph 2.2.3.1 of UR A2 refers to Recommendation 10, thus making it mandatory, and that Table 5 of Recommendation 10 specifies the number of mooring lines, whereas when it was copied into MSC/Circ.1175 the number of lines was omitted. This would mean that UR A2 could be considered as more restrictive than the Circular and thus an IACS member may be disadvantaged in comparison to a non-IACS member.

Further discussion was held by GPG members and it was agreed by all members to add a new footnote to A2.2.3.1 (and A2.1.3(2) which also refers to Recommendation 10) to clarify that Recommendation 10 is not a mandatory requirement. In addition the GPG Chairman has opened a new subject number to discuss the method of making reference to the mandatory/non-mandatory IACS and IMO Instruments in IACS mandatory Resolutions, i.e. footnote and Annex (GPG Small Group on Reference to Mandatory Resolutions, 6158).

LR was also concerned about a lack of harmonisation between UR A2 and CSR for both oil tankers and bulk carriers. Nine members (BV, KR, DNV, ABS, NK, RS, CCS, RINA and LR) agreed that this should be dealt with separately from the adoption of the draft UR A2 and that it should be considered and dealt with as rule change by PT1 and PT2 under the instruction of Hull Panel.

TECHNICAL BACKGROUND

UR A2 (Rev.3, July 2007)

"Shipboard fittings and supporting hull structures associated with towing and mooring on conventional vessels"

1. Background

Following approval of UR A2 (Rev.2) in September 2006, LR proposed to amend TB in order to clarify GPG's agreement *"to align the MSC Circular 1175 and UR A2 and introduced the note into paragraphs A2.1.3 and A.2.2.3 stating that only the breaking strengths in the Table 5 of Rec 10 are considered mandatory; the footnote to Table 5 of Rec 10 is not mandatory and thus A2 does not permit the reduction of the breaking strengths of Table 5 when the greater number of lines are used."*

After GPG discussion in which members could not come to an unanimous decision, GPG Chair in 6111_IGi tasked Hull Panel to answer the following:

"For the application of the load considerations in UR A2.1.3 and A2.2.3, is there justification for accepting a reduction in the breaking strength of mooring and towing lines as permitted by the footnote to Table 5 of REC 10, in association with a corresponding increase in the number of mooring/towing lines?"

Hull Panel agreed to the application of the footnote to Table 5 of IACS Recommendation No.10 and submitted a further revision to UR A2 to incorporate this.

2. Discussion

The proposed revision to UR A2 was agreed by GPG, but there were concerns about the initial Technical Background information submitted by Hull Panel since it referred to the approval of 'towing and mooring arrangements plans'. The technical background information was therefore resubmitted with 6111_PHc (see Appendix 1) without reference to the approved plan, together with a revised Technical Background document for UR A2(Rev.2).

Since the revision to UR A2 (Rev.2) was made for clarification of its original intention of the requirements related to Design Load of Mooring equipment and its supporting structure, it was agreed that it should be applicable to ships with a keel laying date on or after 1 Jan 2007. It was also agreed that UI SC212 should be editorially modified to replace "UR A2 (Rev.2)" with "UR A2 (Rev.2 or Rev.3)".

3. Conclusion

UR A2(Rev.3) and the revised TB for UR A2(Rev.3) were adopted on 10 July 2007 (6111_IGo) *– see also 6111_IGm dated 6 June 2007.*

Prepared by Permanent Secretariat
July 2007

APPENDIX 1 - Hull Panel's Reply to GPG (attachment to 6111_PHc)

1. Hull Panel unanimously agrees that the footnote to Table 5 of IACS Recommendation No. 10 can be applied in determination of the breaking strength of mooring line for the application of the load consideration in UR A 2.2.3 based on the following current/additional provisions:

2. In A 2.3. "Towing and mooring arrangements plan" of the UR, it is required that "towing and mooring arrangements plan" is to be available on board for the guidance of the Master." This plan used for review/survey of shipboard fittings and supporting hull structures by member society can be used as appropriate operation guidance for proper mooring of the vessel in line with the intent of designs of deck fittings.

3. In order to reflect the design conditions, especially for the vessel, of which deck fittings are designed based on the reduced breaking strength of mooring lines and the increased numbers of the mooring lines as permitted by the footnote of Table 5 of IACS Recommendation No. 10, the following information are to be clearly indicated on the plan:

3.1. the arrangement of mooring lines showing number of the lines (N), together with
3.2. the breaking strength of each mooring line (BS)

4. HP will reflect the item 3 above into A 2.3 of the UR and submit for GPG's approval. The proposed changes to UR A2 (Rev. 2) is attached for ready reference.

APPENDIX 2 – Revised TB for UR A2(Rev.2) (attachment to 6111_PHc)

Technical Background

UR A2 (Rev.2, September 2006)

"Shipboard fittings and supporting hull structures associated with towing and mooring on conventional vessels"

1. Scope and objective

Since the original UR A2 was withdrawn in 2005 reflecting the industry feedback, IACS have been receiving further industry inputs with respect to how shipboard fittings were to be designed, used and maintained for ship's safe operation. These feedbacks were sent by shipbuilders, ship operators, tug operators and port authorities. In the meantime, MSC80 (18 to 27 May 2005) adopted MSC/Circ.1175, "Guidance on Shipboard Towing and Mooring Equipment". The revised UR A2 was developed in line with the requirements in the MSC/Circ. 1175. The valuable comments from industry, approximately 20 organisations, are also considered and incorporated into the revision.

2. Points of discussions or possible discussions

The following summarize the changes made in the revision:

1. In view of the concerns of industry about the corrosion, the revision provides the specific corrosion additions to the net thickness, on which basis all strength criteria as specified in the revision are satisfactorily complied with. The general requirements for survey after construction are also provided in order to maintain a sound structural condition under the supervision of the class. (see A2.0, A2.4 and A2.5).
2. The design loads for both towing and mooring are revised in accordance with the MSC/Circ. 1175. In addition to the specified minimum design load requirements, the revision covers a greater design load, which may be specially requested by the applicant, e.g., ship owner or ship operator. (see A2.1.3 and A2.2.3)
3. In selection of towing lines/mooring lines, it is also addressed that side projected area including maximum stacks of deck cargo is to be taken into account, of which concerns were raised by the Port of Rotterdam based on their own feasible study of mooring forces induced by the wind forces due to full stacks of deck cargoes. (see Note to A2.1.3.2 and A2.2.3.1).
4. To ensure safe towing and mooring operations, a preparation of the drawings, "towing and mooring arrangement plan" and "pilot card" for information of the operation for ship's master and pilot respectively is specified. This plan used for review/survey of shipboard fittings and supporting hull structures by classification society can be used as appropriate operation guidance for proper mooring of the vessel in line with the intent of design of deck fittings. (see A2.3)
5. To reflect the design conditions, especially for the vessel, of which deck fittings are designed based on the reduced breaking strength of mooring lines and the increased numbers of the mooring lines as permitted by the footnote of Table 5 of IACS Recommendation No. 10, the following information are to be clearly indicated on the plan:
   .1 the arrangement of mooring lines showing number of the lines (N), together with
   .2 the specified breaking strength of each mooring lines intended to be used (BS). (see A2.3.3)

3. Source/ derivation of proposed requirement

Hull Panel

4. Decision by voting

N.A.

5. GPG Discussion

The following issues were discussed at GPG and decided upon by vote:

1. The draft UR was received from the Hull Panel without a proposed uniform application statement or date. A majority of Members agreed to the uniform application statement proposed by ABS ("contracted for construction from 1 January 2007", with RS preferring the uniform application statement proposed by GPG Chairman ("contracted for construction after 1 July 2007").
2. LR pointed out that there would be a gap between the contract for construction date associated with the amended UR A2 and the 1 January 2007 keel-laying date associated with the entry into force of -the revised SOLAS Reg. II-1/3-8. In order to bridge this gap, all Members agreed to task the Perm Sec to draft a simple UI of SOLAS Reg. II-1/3-8 stating that the requirements in UR A2 (Rev.2) are to be applied for ships with a keel laying date on or after 1 January 2007. This will require Members to apply the requirements in UR A2 when acting on behalf of an Administration, unless otherwise instructed by the Administration, but provide Members additional time to implement the UR in their Rules.

Permanent Secretariat Note [7 September 2006]:

Following initial GPG approval, LR raised concerns that paragraph 2.2.3.1 of UR A2 refers to Recommendation 10, thus making it mandatory, and that Table 5 of Recommendation 10 specifies the number of mooring lines, whereas when it was copied into MSC/Circ.1175 the number of lines was omitted. This would mean that UR A2 could be considered as more restrictive than the Circular and thus an IACS member may be disadvantaged in comparison to a non-IACS member.

Further discussion was held by GPG members and it was agreed by all members to add a new footnote to A2.2.3.1 (and A2.1.3(2) which also refers to Recommendation 10) to clarify that Recommendation 10 is not a mandatory requirement. In addition the GPG Chairman has opened a new subject number to discuss the method of making reference to the mandatory/non-mandatory IACS and IMO Instruments in IACS mandatory Resolutions, i.e. footnote and Annex (GPG Small Group on Reference to Mandatory Resolutions, 6158).

LR was also concerned about a lack of harmonisation between UR A2 and CSR for both oil tankers and bulk carriers. Nine members (BV, KR, DNV, ABS, NK, RS, CCS, RINA and LR) agreed that this should be dealt with separately from the adoption of the draft UR A2 and that it should be considered and dealt with as rule change by PT1 and PT2 under the instruction of Hull Panel.

Technical Background (TB) document for UR A2 (Rev.4 Oct 2016)

1. Scope and objectives

Due to recurrent incidents during mooring and towing and IACS member comments to UR A2, Rev. 3, UR A2 has been reviewed and updated.

For further information see Attachment 1.

2. Engineering background for technical basis and rationale

See Attachment 1.

3. Source/derivation of the proposed IACS Resolution

See Attachment 1.

4. Summary of Changes intended for the revised Resolution

Towing services have been clearly and, in part, newly defined. 'Other towing' has been designated as towing by another ship or a tug, e.g. such as to assist the ship in case of emergency, for the case that equipment is intended to be fitted for this.

Minimum loads have been introduced for the selection of shipboard fittings from industry standards. For shipboard fittings, not selected from an industry standard, design requirements have been introduced. For bollards and bitts, attachment points for the mooring or towing lines have been defined.

Basic requirements have been introduced for strength assessment with finite element analysis of the supporting hull structure as well as for shipboard fittings, not selected from an industry standard.

A safe towing load has been introduced next to the safe working load to better distinguish the purpose (towing or mooring) of different shipboard fittings.

The safety factor in the safe working load for mooring has been reduced to mitigate the impact on scantlings of the modified recommended strength of mooring lines for ships with Equipment Number EN > 2000 according to Recommendation No. 10, being the basis for the design load.

The safe towing load for 'other towing' has been reduced to 80% of the design load to include some safety margin, considering the newly defined purpose of 'other towing'.

Information on the acceptable environmental conditions for the recommended minimum breaking strength of mooring lines for ships with EN > 2000 has been required to be included on the towing and mooring arrangements plan and the pilot card.

The corrosion additions for ships other than CSR ships were modified to ease the survey of hull supporting structures.

A wear allowance was introduced and is to be applied to shipboard fittings, not selected from an industry standard.

See Attachment 1 for more detailed information.

5. Points of discussions or possible discussions

The increase in recommended strength of mooring lines for ships with EN > 2000 according to the draft revision of Recommendation 10 may lead to scantling increase for some ships, refer to technical background of draft revision 3 of Recommendation No. 10. In the past, many ships have already been equipped with stronger and more lines than recommended by Recommendation No. 10 and the higher strength of the lines was, sometimes, sometimes not, considered for the design of fittings and supporting hull structure. Compared to the case that the higher strength of the lines was considered for the design of fittings and supporting hull structure, increase in scantlings is not, or only to a limited extent, to be expected. To mitigate the impact on scantlings, the safety factor in the safe working load for mooring has already been reduced from 1.25 to 1.15. For many smaller ships this will lead to similar or even lower scantlings than before. However, further reducing the safety factor or even reducing it below 1.0 would contradict other internationally accepted recommendations on mooring of ships, e.g., those from the Oil Companies International Marine Forum (OCIMF), refer to OCIMF Mooring Equipment Guidelines 3.

6. Attachments if any

Attachment 1.

Technical background to UR A2 (Rev.4 Oct 2016) 'Shipboard fittings and supporting hull structures associated with towing and mooring on conventional ships'

A2.0. Application and definitions

The scope concerning towing was clearly defined and partly modified in that

- the UR is applicable to 'normal towing' defined as "towing operations necessary for manoeuvring in ports and sheltered waters associated with the normal operations of the ship",
- the UR is applicable to 'other towing' for ships intended to be fitted with equipment for towing by another ship or a tug, e.g. such as to assist the ship in case of emergency as given in SOLAS Regulation II-1/3-4 Paragraph 2 "Emergency towing procedures on ships",
- the UR is not applicable to escort towing as it is a special service in certain estuaries and typically regulated by the respective authorities,
- the UR is not applicable to canal transit towing as it is typically regulated by the respective authorities,
- the UR is not applicable to emergency towing for tankers as regulated by SOLAS regulation II-1/3-4 Paragraph 1 'Emergency towing arrangements on tankers'.

The definitions were updated in that 'special purpose ship' was defined as in MSC.266(84) as a mechanically self-propelled ship which by reason of its function carries on board more than 12 special personnel.

A2.1. Towing

A2.1.3. Load considerations

As the purpose of 'normal towing' and 'other towing' is clearly defined in A2.0, references to the purpose of the towing operations were deleted in A2.1.3.

For 'normal towing' it should be observed that increasingly tugs are in service that have static bollard pull of up to 80 t. The joint 'Guidelines on Design and Layout of Harbour Towage Equipment' of the European Tugowners Association and the European Maritime Pilots' Association recommend observing this for the design of towing equipment for normal towing. For towing fittings providing considerably lower strength the risk for overloading may be increased.

Design loads for 'other towing' were maintained for ships, not subject to SOLAS regulation II-1/3-4 Paragraph 1, but intended to be fitted with equipment for towing by another ship or a tug, e.g. such as to assist the ship in case of emergency as given in SOLAS Regulation II-1/3-4 Paragraph 2. It is to be observed that it is not mandatory to equip ships, not subject to SOLAS regulation II-1/3-4, with fittings designed for 'other towing'. However, in IACS Recommendation No. 10 'Anchoring, Mooring, and Towing Equipment', 2.5.2 it is recommended to provide towing arrangements fore and aft of sufficient strength for 'other towing' service.

A provision was added, giving the design load to be applied in case of the fitting is intended to be used for, both, 'normal towing' and 'other towing' operations. In this case the design load is not to be less than the greater of the design loads for ‘normal towing’ and ‘other towing’.

The Note in A2.1.3 was partly deleted as A2.1.3 2) clearly requires applying the minimum breaking strength of the tow line according to Rec. No. 10 to determine the design load for ‘other towing’. Furthermore, the Note was reformulated. Side projected areas are required to be taken into account “*including that of deck cargoes as given by the loading manual*” instead of “*maximum stacks of deck cargoes*” in order to account also for deck cargo other than container stacks. A second Note was added, stating that “*the increase of the minimum breaking strength for synthetic ropes […] needs not to be taken into account for the loads applied to shipboard fittings and supporting hull structure”* because this increase is related to aging and wear and, in case of polyamide, also allows for strength loss when wet.

A2.1.3 requires that the “*the design load is to be applied to fittings in all directions that may occur by taking into account the arrangement shown on the towing and mooring arrangements plan*”. This provision shall ensure that not only the intended line leads as shown in the arrangement plan are considered for the application of the design load to a fitting but also other line leads if deemed possible as well as realistic based on the given arrangement.

A2.1.4. Shipboard fittings

Minimum load assumptions were added for the selection of shipboard fittings from industry standards, similar to the design loads given by A2.1.3. This ensures that the chosen fittings provide similar load capacity as the hull supporting structure and similar safety margins in TOW and SWL.

A2.1.4 allows for choosing towing bitts (double bollards) explicitly for the towing rope attached with eye splice, which is the usual method in towing. This is possible if the industry standard distinguishes between different methods to attach the line, e.g. as the ISO standard for welded steel bollards (ISO 13795). Some standards for double bollards (e.g. JIS) provide information on maximum applicable rope tension irrespective of the method of application of the rope. In these cases, the bollard is to be selected based on these applicable rope tensions which are considered to be designed for, both, the line attached with eye splice as well as the line applied in figure-of-eight fashion.

More specific requirements were included for shipboard fittings not selected from an accepted industry standard, concerning the acting point of the towing force, allowable stresses, analysis methods, net scantling approach, as well as corrosion additions and wear allowance. It was allowed for load tests as alternative to strength calculations at the discretion of the classification society.

A2.1.5. Supporting hull structure

A sketch of a sample arrangement of reinforced members beneath shipboard fittings was added to the UR and it was pointed out that proper alignment of fitting and supporting hull structure is to be ensured. This is to put more focus on the effective arrangement of supporting hull structures and its alignment with the on deck structure, which is important to ensure structural behaviour in line with the design calculations. Several damage cases reported in the past can be related to ineffective structural reinforcement and alignment.

The acting point of the towing force on shipboard fittings was specified in detail for bollards and bitts to be taken not less than 4/5 of the tube height above the base. This requirement is aligned with ISO 13795 “Welded steel bollards for sea-going vessels”.

An allowable equivalent stress was introduced for strength assessment with finite element analysis equal to 100% of the specified minimum yield point of the material. Furthermore, basic modelling guidance for finite element analysis was added to A2.1.5. The basic mesh requirements for FE models are considered to yield stresses comparable to those calculated by beam theory calculations.

A2.1.6. Safe Towing Load (TOW)

A2.1.6 was modified in that it defines a safe towing load TOW as the load limit for towing purpose instead of a safe working load SWL in order to make the intended use of the fittings visible. The SWL is retained as marking of fittings intended for mooring purpose. This serves the purpose of preventing wrong operation as there are different safety factors for mooring and towing operations and, in particular, different typical attachment methods of the rope to double bollard with respect to mooring and towing operations. Double bollards for towing purpose may be selected for the rope attached with eye-splice (e.g. possible with ISO standard for welded steel bollards, ISO 13795) which, however, could lead to damage of the fitting when used with a rope attached in figure-of-eight fashion, as this attachment method can subject either of the two posts to a force twice as large as that from a rope attached with eye splice. If fittings are intended to be used also for mooring, the provisions for mooring according to A2.2 are to be observed and SWL is to be marked to the fitting in addition to TOW. In this case double bollards are to be selected to also resist the loads from mooring for the rope attached in figure-of-eight fashion. Thus, TOW and SWL as dedicated markings for towing and mooring purpose, respectively, are intended to make the use of double bollards safer as clear load limits are marked with respect to the different methods of attaching the rope to the fitting.

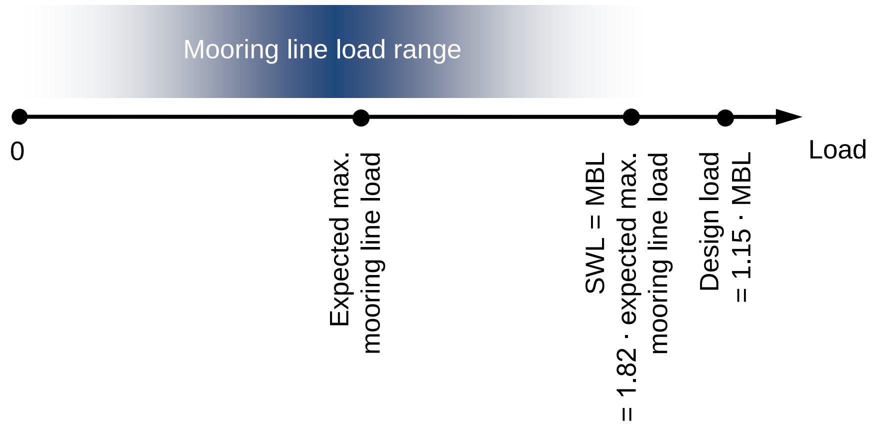
As in UR A2 Rev. 3, the design load for ‘other towing’, given by A2.1.3 (2), is equal to the minimum breaking strength of the tow line according to Rec. No. 10. However, in A2.1.6 3) TOW for ‘other towing’ is limited to not exceed 80% of the minimum breaking strength of the tow line. This aligns the safety factor included in the marked TOW with that of fittings for ‘normal towing’. For the purpose of towing to assist the ship in case of emergency, it is considered necessary to include some additional margin. UR A2 Rev. 3 considered fittings for other towing to be used with the ship’s own tow line that was expected to break under a load equal to its MBL. However, today it is to be expected that such towing in most cases will be performed by tugs using their own lines which have high safety factors and, thus, high strength that is likely to exceed the strength of shipboard fittings for ‘other towing’. The towing line cannot be expected to break before the fitting.

A2.1.6 6) requires to mark TOW (and SWL in case the fitting is intended to be used for, both, towing and mooring) in ‘t’ (tonnes) on the fittings. This has not been defined in UR A2 Rev. 3. The unit ‘t’ was confirmed by industry representatives as typical and preferable unit for the marking of deck fittings. Also, OCIMF recommends using this unit for marking of the load limit. Reasons are that this unit is commonly used, e.g., as load limit for lifting appliances and that the unit ‘kN’ could be confused with ‘t’, which may result in considerable overload as a load in ‘kN’ is equivalent to about ten times a weight in ‘t’.

A2.2. Mooring

A2.2.3. Load considerations

In A2.2.3 1) the safety factor in the design load for hull supporting structures of mooring fittings was modified in consequence of the revision of recommended mooring lines in Recommendation No. 10 where more advanced methods for the selection of mooring lines were introduced for ships with EN > 2000. To partly mitigate the impact of the new recommended line strength on the mooring equipment of ships with EN > 2000 the safety factor in the design load was reduced from 1.25 to 1.15. However, the MBL of the lines, being the design load basis, also include safety margins with respect to the expected load level for the considered environmental conditions, i.e. for ships with EN > 2000 a factor of 1.82 is contained in the recommended MBL. The typical relation of the expected maximum mooring line load for the considered environmental conditions, MBL, SWL, and design load is shown in the figure below. To not reduce the standard compared to the UR A2 Rev. 3, the recommended mooring line strength for ships with EN ≤ 2000 was increased in Recommendation No. 10 by a factor of 1.25/1.15.



Note 1 was reformulated such that side-projected areas are required to be taken into account "*including that of deck cargoes as given by the loading manual*" instead of "*maximum stacks of deck cargoes*" in order to account also for deck cargo other than container stacks. A new Note 2 was added, stating that "*the increase of the minimum breaking strength for synthetic ropes […] needs not to be taken into account for the loads applied to shipboard fittings and supporting hull structure"* because this increase is related to aging and wear and, in case of polyamide, also allows for strength loss when wet. Note 3 was deleted as not applicable anymore to Recommendation No. 10 Rev. 3. The former Note 2 and Note 4 were also deleted as A2.2.3 1) clearly requires applying the minimum breaking strength of the mooring line according to Recommendation No. 10 to determine the design load.

In A2.2.3 2) the design load for supporting hull structures for winches was modified. The intended maximum brake holding load of winches is required to be assumed not less than 80% of the minimum breaking load (MBL) of the mooring line according to the Recommendation No. 10. As the design load is defined as 1.25 times the intended maximum brake holding load, then the minimum design load is equal to the MBL of the mooring line. This was added because the break holding load is considered unreliable for winches with certain brake types and when the brake holding load is not tested and adjusted on a regular basis. Over-tightened winch brakes but also other circumstances may subject the winch to the full MBL of the mooring line. This was confirmed by industry representatives and is in line with OCIMF 'Mooring Equipment Guidelines'.

A2.2.3 4) requires that "*the design load is to be applied to fittings in all directions that may occur by taking into account the arrangement shown on the towing and mooring arrangements plan*". This provision shall ensure that not only the intended line leads as shown in the arrangement plan are considered for the application of the design load to a fitting but also other line leads if deemed possible as well as realistic based on the given arrangement.

A2.2.4. Shipboard fittings

Refer to A2.1.4 for similar modifications. Other than in A2.1.4, mooring bitts (double bollards) are required to resists the loads caused by the mooring rope applied in figure-of-eight fashion, being the standard method and which can subject either of the two posts to a force twice as large as that from a rope attached with eye splice.

A2.2.5. Supporting hull structure

Refer to A2.1.5 for similar modifications. The acting point of the mooring force on shipboard fittings was also specified in detail for bollards and bitts to be taken 4/5 of the tube height above the base. Different from towing, if fins are fitted to the bollard tubes to keep the mooring line as low as possible, the attachment point of the mooring line may be taken at the location of the fins. Except for the latter, this requirement is aligned with ISO 13795 "Welded steel bollards for sea-going vessels".

A2.2.6. Safe Working Load (SWL)

In A2.2.6 2) the SWL was modified to "*not exceed the MBL of the mooring line according to Recommendation No. 10*" instead of "*80% of the design load per A2.2.3*". This is because the safety factor in the design load for mooring was changed to 1.15 and '80%' is not matching this safety factor anymore.

A2.3. Towing and mooring arrangements plan

To A.2.3 1) it was added that it is to be noted in the 'Towing and mooring arrangements plan' that TOW is the load limit for towing purpose and SWL that for mooring purpose. For double bollards it is to be noted that, if not otherwise chosen, TOW is the load limit for a towing line attached with eye-splice. This is in accordance with the definitions made in A2.1.6 and A2.2.6 and was added to ensure that the purpose of the markings on the mooring and towing fittings and the method of use is described in the documents available to the ship's crew.

To A.2.3 2) it was added that the SWL and TOW markings as given by the 'Towing and mooring arrangements plan' are subject to approval by the class society with respect to the purpose (mooring/harbour towing/other towing) and the manner of applying the towing or mooring line load including limiting fleet angles. This shall clarify which information on the 'Towing and mooring arrangements plan' is to be approved by the class society. It is thereby specified that the class society does not need to approve the arrangement of mooring and towing equipment.

A2.3 3) of UR A2 Rev. 3 requires the 'Towing and mooring arrangements plan' to show the number of mooring lines together with the breaking strength of each mooring line in case the deck fittings and their supporting hull structures were designed based on reduced breaking strength of mooring lines with corresponding increase of number of lines or vice versa. This requirement was changed such that the number of mooring lines and the breaking strength of each mooring line are to be shown in general to give overview of the available mooring lines.

To A2.3 2) it was added that the acceptable wind and current speed as given in IACS Recommendation No. 10 for the recommended minimum breaking strength of mooring lines is to be noted in the 'Towing and mooring arrangements plan' for ships with Equipment Number EN>2000. This information is considered important for the ship's crew, in particular, of large ships to be aware of limitations of the mooring equipment and, thus, to enable the early preparation of countermeasures (e.g. use of storm bollards, requesting tug assistance, leaving or not entering port) in the case of deteriorating environmental conditions in order to prevent the ship to come loose from its moorings.

A2.4. Corrosion addition

The corrosion addition for supporting hull structures was modified to evade the problem of having different corrosion allowances for the same structural elements based on UR A2 on the one hand and based on other class rules (e.g. for deck structures) on the other hand. This was found to be a problem for survey. For supporting hull structures the individual corrosion addition according to the society's rules for the surrounding structure is to be applied. The procedure is similar to that of CSR. For all other structures (e.g. pedestals) not selected from an accepted industry standard, 2 mm corrosion addition was retained.

Also for shipboard fittings provisions were added that define the corrosion margins to be considered for design of fittings not selected from an accepted industry standard.

A2.5. Wear allowance

In addition to the corrosion addition, a wear allowance of 1 mm was defined for shipboard fittings, not selected from industry standards. The wear allowance was introduced to not achieve less scantlings than according to ISO standards, e.g. ISO 13795 for welded steel bollards, for the same load cases. In this respect it should be observed that no fabrication tolerances are considered by UR A2 in contrast to some industry standards, e.g. the ISO standards.

Technical Background (TB) document for UR A2 (Rev.5 Sep 2020)

1. Scope and objectives

The scope of this revision is to clarify the determination of deck cargoes side projected area in note 1 of paragraphs UR A.2.1.3 and A.2.2.3.

2. Engineering background for technical basis and rationale

The determination of the deck cargoes side projected area in note 1 of paragraphs UR A.2.1.3 and A.2.2.have been clarified introducing the definition of the condition to be considered.
The side projected area of the deck cargoes should be determined for the ship nominal capacity condition.

The nominal capacity condition is defined in UR A2.0 Application and definitions.

The side projected area of the deck cargoes at nominal capacity should be presented in the ship arrangement (i.e. GA, Capacity Plan, Container Stowage Plan, etc.) being or not being part of a ship's manual (trim and stability booklet, loading manual, cargo securing manual, etc.).

The calculation of the EN referred to in UR A2 for towing and mooring is to be performed considering the side projected area of deck cargoes at nominal capacity condition combined with summer load line with even keel.

3. Source / derivation of the proposed IACS Resolution

None

4. Summary of Changes intended for the revised Resolution:

A2.0 Application and definitions

The nominal capacity condition is defined as the theoretical condition where the maximum possible deck cargoes are included in the ship arrangement in their respective positions. For container ships the nominal capacity condition represents the theoretical condition where the maximum possible number of containers is included in the ship arrangement in their respective positions.

Note 1 Paragraph A.2.1.3:

1. Side projected area including that of deck cargoes as given by ***the ship nominal capacity condition*** ~~*the loading manual*~~ *is to be taken into account for selection of towing lines and the loads applied to shipboard fittings and supporting hull structure.* ***The nominal capacity condition is defined in A2.0.***

Note 1 Paragraph A.2.2.3:

1. If not otherwise specified by Recommendation No. 10, side projected area including that of deck cargoes as given by **the ship nominal capacity condition** ~~**the loading manual**~~ is to be taken into account for selection of mooring lines and the loads applied to shipboard fittings and supporting hull structure. ***The nominal capacity condition is defined in A2.0.***

Also, changes were made to align the text of UR with draft MSC.1/Circ.1175/Rev.1 (refer Annex 2 of SDC 6/13) approved by MSC 101 (refer para 12.9 of MSC 101/24).

5. Points of discussions or possible discussions

None

UR A3 "Anchor Windlass Design and Testing"

Summary

The purpose of Revision 1 of this UR is to solve some issues in paragraphs 2.2 and 6.(a) in order to:

a) consider additional exceptions for the selection of welding consumables; and
b) align the marking examples with ISO4568:2006

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev.1 (Jun 2019)	13 June 2019	1 July 2020
New (Jun 2017)	03 June 2017	1 July 2018

- **Rev.1 (Jun 2019)**

.1 Origin of Change:

☑ Suggestion by IACS member

.2 Main Reason for Change:

To modify requirements regarding welded fabrication taking into account welding consumables which are not specified in W17 nor W23 and to align requirements regarding the marking with requirements of ISO 4568:2006.

Technical Background (TB) document for UR A3 (New June 2017)

1. Scope and objectives

Development of a UR for anchoring equipment, which would include measures to reduce catastrophic failure of windlass hydraulic motors. The MAIB recommended revision of UR A; however, UR A1 and UR A2 do not contain machinery requirements and are the responsibility of the Hull Panel. After discussion with the Hull Panel Chairman, it was suggested that a new UR be developed specifically for the machinery requirements (e.g. UR A3).
Since there is a current project team for a Hull Panel task (PH7011), the comments (if any) of this project team and the Hull Panel should also contribute to the development of the Machinery Panel's UR for anchoring equipment.

The development of the Machinery Panel's UR for anchoring equipment should take into consideration the causes of the catastrophic failures and suggestions for requirements, such as, additional requirements for the windlass, consideration of different windlass types, requirements for the operators station or the required location of the operators station, material requirements and overpressure arrangement in the hydraulic system etc.

2. Engineering background for technical basis and rationale

This task was triggered by the UK MAIB and their report on the investigation of the catastrophic failure of a windlass hydraulic motor on the Stellar Voyager. The MAIB recommended that IACS develop a Unified Requirement (UR) for anchoring equipment, which would include measures to prevent the catastrophic failure of windlass hydraulic motors through over-pressurisation and over-speed.

The intended benefit of the task would be that the UR would include measures that would reduce the potential to cause injury to persons. Please note that the MAIB Safety Bulletin 1/2009 documents that there had been similar catastrophic failures of hydraulic anchor windlasses on four vessels.

3. Source / derivation of the proposed IACS Resolution

- Marine Accident Investigation Branch (MAIB) Report on the investigation of the catastrophic failure of windlass hydraulic motor on board Stellar Voyager off Tees Bay resulting in a major injury on 23 March 2009, Report No. 25/2009, December 2009.
- MAIB Safety Bulletin 1/2009 Catastrophic Failure of High Pressure Hydraulic Anchor Windlasses

Development of a draft UR for anchoring equipment which would include measures to prevent the catastrophic failure of windlass hydraulic motors, taking into account outcome or progress of the PT 54 under Hull Panel.

4. Summary of Changes intended for the revised Resolution

None

5. Points of discussions or possible discussion

The task was triggered by the UK MAIB and their report on the investigation of the catastrophic failure of a windlass hydraulic motor on the Stellar Voyager. The MAIB recommended that IACS develop a Unified Requirement (UR) for mooring and anchoring equipment, which would include measures to prevent the catastrophic failure of windlass hydraulic motors through over-pressurisation and over-speed.

An anchor windlass questionnaire was distributed to industry, responses to questions include concerns related to:

> *Anchoring in unrestricted areas triggers most failures of the windlass due to extreme overload. This happens mostly in a combination of strong wind, wave height and deep water. Windlass motors are very sensitive to load conditions due to their very low pulling capacity (nominal pull = 6,5% of chain MBL, max pull = 10% of MBL). What damages the motor is rendering when weighing anchor under high chain tension. Very few persons on-board a ship is aware of the specifications and the limitations of a windlass. Most persons believe the windlass is much stronger than it looks like. Classification societies supervise the building and installation of the anchoring equipment. Next time they make an inspection is at the 5 years docking. In the intermediate period, the anchoring equipment is left to the maintenance / inspection system on-board.*

> *The increased duty pull (1.5 times the nominal pull, per Rec. 10) is considered sufficient for dynamic loads when heaving anchor. However, braking loads associated with dropping the anchor are not.*

> *Technology for increased duty pull required for deeper anchorages and additional dynamic loads in waves, is available. The size of the windlass would not considerably increase.*

> *Regarding the necessity of the windlass to be able to recover the full length of chain cable and anchor, abrupt changes in depth represent a situation in which higher duty pull of the windlass would be beneficial, if the anchor drags towards the deeper water.*

Clarification on the different IACS panels and discussions occurring simultaneously were offered by Machinery Panel. Subject discussions in Hull Panel PT 54, and Machinery Panel task PM9910 were ongoing.

Panel Discussions:

The cause of the failure on Stella Voyager and other reference accidents was that the anchor chain and anchor weight exceeded the capacity of the hydraulic motor during the retrieval operation. The anchor chain rendered (was released), the hydraulic motor reversed, becoming a pump in a closed loop system. The resulting overpressure led to the catastrophic failure of the motor casing. Further, the safety relief valve was not dimensioned for handling rapid and continuous pressure rises.

The Panel discussed converting the existing Rec.10 into a UR and incorporating additional concerns from MAIB and industry.

Uncertain whether an increase in the capacity of the safety relief system would contribute to uncontrolled release of the anchor. This should be commented and investigated. Note that although the MAIB did not agree, the manufacturer indicated that the cause of the accident was over-speed and not overpressure. The MAIB identified over-speed as a hazard and it needs to be considered whether increased capacity of the safety relief system can contribute to over-speed incidents.

A proposal to define the term "ductile material" in terms of min. elongation, etc. was offered. This was considered redundant to the Material URs.

The MAIB report recommended OCIMF include guidance on weighing the anchor at the next revision of their publication for anchoring systems and procedures, lessons learned from the accident discussed in the report and minimising the anchor chain tension when heaving in on the windlass. The report recommended the windlass manufacturer provide comprehensive technical and operational instructions for all components of the windlass machinery. These recommendations have been incorporated in UR A3.1.3

Survey requirements for manufacture and testing have been included in UR A3.4 and A3.5 per the MAIB report recommendations.

The UR draft should include General requirements, Application scope, Definition, Plans and documents, Material, Design requirements, Test requirements and so on (reference to IACS Rec.10 & ISO 4568).The key issue is to solve the problem raised by MAIB on the prevention of personal injury caused by overload or over speed on hydraulic motor.

The PT raised some questions regarding design criteria and testing which are addressed in the following summary from the Machinery Panel's response:

- Regarding duty pull, the Machinery Panel elected to align the requirements with ISO 4568, Clause 5.4 and removing the wind and current criteria as had been agreed in earlier discussions. The given windlass capacity is related only to the weight of chain and anchorage depth. For anchorage depth deeper than 82.5 m, another formula is introduced in compliance with ISO 4568, Clause 5.4. For both cases, buoyancy is considered and the hawse pipe efficiency is assumed at 70%. For this, the anchor masses are defined as those provided in UR A1 and Recommendation 10. This is a function of a 30-minute continuous duty pull corresponding to the Grade and diameter of chain.

- Hull supporting structure is required to be efficiently bedded to the deck and is to comply with UR S27 (Strength Requirements for Fore Deck Fittings and Equipment). Supporting structure design bases are detailed in Class requirements, these requirements must define operating loads, sea loads and forces so as to permit the designer/shipyard design flexibility for structural arrangements.

- Regarding testing, the UR will permit holding power of the brake to be verified by testing or by calculation. This is satisfactory for preliminary design approvals; ultimately, all windlasses are to be tested under working conditions after installation on-board. Each unit is to be independently tested for braking, clutch functioning, lowering and hoisting of chain cable and anchor, proper riding of the chain over the cable lifter, proper transit of the chain through the hawse pipe and the chain pipe, and effecting proper stowage of the chain and the anchor. The braking capacity is to be tested by intermittently paying out and holding the chain cable by means of the application of the brake. Where the available water depth is insufficient, the proposed test method will be specially considered.

Regarding para. 3.1.1.(b) a discussion has been made in the panel about the need to include or not safety factors to be used in calculation.
It is to be noted that the original wording of the paragraph did not include a safety factor. After a deep discussion, the Panel has agreed to maintain the original wording, just as prescriptive text to raise attention for dynamic loads and not to include a safety factor.

Regarding Section 3.4, it is considered that a suitable protection system is to be provided particularly for axial piston hydraulic motor in considering the fact that most of secondary accident occurs by the failure of axial hydraulic motor, as reported for M/V "Stellar Voyager".

Technical Background (TB) document for UR A3 (Rev.1 Jun 2019)

1. Scope and objectives

To modify requirements regarding welded fabrication taking into account welding consumables which are not specified in W17 nor W23 and to align requirements regarding the marking with requirements of ISO 4568:2006.

2. Engineering background for technical basis and rationale

This task was triggered by a member's suggestion regarding some unclear points on UR A3 (New June 2017).

After the viewpoint of each member was expressed and based on a qualified majority, it was concluded that the requirements for welding consumables and marking should be modified.

3. Source / derivation of the proposed IACS Resolution

- ISO 4568:2006
- UR W17 and W23

4. Summary of Changes intended for the revised Resolution

1. Welding consumables
   Regarding "Welding consumables are to be type-approved by the class society" in section 2.2, one member expressed concern that there are no suitable type-approved welding consumables depending on used base materials.
   After discussion it was agreed by the qualified majority that welding consumables which fall outside the scope of UR W17 and W23 are to comply with the Rules of the class society or national/international standard.
   In addition, it is unanimously agreed to modify "type-approved" into "approved" since UR W17 and W23 deal with "approval" and not "type-approval".

   (Supplementary explanation)
   Even when the UR W17 and UR W23 are not applicable, each society may have applicable additional requirements that continue to apply.
   When the UR W17 and UR W23 are not applicable, and the society has no applicable additional requirements, the approval of consumables should not be required. In this case, the consumables are to comply with the national or international standard.

2. Marking
   One member raised a problem that the example of marking specified in section 6 differs from ISO 4568:2006 despite being based on the ISO standard.
   After discussion it is unanimously agreed to align the requirements with ISO 4568:2006.

3. Application of "2.2 Welded Fabrication"
   One member proposed to clarify the application of "2.2 Welded Fabrication" since it is not stipulated though the material requirements (section 2.1) are clearly written that they are applied only to "materials used in the construction of torque-transmitting and load-bearing parts of windlasses".
   Most members agreed to apply section 2.2 only to torque-transmitting and load-bearing parts, but the majority considered that paragraph 2.2 can be read as continuation of 2.1 and modification is not necessary.

5. Points of discussions or possible discussion

Technical Background for Recategorization of UR's on Containers as Recommendations

1. Scope of objectives

As a consequence of disbanding the CG/Containers, it was decided to downgrade the UR's on Containers to REC's.

2. Points of discussions or possible discussions

- The initial discussion on the need to keep CG/Containers took place at GPG 46 in 1999. In the 1998 annual progress report, the Chairman of CG/C reported GPG that due to some lack of enthusiasm within the CG/C, GPG attention was requested to intensify the CG/C activities.
- At GPG 47 meeting, GPG noted slow progress in CG/C and asked he Chairman of CG/C to submit to GPG a reasoning for this fact.
- As a follow-up to GPG 47, GPG discussed the future of CG/C and decided to disband it, having noted that other organizations such as ISO have a similar rules. (Date: 18 January 2000)

Prepared by the IACS Permanent Secretariat

UR C6 “Requirements for Lashing Software”

Summary

UR C6 provides harmonised performance standards and requirements to facilitate consistent approval of lashing software.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
NEW (May 2024)	15 May 2024	1 July 2025

- **NEW (May 2024)**

1 Origin of Change:

☑ Action initiated to address the issue announced at CCC8/12 on the absence of harmonised performance standards and guidelines required for consistent approval of lashing software.

2 Main Reason for Change:

The main technical reason for the change is the absence of harmonised performance standards and guidelines required to facilitate consistent approval of lashing software. This issue was raised at CCC8/12 to justify the Committee’s decision to reject the draft unified interpretation proposed by IACS to recognise the use of lashing software as a supplement to approved Cargo Securing Manual (CSM).

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None

4 History of Decisions Made:

Following the issue announced at CCC8/12 on the absence of harmonised performance standards and guidelines for lashing software, the Hull Panel deemed it necessity to resolve unified requirements with the objective to provide requirements for lashing software to facilitate consistent approval of lashing software.

Therefore, a Project Team, PT PH51, was ad hoc nominated by the Hull Panel and commissioned to develop the harmonised performance standards and requirements for lashing software in UR C6.

5 Other Resolutions Changes:

No other solutions are required to be changed.

6 Any hinderance to MASS, including any other new technologies:

No hinderances to MASS are available.

7 Dates:

Original Proposal:	Developed by PT PH51	
Panel Approval:	11 April 2024	Ref: PH22017_IHau
GPG Approval:	15 May 2024	Ref: 23013_IGg

****

Part B. Technical Background

List of Technical Background (TB) documents:

Annex 1. **TB for Original Resolution, UR C6 (New May 2024)**

See separate TB document in Annex 1.

Technical Background (TB) document for UR C6 (New May 2024)

1. Scope and objectives

UR C6 (May 2024) is the original version of the newly introduced unified requirements with the aim to provide harmonised performance standards and requirements for lashing software; hence, achieving a uniform implementation and facilitating consistent approval in practice.

UR C6 (May 2024) achieves this objective by providing requirements on operation manual and functions of lashing software, prescribing test loading conditions, and presenting recommendations on approval, acceptable tolerance, and survey regime of lashing software.

2. Engineering background for technical basis and rationale

One of the technical basis of UR C6 (May 2024) traces back to SOLAS regulation where VI/5.6 states:

> "All cargoes, other than solid and liquid bulk cargoes, cargo units and cargo transport units shall be loaded, stowed and secured throughout the voyage in accordance with the Cargo Securing Manual approved by the Administration. In ships with ro-ro spaces, as defined in regulation II-2/3.41, all securing of such cargoes, cargo units and cargo transport units, in accordance with the Cargo Securing Manual, shall be completed before the ship leaves the berth. The Cargo Securing Manual shall be drawn up to a standard at least equivalent to relevant guidelines developed by the Organization."

Furthermore, the approved CSM should be drawn up in accordance with the recommendations contained in the revised guidelines for the preparation of CSM contained in MSC.1/Circ.1353/Rev.2, as approved by MSC 102.

As actual loading conditions of the container ships can vary significantly due to varying container carrying arrangements and weights for different voyages, deviations from the sample loading conditions indicated in the approved stowage and securing plans can exist. Therefore, evaluation of actual loading conditions for compliance with container lashing rules by only using the stowage and securing plans in the approved CSM can be challenging without an automated means.

IACS noted that paragraph 3.2.5 of chapter 3 of MSC.1/Circ.1353/Rev.2 allows for a loading computer to be accepted as an alternative to documentation used to evaluate forces acting on non-standardized cargo units described in paragraphs 3.2.1 to 3.2.4 of MSC.1/Circ.1353/Rev.2, as follows:

> ".5 other operational arrangements such as electronic data processing (EDP) or use of a loading computer may be accepted as alternatives to the requirements of paragraphs 3.2.1 to 3.2.4 above, providing that this system contains the same information."

With the intent of providing a means to efficiently evaluate actual stowage and securing of cargo containers, IACS considered that lashing software, currently available, can be used by the crew as a supplement to the approved stowage and securing plans included in the approved CSM (MSC.1/Circ.1353/Rev.2, chapter 4).

In order to formally recognise the use of lashing software as a supplement to the approved CSM on an international basis, IACS proposed a draft unified interpretation to CCC8/12. The proposal received support in principle from the Sub-Committee. However, the general view of the Sub-Committee was that before mandating approval of the lashing software by the Administration, harmonised performance standards and guidelines are needed to allow the approval of lashing software to be carried out in a consistent manner. Subsequently, the Sub-Committee invited Member States and organisations to submit a new output proposal to the Committee.

UR C6 (May 2024) addresses the absence of harmonised performance standards and guidelines for lashing software by providing requirements to facilitate consistent approval of lashing software.

2a. Specification of the data utilised in the development/revision of the proposed IACS Resolution, if any

N/A

3. Source/derivation of the proposed IACS Resolution

The source of the information was obtained through the work of a project team supervised by the Hull Panel.

4. Summary of Changes intended for the revised Resolution:

UR C6 (May 2024) - Requirements for Lashing Software is the original version of this UR.

5. Points of discussions or possible discussions

UR C6 (May 2024) was made through discussions of the draft version provided by the project team within the Hull Panel which involved mainly incorporating individual comments and acceptance of the consolidated text.

6. Attachments if any

No documents are attached.

UR C7 "Approval and Certification of Container Securing Systems"

Summary

A new UR to define the scope of approval and certification of container securing systems is developed.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
NEW (May 2024)	15 May 2023	1 July 2025

- **NEW (May 2024)**

1 Origin of Change:

☑ Action initiated to identify the regulatory gap regarding approval and certification of container securing systems.

2 Main Reason for Change:

The main technical reason for the change is the regulatory gap among the Member Societies regarding the approval and certification of container securing systems.

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None

4 History of Decisions Made:

The project, PT PH51, was initiated by the Hull Panel to address the subject of Container Loss at Sea. The project team was commissioned to identify the gaps between the Rules of member Societies regarding the approval and certification of container securing systems to define the scope of approval and certification of container securing systems.

5 Other Resolutions Changes:

No other solutions are changed.

6 Any hinderance to MASS, including any other new technologies:

No hinderance to MASS available.

7 Dates:

Original Proposal:	Developed by PT PH51	
Panel Approval:	11 April 2024	Ref: PH22017aIHl
GPG Approval:	15 May 2024	Ref: 23013_IGg

****

Part B. Technical Background

List of Technical Background (TB) documents:

Annex 1. **TB for Original Resolution, UR C7 (New May 2024)**

See separate TB document in Annex 1.

Technical Background (TB) document for UR C7 (New May 2024)

1. Scope and objectives

UR C7 (May 2024) is the original version of the newly introduced unified requirements with the aim to define the scope of approval and certification of container securing systems.

UR C7 (May 2024) achieves this objective by describing the plan, drawings and items to be approved or certified. The minimum requirements on the content of the plans or certification procedures have also been given.

2. Engineering background for technical basis and rationale

It is imperative to the safety of the ship and the protection of the cargo and personnel that the cargo is secured properly especially accounting for strength of the ship structures and the securing devices. Hereto, the Member Societies shows regulatory gap regarding the approval and certification of container securing items. In order to identify this regulatory gap and define the approval and certification scope of container securing systems, a literature review involving Rules and guidelines of all Member Societies, and IMO and ISO regulations was conducted. UR C7 (May 2024) is the outcome of this study targeting to fill the gap by defining the minimum requirements for approval and certification of container securing systems recommended to increase safe transportation of containers and other standardised cargo.

2a. Specification of the data utilised in the development/revision of the proposed IACS Resolution, if any

N/A

3. Source/derivation of the proposed IACS Resolution

The source of the information was obtained through the work of a project team supervised by the Hull Panel.

4. Summary of Changes intended for the revised Resolution:

UR C7 (May 2024) - Approval and Certification of Container Securing Systems is the original version of this UR.

5. Points of discussions or possible discussions

UR C7 (May 2024) was made through discussions of the draft version provided by the project team within the Hull Panel which involved mainly incorporating individual comments and acceptance of the consolidated text.

UR D3 "General design parameters"

Summary

UR D3 requirements provide general design parameters applicable to mobile offshore drilling units contracted for construction on and after 1 January 2013. This revision has been developed as part of IACS effort to remove Member's reservations.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev.6 (Nov 2018)	30 November 2018	1 January 2020
Rev.5 (Jan 2012)	13 January 2012	1 January 2013

New (1979)	No Record	-

- **Rev.6 (Nov 2018)**

.1 Origin for Change:

☒ Suggestion by IACS member

.2 Main Reason for Change:

In addition to the change described below a typo has been identified in the shear stress formulation under D3.5.1.

UR D3 was reviewed as part of IACS effort to remove Member's reservations. During the revision process Members identified 1 paragraph duplicating a requirement in LL. This paragraph, UR D3.9.2, describes how to correct the freeboard for units with Moonpools. The calculation of freeboard is a statutory requirement and the content of UR D3.9.2 is covered by LL, UI LL48 and LL53, which interpret how correction for moonpools is to be calculated with respect to the requirements of Chapter III of the International Convention on Load Lines. The only item in sec 9.2 that is not strictly covered by these Unified Interpretations, are sec 9.2.2:

"The procedure described in D3.9.2.1 should also apply in cases of small notches or relatively narrow cut-outs at the stern of the unit."

The correction of freeboard due to such notches are however very small and it is therefore concluded that the calculation of freeboard should be dealt with as a strictly statutory requirement, and members do not deem it necessary to keep a unified requirement covering the same.

.3 List of non-IACS Member Classification Societies contributing through the TC Forum and/or participating in IACS Working Group:

None.

.4 History of Decisions Made:

IACS Member verified the UR text in view of removing their reservations.
It has been proposed to correct a typo in the shear stress formulation and to simplify the UR text removing paragraph D3.9.2.2

.5 Other Resolutions Changes:

None.

.6 Dates:

Original Proposal: 6 April 2018 (Ref: PH18009)
Panel Approval: 13 November 2018 (Ref: PH18009)
GPG Approval: 30 November 2018 (Ref: 18199_IGb)

- **Rev.5 (Jan 2012)**

.1 Origin for Change:

- ☑ Based on IMO Regulation (2009 MODU CODE in the annex to IMO Resolution A.1023(26))
- ☑ Other (in order to fit in with the development of offshore safety technology and practice, some current UR D related stability and safety feature requirements are updated and some new requirements are added.)

.2 Main Reason for Change:

To revise UR D items related to safety feature requirements, in order to comply with 2009 MODU CODE in the annex to IMO Resolution A.1023(26) and meet the requirement of offshore technology development.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

Action to create task decided at 10th statutory panel meeting. Task No.30 was initially assigned by statutory panel to this undertaking. The task was postponed to 2011 due to the constraint of 2010 budget of the statutory panel, and the task number was changed to No.34. A dedicated project team was created to execute this task.

Form A was approved by GPG on 26 May 2011. Preliminary versions of the proposed UR and technical background documents were circulated among the statutory members for review.

Final version of the revised UR and technical background documents approved by the Statutory Panel on 29th September 2011.

.5 Other Resolutions Changes

UR D4, 6, 7 & 11

.6 Dates:

Original proposal: February 2011 *Made by:* Statutory panel
Panel Approval: 29 September 2011

Part B. Technical Background

List of Technical Background (TB) documents for UR D3:

Annex 1. **TB for Rev.5 (Jan 2012)**

See separate TB document in Annex 1.

◄▲►

Annex 2. **TB for Rev.6 (Nov 2018)**

See separate TB document in Annex 2.

◄▲►

Note:

1) There are no separate Technical Background (TB) documents for UR D3 New (1979), Rev.1 (1987), Rev.2 (1989), Rev.3 (1990), Rev.4 (1996), Corr.1 (July 2001) and Corr.2 (Oct 2007).

Technical Background for UR D3 Rev.5, Jan 2012

1. Scope and objectives

This revision involves current stability requirements of UR D3.7, 3.8, 3.9, 4.4, 6.4 & 7 and safety requirements of UR D11. All these works are done to make the safety requirements in accordance with IMO 2009 MODU CODE and to serve the needs of offshore technology development.

2. Engineering background for technical basis and rationale

2009 MODU CODE in annex of IMO Resolution A.1023(26) was adopted on 2 December 2009. The stability and safety requirements of UR D3.7, 3.8, 3.9, 4.4, 6.4, 7 & 11 should comply with the applicable provision in 2009 MODU CODE, and some current requirements are modified for this purpose. Some current requirements in UR D are no longer applicable, such as the requirements of intermediate fire water tanks which are seldom use in the units. Base on investigations of actual design, these requirements have been replaced by more suitable and precise ones. Many safety systems, such as, combustible gas detection and alarm system, hydrogen sulphide detection and alarm system, respiratory protection equipment for hydrogen sulphide, are very important for the unit safety. But there are no requirements for these systems in the current UR D. So the requirements for these systems have been added.

3. Source / derivation of the proposed IACS Resolution

The source of the information was obtained through work performed by the dedicated project team and additional input from the statutory panel.

4. Summary of Changes intended for the revised Resolution:

1. UR D3.7.3 (1)
With the damage region assumption set out in D4.4.1, D5.6.1 and D6.4.1, not only single compartment but also all the possible combinations of compartments should be considered damaged during the stability calculation and analysis.

The force and moment caused by the wind to make the floating unit to incline should be called 'wind heeling force' and 'wind heeling moment' for consistency with MODU Code 2009 from the beginning to the end.

2. UR D3.7.3 (2))
'with the assumption of no wind' added here is to make a clear difference between the two damage stability requirements for column stabilized units specially, which are usually called 'light collision damage with wind' and 'remote flooding without wind'.

3. UR D3.8.3 (1)
The modification is consistent with 3.4.1.2 of IMO MODU Code 2009.

4. UR D3.8.3 (2) (b)

The weathertight border should end with the smaller of the second intercept angle or the smallest downflooding angle of all openings without watertight or weathertight protection.

5. UR D3.8.3 (2) (c)
The added is to be consistent with Fig 4.

6. UR D 3.8.3 (3) (b)
The added is to emphasize that the range of positive stability should end with the smaller of the second intercept of the righting moment curve and the horizontal coordinate axis or the smallest downflooding angle of all openings without watertight or weathertight protection.

7. UR D 3.9.2
The modification is consistent with 3.7.9 & 3.7.15 of IMO MODU Code 2009.

5. Points of discussions or possible discussions

The UR was developed by the project team (PT) for Task No.34 Discussion on the draft documents prepared by the PT were reviewed and discussed within the Statutory Panel at panel meetings and via email correspondence.

One point that required additional discussion concerned the application of 3.6.5.1 and 3.6.5.2 of the MODU Code. Referring to the comparable text in the revised UR D, the Panel understands that D7.4.2(3)(i) applies to all doors that are used, regardless if they are (normally open or normally closed) as opposed to D7.4.2(3)(ii), which refers to doors or hatch covers in self-elevating units, or doors that are normally closed and located above the deepest draft in CSDU's which only need to be of the quick acting type. While the Panel noted that this revision to the MODU Code goes beyond that required in SOLAS for conventional ships engaged on international voyages which is understood to be cargo ships, all Members agreed that doors and hatch covers which are used during the operation of the unit while afloat, regardless if they are normally open or normally closed, are required to be remotely controlled.

6. Attachments if any

None

Technical Background (TB) document for UR D3 (Rev.6 Nov 2018)

1. Scope and objectives

UR D3 requirements provide general design parameters applicable to mobile offshore drilling units. This revision has been developed as part of IACS effort to remove Member's reservations.

2. Engineering background for technical basis and rationale

During the revision process Members identified 1 paragraphs which is covered by LL and UI LL48 and LL53. This paragraph D3.9.2 was removed to avoid duplication the statutory requirement in UR D3. In addition, A typo has been corrected.

3. Source / derivation of the proposed IACS Resolution

None.

4. Summary of Changes intended for the revised Resolution:

D3.5 Allowable stresses
$\tau_i^* = \eta \sigma_y \Pi$ for shear stress. The misprint was corrected

D3.9.2, was identified as covered by LL and UI LL48 and LL53 and deleted.

5. Points of discussions or possible discussions

None.

6. Attachments if any

Part B. Technical Background

List of Technical Background (TB) documents for UR D4:

Annex 1. **TB for Rev.3 (Jan 2012)**

See separate TB document in Annex 1.

◄▲►

Note:

1) There are no separate Technical Background (TB) documents for UR D4 New (1979), Rev.1 (1990) and Rev.2 (1996).

Technical Background for UR D4 Rev.3, Jan 2012

1. Scope and objectives

This revision involves current stability requirements of UR D3.7, 3.8, 3.9, 4.4, 6.4 & 7 and safety requirements of UR D11. All these works are done to make the safety requirements in accordance with IMO 2009 MODU CODE and to serve the needs of offshore technology development.

2. Engineering background for technical basis and rationale

2009 MODU CODE in annex of IMO Resolution A.1023(26) was adopted on 2 December 2009. The stability and safety requirements of UR D3.7, 3.8, 3.9, 4.4, 6.4, 7 & 11 should comply with the applicable provision in 2009 MODU CODE, and some current requirements are modified for this purpose. Some current requirements in UR D are no longer applicable, such as the requirements of intermediate fire water tanks which are seldom use in the units. Base on investigations of actual design, these requirements have been replaced by more suitable and precise ones. Many safety systems, such as, combustible gas detection and alarm system, hydrogen sulphide detection and alarm system, respiratory protection equipment for hydrogen sulphide, are very important for the unit safety. But there are no requirements for these systems in the current UR D. So the requirements for these systems have been added.

3. Source / derivation of the proposed IACS Resolution

The source of the information was obtained through work performed by the dedicated project team and additional input from the statutory panel.

4. Summary of Changes intended for the revised Resolution:

UR D4.4.1 - The modification is consistent with 3.5.6 of IMO MODU Code 2009.

5. Points of discussions or possible discussions

The UR was developed by the project team (PT) for Task No.34 Discussion on the draft documents prepared by the PT were reviewed and discussed within the Statutory Panel at panel meetings and via email correspondence.

One point that required additional discussion concerned the application of 3.6.5.1 and 3.6.5.2 of the MODU Code. Referring to the comparable text in the revised UR D, the Panel understands that D7.4.2(3)(i) applies to all doors that are used, regardless if they are (normally open or normally closed) as opposed to D7.4.2(3)(ii), which refers to doors or hatch covers in self-elevating units, or doors that are normally closed and located above the deepest draft in CSDU's which only need to be of the quick acting type. While the Panel noted that this revision to the MODU Code goes beyond that required in SOLAS for conventional ships engaged on international voyages which is understood to be cargo ships, all Members agreed that doors and hatch covers which are used during the operation of the unit while afloat, regardless if they are normally open or normally closed, are required to be remotely controlled.

6. Attachments if any - None

UR D6 “Surface type drilling units”

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev.1 (Jan 2012)	13 January 2012	1 January 2013
NEW (1979)	*No Record*	-

- **Rev.1 (Jan 2012)**

.1 Origin for Change:

☑ Based on IMO Regulation (2009 MODU CODE in the annex to IMO Resolution A.1023(26))

☑ Other (in order to fit in with the development of offshore safety technology and practice, some current UR D related stability and safety feature requirements are updated and some new requirements are added.)

.2 Main Reason for Change:

To revise UR D items related to safety feature requirements , in order to comply with 2009 MODU CODE in the annex to IMO Resolution A.1023(26) and meet the requirement of offshore technology development.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

Action to create task decided at 10th statutory panel meeting. Task No.30 was initially assigned by statutory panel to this undertaking. The task was postponed to 2011 due to the constraint of 2010 budget of the statutory panel, and the task number was changed to No.34. A dedicated project team was created to execute this task.

Form A was approved by GPG on 26 May 2011. Preliminary versions of the proposed UR and technical background documents were circulated among the statutory members for review.

Final version of the revised UR and technical background documents approved by the Statutory Panel on 29th September 2011.

.5 Other Resolutions Changes

UR D3, 4, 7 & 11

.6 Dates:

Original proposal: February 2011 *Made by:* Statutory panel
Panel Approval: 29 September 2011
GPG Approval: 13 January 2011 (Ref. 11083_IGi)

- **New (1979)**

No TB document available.

Part B. Technical Background

Technical Background for UR D7 Rev.3, Jan 2012

1. Scope and objectives

This revision involves current stability requirements of UR D3.7, 3.8, 3.9, 4.4, 6.4 & 7 and safety requirements of UR D11. All these works are done to make the safety requirements in accordance with IMO 2009 MODU CODE and to serve the needs of offshore technology development.

2. Engineering background for technical basis and rationale

2009 MODU CODE in annex of IMO Resolution A.1023(26) was adopted on 2 December 2009. The stability and safety requirements of UR D3.7, 3.8, 3.9, 4.4, 6.4, 7 & 11 should comply with the applicable provision in 2009 MODU CODE, and some current requirements are modified for this purpose. Some current requirements in UR D are no longer applicable, such as the requirements of intermediate fire water tanks which are seldom use in the units. Base on investigations of actual design, these requirements have been replaced by more suitable and precise ones. Many safety systems, such as, combustible gas detection and alarm system, hydrogen sulphide detection and alarm system, respiratory protection equipment for hydrogen sulphide, are very important for the unit safety. But there are no requirements for these systems in the current UR D. So the requirements for these systems have been added.

3. Source / derivation of the proposed IACS Resolution

The source of the information was obtained through work performed by the dedicated project team and additional input from the statutory panel.

4. Summary of Changes intended for the revised Resolution:

1. UR D7.4.2
The modification is to eliminate the logical confusion and to be consistent with IMO MODU Code 2009.

2. UR D7.4.3 (1)
The modification is to eliminate the logical confusion and make a clear presentation.

3. UR D7.4.3 (4)
There is no D7.4.3(3), and whether it doesn’t exist ever or there is something omitted should be clear. According to the content, the requirement of D7.4.2(3) (i) and (ii) should be complied with.

5. Points of discussions or possible discussions

The UR was developed by the project team (PT) for Task No.34 Discussion on the draft documents prepared by the PT were reviewed and discussed within the Statutory Panel at panel meetings and via email correspondence.

One point that required additional discussion concerned the application of 3.6.5.1 and 3.6.5.2 of the MODU Code. Referring to the comparable text in the revised UR D, the Panel understands that D7.4.2(3)(i) applies to all doors that are used, regardless if they are (normally open or normally closed) as opposed to D7.4.2(3)(ii), which refers to doors or hatch covers in self-elevating units, or doors that are normally closed and located above the deepest draft in CSDU's which only need to be of the quick acting type. While the Panel noted that this revision to the MODU Code goes beyond that required in SOLAS for conventional ships engaged on international voyages which is understood to be cargo ships, all Members agreed that doors and hatch covers which are used during the operation of the unit while afloat, regardless if they are normally open or normally closed, are required to be remotely controlled.

UR D8 'Hazardous areas'

Summary

In Rev.3 of this Resolution, an amendment was made to reflect the latest IMO Resolution.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev.3 (Feb 2021)	24 February 2021	1 July 2022
Rev.2 (1996)	1996	-
Rev.1 (1990)	1990	Unknown
New (1979)	1979	Unknown

- **Rev.3 (Feb 2021)**

1 Origin of Change:

☑ Other (Periodical review to reflect the latest IMO Resolutions)

2 Main Reason for Change:

There was a need to update this UR to reflect the latest IMO Resolutions related to 2009 MODU Code.

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None

4 History of Decisions Made:

Some text of 2009 MODU Code (a non-mandatory IMO Code) are reflected in this UR so that those requirements can be uniformly applied among IACS members as mandatory class requirements.

5 Other Resolutions Changes:

None

6 Any hinderance to MASS, including any other new technologies:

None

7 Dates:

Original Proposal:	25 February 2019 (Ref: PM5901gIMh)

Technical Background (TB) document for UR D8 (Rev 3 Feb 2021)

1. Scope and objectives

UR D8(Rev.2) does not reflect the latest IMO Resolutions related to 2009 MODU Code. Rev.3 has been developed to cover hazardous area requirements.

2. Engineering background for technical basis and rationale

The Panel agreed unanimously to update the UR to align it with 2009 MODU Code amending the requirements for hazardous areas.

3. Source / derivation of the proposed IACS Resolution

2009 MODU Code.

4. Summary of Changes intended for the revised Resolution:

Sections D8.1 to D8.3 specifying hazardous areas requirements related to classifications of said areas and ventilation have been amended.

5. Points of discussions or possible discussions

Sections 6.1 and 6.2, Paragraphs 6.3.1 and 6.3.2, the second sentence of Paragraph 6.4.1 as well as Paragraph 6.4.4 of 2009 MODU Code have been covered by this revision.

Also, history of decision made mentioned in para 4 of history file of Rev.3 be referred.

Technical Background (TB) document for UR D9 (Rev.4 Feb 2021)

1. Scope and objectives

UR D9(Rev.3) does not reflect the latest IMO Resolutions related to 2009 MODU Code. Rev.4 has been developed to cover vent pipes protection requirement.

2. Engineering background for technical basis and rationale

The Panel agreed unanimously to update the UR to align it with 2009 MODU Code adding the requirement for vent pipes protection.

3. Source/derivation of the proposed IACS Resolution

2009 MODU Code.

4. Summary of Changes intended for the revised Resolution:

Paragraph D9.7.3 related to vent pipes protection has been added.

5. Points of discussions or possible discussions

Paragraph 4.8.5 of 2009 MODU Code has been covered in Paragraph D9.7.3 of UR D9.

Also, history of decision made mentioned in para 4 of history file of Rev.4 be referred.

UR D11 "Safety features"

Summary

UR D11 is updated to provide clarity of "near other openings of accommodation spaces".

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Corr.1 (Dec 2022)	14 December 2022	-
Rev.4 (Dec 2021)	24 December 2021	01 January 2023
Rev.3 (Jan 2012)	13 January 2012	01 January 2013
Rev.2 (1996)	1996	-
Rev.1 (1990)	1990	-
New (1979)	1979	-

- ### Corr.1 (Dec 2022)

1 Origin for Change:

☑ Suggestion by an IACS member

2 Main Reason for Change:

To remove the reference to "explosion proof" driller's cabins as the whole driller's cabin cannot be made explosion proof. This clarification was overlooked during the last revisions to UR D11.

3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

4 History of Decisions Made:

UR D 11.7 was corrected to remove the words "explosion proof" from D11.7.1 c.

5 Other Resolutions Changes

None

6 Any hinderance to MASS, including any other new technologies:

None

7 Dates:

Original proposal	: 18 October 2022	(Made by Safety Panel)
Panel Approval	: 29 November 2022	(Ref: PS17010fISzl)
GPG Approval	: 14 December 2022	(Ref: 21121_IGh)

- **Rev.4 (Dec 2021)**

1 Origin for Change:

☑ Suggestion by an IACS member

2 Main Reason for Change:

To clarify the phrase "*near other openings of accommodation spaces*" in UR D 11.7 with regard to the fitting of fixed automatic combustible gas detection and alarm system.

3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

4 History of Decisions Made:

UR D 11.7 was revised to clarify where fixed automatic combustible gas detection and alarm system are required and not required to be fitted. The discussion prompted a revision of UR D 11 as detailed in annex 2.

5 Other Resolutions Changes

None

6 Any hinderance to MASS, including any other new technologies:

None

7 Dates:

Original proposal	: 21 June 2021	(Made by Safety Panel)
Panel Approval	: 29 November 2021	(Ref: PS17010fISzi)
GPG Approval	: 24 December 2021	(Ref: 21121_IGf)

- **Rev.3 (Jan 2012)**

.1 Origin for Change:

☑ Based on IMO Regulation (2009 MODU CODE in the annex to IMO Resolution A.1023(26))

☑ Other (in order to fit in with the development of offshore safety technology and practice, some current UR D related stability and safety feature requirements are updated and some new requirements are added.)

.2 Main Reason for Change:

To revise UR D items related to safety feature requirements, in order to comply with 2009 MODU CODE in the annex to IMO Resolution A.1023(26) and meet the requirement of offshore technology development.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

Action to create task decided at 10th statutory panel meeting. Task No.30 was initially assigned by statutory panel to this undertaking. The task was postponed to 2011 due to the constraint of 2010 budget of the statutory panel, and the task number was changed to No.34. A dedicated project team was created to execute this task.

Form A was approved by GPG on 26 May 2011. Preliminary versions of the proposed UR and technical background documents were circulated among the statutory members for review.

Final version of the revised UR and technical background documents approved by the Statutory Panel on 29th September 2011.

.5 Other Resolutions Changes

UR D3, 4, 6 & 7

.6 Dates:

Original proposal	: February 2011	(Made by: Statutory panel)
Panel Approval	: 29 September 2011	
GPG Approval	: 13 January 2011	(Ref: 11083_IGi)

- **Rev.2 (1996)**

No HF/TB document available.

- **Rev.1 (1990)**

No HF/TB document available.

- **New (1979)**

No HF/TB document available.

Part B. Technical Background

List of Technical Background (TB) documents for UR D11:

Annex 1. **TB for Rev.3 (Jan 2012)**

See separate TB document in Annex 1.

Annex 2. **TB for Rev.4 (Dec 2021)**

See separate TB document in Annex 2.

Note: *There are no separate Technical Background (TB) documents for UR D11 New (1979), Rev.1 (1990), Rev.2 (1996) and Corr.1 (Dec 2022).*

Technical Background for UR D11 Rev.3, Jan 2012

1. Scope and objectives

This revision involves current stability requirements of UR D3.7, 3.8, 3.9, 4.4, 6.4 & 7 and safety requirements of UR D11. All these works are done to make the safety requirements in accordance with IMO 2009 MODU CODE and to serve the needs of offshore technology development.

2. Engineering background for technical basis and rationale

2009 MODU CODE in annex of IMO Resolution A.1023(26) was adopted on 2 December 2009. The stability and safety requirements of UR D3.7, 3.8, 3.9, 4.4, 6.4, 7 & 11 should comply with the applicable provision in 2009 MODU CODE, and some current requirements are modified for this purpose. Some current requirements in UR D are no longer applicable, such as the requirements of intermediate fire water tanks which are seldom use in the units. Base on investigations of actual design, these requirements have been replaced by more suitable and precise ones. Many safety systems, such as, combustible gas detection and alarm system, hydrogen sulphide detection and alarm system, respiratory protection equipment for hydrogen sulphide, are very important for the unit safety. But there are no requirements for these systems in the current UR D. So the requirements for these systems have been added.

3. Source/derivation of the proposed IACS Resolution

The source of the information was obtained through work performed by the dedicated project team and additional input from the statutory panel.

4. Summary of Changes intended for the revised Resolution:

1. UR D11.1.1

Because drilling units are different from ships, additional items, such as, gas detection, hydrogen sulphide detection, emergency shutdown, BOP control positions etc., have been added on the basis of ship's fire control plan.

SOLAS II-2/15.2.4. and IMO.A.952 (23) has been referenced for developing this requirement.

2. UR D11.2.4

In actual practice, the intermediate tank with replenishment pump is seldom installed in the MODU. For surface and column-stabilized and self-elevating units in floating conditions, the fire water normally come from more than one sea chest, and one sea chest supplying system failure can not put the other systems out of action.

For self-elevating units in non-floating conditions, the fire water is supply through following ways:

(a) While unit lifting or lowering, drilling water is normally supplied to fire fighting and engine cooling systems. This is a normal operation practice of some companies.

Alternatively, buffer tanks (or ballast tanks) also can supply water to fire fighting purpose.

(b) During unit is in the elevating positions fire fighting water is supplied from sea water main charged by more than one submersible pumps.
This new provision is developed based on above actual practice. Normally, the drilling water tank volume is far more than 40 m3. Water stored in tank of 40 m3 can maintain two 19mm nozzle jetting for one hour. If 10 m3 was specified it could be considered not enough.

3. UR D11.3.2

The new paragraph has been added because drilling and well test areas are really needed to protect. The existing units investigated by us are really protected with water spray system or fire monitors. ISO 13703, API RP 2030 and NFPA 15 have been referenced to make this new paragraph. Regarding the water application rate, 10 l/min•m2 is specified by ISO and DNV, and 20.4 l/min•m2 is required by API RP 2030. Water spray is not only for cooling purpose but also for diluting gas concentration to avoid explosion. Also considering blowout fire is more powerful, so rate of 20.4 l/min•m2 is required.

4. UR D11.3.3

Now, oil base mud is often used in drilling operations. Foam is the best medium to extinguish oil pool fire. So foam system is required to protect mud processing area. Regarding the delivering rate 6.5 and 4.1 l/min•m2, the origin is from NFPA.11.

5. UR D 11.4.1 to 11.4.3

The revised requirements are applicable to helicopter facilities without considering with refuelling capabilities or with no refuelling capabilities. This revision is consistent with 2009 MODU Code. The delivering rate 6 l/min.m2 is maintained in order to be consistent with MODU CODE and ICAO requirement.

6. UR D11.5.1

This revision makes the requirements clearer and precise. MODU CODE, CFR 46 Part 113, IMO A.1021 (26) and MSC/ Circ.887 have been referenced for making this revision.

7. UR D11.5.4

The public address requirements are consistent with SOLAS, LSA CODE 7.2.2 and 2009 MODU CODE 5.7.3.

8. UR D11.6
This paragraph has been deleted. There are no special emergency control stations on the existing unit. General alarm actuating location requirement is moved to D11.5.1. Emergency shutdown requirement is covered in D10.5.1.

9. UR D11.7

Based on the existing text, general requirement and specific requirements for protection of galleys, electrical rooms, drilling areas, mud processing areas and well test areas have been added to enable the whole system requirements more completeness and easily operable. SOLAS, MODU Code and other materials have been referenced for making this revised paragraph.

UR D11.8 (New section added)
During the drilling operation, if hydrogen sulphide gas is present it could be very dangerous to personnel. So it is very necessary to optimizing the arrangement of hydrogen sulphide detectors and ensuring the availability of the Hydrogen sulphide detection and alarm system. In this paragraph, the provision of Ch.9.12 of MODU Code has been incorporated into this new URD.
The requirement of two level alarms comes from API RP 49.

UR D11.9 (New section added)
To make the requirements for respiratory protection equipment for hydrogen sulphide more suitable for MODU, API RP 49 and 29 CFR 1910.134 have been referenced and actual conditions of MODU are considered for developing this new UR D.

5. Points of discussions or possible discussions

The UR was developed by the project team (PT) for Task No.34 Discussion on the draft documents prepared by the PT were reviewed and discussed within the Statutory Panel at panel meetings and via email correspondence.

One point that required additional discussion concerned the application of 3.6.5.1 and 3.6.5.2 of the MODU Code. Referring to the comparable text in the revised UR D, the Panel understands that D7.4.2(3)(i) applies to all doors that are used, regardless if they are (normally open or normally closed) as opposed to D7.4.2(3)(ii), which refers to doors or hatch covers in self-elevating units, or doors that are normally closed and located above the deepest draft in CSDU's which only need to be of the quick acting type. While the Panel noted that this revision to the MODU Code goes beyond that required in SOLAS for conventional ships engaged on international voyages which is understood to be cargo ships, all Members agreed that doors and hatch covers which are used during the operation of the unit while afloat, regardless if they are normally open or normally closed, are required to be remotely controlled.

Technical Background (TB) document for UR D11 (Rev.4 Dec 2021)

1. Scope and objectives

An IACS member sought clarification of the phrase "*near other openings of accommodation spaces*" in UR D 11.7.1(g) with regard to the fitting of fixed automatic combustible gas detection and alarm system.

2. Engineering background for technical basis and rationale

Fixed automatic combustible gas detection and alarm system should be provided to openings leading to the accommodations where the risk of gas entering into the accommodations is present.

3. Source/derivation of the proposed IACS Resolution

1. The Panel considered the risk of ingress of combustible gas into the accommodation space relative to the effectiveness/reliability of the ventilation over-pressurization, the gas tight effectiveness of external door arrangements (self-closing, gas tight, airlock) and the location of doors and other openings with respect to the hazardous area.

2. It was noted that:

- UR D 11.7.1(g) appears to provide clarification of the MODU Code 9.11.1 which states, "*A fixed automatic gas detection and alarm system should be provided to the satisfaction of the Administration so arranged as to monitor continuously all enclosed areas of the unit in which an accumulation of flammable gas may be expected to occur and capable of indicating at the main control point by aural and visual means the presence and location of an accumulation.*"
- NORSOK S-001 "Technical Safety" and NMA MODU Fire Regulations do not require gas detectors in locations other than the ventilation intakes for accommodation spaces.

4. Summary of Changes intended for the revised Resolution:

1. Fixed automatic combustible gas detection and alarm system is to be provided for:

- Ventilation i*ntake of positive pressure explosion-proof driller's cabin.*
- Ventilation intakes of accommodation spaces.
- *Ventilation intakes of enclosed machinery spaces contiguous to hazardous areas and containing internal combustion engines, boilers; or non-explosion proof electrical equipment*
- Air intakes to all combustion engines or machinery, including internal combustion engines, boilers, compressors or turbines, located outside of an enclosed machinery space
- At each access door to accommodation spaces.
- Near other openings, including emergency egress, of accommodation spaces, regardless if these openings are fitted with self-closing and gastight closing appliances.

2. Fixed automatic combustible gas detection and alarm systems are not required:

- Near access doors to accommodation spaces where these form part of an air-lock which is provided with a gas detection and alarm system between the two doors of the air-lock.
- [Near emergency egress doors which are fitted with a panic bar or similar mechanism to prevent use other than in an emergency].
- Near other openings which are provided with closing appliances of non-opening type, e.g. bolted closed maintenance ways etc.

5. Points of discussions or possible discussions

1. Initial discussions considered that "*near other openings*":

- excluded ventilation outlets - as they are not specifically mentioned and there is no known source of gas release from the accommodations given that air flow is exhausting from the ventilation outlet. However, some Members considered that ventilation outlets should be included in order to provide gas detectors to give warning of ingress of gas into the accommodations in the event the ventilation system shuts down;
- included exterior doors of the accommodations - because they are in use (opened and closed) as a normal operation and are not required to be gas tight;
- included emergency egress doors which are fitted with a panic bar or similar mechanism to prevent use other than in an emergency because it is desirable for those egressing the accommodations to know if combustible gas exists outside of the door
- excluded windows and sidescuttles of the non-opening type as there is no risk of ingress of combustible gas.

2. Views on the need for a fixed automatic combustible gas detection and alarm system "*near other openings*" of accommodation space were mixed due to different assumptions on:

- the effectiveness/reliability of the ventilation over-pressurization to control the movement of gases
- external door arrangement (self-closing, gas tight, airlock)
- location of doors and other openings with respect to the hazardous area.

3. During discussion, it was proposed to revise:

- UR D8.3 to require a minimum capacity (air changes per hour) in accordance with an agreed national or international standard (e.g., ISO15138) for the ventilation system for the accommodation space (It was subsequently determined that as ISO 15138 follows a goal and functional requirement approach and does not specify a figure for the number of changes required, it was not appropriate to refer to ISO 15138); and
- UR D11.7.1.g to require a fixed automatic combustible gas detection and alarm system to be provided for ventilation intakes and near other openings of accommodation spaces which face hazardous areas unless these other openings are defined emergency egress doors or are fitted with self-closing and gastight closing appliances or with an airlock (this was analogous to SOLAS II-2/4.5.2.1 which prohibits access doors, air

inlets and openings to accommodation spaces, service spaces, control stations and machinery spaces from facing the cargo area).

4. An alternative proposal considered that:

A combustible gas detection and alarm system need not be provided where the opening:

- is through an air lock; or
- is provided with a closing appliance of a non-opening type (e.g. bolted closed maintenance access way etc.); or
- is a defined emergency egress door as identified on the fire control plan or is marked as such in accordance with 2009 MODU Code 9.4.1.4.

Arrangements which meet ISO 13702 or NORSOK S-001 are considered to meet this requirement.

5. Different views existed as to the intent of providing fixed automatic combustible gas detection and alarm system to other openings:

- to ensure that all significant access points that gas could enter an accommodation space are fitted with gas detection; versus
- in the event of a gas release where a cloud could easily migrate to the access doors it is prudent to provide gas detection at the access doors (including self-closing gas-tight doors and emergency egress doors) in order to adequately notify the crew of the gaseous condition that exists outside of access door in order to facilitate a safe response to implement emergency shutdown procedures

6. As a possible compromise, it was proposed:

- The ventilation system for the accommodation spaces is to be capable of maintaining a positive pressure in relation to the outside atmosphere (refer to International standards e.g. IEC 60092-502:1999) appropriate for the safe use of the space, assuming all doors and windows are closed.
- A differential pressure monitoring device or a flow monitoring device, or both, shall be provided in the space for monitoring the satisfactory functioning of pressurization. An alarm is to be given at a normally manned station in case the overpressure is lost.
- As an alternative to pressure and/or flow monitoring and alarm requirement, a gas detector provided outside each access door with an alarm given at a normally manned station, may be accepted.

7. After re-focusing on the original question as to what constituted "*near other openings*", it was agreed that the proposal in paragraph 6, above, went beyond the original issue raised and agreed to a revision or D11.7 as summarized in item 4, above.

Technical Background Document
WP/SRC Task 1
UR Z 15 – Proposed

Objective and Scope:

To review existing UR D 12 and relocate it as a UR under UR Z.

Source of Proposed Requirements:

WP/SRC members discussed and reviewed the requirements contained in UR D 12 through correspondence and their meeting. Reservations against UR D 12 were also dealt with at this time as contained in the proposed draft.

Points of Discussion:

WP/SRC unanimously agreed to the proposed draft UR Z 15.

Date of submission: 6 May 1999
By WP/SRC Chairman's e-mail

Technical Background Document

New UR Z 15 and deletion of D12
(Survey after Construction, MODUs)

Objective and Scope:

Re-locate the current MODU survey requirements from UR D12 to a new UR Z.

Source of Proposed Requirements:

WP/SRC Chairman reported in his annual progress report(March 1999, GPG 46) that WP/SRC Members had discussed and reviewed the requirements contained in UR D 12 through correspondence and at their last meeting and had relocated the text of D 12 to a new UR Z15.

The task was carried out as part of Annual review of Implementation of IACS Requirements.

Points of Discussion:

WP/SRC unanimously agreed to the proposed draft UR Z 15.

Council in May 1999 decided that the proposed draft paragraph 2.2.2 should be deleted since it would require Members to periodically check all CSDU's lightship characteristics as a condition of class in the event that it was not checked as a statutory requirement.

Paragraph 2.2.2, which has now been deleted, read as follows:

> 2.2.2 For Column Stabilized Units, a deadweight survey is to be conducted as part of classification surveys at interval not exceeding 5 years or at time of Special Surveys, or as part of statutory surveys at interval specified by the Flag Administrations. Where the deadweight survey indicates a change from the calculated light ship displacement in excess of 1% of the operating displacement, an inclining test is to be conducted.

Note:

Council Chairman announced approval of UR Z15(ex D12) on 15 May 1999 subject to the following conditions:

- Deletion of paragraph 2.2.2;
- Adoption of UR Z18(ex M20) for Z15.5.1 and Z15.6.1;
- Editorial corrections.

UR Z18 was finally approved on 23 November 2001(9056aIAe, 29/01/2002):

- M20 was deleted;
- Z18 "Periodical Survey of Machinery" created excluding tail shaft survey requirements;
- Z21 created for the tail shaft survey requirements.

ABS suggested to re-word Z15.5.1 to avoid the need for filing of reservations on Z15.5.1 simply because it invokes the requirements of Z21. Agreed.

IACS UR E4 (1978)
Earthing of non-current-carrying parts

Technical Background Document

Objective and Scope:

The objective was to review of UR E4 taking into account the relevant standard IEC60092-401.
The scope was to delete or correct UR E4 in accordance with IEC standard.

Source of Proposed Requirements:

The proposed requirements have been based on the present Rule requirements of the IACS members and standard IEC60092-401.

Points of Discussion:

WP/EL unanimously agreed to delete UR E4. This UR does not reflect practice as exemplified in IEC60092-401 ‘Electrical installation in ships. Part 401: Installation and test of completed installation’ and does not answer the present status of affairs.

Technical Background Document

E5 (Rev.1, Sept. 2005)

IACS WP/EL Task No.67
To specify the voltage tolerance for DC distribution systems in the Unified Requirement E5 “Voltage and frequency variations”

Objective and Scope:
The main aim of this Task is to add new requirement of the voltage variations for d.c. distribution system in UR E5 taking into consideration the relevant requirements and standards.

Background for the Proposed Revision:
The IEC60092-101 has been amended since 1995 and new paragraphs related with the characteristics of power supply systems have been added. It makes reference to the voltage and frequency variations for both a.c. and d.c. distribution systems. However, the existing UR E5 which was adopted in 1979 has not stated the voltage variations for d.c. distribution systems but also stated the voltage and frequency variations for a.c. distribution systems.
It is timely that the allowable voltage variations for d.c. distribution systems are stated in E5 taking account of the currently increasing number of the d.c. control and instrumentation equipment in ships.

Points of Discussion:
First, since the combination systems of battery and its charger are common as d.c. distribution systems in ships, NK proposed the new requirement of d.c. voltage variations for such systems as a standard model in ships taking account of the following statutory regulations and international standards. It was + 12% to – 22%, which overcomes the variation of ±10% in the 3rd bullet.
-SOLAS II-1/42.3.2.1, 42.4, 43.3.3.1 and 43.4:
The allowable battery source quality is ±12%.
-IEC60092-352 (1997) Clause 10:
The allowable voltage drop of the cable from a battery to a load is –10%.
-IEC60092-101 amendment 1(1995-04) Clause 2.8.3:
The allowable voltage variation for d.c. electrical equipment is ±10%.

After that, during the discussion, the following points were clarified.

- The requirement of E5 is intended for the voltage and frequency variations on the basis of designed rated value of the electrical equipment, i.e. the value is given at the consumer side.
- The new requirement should be developed based on the IEC60092-101 because the voltage variations specified in it are assumed to include the source quality and the voltage drop of the cable from a source to a consumer.
- Since the essential d.c. electrical equipment in ships are control and instrumentation equipment, the relevant requirement in UR E10 (Rev.4, May 2004), which are equivalent to IEC60092-504 (2001-03), should reflect to the new requirement.

Consequently, it was decided to approve the new requirement as a revision of E5 on the following concepts:

(1) The d.c. distribution systems are divided into two categories. One of them is for components supplied by d.c. generators or converted by rectifiers, and the other is for components supplied by electrical batteries.
(2) The allowable voltage variations are developed in each case of (1) above according to the value specified in IEC60092-101 amendment 1(1995-04) Clause 2.8.3 and IEC60092-504 (2001-03) Table1 item 4a.

Submitted by WP/EL Chairman
31 Jan 2005

UR E7 "Cables"

Summary

In Rev.5 of this Resolution, the way to refer to instruments other than those specified by IACS was unified.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev.5 (Feb 2021)	12 February 2021	1 July 2022
Rev.4 (Apr 2016)	21 April 2016	1 July 2017
Rev.3 (May 2006)	16 May 2006	-
Rev.2 (June 2000)	15 June 2000	-
Rev.1 (1990)	1990	-
New (1975)	1975	-

- **Rev.5 (Feb 2021)**

1 Origin of Change:

☑ Other (Update to comply with the required format when industry standards are referred to)

2 Main Reason for Change:

There was a need to update this UR to comply with the following format when industry standards are referred to:

[Standard Designation], [version/revision, if applicable], [year of publication] (examples: API Spec 2F, 6th Edition, 1997; ISO 4624, 2002), where [version/revision, if applicable] and/or [year of publication] are decided by IACS and are not necessarily to be the current/latest version.

4 History of Decisions Made:

None

5 Other Resolutions Changes:

None

6 Any hinderance to MASS, including any other new technologies:

None

7 Dates:

Original Proposal: 28 October 2019 (Ref: PM18939_IMd)
Panel Approval: 9 November 2020 (Ref: PM20906_IMf)
GPG Approval: 12 February 2021 (Ref: 20206cIGb)

- **Rev.4 (April 2016)**

.1 Origin of Change:

☑ Suggestion by IACS member (e-mail dated 27th January 2015)

.2 Main Reason for Change:

The withdrawal or replacement of several IEC standards mentioned in the current UR E7 (Rev.3) makes it necessary to revise the UR content accordingly. Moreover, further consideration should be given to cables not manufactured to the IEC publications identified in the UR.

.3 List of non-IACS Member Classification Societies contributing through the TC Forum and/or participating in IACS Working Group:

Form A was agreed at the 21st Panel Meeting (March 2015).
The final text has been adopted by the Machinery Panel by correspondence in December 2015.

IACS UR E7 (1975, Rev. 1 1990)
Cables and insulated wires

Technical Background Document

Objective and Scope:

The objective was to review of UR E7 taking into account the present Rule requirements of the IACS members.
The scope was to delete reference to "insulated wires" and amend reference to IEC92 series to read – IEC60092.

Source of Proposed Requirements:

The proposed requirements have been based on the present Rule requirements of the IACS members.

Points of Discussion:

WP/EL unanimously agreed to delete reference to "insulated wires", as "insulated wires" are not to be of a type approved by the Classification Society in accordance with Rule requirements of the IACS members.

IACS UR E7 (Rev. 3, May 2006)
IACS Machinery Panel Task No.PM5407

Technical Background document

Objective and Scope:

The aim of this Task is to revise UR E7 to ensure that valid and relevant standards are referred to.

Background for the Proposed Revision:

- IEC has withdrawn the referenced standard IEC 60092-3.
- The standard was replaced with a number of other standards, this is duly marked in documents found in the IEC database under the technical committee SC 18A (attached)
- The same committee which is responsible for developing standards for ship cables has developed further standards for special cables used onboard.
- It is therefore opportune to add these standards to UR E7 in order to make the list of cable standards complete.

Permanent Secretariat Note:

1. GPG agreed that no uniform implementation date was needed.

2.1 Machinery Panel Member proposed to modify para. 3 in order to give the UR its meaning. It was further improved by the GPG Chairman as follows:

MCH Panel's proposed para 3	Panel Member's proposed para.3 (further modified by the GPG Chairman, and 3/4 majority of GPG members agreed to)
3. Cables manufactured to other standards than those specified in 2 are subject to special consideration by the Classification Society in each particular case."	*3. Cables manufactured and tested to standards other than those specified in 2 will be accepted provided they are in accordance with an acceptable and relevant international or national standard.* ***Reason:*** *This is to take* exception to the inclusion of "special consideration" in the UR and making the point, as has been made in the past, that the inclusion of "special consideration" within a UR, without specifying the requirements or criteria for how that "special consideration" is to be applied does not constitute a "unified

	requirement" since it leaves the determination of acceptability to each Society. Member therefore proposed a text it considered to constitute a "unified requirement" not relying on "special consideration."

2.2 It was then challenged by another Panel Member telling that:

Member considers the phrase "acceptable and relevant international or national standard" too vague and reducing the responsibility of Class for this matter. Who knows whether "acceptable and relevant" national standards of one country will be applicable in other country?

The phrase "subject to special consideration by the Classification Society in each particular case" is more versatile and covers all cases not mentioned in items 1 and 2 of E7.

As a compromise we may add new item 4 to E7 (after item 3 proposed by IGb):

"4. Cables manufactured to other standards than those specified in 2 and 3 are subject to special consideration by the Classification Society in each particular case."

But the version of E7 proposed by the Machinery Panel seems better.

2.3 With detailed 'Reasons' provided in the table above, 3/4 majority support of GPG remained unchanged. GPG approved.

3. Panel Member

3.1 A member stated that it was opposed to the revision. This member maintained the position that it is not sure that national standards acceptable to one Society would be acceptable to all other Societies, so it does not consider that the new UR E7 revision will work. A Member advises that it prefers the text proposed by the Machinery Panel to GPG circulated with IGa, 10 March.

3.2 In that respect, Council Chairman pointed out that the text of item 3 of the UR:

3 Cables manufactured and tested to standards other than those specified in 2 will be accepted provided they are in accordance with an acceptable and relevant international or national standard.

leaves it to each Society to determine, for themselves, whether they consider a particular national or international standard to be acceptable and relevant or not.

3.3 This Member maintained its position.

Technical Background (TB) document for UR E7 (Rev.4 Apr 2016)

1. Scope and objectives

The withdrawal or replacement of several IEC standards mentioned in the actual UR E7 makes it necessary to revise the UR content accordingly. Moreover, further consideration should be given to cables not manufactured to the IEC publications identified in the UR.

2. Engineering background for technical basis and rationale

The specific procedures for revision of UR E7 are as follows:

a) Identify the standards mentioned in the UR that have been withdrawn or replaced by new ones.
b) Consider approach for cables not manufactured to IEC standards identified in the UR
c) Revise UR E7 accordingly.
d) Specify the implementation date of the UR.

3. Source/derivation of the proposed IACS Resolution

N/A

4. Summary of Changes intended for the revised Resolution:

UR E7.2 has been updated on the basis of the following IEC standard equivalency Table:

IEC Publications in E7	Replaced by
60092-350	N/A
60092-351	IEC/TR 60092-360
60092-352	N/A
60092-353	N/A
60092-354	N/A
60092-359	IEC/TR 60092-360
60092-373	IEC/TR 60092-370
60092-374	IEC/TR 60092-370
60092-375	IEC/TR 60092-370
60092-376	N/A

5. Points of discussions or possible discussions

One member proposed to consider adding a wording to exempt communication cables for non-important consumers from the type approval requirement whereas another member considered it applicable to all cables.

All the member comments were in favor of considering an equivalency of "international or national standards" to IEC Standards listed in paragraph 2. The following amendment was proposed by the Chairman accordingly:

"3. Cables manufactured and tested to standards other than those specified in 2 will be accepted provided they are <u>of an equivalent or higher safety level than those listed in paragraph 2</u>~~in accordance with an acceptable and relevant international or national standard~~."

One member finally proposed the following text:

"3. Cables manufactured and tested to standards other than those specified in 2 will be accepted provided they are in accordance with an acceptable and relevant international or national standard <u>and are of an equivalent or higher safety level than those listed in paragraph 2.</u>"

One member suggested introducing the following relaxation of the requirement in paragraph 3 for those specific cables (e.g. flexible cables used for crane, etc.) which would be very hard to comply with the proposed amendment to paragraph 3. In this regard, following text was suggested to be added to the end of paragraph 3:

<u>"…However, cables such as flexible cable, fiber-optic cable, etc. used for special purposes may be accepted provided they are manufactured and tested in accordance with the relevant standards accepted by the Classification Society."</u>

The following text was finally adopted by the Machinery Panel:

1. Cables are to be of a type approved by the Classification Society.

2. Cables manufactured in accordance with the relevant recommendations of IEC Publication 60092-350, ~~60092-351,~~ 60092-352, 60092-353, 60092-354, ~~60092-359,~~<u>60092-360</u> ~~60092-373, 60092-374, 60092-375~~<u>, 60092-370</u> and 60092-376 will be accepted by the Classification Society provided that they are tested to its satisfaction.

3. Cables manufactured and tested to standards other than those specified in 2 will be accepted provided they are in accordance with an acceptable and relevant international or national standard <u>and are of an equivalent or higher safety level than those listed in paragraph 2. However, cables such as flexible cable, fiber-optic cable, etc. used for special purposes may be accepted provided they are manufactured and tested in accordance with the relevant standards accepted by the Classification Society.</u>

Technical Background (TB) document for UR E7 (Rev. 5 Feb 2021)

1. Scope and objectives

UR E7(Rev.4) does not reflect the agreed format for referencing the IEC standards. Rev.5 has been developed to comply with the agreed format.

2. Engineering background for technical basis and rationale

Format for references to Industry standards

> ***Format:***
> *[Standard Designation], [version/revision, if applicable], [year of publication] (examples: API Spec 2F, 6th Edition, 1997; ISO 4624, 2002), where [version/revision, if applicable] and/or [year of publication] are decided by IACS and are not necessarily to be the current/latest version.*

3. Source / derivation of the proposed IACS Resolution

None

4. Summary of Changes intended for the revised Resolution

UR E7 has been updated to specify the revision/version of the IEC standards as follows:

IEC standards	**Replaced by**
IEC 60092-350	IEC 60092-350:2020
IEC 60092-352	IEC 60092-352:2005
IEC 60092-353	IEC 60092-353:2016
IEC 60092-354	IEC 60092-354:2020
IEC 60092-360	IEC 60092-360:2014
IEC 60092-370	IEC 60092-370:2019
IEC 60092-376	IEC 60092-376:2017

5. Points of discussions or possible discussions

The investigation for the year of publication of the standards started beginning of 2019. At that time 60092-370:2009 was applicable; however as of November 2019, a new edition of the aforesaid standard has been published, therefore the 2019 edition is stated in the UR.

None

Technical Background –

(New) UR M61 'Starting arrangements of internal combustion engines'

deletion of
UR M49 'Availability of machinery' and
UR E8 'Starting arrangements of internal combustion engines'

1. General

There had been a long discussion in 1998-1999 with respect to the definitions of "deadship" and "blackout". The main reason was that the SOLAS definitions of blackout and deadship condition were quite different from those given in UR M49 (Rev.1, 1996).

2. UR M 49

At present, Rev.1 of M49 (1996) is effective.

In 1998, WP/MCH suggested that a footnote be added to UR M49.1 in order to make reference to SOLAS II-1/42.3.4 and 43.3.4. GPG 44 (1998) also considered that the existing UR M49.1 was to be isolated from M49.2, the latter together with UR E8 being relocated as new UR M61.

At the same time, GPG 44 decided that approval of Rev.2 of UR M49 be put in abeyance until the development of UI SC 124 was finalized.

UR M49 (Rev.2) and M61(New), so prepared by the Permanent Secretariat, were passed to WP/MCH for review. In particular, WP/MCH was to clarify the scope of application of **M49** and **M61** to non-SOLAS ships (part of WP/MCH Task 41).

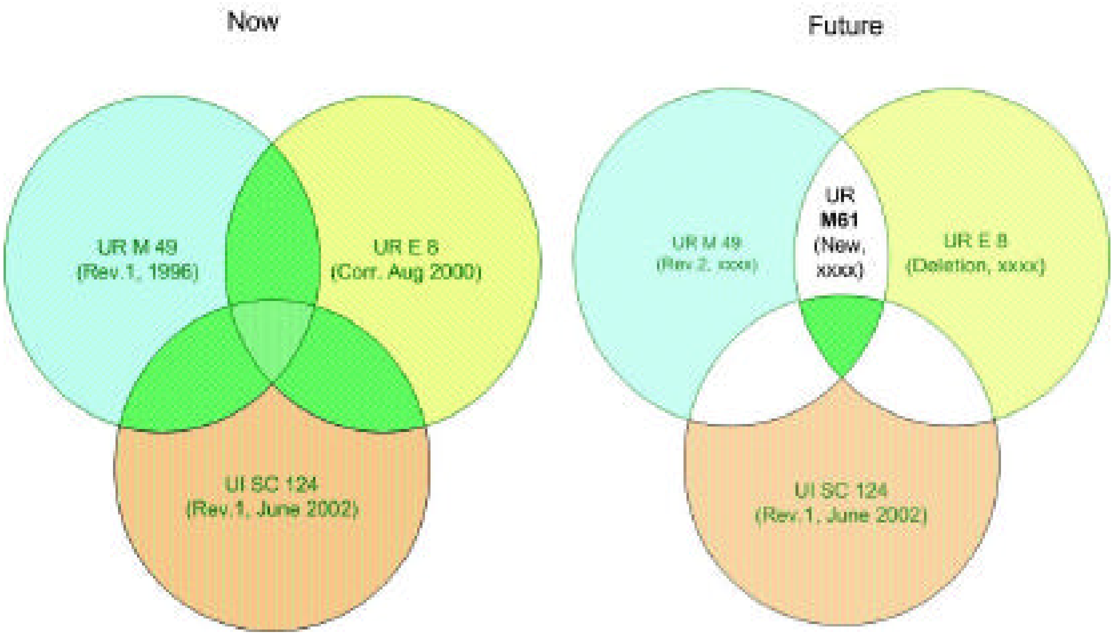
WP/MCH reported to GPG 52 (March 2002) that M49 should apply to all ships subject to further debate. WP/MCH consequently suggested in March 2003 (GPG 54) that an application note should be added to UR M49 to the extent that M 49 applies to non-SOLAS vessels. The draft footnote read: *These requirements (M49) apply only to ships required to comply with SOLAS [and ships above 200 GRT].*
WP/MCH Chairman later confirmed in consultation with experts that the square bracket be removed. However, Council did not approve it (June 2003).

3. UI SC 124

GPG 44 (1998) found that the draft text of SC 124 did not clarify the definition of "deadship" and "blackout". UI SC 124 was then withdrawn and WP/MCH was tasked to develop an interpretation of the two terms with a view to elaborating a definition to be used in UR M49 and SC 124 and if necessary other resolutions. However, WP/MCH failed to reach a common understanding of the term "deadship condition" in 1998.
Hence, GPG 46 (1999) attempted to develop a generally agreeable definition. With assistance from the WP/MCH, GPG/Council finally approved UI SC 124 in

May 1999. It was submitted to IMO DE (DE 43/Inf.5). Revised in June 2002 and submitted to IMO MSC 76.

Status at this point



4. Tasking of WP/MCH

In August 2003 GPG tasked WP/MCH to consider

M49:

a. whether the text of UR M49.1(draft Rev.2, xxxx) should be amended in light of UI SC 124(Rev.1, June 2002) ;
b. whether the wording [and ships above 200GRT] should be deleted from the note to UR M49(draft Rev.2, xxxx) or retained;

M61:

c. whether the text of new draft UR M61 is appropriate, taking into account 7225_NVc of 26 May 98 from the then GPG Chairman.

5 WP/MCH submission

The WP concluded that text of UR M 61 is not adequate and changes suggested previously by GPG need to be introduced. However with the introduction of these changes M61.3 would become a word by word copy of SOLAS regulation II-1/44. Therefore WP did not see any need for this requirement as a class one and proposed to GPG to delete M61.3.

IMO has adopted MSC/Circ.736 (which is recommendatory) that interpreted SOLAS regulation II-1/44.1. There was a need to draft a UI that would simply reference the relevant paragraphs of this circular with respect to the regulation in question. This arrangement will create uniform application on behalf of the Flags in cases where a particular Flag is silent on circular application.

With the publication of the revised SC124 the need for UR M49 as it stands were now be brought into question. The origins of the UR M49 stem from SOLAS II-1/26.4 with the need to define what "dead ship" conditions entailed. In view of the latest SC124 it would now seem sensible to make a new UIs for SOLAS II-1/26.4 and HSC 9.1.5 and delete M49. In doing this it would make it clear that the requirements are only applicable to SOLAS/HSC vessels and obviate the discussions regarding the notes to M49. The definition of "dead ship" in the new UIs would be consistent with SC124.

With the above in mind WP/MCH:

i) proposed to delete M61.3,
ii) suggested to draft a UI that would reference relevant paragraphs of SOLAS Reg. II-1/44.1 and MSC/Circ.736,
iii) sought approval for the deletion of UR M49 and drafting of UI for SOLAS II-1/26.4 and HSC 9.1.5.

GPG concurred and approved the subsequent drafts and deletion of UR M49 and UR E8 (as per 3097cIGf of 12 November 2003; tacit 19 November) .

****

Permanent Secretariat 21 November 2003.

UR E9 “Earthing and bonding of cargo tanks/ process plant/piping systems for the control of static electricity”

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev.1 (October 2012)	29 October 2012	1 January 2014
NEW (1988)	*No record*	-

- **Rev.1 (October 2012)**

.1 Origin for Change:

☑ Other (OCIMF)

.2 Main Reason for Change:

OCIMF highlighted cases of valve installations on board product carriers that were improperly bonded to the hull, and as a consequence, the resistance between the valve and the hull of the ship was higher than required by E9.1
It resulted that wafer-type valves were involved, and due to their design, the connecting bolts, unlike for other type of valves, did not provide a proper means of bonding the valve to the hull.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None.

.4 History of Decisions Made:

Form A approved 11th April 2011.

.5 Other Resolutions Changes

None.

.6 Dates:

Original proposal: *30th June 2011 Made by: Machinery Panel*
Panel Approval: *07 September 2011*
GPG Approval: *29 October 2012 (Ref. 11075_IGd)*

- **NEW (1986)**

No TB document available.

Part B. Technical Background

List of Technical Background (TB) documents for UR E9:

Annex 1. **TB for Rev.1 (October 2012)**

See separate TB document in Annex 1.

◄▼►

Note: *There are no separate Technical Background (TB) document for the original resolution (1988).*

Technical Background for UR E9 Rev.1, Oct 2012

1. Scope and objectives

OCIMF highlighted cases of valve installations on board product carriers that were improperly bonded to the hull, and as a consequence, the resistance between the valves and the hull of the ship was higher than required by E9.1.

The UR is to be modified to improve its clarity and avoid re-occurrence of the highlighted cases.

2. Engineering background for technical basis and rationale

Normally valves are connected to the piping system by bolts; unless the valve or piping are applied with a heavy layer of paint before fitting the bolts, the bolts also electrically bond the valve to the piping, and the piping system is properly bonded to the hull structure, therefore it is not normally needed to have separate bonding straps connected to the valves.

An analysis of the case however revealed that wafer-type valves were involved; wafer type valves are not attached by bolts to the piping flange, but just squeezed in between two flanges, often with the additional use of a gasket and the bolts connect the two flanges without even touching the valve.
Therefore, unless the gaskets are electrically conductive, the valve body will be electrically isolated from the piping.

3. Source/derivation of the proposed IACS Resolution

SOLAS Reg. II-2/4.5.3 Cargo Tank Venting
SOLAS Reg. II-2/11.6 Protection of cargo tank structure against pressure or vacuum in tankers.

4. Summary of Changes intended for the revised Resolution:

- In order to better identify the cases which require a bonding strap and call the surveyor attention to wafer-style valve with non-conductive (e.g. PTFE) gaskets or seals.

- Instead of "earth" use the term "the hull of the ship".

5. Points of discussions or possible discussions

The term "wafer-style valve" was subject to discussions, but it was agreed to keep this term in the document.

UR E10 "Test Specification for Type Approval"

Summary

Item 8 (inclination test) is revised for the part relevant to Gas Carriers and Chemical Carrier, in alignment with Note 3 to M46.2 which is updated accommodating the reference clause nos. of the IGC Code and the IBC Code that were previously specified in UI SC6 and UI SC290. In parallel, the reference standards are also updated as per the latest and valid version.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev.10 (August 2024)	26 August 2024	1 January 2026
Rev.9 (August 2023)	07 August 2023	1 July 2024
Corr.1 (Jan 2022)	16 January 2022	-
Rev.8 (Feb 2021)	12 February 2021	1 July 2022
Rev.7 (Oct 2018)	25 October 2018	1 January 2020
Rev.6 (Oct 2014)	31 October 2014	1 January 2016
Rev.5 (Dec 2006)	13 December 2006	1 January 2008
Rev.4 (May 2004)	31 May 2004	-
Corr.1 (July 2003)	16 July 2003	-
Rev.3 (May 2001)	17 May 2001	-
Rev.2.1 (July 1999)	28 July 1999	-
Rev.2 (1997)	12 May 1997	-
Rev.1 (1993)	1993	-
New (1991)	1991	-

- **Rev.10 (August 2024)**

1 Origin of Change:

☑ Suggestion by IACS member

2 Main Reason for Change:

Reference clause nos. of the IGC Code and the IBC Code which are the main part of interpretation in UI SC6 and UI SC290 have been transferred to UR M46 (Note 3 to M46.2). As there is similar sentence in item 8 of UR E10, the relevant part of item 8 is to be revisited for update.

Taking the opportunity, the latest edition of the reference standards are also checked and updated accordingly.

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None.

4 History of Decisions Made:

The Panel considered the revision of UI SC6, UI SC290 and UR M46, and after deliberations decided to delete the redundant UIs (i.e. UI SC6 and UI SC290) and add reference clause nos. of the IGC Code and the IBC Code to UR M46 (Note 3 to M46.2).

In the course of discussion, it was found that similar requirements as Note 3 to M46.2 is present in item 8 of UR E10 (inclination test), and the Panel decided to update relevant part of UR E10 as well.

5 Other Resolutions Changes:

- UI SC6
- UI SC290
- UR M46

6 Any hinderance to MASS, including any other new technologies:

None.

7 Dates:

Original Proposal:	19 January 2024	(Ref: PM24002_RIa)
Panel Approval:	02 July 2024	(Ref: PM24002_IMf)
GPG Approval:	26 August 2024	(Ref: 24102bIGe)

- **Rev.9 (August 2023)**

1 Origin of Change:

☑ Suggestion by IACS member

2 Main Reason for Change:

The industry standards year of reference is indicated in the UR pursuant to IACS policy. The modification clarifies how to proceed when latest standard is different from the one indicated in the UR, especially when the latest is less demanding or with hardly comparable differences.

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None.

4 History of Decisions Made:

1. Members agree to the proposal, which is reflected in the Note of the table, made in PM20906kIMk that a later revision of the specified standard in the UR may be used if technical specifications are deemed equivalent by the Society.
2. In line 14, additionally to IEC 61000-4-3:2020, the previous version of the standard, IEC 61000-4-3:2006+AMD1:2007+AMD2:2010, was also added as proposed in PM20906kIMj and agreed by qualified majority of member.

3. In PM20906kIMk, implementation date has been chosen to be 1 July 2024, considering the time each member needs to amend their rules and considering clause C5.2.2-4 of IACS Procedures Volume 1.

Additionally, members agreed to avoid retroactively applying UR E10 to existing types of equipment which have already been approved.

5 Other Resolutions Changes:

None.

6 Any hinderance to MASS, including any other new technologies:

None.

7 Dates:

Original Proposal	: 26 November 2021	(Ref: PM20906kIMg)
Panel Approval	: 14 April 2023	(Ref: PM20906kIMl)
GPG Approval	: 07 August 2023	(Ref: 20206iIGc)

- **Corr.1 (Jan 2022)**

1 Origin of Change:

☑ Suggestion by IACS member

2 Main Reason for Change:

To correct uniform application statement No.4 in Note of Rev.8 so that it is simply to be applied based on the “application for type approval” date only.

This is to avoid confusions due to three types of implementation concept based on:

1) the date specified in the implementation statement (e.g. application statements No. 1 and 2) not referred to the dates in 2) and/or 3) below;

2) the date of “application for type approval” of the equipment (e.g. application statements No. 3 and 7); and

3) the date of “contract for construction” of the ship (e.g. application statement No.4).”

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None.

4 History of Decisions Made:

During the discussion, a need for flexibility of application of the technical criteria specified in UR E10 was considered, but it was agreed that such a need would not be necessary. This is to say that Rev.8 of this Resolution (including this corrigendum) is to be uniformly applied to equipment for which the date of "application for type approval" is dated on or after 1 July 2022.

5 Other Resolutions Changes:

None.

6 Any hinderance to MASS, including any other new technologies:

None.

7 Dates:

Original Proposal	: 27 April 2021	(Ref: PM20906kIMa)
Panel Approval	: 01 November 2021	(Ref: PM20906kIMe)
GPG Approval	: 16 January 2022	(Ref: 20206cIGf)

- **Rev.8 (Feb 2021)**

1 Origin of Change:

☑ Other (Update to comply with the required format when industry standards are referred to)

2 Main Reason for Change:

There was a need to update this UR to comply with the following format when industry standards are referred to:

[Standard Designation], [version/revision, if applicable], [year of publication] (examples: API Spec 2F, 6th Edition, 1997; ISO 4624, 2002), where [version/revision, if applicable] and/or [year of publication] are decided by IACS and are not necessarily to be the current/latest version.

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None.

4 History of Decisions Made:

None.

5 Other Resolutions Changes:

None.

6 Any hinderance to MASS, including any other new technologies:

None.

7 Dates:

Original Proposal	: 28 October 2019	(Ref: PM18939_IMd)
Panel Approval	: 09 November 2020	(Ref: PM20906_IMf)
GPG Approval	: 12 February 2021	(Ref: 20206cIGb)

- **Rev.7 (Sep 2018)**

.1 Origin for Change:

☑ Suggestion by IACS member

.2 Main Reason for Change:

The main reason for revising the document was related to wireless applications, and what requirements that should apply to such equipment. Technology advancements and the use of wireless data communication links have increased electromagnetic frequencies, from 2 GHz to 6 GHz.

The electromagnetic compatibility (EMC) of these emissions at these higher frequencies on nearby equipment needs evaluation. UR E10 lists test requirements for electromagnetic and radiated emissions at frequencies up to 2 GHz depending on the maximum working frequency of the equipment under test in accordance with IEC 61000-4-3 and CISPR 16-2-1 and 16-2-3 respectively. Refer to test items nos. 14, 19 and 20 of UR E10 Rev.6. Accordingly, tests nos. 14 and 19 have been revised to address the increased electromagnetic frequencies. Moreover, test item 5 (dry heat) and the referenced Note 1 have been revised to align with Table 1/Item 7 and Note "d" of IEC60092-504:2016, respectively.

A change in the Notes of the Application statement was considered necessary following a query submitted by a member society after discussion at the 26th Panel meeting.

.3 List of non-IACS Member Classification Societies contributing through the TC Forum and/or participating in IACS Working Group:

None.

.4 History of Decisions Made:

The IACS Machinery Panel agreed to carry out the task by a Project Team. Forms A and 1 were agreed in the Panel on 23 April 2014. Forms A and 1were approved by GPG on 9 May 2014.

PM17601 outcome (16 Jan. 2018) on the Notes of the implementation statement updated to address equipment type approval and installation on new constructed ships.

.5 Other Resolutions Changes

UR E22

.6 Dates:

Original Proposal: March 2014 Made by: Machinery Panel
Panel Approval: September 2018 by Machinery Panel (Ref. 28th Panel meeting)
GPG Approval: 25 October 2018 (Ref: 14062_IGg)

- **Rev.6 (Oct 2014)**

.1 Origin for Change:

☑ Suggestion by IACS member

.2 Main Reason for Change:

The main reason for revising the document was related to wireless applications, and what requirements that should apply to such equipment. During the panels work, it was decided to isolate this as a separate task. The documents would also undergo a general review to decide possible needs for general improvements / clarifications.

.3 List of non-IACS Member Classification Societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

The IACS Machinery Panel agreed to carry out the task by a Project Team.
Form A & 1 were agreed in the Panel in Aug 2008.
Forms were approved by GPG in September 2008.

.5 Other Resolutions Changes

UR E22

.6 Dates:

Original Proposal: August 2008 Made by: Machinery Panel
Panel Approval: September 2014 by Machinery Panel (20th Panel meeting)

Note: *There are no technical background (TB) documents exist for Original version (1991), Rev.1 (1993), Rev.2 (1997) and Corr.1 (July 2003).*

Technical Background Document
WP/EL Task 38 "To Review UR E10, Rev.2.1"

1. Objective and Scope:
Correct an editorial nature error to test item 14 : "Radiated Radio Frequency" , i.e. replacing "80 kHz to 1 GHz" with "80 MHz to 1 GHz".

2. Source of Proposed Requirements:
The proposed correction was submitted by GPG correspondence (Mr.Kaji of NK message of 29 July 1998). IEC 1000-4-3 (1995) Standard.

3. Points of Discussion:
WP/EL unanimously agreed to correct test item 14 : "Radiated Radio Frequency" , i.e. replacing "80 kHz to 1 GHz" with "80 MHz to 1 GHz".

E 10 (Rev.3)

Technical Background Document
<u>WP/EL Task 39 "Revision of IACS UR E10 Testing procedure for electrical, control and instrumentation equipment, computers and peripherals covered by classification"</u>

Objective and Scope:
To revise UR E10 in order to investigate the difference between IEC 60945, IEC60533 and to align with IEC Standards.

Source of Proposed Requirements:
IACS WP/EL 28th Progress Report
IEC 60945, IEC 60533, IEC 60092-504 Standards

Points of Discussion:
The existing UR E10 had undergone an extensive review during the meeting. Test requirements are harmonized with IEC 60092-504 „Electrical Installations in Ships" Part 504: Special features – Control and instrumentation", IEC 60533 "Electrical and electronic installations in ships – Electromagnetic compatibility" and IEC 60945 "Maritime navigation and radiocommunication equipment and systems. General requirements- Methods of testing and required test results".
DNV proposed to add a new test concerning influence of mobile phones on electrical equipment. With some other changes the corrected draft of the UR agreed by WG was forwarded to GPG for consideration attached to the 30th WP/EL Progress Report

Submitted by WP/EL Chairman in January 2001

Technical Background

UR E10 (Rev.4)

IACS WP/EL Task No.49 "To clarify the equipment to be covered by UR E10 "Type Test Specification" and to investigate the adequacy of the DC power supply tests in item 4 "Power supply variations" of the table in UR E10."

Objective and Scope:
1. To redefine more closely the equipment to which E10 is required to be applied.
2. To investigate if the test procedure for DC power supply voltage variation in item 4 a) of the Table "Type testing condition for equipment covered by E10.1" is adequate.

Source of Proposed Requirements:
IACS UR E10 (Rev. 3, May 2001)
Draft of AHG/COMP "Onboard Use and Application of Computers".
IEC Pub. 60092-504

Points of Discussion:
There appears to exist different interpretations among IACS member societies for the scope of applications of E10 for onboard equipment and systems, especially for onboard computer based systems and peripherals. At least, further breakdown of the listed equipment in E10.1 is necessary for uniform implementation of E10 among IACS member societies.
The existing UR E10 had undergone an extensive review during the meeting. ABS proposed to postpone this objective due to several reasons taking into account of the currently undergoing Tasks in IACS, e.g., L[5], AHG/COMP, AHG/EMC, etc.
However, during the discussion, it was decided that the scope of application in E10.1 was slimmed and the application of E10 was limited for "Type Approval".
NK submitted the investigation of the test procedure for DC power supply voltage variation in item 4 of the Table of E10. It appears that the duration time and the cycle period for "voltage cyclic variation" and "voltage ripple" are not specified for the test conditions of DC supply variation.
However having considered all *pro et contra* after discussion it was decided to stay tests without change as it is. Additionally it was proposed to investigate some suppositions in EMC/AHG.
It was decided to approve new Draft of UR E10 on following conditions:

- To change Type Test Specification in title and para.E10.1 of UR E10 to 'Test Specification for Type Approval'.
- To retain "monitoring, control protection and safety" and "interior communication" services and to delete all other services in the current E10.1.
- To stay 'voltage cycling variation' and 'voltage ripple' (para.4 of E10 Table) without change as it is.

With some other changes the corrected draft of the UR agreed by WG was forwarded to GPG for consideration attached to the 33rd WP/EL Progress Report.

Technical Background Document
UR E10 (Rev.5, Dec. 2006)

IACS Machinery Panel Task No. PM5603

Objective and Scope:
The aim of this Task was to:
1) To align UR E10 with test requirements found in IEC 60068-2-6 test Fc
2) To examine UR E10 requirements on RMC/RFI in the light of the new edition of IEC 60945 and amend as found necessary
3) To unify low temperature test conditions between UR E10, UR M40 and other relevant industry standards (e.g. IEC 60945).
In addition minor alterations was introduced to enhance the quality of the test standard and to make it more up-to-date.

Background for the Proposed Revision:
Test number 3,
External power supply failure, special conditions for the test has been added if the equipment under test needs a longer time for start up, e.g. booting sequence and for equipment which requires booting.

Points of Discussion:
This has been added in order to ensure a uniform implementation of the test requirement.
Test number 7,
Vibration, last bullet in the comment field does not specify the limitations given in the IEC standard. A request from Siemens revealed the flaw in E10.
The limitations are of importance to ensure adequate stress level of the equipment under endurance test.

Points of Discussion:
When a resonance frequency is detected during vibration test, we have to ensure that no damage to the equipment is likely to occur at this frequency. This is done by performing an endurance test. In case several frequencies are detected the endurance test may be carried out as swipe test, but only within frequency limits specified.
This is agreed to be technically correct and introduced in E10.
Test number 15,
Conducted low Frequency, IEC 60945 has deleted the test Immunity to conducted low frequency interference.

Points of Discussion:
The test referred to in E10 was on the basis of IEC 60533, but the origin for IEC 60533 was IEC 60945.
We have therefore investigated whether this test is of relevance to ship installations. We have had confirmation from test laboratories performing the testing of equipment that it is, but that the test standard referred to is incorrect. We have therefore added a drawing to show an adequate test set-up which is suitable for performing this test.
This is agreed to be technically correct and introduced in E10.
Test number 21, flame retardant test where an alternative has been added.

Points of Discussion:
The test piece required for the test specified in IEC 60092-101 is very large and in many cases it is not available such large pieces for testing. IEC 60695-11-5 being a newer

standard does fulfil the intention of the IEC 60092-101 and may be used as an alternative. The evidence of flame retardation for cables is described sufficiently in IEC 60092-101.

Task number 3 was to unify low temperature test conditions between UR E10, UR M40 and other relevant industry standards (e.g. IEC 60945). This did not have any effect on the standard and is only enclosed as a reminder of the work being carried out.

Points of Discussion:
In order to examine low temperature test standard an investigation of environmental conditions has been conducted.
Environmental conditions – elaboration of requirements in different standards:
M40
(1981)

Ambient conditions – Temperatures
M40.1 The ambient conditions specified under M40.2 are to be applied to the layout, selection and arrangement of all shipboard machinery, equipment and appliances as to ensure proper operation.
M40.2 Temperatures
Air

Installations, components	Location, arrangement	Temperature range (°C)
Machinery and electrical installations[1]	In enclosed spaces	0 to +45
	On machinery components, boilers In spaces subject to higher and lower temperatures	According to specific local conditions
	On the open deck	–25 to +45

Water

Coolant	Temperature (°C)
Seawater Charge air coolant inlet to charge air cooler	32 see UR M28

NOTES
1. Electronic appliances are to be suitable for proper operation even with an air temperature of +55°C.
2. The Classification Society may approve other temperatures in the case of ships not intended for unrestricted service.

Conclusion:
Lower temperature in enclosed spaces is 0°C

Low temperature test IEC 60945 (protected equipment)
−15 °C ± 3 °C
IEC 60945 states

(Equipment protected from the weather should not experience such low temperatures, and IEC 60721-3-6 gives +5 °C as the minimum temperature. However, since this standard deals with vital navigation and radiocommunication equipment which will be required to start operating in a dead ship, clause 8 calls for – 15 °C for protected equipment and −20 °C for portable (life saving) equipment.) IEC 60721-3-6 states:
(IEC 60721-3-6 Classification of environmental conditions. Part 3: Classification of groups of environmental parameters and their severities. Ship environment, abstract: Classifies groups of environmental parameters and their severities to which a product is subjected when installed aboard a ship. Ships where products may be permanently or temporarily installed include ships propelled by mechanical means and ships not propelled by mechanical means.)

As we read IEC 60721-3-6 +5°C covers products installed in totally weather protected, heated and ventilated locations after warm-up, otherwise -25°C applies. This has been adopted by IEC 60945, but modified.

E10
IEC Publication 60068-2-1
+5°C ± 3°C

Overall conclusion:
+5°C ± 3°C is correct for products installed in totally weather protected, heated and ventilated locations after warm-up. There may be equipment required to start operating in a dead ship condition which may need a lower temperature.

Effect on E10.
To keep the 5°C for the moment, but to return to the task when doing a total upgrade of the URs with respect to temperature limitations.

Submitted by Machinery Panel Chair
23 November 2006

<u>Permanent Secretariat Note (December 2006):</u>
• Rev. 5 of UR E10 approved by GPG and Council, 13 December 2006 (6206_IGc).
• Machinery Panel proposed implementation date of 1 January 2008 and this was agreed by GPG/Council.

Technical Background (TB) document for Rev.6 (Oct 2014)

1 Scope and objectives
- Adoption of tests for wireless applications used on board ships in response to queries from the industry.
- Proposal for a broad-band random vibration test according to IEC 60068-2-64 which is less dependent on the test-setup of the EUT than the test method according to IEC 60068-2-6 Test Fc.
- Proposal for a change of test parameters down to a temperature -5°C for the cold test. A temperature of +5 °C has absolutely no influence to the EUT.
- Adoption of revised international testing standards e.g. IEC 61000-4-4 (Burst).

2 Engineering background for technical basis and rationale
Clarification of content necessary for test 2 (Performance test), test 5 (Dry heat), test 6 (Damp heat) alternative test for 7 (Vibration), test 12 salt mist , test 15 (Conducted low Frequency), test 17 (Burst), test 18 (Surge voltage) and test 19 (Radiated emission) .

3 Source/derivation of the proposed IACS Resolution
Following queries from the industry and also changes, clarifications and updates of IEC test standards.

4 Summary of Changes intended for the revised Resolution
General comment:
The term performance test used throughout the UR was clarified in note b) and distinguished from the performance test required in test 2.
Addition of procedure for Test No. 2 Performance Test Added for clarification that depending on the equipment under test (EUT) specific testing is necessary. E.g. IEC 60255 for protection relays Change of test parameter and addition under "other information" for Test No. 5 Dry Heat
Depending on the size of the EUT and climatic conditions 2 hours are often not sufficient to achieve stable conditions. It is therefore agreed that the next severity level specified in the source standard IEC 60068-2-2 is required. Under "Other information" a clause has been added for equipment which is to be proven to be suitable to be installed where higher ambient temperature is expected, e.g. exhaust manifolds which will require a higher test temperature.
Addition of other information for Test No. 6 Damp heat The stabilizing period before the start of the first cycle was added for clarification in "other information" column. This is in line with the requirement found in the source standard IEC 60068-2-30.

Addition of other information for Test No. 7 Vibration Practical experience shows that electronic fuel oil injection systems may be exposed to higher vibration levels. Such system was consequently included as example for equipment that may require test at increased vibration levels and frequency range. A general note has been added that the increased frequency range has to be agreed in each case. The example of increased values has been kept.

Remark to Test No.11 Cold
The international standard IEC 60945, 60092-504, 101 are not consistent and harmonized.
IACS UR M40 is also not harmonized with the UR E10. It is highly recommended to harmonize the standards. Therefore the requirements were not changed by the PT.

Other information to Test No. 12 Salt Mist Added for clarification to ensure that any deterioration or corrosion is superficial in nature.

Change of test parameters in test No. 14 Electromagnetic Field The frequency range was increased up to 6GHz to ensure that equipment which uses frequency band higher than 2 GHz is also tested.

The panel is of the opinion that the requirements to EMC at 6GHz as proposed by the PT would prohibit the use of wireless equipment onboard as they would radiate a signal with strength that is beyond the limit set.
The panel is therefore of the opinion that the technical solution proposed by the PT is not technically sound and have deleted this in the test specification.

Remark to Test No.15 Conducted low Frequency It is not required to exceed the power limit of 2W and hence it is acceptable to decrease the voltage applied during the test to keep within the power limit.

Clarification for Test 18, Surge Voltage:
The test description was inaccurate and contained incorrect symbols. This has been corrected according to the source standard. For practical purpose no change in the testing scope.

Change of Test No. 19 Radiated emissions
Quasi peak detection was defined only for frequencies up to 1 GHz and makes no sense for the protection of receiver / transmitter technology above 1 GHz (no AM or FM). Therefore the PT decreases the frequency range to 1GHz and added test no. 20.
Open point: The limits for 156-165MHz 24 dBuV/m to be checked for the general power distribution zone.
An editorial correction is being made to the table for equipment installed in the bridge and deck zone. For the frequency range 0.3 – 30 MHz, the limits are being editorially corrected from "50 – 34 dBmicroV/m" to "52 – 34 dBmicroV/m". It was determined the value indicated in Rev. 5 of UR E10 was incorrect. The corrected value is in agreement with IEC 60092-504 and IEC 60945.

The panel has deleted test 20 in lieu of not agreeing to 6 GHz. It has therefore been agreed to re-instate 2 GHz in test 19 in line with IEC 60945.

Addition of Test No. 20
With reference to CISPR 22 only the peak or average peak value shall be used for frequencies above 1GHz. Quasi peak detection was defined only for frequencies up to 1 GHz and makes no sense for the protection of receiver / transmitter technology above 1 GHz (no AM or FM). Category B of CISPR-22, to be used for living areas (PC, radio, television, communication) was chosen because the source and the sink of disturbances are close together similar as on ships. It should be taken into consideration that according to CISPR-22 the limits for radiated emissions above 1GHz depend on the maximum used frequency of the EUT.
The Machinery Panel has agreed to delete the proposed test.

5 Points of discussions or possible discussions

Test E10.1 General

There was a comment of a member stated that E10 is not applied to all internal communication equipment as listed in 10.1. When this question was circulated a number of the societies quoted as applying the E10 to mandatory and/or essential internal communication. Based on this a society was tasked to provide their interpretation of "internal communication", i.e. to agree what is "mandatory/essential". A society states that UR E10 is a test specification for TA and not a source or reference document for defining "internal communication". It was proposed to expand the expression to "communication" thereby including data communication and wireless communication links as applicable areas of utilisation of the test requirements; however, there was not sufficient agreement. It was finally concluded that each society may choose to apply E10 to type approval of any communication systems in accordance to their own interpretation of the term.
Result in this draft version of E10: application changed to remove "internal communication".

Test No. 7 Vibration
There was a discussion within the PT regarding vibration tests for equipment mounted on Diesel engines. Additional testing on increased vibration levels and frequencies seems to be necessary for equipment mounted on electronic controlled Diesel engines. (Example: Pressure variations in the injection system for common rail engines appr. 230Hz, Turbocharger: 15000rpm angular frequency appr. 250Hz, medium or high speed engines e.g. MTU 20cyl. 1800rpm) Increasing the vibration test level up to 300Hz was not accepted by the PT in order to be harmonized with IEC 60092-504. A proposal by CIMAC for testing equipment mounted in close proximity to hydraulic valves, fuel boosters and exhaust valves in accordance with IEC 60068-2-64 (1993), Test Fh: Vibration, broadband random (digital control) was withdrawn and also not accepted by the majority of the PT.
Result in this draft version of E10: No changes
Proposal by the PT:
For future revisions of UR E10 it is recommended to observe the outcome of ISO/NP 20283-4 "Mechanical vibration — Measurement of vibration on ships — Part 4: Measurement and evaluation of vibration of the ship propulsion machinery‟.
In addition to it is recommended to make a note to ISO / IEC for further examination.

Test No. 11 Cold
The international standard IEC 60945, 60092-504, 101 are not consistent and harmonized.
IACS UR M40 is also not harmonized with the UR E10. A test with 5 deg. C has no influence on any equipment to be tested. Dead ship / cold iron condition were not taken into consideration.
Result in this draft version of E10: No changes
Proposal by the PT:
It is recommended by the PT to make a note to ISO / IEC to harmonize the testing standards.

Test No. 17 Burst
IEC recommends repetition rates of 100 kHz which are closer to reality. 5 kHz repetition rates are traditional; however. The test was not changed to be consistent with e.g. IEC 60945. The recommendation from IEC should be observed for further revisions.

Test No. 14,16, 19 and 20 Electromagnetic field, conducted and radiated
Emission.

The upper test frequency in test no. 19 was in the PT agreed to be 6 GHz.
When the PT's result was circulated in the panel it was agreed that no equipment communicating within the specified increased frequency range would be able to comply with the requirements to radiated emission. It was hence agreed to maintain the existing frequency limits (2GHz), and to solve this matter in a separate task.

After Machinery Panel discussion:
The panel is of the opinion that the requirements to EMC at 6GHz as proposed by the PT would prohibit the use of wireless equipment onboard as they would radiate a signal with strength that is beyond the limit set.
The panel is therefore of the opinion that the technical solution proposed by the PT is not technically sound and have deleted this in the standard.
Further study on developing criteria for EMC test up to 6 GHz is recommended.

10.1 The panel did agree to limit the test specification application scope.

Technical Background (TB) document for UR E10 (Rev.7 Oct 2018)

1 Scope and objectives

Adoption of tests for wireless applications for use on board ships relating to queries from the industry. The revision considers the increase of the frequency range for electromagnetic emissions up to 6 GHz and the application a quasi-peak detection and average detection to test radiated emissions for below and above 1 GHz, respectively.

2 Engineering background for technical basis and rationale

An evaluation of the effects of the higher frequency emissions (2 to 6 GHz) and the use of wireless data communication links on the function of nearby equipment and systems was considered necessary. The evaluation considered also testing radiated emissions within the limits of the maritime mobile VHF radio band for the general power distribution zone and the correctness of the testing method for radiated emissions within the limits of the maritime mobile VHF radio band (156 MHz to 165 MHz).

The wording of IEC 60092-504:2016 for dry heat test was used for alignment of test item 5 and the referenced Note 1.

A comparison between UR E10 test 14 and pertinent standards CISPR24, IEC61000-6-1, IEC 61000-6-2, 61000-4-3, IEC 60945, 60092-504, IEC 60533, ETSI EN 301 843-1 as well as between UR E10 test 19 and CISPR 22, CISPR 16-1-1, CISPR 16-1-4, CISPR 16-2-3, IEC 61000-6-3, IEC 61000-6-4, IEC 60945, IEC 60092-504, IEC 60533, ETSI EN 301 843-1 and ECMA-358 was undertaken by the Project Team.

3 Source/derivation of the proposed IACS Resolution

Following queries from the industry and also changes, clarifications and updates of IEC test standards.

4 Summary of Changes intended for the revised Resolution

a. Change of Test No. 5 Dry Heat
   Following a proposal by a member society, the test has been aligned with Test no. 7 of Table 1 of IEC 60092-504:2016 to consider non-heat and heat dissipating equipment. The reference to Note 1 has been moved from Column "Test Parameters" to "Test".

b. Change of test parameters in Test No. 14 Electromagnetic Field
   The frequency range was increased up to 6 GHz to ensure that equipment which uses frequency band higher than 2 GHz is also tested in accordance with test No.14 of the IEC Publication 60092-504:2016.

   The test parameters other than "Frequency Range" have not been modified.
   A clarification for receivers/transmitters exclusion band from immunity tests has been added to "Other Information".

c. Change of Test No. 19 Radiated Emissions

Quasi peak detection is defined for limits up to 1 GHz and average detection above 1 GHz. In this regard for limits below 1 GHz the previous 2000 MHz has been decreased to 1000 MHz.

It should be taken into consideration that according to CISPR 22 the limits for radiated emissions above 1GHz depend on the maximum used frequency of the EUT and such is addressed in the "other information" adding the wording "procedure in accordance with the standard". CISPR 22 has not been included as referenced standard, however the instruction that the procedure should be in accordance with the standard has been retained as the 3 m distance is the normal recommendation of standards such as IEC 60945:2002 and 60092-504:2016. The limits of 24 dBμV/m for 156-165MHz has been maintained specifying that such a limit is applicable for the repeated measure with a receiver bandwidth of 9 kHz as per IEC Publication 60945.

Following a proposal by a member society, a note for exemption of radio equipment using wireless systems has been added.

d. Change of Note 1 in the Table "Type testing condition for equipment covered by E10.1".
Following a proposal by a member society, the wording has been aligned with Table 1/Note d of IEC 60092-504:2016.

e. Change of Notes in Implementation Statement
Following a query submitted by a member society during the 26th Panel meeting, the Panel agreed to review Footnote 2 of UR E10 Rev.6 to address the case of equipment, for which the manufacturers request a renewal of the type approval certificates without further testing to the new standards of Rev. 7, based on equipment satisfactory service history. The Panel reviewed the request under a separate task and decided to reflect its conclusion by updating the Notes in the application statement of UR E10 Rev.7.

5 Points of discussions or possible discussions

a. Test 19 Radiated Emission of IEC 60092-504:2016 was revised to cover frequency range up to 6 GHz, which was 2 GHz in IEC 60092-504:2001, but retained the same limit value of 54 dBμV/m with no change. It was also noted that the limit value of 54 dBμV/m for frequency range between 30 to 6000 MHz is different from the limit values for frequency range above 1 GHz stipulated in CISPR 22.

IACS contacted IEC TC18 regarding the technical background of the increment of frequency range up to 6 GHz while keeping the limit value at 54 dBμV/m.

IEC TC 18 Chair's reply was as follows: "…*The frequency range has been increased to 6GHz to accommodate the increased use on ships of emerging W-LAN and Bluetooth technologies.*

The proposal to splitting the frequency range further and using two limits (similar to EN 55022:2011) was also considered, but rejected because that would put the arrangements in conflict with IEC 60945 for Bridge mounted equipment.
The above rationale being driven by the fact that the bridge of a ship is a

particularly sensitive location due to its dense concentration of radionavigation, radiocommunication and marine control system equipment. Leading to the conclusion: that the requirement in Table 1 of the new IEC 60092-504:2016, should be maintained.

This conclusion is based on discussion within IEC TC 18/MT 2 who are responsible for IEC 60092-504. A recent meeting of the German EMC committee (16 February 2017), where this subject was raised, also agreed the current TC 18 conclusion.

Therefore, it would not be the intention of Chair or Secretary of TC 18 to recommend amendment of the standard at this time. However, a potential future revision of this standard can be conducted in cooperation with TC 80, where alignment to other applicable standards can be considered, as maybe applicable".

Following IEC TC 18 reply, the Panel agreed to proceed with alignment with the revised IEC 60092-504:2016 (the other proposals were to adopt an approach for test 19 based on CISPR22 and then bring the matter to the attention of TC18 or to deviate from IEC requirements and introduce new limits).

b. IEC 60092-504:2016 does not distinguish between average and peak limits and leaves it open to which of these criteria the limit of 54 dBµV/m applies. The agreed test 19 specifies the quasi-peak measuring receiver up to 1 GHz and the measuring receiver with average detector above 1 GHz.

c. For Test n. 19, a member society proposed to add a clarification in the column "Other information" for the radio equipment used for wireless systems exclusion from the test which was agreed as follow:

"Equipment intended to transmit radio signals for the purpose of radio communication (e.g. wifi router, remote radio controller) may be exempted from limit, within its communication frequency range, subject to the provisions in UR E22.5.2."

d. A proposal by a member society to revise the recommendation for Q in test no. 7 (Vibration) to read that Q should not be higher than 5 without exceeding 10 has not been agreed.

e. A proposal by a member society to replace 2 GHz by 6 GHz in test no. 14 and 2000 MHz by 6000 MHz in tests no. 19 of UR E10 Rev.6 has not been agreed.

f. Regarding Test no. 14 a member society proposed to add a clarification in the column "Other information" for the receivers/transmitters exclusion from the immunity test which was agreed as follow:

"if an equipment is intended to receive radio signals for the purpose of radio communication (e.g. wifi router, remote radio controller), then the immunity limits at its communication frequency do not apply, subject to the provisions in UR E22.5.2."

Technical Background (TB) document for UR E10 (Rev.8 Feb 2021)

1. Scope and objectives

UR E10(Rev.7) does not reflect the agreed format for referencing the IEC and CISPR standards. Rev.8 has been developed to comply with the agreed format.

2. Engineering background for technical basis and rationale

Format for references to Industry standards

Format:
[Standard Designation], [version/revision, if applicable], [year of publication] (examples: API Spec 2F, 6th Edition, 1997; ISO 4624, 2002), where [version/revision, if applicable] and/or [year of publication] are decided by IACS and are not necessarily to be the current/latest version.

3. Source/derivation of the proposed IACS Resolution

None

4. Summary of Changes intended for the revised Resolution

UR E10 has been updated to specify the revision/version of the IEC and CISPR standards as follows:

Publications in E10	Replaced by
IEC 60092-504	IEC 60092-504:2016
IEC 60533	IEC 60533:2015
IEC 60068-2-2	IEC 60068-2-2:2007
IEC 60068-2-30	IEC 60068-2-30:2005
IEC 60068-2-6	IEC 60068-2-6:2007
IEC 60068-2-1	IEC 60068-2-1:2007
IEC 60068-2-52	IEC 60068-2-52:2017
IEC 61000-4-2	IEC 61000-4-2:2008
IEC 61000-4-3	IEC 61000-4-3:2020
IEC 61000-4-6	IEC 61000-4-6:2013
IEC 61000-4-4	IEC 61000-4-4:2012
IEC 61000-4-5	IEC 61000-4-5:2017
CISPR 16-2-3	CISPR 16-2-3:2016
IEC 60945	IEC 60945:2002
CISPR 16-2-1	CISPR 16-2-1:2017
IEC 60092-101	IEC 60092-101:2018
IEC 60695-11-5	IEC 60695-11-5:2016

5. Points of discussions or possible discussions

The year of publication indicates the year when the standard as consolidated edition or its latest amendment has been published. For CISPR 16-2-3:2016, for which Amendment 1 has been issued in 2019, the 2016 edition has been stated as 2020 is the review year of the standard.

6. Attachments if any

None

Technical Background (TB) document for UR E10 (Corr.1 Jan 2022)

1. Scope and objectives

To correct uniform application statement No. 4 in Note of Rev.8 so that it is simply to be applied based on the “application for type approval” date.

2. Engineering background for technical basis and rationale

None

3. Source/derivation of the proposed IACS Resolution

None

4. Summary of Changes intended for the revised Resolution:

The change made to uniform application statement No. 4 in Note of Rev.8 is as follows:

> *“4. Equipment intended to be installed on ships contracted for construction on or after 1 January 2022 is to comply with Rev.7 ~~and Rev.8~~ of this UR.”*

5. Points of discussions or possible discussions

None

6. Attachments if any

Technical Background (TB) document for UR E10 (Rev.9 August 2023)

1. Scope and objectives

Rev. 9 of UR E10 has been developed to precise the way to proceed when latest standard is different from the one indicated in the UR.

2. Engineering background for technical basis and rationale

None.

2a. Specification of the data utilised in the development/revision of the proposed IACS Resolution, if any

N/A.

3. Source/derivation of the proposed IACS Resolution

None.

4. Summary of Changes intended for the revised Resolution:

Note of the table concerning the column "Procedure" has been modified by replacing indication to apply the latest edition of the normative reference by the possibility to use later versions or revisions of the standards specified if they are deemed equivalent to the technical specification of the UR.

In the specific case of line 14 for which IEC 61000-4-3:2020 and previous version IEC 61000-4-3:2006+AMD1:2007+AMD2:2010 are mentioned, it was noted that the test laboratories typically confirm compliance with the version of the standard that are covered by their accreditation and that many test laboratories are still accredited according to the previous version of the standard as the latest version of IEC 61000-4-3 introduces requirements for testing using multiple test signal, etc. that may require new expensive test equipment. Therefore, in this case, they cannot confirm compliance with the latest version under their current accreditation. It is acceptable considering test 14 in IACS UR E10 will be performed identically, no matter which version of the standard is applied.

5. Points of discussions or possible discussions

None.

6. Attachments if any

None.

Technical Background (TB) document for UR E10 (Rev.10 August 2024)

1. Scope and objectives

In the course of revision of Note 3 to M46.2, it was proposed to update item 8 (inclination) of UR E10 where similar requirements as Note 3 to M46.2 is present.

2. Engineering background for technical basis and rationale

The inclination requirement for emergency source of electrical power on gas carriers and chemical tankers is addressed in UI SC6 and UI SC290. The two UIs are dealing with the same issue and the same contents, with the only difference of the reference clause nos. for IGC Code between old and new IGC Code, i.e. UI SC6 refers to 1983 IGC Code and UI SC290 mentions 2014 IGC Code.

The duplication of the UIs is thought to be originated from GPG instruction (ref. 18902_IGe and PM5901fIMl: "creating UIs that will be published as “new” and also revising the old UIs by adding the references to the old IGC Code that will be published as Revisions").

This panel is of the view that the instruction would be applicable when specific requirement of old IGC Code has been revised or replaced by new IGC Code. However in this case, the requirement is same and the two UIs are just indicating the re-adjusted clause number of old & new IGC Code, thus not advisable.

In the meantime, it is observed that the same inclination requirement is already covered by UR M46 (Note 3 of M46.2).

Still, it was found that similar requirements as Note 3 to M46.2 is present in item 8 of UR E10 (inclination test).

2a. Specification of the data utilised in the development/revision of the proposed IACS Resolution, if any

None.

3. Source/derivation of the proposed IACS Resolution

UI SC6, UI SC 290
SOLAS II-1/Reg.43.6
1983 IGC Code, clause 2.9.2.2
2014 IGC Code, clause 2.7.2.2
IBC Code, clause 2.9.3.2

4. Summary of Changes intended for the revised IACS Resolution:

Note 3 to M46.2 has been updated, adding reference clause nos. of the IGC Code (both 1983 IGC Code and 2014 IGC Code) and the IBC Code. By the transfer of the reference clauses, UI SC6 and UI SC290 have been deleted. Likewise, UR E10 item 8 has been updated as per Note 3 to M46.2, adding reference clause nos. of the IGC Code (both 1983 IGC Code and 2014 IGC Code) and the IBC Code.

Taking the opportunity, the latest edition of the reference standards are also checked and updated accordingly.

5. Points of discussions or possible discussions

One member opined that the update of UR E10 could be addressed at a later stage.

6. Attachments if any

None.

UR E11 "Unified requirements for systems with voltages above 1 kV up to 15 kV"

Summary

In Rev.4 of this Resolution, the way to refer to instruments other than those specified by IACS was unified.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev.4 (Feb 2021)	12 February 2021	1 July 2022
Corr.1 (April 2018)	12 June 2018	-
Rev.3 (Feb 2015)	23 Feb 2015	1 July 2016
Rev.2 (July 2003)	16 July 2003	-
Rev.1 (May 2001)	17 May 2001	-
New (1991)	1991	-

- **Rev.4 (Feb 2021)**

1 Origin of Change:

☑ Other (Update to comply with the required format when industry standards are referred to)

2 Main Reason for Change:

There was a need to update this UR to comply with the following format when industry standards are referred to:

[Standard Designation], [version/revision, if applicable], [year of publication] (examples: API Spec 2F, 6th Edition, 1997; ISO 4624, 2002), where [version/revision, if applicable] and/or [year of publication] are decided by IACS and are not necessarily to be the current/latest version.

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None

4 History of Decisions Made:

None

5 Other Resolutions Changes:

None

6 Any hinderance to MASS, including any other new technologies:

None

7 Dates:

Original Proposal: 28 October 2019 (Ref: PM18939_IMd)
Panel Approval: 9 November 2020 (Ref: PM20906_IMf)
GPG Approval: 12 February 2021 (Ref: 20206cIGb)

- **Corr.1 (June 2018)**

.1 Origin for Change:

☑ Suggested by IACS member

.2 Main Reasons for Change:

The checking and updating of international standards that referenced by IACS resolutions has been carried out by Machinery panel. As a result, it is found that there is a need to update the international standards that referred in the IACS resolution UR E11.

.3 List of non-IACS Member Classification Societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

Delete word "Publication" in the standards referenced;
Delete word "Standard" in the standards referenced;

.5 Other Resolutions Changes

None

.6 Dates:

Original Proposal: 22nd May 2015, made by Machinery Panel
Panel Approval:11 May 2018 (Ref: PM5901)
GPG Approval: 12 June 2018 (Ref: 18082_IGc)

- **Rev.3 (Feb 2015)**

.1 Origin for Change:

☑ Suggestion by an IACS member

.2 Main Reason for Change:

The test requirements in UR E11 do not reflect the corresponding requirements in the relevant IEC publications, in particular test requirements in UR E11 7.2.6 'Test after installation' need to be updated.

.3 List of non-IACS Member Classification Societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

Form A agreed by Panel and submitted to GPG under 12163_PMa.

.5 Other Resolutions Changes

None

.6 Dates:

Original Proposal: 14 September 2014 Made by: Machinery Panel
Panel Approval: 6 February 2015
GPG Approval: 23 February 2015 (Ref: 12163_IGb)

Note: *There are no Technical Background (TB) documents available for the New (1991).*

Annex 1 Technical Background (TB) document for Rev.1 (May 2001)

Technical Background Document
WP/EL Task 1A "Annual Review UR- Review UR E11"

Objective and Scope:
To correct UR E11 in order to eliminate existing reservations and to align with IEC Standards.

Source of Proposed Requirements:
The proposed requirements have been based on the present Rule requirements of IACS members and IEC Standards.

Points of Discussion:
During the XXI WP/EL Meeting it was decided that maximum application voltage should be increased to 15 kV to be in line with IEC 60092-503 and IEC 60092-508 new proposals but where necessary for special application, higher voltages may be accepted by the Society. The table 1.2 nominal voltages/frequencies was deleted because it was not a requirement. During discussion several paragraphs were deleted because they were not specific for HV systems. Added requirement for directly earthed neutral or other neutral earthed systems. Added a higher protection against tool penetration inside the enclosure. Included requirements for the acceptance of liquid cooled transformers.
Added installation requirements where high voltage cables of different voltage ratings are installed on the same cable tray. Number of other comments including editorial changes was made which are incorporated in the final draft.
The corrected draft of the UR agreed by WP was forwarded to GPG for consideration attached to the 30th WP/EL Progress Report.

Submitted by WP/EL Chairman in January 2001

Annex 2 Technical Background (TB) document for Rev.2 (July 2003)

Technical Background Document
WP/EL Task 1A "Annual Review UR- Review UR E11 (Rev.1, May 2001)"

Objective and Scope:
GPG at its 52nd meeting reviewed 31 Progress Report WP/EL and decided to ask WP/EL to consider ABS' comments on UR E11 and RINA reply with a view to clarifying requirements in para. 6.3.2, which pertains to the number of power sources for operating switches and circuit breakers.

Source of Proposed Requirements:
The proposed requirements have been based on the present Rule requirements of IACS members and IEC Standards.

Points of Discussion:
During the XXIV WP/EL Meeting it was decided that two external supply sources are necessary for auxiliary circuits.
Auxiliary circuits – circuits, which are necessary in the switchgear and control gear assemblies to ensure the safe operation of the HV power circuits. Such circuits include control, protection, measuring circuits and so on. In addition they are not derived from their power circuits but from external source(s) with external supply(ies).
Auxiliary circuits are not opposed to normal supply because normal supply is not used for HV installation: each consumer is not provided with its own auxiliary transformer. Only external supplies are used for control and protection purposes. In case of failure of external supply, the power system is not more protected (e.g. short circuit protection, overload protection, and all the other safety protections are not working) and the power supply is to be tripped.
Where the main switchboard is divided in two parts, having only one source of supply for each section, it means that half of the power is not more available due to a single failure of this source (half of the power in all the cases for HV installation is more than one generator). This is not acceptable.
Taking into account all above mentioned, two external supply sources are necessary for auxiliary circuits.
The corrected draft of the UR agreed by WG was forwarded to GPG for consideration attached to the 32nd WP/EL Progress Report.

Annex 3 Technical Background (TB) document for Rev. 3 (Feb 2015)

1. Scope and objectives

To update UR E11 in line with the latest versions of IEC standards, in particular IEC 60502-1 (2009) and IEC 60502-2 (2005) with respect to testing.

2. Engineering background for technical basis and rationale

Update in accordance with IEC

3. Source/derivation of the proposed IACS Resolution

IEC 60502-1 (2009)
IEC 60502-2 (2005)
IEC 60076-11 (2004)

4. Summary of Changes intended for the revised Resolution

2.3.2 Creepage distances

It was considered that the phrase 'standard component' could be open to interpretation and further, associated electrical equipment may comprise non-standard components to which the requirements should still apply. It was therefore deemed appropriate to change the wording such that it is applicable to all parts described by the criteria within requirement. Further, it was considered appropriate to refer to the specified International Standard, which addresses creepage distances, rather than the more generic "relevant IEC Publications".

4.1 Power Transformers, General

IEC60726 has been replaced by IEC60076-11:2004, Power transformers - Part 11: Dry-type transformers.

6.2.3 Shutters

Additional wording: Shutters are to be clearly market for incoming and outgoing circuits. This may be achieved with the use of colours or labels.

6.2.5 Internal Arc Classification

The standard allows IAC test in different combinations:
Accessibility type A: Accessible by authorized personnel only.
Accessibility type B: Accessible by general public.
F- Front access
L-Lateral access
R-Rear access

This means a switchgear which has been tested IAC A FL must not be accessible from the rear (R) when energized, as this has not been tested.

7.1 Electrical equipment
An adequate, unobstructed working space is to be left in the vicinity of high voltage equipment for preventing potential severe injuries to personal performing maintenance activities.

7.2.6 Test after installation
The test requirements did not reflect the corresponding requirements in the most recent relevant IEC publications. Therefore, 7.2.6 is updated in accordance with IEC 60502-1 (2009) and IEC 60502-2 (2005) with respect to testing.

5. Points of discussions or possible discussions

Regarding creepage distances in 2.3.2, one member advised that the current values of 25 mm/kV and 16mm/kV are more stringent than that applied in the IEC 60092 series. The member’s Rules are in line with these standards and it has hence currently a reservation in place.

One member proposed to introduce loss of service continuity categories for switchgears; however, this was not supported by the majority as maintaining service continuity is considered a system level issue that can be managed in a number of ways.

Regarding Internal Arc Classification (IAC), one member considered that switchgear and controlgear assemblies will be accessible from all sides and as such should always be tested as such. Following further consideration the Panel agreed to leave accessibility requirements installation and location dependent.
One member opined that requirements for arc flash/internal arc protection are covered by IEC 62271-200 and need not be addressed in UR E11, however, other members agreed to introducing the requirements in the current form.

6. Attachments if any

N/A

Technical Background (TB) document for UR E11 (Corr.1 June 2018)

1. Scope and objectives

To make amendment to UR E11 in order to update the international standards that referenced in this IACS resolutions.

2. Engineering background for technical basis and rationale

None.

3. Source / derivation of the proposed IACS Resolution

The task of checking and updating of international standards that referenced by IACS resolutions carries out every five years. From 21st Meeting of IACS MP, the working scope extended from IEC standards referenced to all MP related international standards.

4. Summary of Changes intended for the revised Resolution:

None.

5. Points of discussions or possible discussions

None.

6. Attachments if any

None.

Technical Background (TB) document for UR E11 (Rev.4 Feb 2021)

1. Scope and objectives

UR P4(Rev.3) does not reflect the agreed format for referencing the IEC standards. Rev.4 has been developed to comply with the agreed format.

2. Engineering background for technical basis and rationale

Format for references to Industry standards

> ***Format:***
> *[Standard Designation], [version/revision, if applicable], [year of publication] (examples: API Spec 2F, 6th Edition, 1997; ISO 4624, 2002), where [version/revision, if applicable] and/or [year of publication] are decided by IACS and are not necessarily to be the current/latest version.*

3. Source/derivation of the proposed IACS Resolution

None

4. Summary of Changes intended for the revised Resolution

UR E11 has been updated to specify the revision/version of the IEC standards.

IEC standards	**Replaced by**
IEC 60092-201	IEC 60092-201:2019
IEC 60092-503	IEC 60092-503:2007
IEC 60034-15	IEC 60034-15:2009
IEC 60076-11	IEC 60076-11:2018
IEC 60092-353	IEC 60092-353:2016
IEC 60092-354	IEC 60092-354:2020
IEC 62271-200	IEC 62271-200:2011
IEC 62271-201	IEC 62271-201:2014
IEC 60076	applicable Parts of the IEC 60076 Series

5. Points of discussions or possible discussions

The investigation for the year of publication of the standards started beginning of 2019. At that time 60092-201:1994 was applicable; however as of mid 2019 a new edition of the aforesaid standard has been published, therefore the 2019 edition is stated in the UR.

Previous editions of the UR stated in 4.1 "Liquid cooled transformers have to comply with IEC 60076". As IEC 60076 is a series of standards, whose number exceeds 20, on power transformers, and not all parts are on liquid cooled transformers, the above sentence has been revised to read "Liquid cooled transformers have to comply with the applicable Parts of the IEC 60076 Series".

6. Attachments if any

None

UR E12 "Electrical Equipment allowed in paint stores and in the enclosed spaces leading to paint stores"

Summary

In Rev.2 of this Resolution, the way to refer to instruments other than those specified by IACS was unified.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable

E 12 (Rev.1)

Technical Background Document
WP/EL Task 1A “Annual Review UR- Review UR E12”

Objective and Scope:
To correct UR E12 in order to align with IEC Standard.

Source of Proposed Requirements:
The proposed requirements have been based on the revised IEC 60092-502 Standard.

Points of Discussion:
The text has been revised taking into account the IEC 60092-502. We have deleted the reference to IACS Recommendation No.22 and insert in lieu the IEC 60092-502.
The corrected draft of the UR agreed by WP was forwarded to GPG for consideration attached to the 30th WP/EL Progress Report.

Submitted by WP/EL Chairman

Technical Background (TB) document for UR E12 (Rev.2 Dec 2020)

1. Scope and objectives

UR E12(Rev.1) does not reflect the agreed format for referencing the IEC standards. Rev.2 has been developed to comply with the agreed format.

2. Engineering background for technical basis and rationale

Format for references to Industry standards

[Standard Designation], [version/revision, if applicable], [year of publication] (examples: API Spec 2F, 6th Edition, 1997; ISO 4624, 2002), where [version/revision, if applicable] and/or [year of publication] are decided by IACS and are not necessarily to be the current/latest version.

3. Source/derivation of the proposed IACS Resolution

None

4. Summary of Changes intended for the revised Resolution:

UR E12 has been updated to specify the revision/version of the IEC standards as follows:

IEC standards	Replaced by
IEC 60092-502	IEC 60092-502:1999

5. Points of discussions or possible discussions

None

6. Attachments if any

UR E13 "Test requirements for Rotating Machines"

Summary

In Corr.1 of Rev.3 of this Resolution, the second sentence of paragraph 4.5 has been corrected.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Corr.1 (May 2022)	06 May 2022	-
Rev.3 (Dec 2020)	11 December 2020	1 January 2022
Corr.1 (June 2018)	12 June 2018	-
Rev.2 (Aug 2015)	July 2015	1 January 2017
Corr.1 (May 2004)	May 2004	-
Rev.1 (May 2001)	May 2001	-
New (1996)	1996	-

- **Corr.1 (May 2022)**

1 Origin of Change:

☑ Suggestion by IACS member

2 Main Reason for Change:

To correct the second sentence of paragraph 4.5 so that it is to be referred the tables of IEC 60034-1:2017. This is because the tables related to the limits of temperature rise in this IEC are not specified in Table 1, but in some other table.

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None

4 History of Decisions Made:

During the discussion, the following three options for corrections were proposed, Option 2 has been agreed by Machinery Panel.

Option 1: *The limits of temperature rise are those specified in Table ~~1~~8 of IEC 60034-1:2017 …*

Option 2: *The limits of temperature rise are those specified in ~~Table 1~~ the relevant table of IEC 60034-1:2017 …*

Option 3: *The limits of temperature rise are those specified in ~~Table 1 of~~ IEC 60034-1:2017 …*

5 Other Resolutions Changes:

None

6 Any hinderance to MASS, including any other new technologies:

None

7 Dates:

Original Proposal	: 18 October 2021	(Ref: PM20906qIMa)
Panel Approval	: 08 March 2022	(Ref: PM20906qIMc)
GPG Approval	: 06 May 2022	(Ref: 20206_IGo)

• Rev.3 (Dec 2020)

1 Origin of Change:

☑ Other (Update to comply with the required format when industry standards are referred to)

2 Main Reason for Change:

There was a need to update this UR to comply with the following format when industry standards are referred to:

[Standard Designation], [version/revision, if applicable], [year of publication] (examples: API Spec 2F, 6th Edition, 1997; ISO 4624, 2002), where [version/revision, if applicable] and/or [year of publication] are decided by IACS and are not necessarily to be the current/latest version.

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None

4 History of Decisions Made:

None

5 Other Resolutions Changes:

None

6 Any hinderance to MASS, including any other new technologies:

None

7 Dates:

Original Proposal	: 28 October 2019	(Ref: PM18939_IMd)
Panel Approval	: 09 November 2020	(Ref: PM20906_IMf)
GPG Approval	: 11 December 2020	(Ref: 20206_IGb)

- **Corr.1 (June 2018)**

1 Origin for Change:

☑ Suggested by IACS member

2 Main Reasons for Change:

The checking and updating of international standards that referenced by IACS resolutions has been carried out by Machinery panel. As a result, it is found that there is a need to update the international standards that referred in the IACS resolution UR E13.

3 List of non-IACS Member Classification Societies contributing through the TC Forum and/or participating in IACS Working Group:

None

4 History of Decisions Made:

Delete word "Publication" in the IEC standards referenced;

5 Other Resolutions Changes

Note: There are no Technical Background (TB) documents available for the New (1996) and Corr.1 (May 2004).

E 13 (Rev.1)

Technical Background Document

WP/EL Task 1A "Annual Review UR- Review UR E13"

Objective and Scope:
To correct UR E13 in order to eliminate existing reservations and to align with IEC Standards.

Source of Proposed Requirements:
During XIX WP/EL Meeting it was claimed that in UR E13 there are editorial mistakes concerning overload/overcurrent and overspeed tests.

Points of Discussion:
It was discussed whether there is a practically justified need to carry out overload/overcurrent tests as a Routine tests for a.c. generators and motors? After much discussion most members expressed the opinion that overload/overcurrent tests as a Routine tests are applicable for machines of essential services rated above 100 kW/kVA.

The question of 50 or 100 kW was raised. It was decided that all machines of 100kW and over, intended for essential services, are to be surveyed by the Society during testing and, if appropriate, during manufacturing. As regards to overspeed test WP/EL members decided that one is not applicable for squirrel cage motors.

The new requirement regarding the shaft material for electric propulsion motors and for main engine driven generators where the shaft is part of the propulsion shafting is included to current UR.

The corrected draft of the UR agreed by WP was forwarded to GPG for consideration attached to the 30th Progress Report WP/EL.

Submitted by WP/EL Chairman in January 2001.

Technical Background document for UR E13 (Rev.2 Aug 2015)

1. Scope and objectives

Revise IACS UR E13/4.7 to ensure that the ability of the generator and its excitation system to maintain a short-circuit is reflected in the UR. Further reservations to the existing UR and possible editorial comments shall be corrected.

2. Engineering background for technical basis and rationale

<u>Paragraph 4.4 (Verification of the voltage regulation system)</u>
The sentence has been added to clarify that voltage regulation during transient conditions need not be tested during factory testing provided that calculated values based on earlier type test records are available.

<u>Paragraph 4.7 (Verification of steady short-circuit conditions)</u>
The paragraph has been updated, taking into account both the stationary short circuit current delivered by the generator, as well as the transient behaviour of this short circuit current.

The stationary short circuit current shall be verified by testing. The test criterion is that a current of at least three times the rated current for duration of at least 2 s is achieved without any damage to the generator. If precise data is available, the test criteria can be modified to fit duration of any time delay, which will be fitted in the tripping device for discrimination purposes.

The transient short circuit current, i.e. the decrement curve for the generator, shall be documented by the manufacturer. This documentation may be based on the manufacturer's simulation model for the generator and the voltage regulator. The simulation model may be used where it has been validated through previous type test on the same generator model. The influence of the automatic voltage regulator shall be taken into account, and the setting parameters for the voltage regulator shall be noted together with the decrement curve. Such a decrement curve shall be available when the setting of the distribution system's short-circuit protection is calculated.

3. Source / derivation of the proposed IACS Resolution

Field experience and manufacturers feedback.

4. Summary of Changes intended for the revised Resolution:

See paragraph 2.

5. Points of discussions or possible discussions

The changes to 4.4 and 4.7 were agreed by all members. There was some discussion about the appropriate wording for the last sentence of 4.7 and the current text (*'… where this has been validated through the previous type test on the same model'*) was agreed as a compromise solution.

6. Attachments if any

None

Technical Background (TB) document for UR E13 (Corr.1 June 2018)

1. Scope and objectives

To make amendment to UR E13 in order to update the international standards that referenced in this IACS resolutions.

2. Engineering background for technical basis and rationale

None.

3. Source / derivation of the proposed IACS Resolution

The task of checking and updating of international standards that referenced by IACS resolutions carries out every five years. From 21st Meeting of IACS MP, the working scope extended from IEC standards referenced to all MP related international standards.

4. Summary of Changes intended for the revised Resolution:

None.

5. Points of discussions or possible discussions

None.

6. Attachments if any

None.

Technical Background (TB) document for UR E13 (Rev.3 Dec 2020)

1. Scope and objectives

UR E13(Rev.2) does not reflect the agreed format for referencing the IEC standards. Rev.3 has been developed to comply with the agreed format.

2. Engineering background for technical basis and rationale

Format for references to Industry standards

[Standard Designation], [version/revision, if applicable], [year of publication] (examples: API Spec 2F, 6th Edition, 1997; ISO 4624, 2002), where [version/revision, if applicable] and/or [year of publication] are decided by IACS and are not necessarily to be the current/latest version.

3. Source/derivation of the proposed IACS Resolution

None

4. Summary of Changes intended for the revised Resolution:

UR E13 has been updated to specify the revision/version of the IEC standards as follows:

IEC standards	**Replaced by**
IEC 60092-301	IEC 60092-301:1980/AMD2:1995
IEC 60034-1	IEC 60034-1:2017
IEC 60034-5	IEC 60034-5:2000+AMD1:2006

5. Points of discussions or possible discussions

None

6. Attachments if any

None

****

Technical Background (TB) document for UR E13 (Corr.1 May 2022)

1. Scope and objectives

To correct the second sentence of paragraph 4.5 so that it is to be referred the tables of IEC 60034-1:2017.

2. Engineering background for technical basis and rationale

None

3. Source/derivation of the proposed IACS Resolution

None

4. Summary of Changes intended for the revised Resolution:

The change made to the second sentence of paragraph 4.5 of Rev.3 is as follows:

The limits of temperature rise are those specified in ~~Table 1~~ <u>the relevant table</u> of IEC 60034-1:2017 adjusted as necessary for the ambient reference temperatures specified in UR M40.

5. Points of discussions or possible discussions

A member suggested that the IEC 60034-5 referred to in paragraph 4.11 should be amended as a new edition has been published. However, as this suggestion is a revision of the UR, Machinery Panel agreed to consider it as a separate item rather than as the correction of the UR in this time.

6. Attachments if any

None

UR E15 "Electrical Services Required to be Operable Under Fire Conditions and Fire Resistant Cables"

Summary

In Rev.5 of this Requirement, updates include the definition of 'high fire risk areas' in Notes for routing electrical cables, as well as the relevant edition of applicable standards.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev.5 (Jan 2025)	31 January 2025	1 July 2026
Rev.4 (Dec 2020)	11 December 2020	1 January 2022
Rev.3 (Dec 2014)	05 December 2014	1 January 2016
Rev.2 (Feb 2006)	07 February 2006	-
Rev.1 (May 2004)	31 May 2004	-
New (Nov 1999)	19 November 1999	-

- **Rev.5 (Jan 2025)**

1 Origin of Change:

☑ Based on IACS Requirement (Amendments to UI SC11)

2 Main Reason for Change:

During the preparation of draft Rev.5 of UR E15, it was noted that the definition of 'other high fire risk areas' needs to be developed.

3 Surveyability review of UR and Auditability review of PR
N/A

4 Human Element issues assessment
N/A

5 List of non-IACS Member classification societies contributing or participating in IACS Working Group:
None

6 History of Decisions Made:
The revision was developed in consultation with the Safety panel (PS23054).

7 Other Resolutions Changes:
UI SC11 (Rev.2)

8 Any hinderance to MASS, including any other new technologies:

N/A

9 Dates:

Original Proposal	: 21 June 2023	(Made by: PM23402_IMc)
Panel Approval	: 16 January 2025	(Ref: PM20906rIMr)
GPG Approval	: 31 January 2025	(Ref: 24193_IGf)

• Rev.4 (Dec 2020)

1 Origin of Change:

☑ Other (Update to comply with the required format when industry standards are referred to)

2 Main Reason for Change:

There was a need to update this UR to comply with the following format when industry standards are referred to:

[Standard Designation], [version/revision, if applicable], [year of publication] (examples: API Spec 2F, 6th Edition, 1997; ISO 4624, 2002), where [version/revision, if applicable] and/or [year of publication] are decided by IACS and
are not necessarily to be the current/latest version.

To take this opportunity, references to IMO instruments have been specified in the following format based upon confirmation of amendments up to the latest one:

In case where the number of amendments is large:

regulation/paragraph x.x.x of SOLAS Chapter X/MARPOL Annex X/the XXX Code, as amended by IMO resolutions up to MSC.xx(xx)/MEPC.xx(xx)

In case where the number of amendments is small:

regulation/paragraph x.x.x of SOLAS/MARPOL/the XXX Code, as amended by resolutions MSC/MEPC.xx(xx), (...) and MSC/MEPC.xx(xx)

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None

4 History of Decisions Made:

None

5 Other Resolutions Changes:

None

6 Any hinderance to MASS, including any other new technologies:

None

7 Dates:

Original Proposal: 28 October 2019 (Ref: PM18939_IMd)
Panel Approval: 09 November 2020 (Ref: PM20906_IMf)
GPG Approval: 11 December 2020 (Ref: 20206_IGb)

- **Rev.3 (Dec 2014)**

1 Origin for Change:

☑ Suggestion by IACS member

2 Main Reason for Change:

In UR E15 (Rev.2), the definition for "high fire risk areas" includes machinery spaces as defined by Chap. II-2 / Reg. 3.30 of SOLAS. However, "machinery spaces as defined by Chap. II-2 / Reg. 3.30 of SOLAS" include spaces having little or no fire risk as defined by MSC/Circ.1120 like ventilation and air-conditioning rooms as well as stabilizer equipment rooms, etc.

Therefore, it is necessary to amend the definition for "high fire risk areas" specified by UR E15 (Rev.2) to make reference to MSC/Circ.1120.

The task was also triggered by an external party who raised the issue that IACS UI SC165 does not strictly align with MSC Circular 1120. Original Machinery Panel task PM9400 dealt with aspects of this task. Machinery Panel did not support the proposal to nominate a fire resistant duration. Instead, Machinery Panel was of the opinion that effort may be better directed be put into the routing, rather than the fire resistance properties, of the cable and considered this matter further with a view to considering updating of IACS UR E15 where necessary improvements were identified.

3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

4 History of Decisions Made:

The issue was raised within the Machinery Panel. After some discussion it was agreed to draft an IACS UR E15 (Rev.3) and associated HF and TB and to withdraw UI SC165.

5 Other Resolutions Changes

None

6 Dates:

Original Proposal: March 2013 made by Machinery Panel
Panel Approval: September 2014 by Machinery Panel
GPG Approval: 05 December 2014 (Ref: 13087_IGc)

Technical Background Document
WP/EL Task 30 “Use of Fire Resisting Type Electrical Cables and for Electrical Services Required to be Operated under the Fire Conditions” UR E15 (New)

1. Objective and Scope:

To identify constructional standards for fire resistant type electric cables and to develop unified requirements on their use for electrical services which are required to be operated under fire conditions.

2. Source of Proposed Requirements:

The proposed requirements were developed by WP/EL members through their experience in surveying of electrical services which are required to be operated under fire conditions.
SOLAS-74 and IMO Code on Alarms and Indicators {A.686 (17)}, UI SC10 (Rev.1 1997), Class Rules, International and National Standards and Specifications for Cables.

3. Points of Discussion:

WP/EL unanimously agreed to the draft UR

- - - - - - - - -

Date of submission: 13 May 1999
By WP/EL Chairman

Technical Background

E 15(Rev.1, 2004)

IACS WP/EL Task No.60 “To revisit the Unified Requirements E15 to facilitate uniform implementation, by further clarification of the intent of the requirements including development of the definition of “fire zone and deck”.

Objective and Scope:
To revisit the requirements and notes in UR E15 “Electrical Services Required to be Operable Under Fire Conditions and Fire Resistant Cables” taking into consideration the various arrangements and possibilities for maintaining electrical services under fire conditions. Particularly, to develop definitions, practicability of maintaining the functionality, etc., as may be necessary to further clarify the intent and improve the uniform application of E15 in the area as indicated under Work Specification.

Background for the Proposed Revision:
Since the adoption of UR E15 in May 1999, various shipbuilders sought (and are still seeking) clarifications as to the interpretation of UR E15 including the following issues:
(a) A “fire zone” can mean anything between main vertical/horizontal zones in SOLAS Reg. II-2/2.2.1 and any single space listed in SOLAS Reg. II-2/2.3.3 or 2.4.2. Reference to “high fire risk area” earlier in E15.2.1 suggests the latter approach may be closer to the intent, which needs to be clarified. Reference to decks could be superfluous when fire zone is properly defined. It could be even misleading without reference to bulkhead, another element consisting the boundary of zone or area.
(b) E15.3.1 suggests that services in E15.2.2 may not be supplied under local fire at an “apparatus”. This could contradict E15.2.2 when read literally.
(c) There is room for further refinements, including but not limited to “duplicated system” in the second paragraph of E15.2.1 (PA system is a single system with duplicated elements so as to maintain functionality – see LSA Code 7.2.2.1, a system with supply from main and emergency sources is another example.), “apparatus” in E15.3.1 (undefined), etc.

Points of Discussion:
It is considered that the confusion has been caused by the terminologies of “deck and the undefined “fire zone” in E15 since there are various arrangements of cables for electrical services to be operable under fire conditions. Re-investigation was mainly made for the following points:
(a) Correction to follow the latest IEC Standards for “fire resistant cables” in E15.1,
(b) Requirement for distinguishing the fire resistant cable from flame retardant cables or other non-fire resistant cables in E15.1,
(c) Clarification of the original intent in E15.2.1 taking into account of the practicable application,
(d) Development of the definition for “high fire risk areas” in E15.2.1,
(e) Revisiting the list of services in E15.2.2,
(f) Refining E15.3.1 for further clarification of the original intent, and

(g) Several editorial corrections.
It was also investigated if Section 1 subclause 4 of IEC 60092-352 (1997) should be incorporated in E15, which states “In circuits used for fire alarm, detection, extinguishing services, remote stopping and similar control circuits, fire resistant cables shall be considered unless the systems are self-monitoring type or failing to safety or the systems are duplicated”. However, it was concluded that the above statement is not included in E15 revision since it is not the intent of E15.2.1.
The wording “provided their functionality can be maintained “ in the second paragraph of E15.2.1 was deleted since it is not considered practicable to maintain the functionality after the cables to these services are damaged. However, if the system failure is detected and alarmed under self-monitoring functions, the crew can recognize the failure and would establish the compensating routines or procedure.
Further, the system fails to a safe mode and duplicated with cable runs are also compensating such failure.

Note:
A GPG Member suggested that E15.1 should also refer to IEC 60331-21 for cables with diameter of less than 20 mm. E15.1 was so amended.

Technical Background
UR E15 (Rev. 2, Feb 2006)

IACS Machinery Panel Task PM5402:
To modify the IACS UR E15 “Electrical Services Required to be Operable Under Fire Conditions and Fire Resistant Cables”

Scope and objectives
Revisit E15 in order to clarify some requirements which are ambiguous and may cause misunderstandings.
At the same time, make E15 more to the point, i.e. shorter, and restructure it to make it more readable and to separate guidance information from requirements, and present it accordingly.

Points of discussion
Rev. 2 is agreed unanimously by Machinery Panel Members.

Submitted by MCH Panel Chairman
27 Dec 2005

Permsec’s Note: GPG Discussion (s/n 6003, 24 Jan 2006)

1. A GPG Member commented that in Figure 1 of the UR, the style of the lines connecting ESB with DB, DB with DB, and DB with "Electrical consumers" should be changed into the dashed line indicating "Flame retardant cable". MCH Panel Chairman confirmed that was what the Machinery Panel had intended. Hence, this proposal was accepted.

2. A MCH Panel Member also commented on the same cables mentioned by the GPG Member, but recommended that these cables should be "Fire resistant cables". MCH Panel Chairman confirmed that it would be meaningless to use the fire resistant type for these cables since any equipment located inside a high fire risk area should be considered not operable under fire conditions. Hence, this proposal was not accepted.

Implementation (6003_ICa, 6 Feb 2006):
The revised UR E15 was adopted on 6 Feb. 06. In accordance with IACS Procedures, IACS Societies are to incorporate the revised UR into their Rules and/or procedures within one year of adoption by IACS Council.

Technical Background
UR E15 (Rev. 3, Dec 2014)

1. Scope and objectives

Amend the definition of "high fire risk areas" specified by UR E15 (Rev.2) to make reference to MSC/Circ.1120.

2. Engineering background for technical basis and rationale

UR E15 (Rev.2) defines "high fire risk areas" to include machinery spaces such as those defined in Chap. II-2 / Reg. 3.30 of SOLAS. However, "machinery spaces as defined by Chap. II-2 / Reg. 3.30 of SOLAS" include some spaces which have little or no fire risk (as defined by MSC/Circ.1120) such as ventilation and air-conditioning rooms as well as stabilizer equipment rooms, etc.

There are some opinions that the current version of the UR goes too far because it requires that spaces which have little or no fire risk (as defined by MSC/ Circ.1120) be treated as high fire risk areas.

Therefore, it is necessary to amend the definition of "high fire risk areas" specified in UR E15 so that it makes reference to MSC/Circ.1120.

3. Source / derivation of the proposed IACS Resolution

Interpretation of machinery spaces having little or no fire risk specified by MSC/Circ.1120.
IEC 60092-353:2011
IEC 60331-1
IEC 60331-2
IEC 60331-21

4. Summary of Changes intended for the revised Resolution:

The definition for "high fire risk area" in note a) (i) was amended to exclude spaces defined by of SOLAS Chap. II-2 / Reg. 9.2.2.3.2.2 paragraphs (10) as "auxiliary machinery spaces having little or no fire risk". This amendment specifies that spaces having little or no fire risk as defined by SOLAS and MSC/Circ.1120 (i.e., spaces containing generators and major electrical units; refrigerating, stabilizing, ventilation and air conditioning machinery; and trunk to such spaces, provided they are not handling or using flammable liquids) are not considered to be high fire risk areas.

Paragraph 2.a) was amended to reference updated IEC Standards.

Paragraph 3 was added to E15 concerning electrical cables for the emergency fire pump in agreement with the interpretation for SOLAS Reg. II-2/10.2.2.3.2.2 in MSC/Circ.1120; however, the reference to paragraph 1 of E15 was rectified to refer instead to paragraph 2 (a) as the IMO Circular reflects an earlier revision of the UR and paragraph 2 (a) is now applicable for the specification of fire rated cables.

5. Points of discussions or possible discussions

None.

6. Attachments if any

None.

Technical Background (TB) document for UR E15 (Rev.4 Dec 2020)

1. Scope and objectives

UR E15(Rev.3) does not reflect the agreed format for referencing the IEC standards. Rev.4 has been developed to comply with the agreed format.

2. Engineering background for technical basis and rationale

A) Format for references to Industry standards

Format:
[Standard Designation], [version/revision, if applicable], [year of publication] (examples: API Spec 2F, 6th Edition, 1997; ISO 4624, 2002), where [version/revision, if applicable] and/or [year of publication] are decided by IACS and are not necessarily to be the current/latest version.

B1) Format for references to IMO instruments (where the number of amendments is large)

Format:
regulation/paragraph x.x.x of SOLAS Chapter X/MARPOL Annex X/the XXX Code, as amended by IMO resolutions up to MSC.xx(xx)/MEPC.xx(xx)

B2) Format for references to IMO instruments (where the number of amendments is small)

Format:
regulation/paragraph x.x.x of SOLAS/MARPOL/the XXX Code, as amended by resolutions MSC/MEPC.xx(xx), (...) and MSC/MEPC.xx(xx)

3. Source/derivation of the proposed IACS Resolution

None

4. Summary of Changes intended for the revised Resolution:

UR E15 has been updated to specify the revision/version of the IEC standards and MSC Circulars as follows:

IEC standards	Replaced by
IEC 60331-1	IEC 60331-1:2018
IEC 60331-21	IEC 60331-21:1999+AMD1:2009
IEC 60331-2	IEC 60331-2:2018
IEC 60331-23	IEC 60331-23:1999
IEC 60331-25	IEC 60331-25:1999
MSC Circulars	**Replaced by**
MSC/Circ.1120	MSC/Circ.1120 as amended by MSC.1/Circ.1436 and MSC.1/Circ.1510

5. Points of discussions or possible discussions

None

6. Attachments if any

None

Technical Background (TB) document for UR E15 (Rev.5 Jan 2025)

1. Scope and objectives

1.1 To amend for the definition of "other high fire risk areas" and "high fire risk areas in the 'Notes' used in UR where electrical cables may be routed and pass through the concerned spaces.
1.2 To amend the referred international standard for electric cables for fire resistant type.
1.3 Renumbering the 'Notes' to ensure they apply to the entire UR, not just section 15.3, for the benefit of readers.

2. Engineering background for technical basis and rationale

The definition of "other high fire risk area" and "high fire risk area" were not clearly specified in the SOLAS regulations. For this reason, the Machinery Panel, in consultation with the Safety Panel, developed a necessary unified interpretation to address the gap through the revision 2 of UI SC 11 and revised Notes in UR E15.

The referred standard IEC 60331-21 is for fire only test at 750 ℃ and IEC 60331-2 describes fire test with shock at 830 ℃.

2a. Specification of the data utilised in the development/revision of the proposed IACS Resolution, if any

N/A

3. Source/derivation of the proposed IACS Resolution

UI SC11 (Rev.2)

4. Summary of Changes intended for the revised Resolution:

4a. Determination of other high fire risk areas

The spaces classified as 'other high fire risk areas' are newly described in Rev.2 of UI SC 11, which includes the following,
.1 cargo spaces except cargo tanks for liquids with flashpoint above 60°C and except cargo spaces exempted in accordance with SOLAS regulations II-2/10.7.1.2 or II-2/10.7.1.4;
.2 vehicle, ro-ro and special category spaces;
.3 spaces containing flammable liquids; and
.4 pantries containing cooking appliances.

The complementary Notes (v and vi) have been evaluated and agreed unanimously by the Safety Panel.

The amendments in the Notes are considered to provide the intended consistency between SOLAS regulation II-1/45.5.3 and IACS UI SC11 (as provided in the Annex to SSE 11/10/4) on one side, and IACS UR E15 on the other side, as follows:
UR E15 Note 1 (i) – reflects SOLAS regulation II-1/45.5.3
UR E15 Note 1 (ii) – reflects Interpretation No. 3 of UI SC11
UR E15 Note 1 (iii) – reflects SOLAS regulation II-1/45.5.3 and Interpretation No. 4 of UI SC11
UR E15 Note 1 (iv) – reflects SOLAS regulation II-1/45.5.3
UR E15 Note 1 (v) – reflects Interpretation No. 1 of UI SC11
UR E15 Note 1 (vi) – reflects Interpretation No. 2 of UI SC11

4b. Reference standard for tests for electric cables under fire conditions

The Working group is of the opinion that the IEC 60331-21 is not required to be additionally tested when IEC 60331-2 is carried out.

5. Points of discussions or possible discussions

None

6. Attachments if any

None

UR E17 "Generators and generator systems, having the ship's propulsion machinery as their prime mover, not forming part of the ship's main source of electrical power"

Summary

In Rev.1 of this Resolution, the way to refer to instruments other than those specified by IACS was unified.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev.1 (Feb 2021)	12 February 2021	1 July 2022
New (June 2002)	June 2002	-

- **Rev.1 (Feb 2021)**

1 Origin of Change:

☑ Other (Update to comply with the required format when industry standards are referred to)

2 Main Reason for Change:

There was a need to update this UR to comply with the following format when industry standards are referred to:

[Standard Designation], [version/revision, if applicable], [year of publication] (examples: API Spec 2F, 6th Edition, 1997; ISO 4624, 2002), where [version/revision, if applicable] and/or [year of publication] are decided by IACS and are not necessarily to be the current/latest version.

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None

4 History of Decisions Made:

None

5 Other Resolutions Changes:

None

6 Any hinderance to MASS, including any other new technologies:

None

7 Dates:

Original Proposal:	28 October 2019 (Ref: PM18939_IMd)
Panel Approval:	9 November 2020 (Ref: PM20906_IMf)
GPG Approval:	12 February 2021 (Ref: 20206cIGb)

- **New (June 2002)**

No history file or TB document available.

****

Part B. Technical Background

List of Technical Background (TB) documents for UR E17:

Annex 1. **TB for Rev.1 (Feb 2021)**

See separate TB document in Annex 1.

◄▼►

Note: *There is no separate Technical Background (TB) document for the original version (June 2002).*

Technical Background (TB) document for UR E17 (Rev.1 Feb 2021)

1. Scope and objectives

UR E17 (Original version) does not reflect the agreed format for referencing the IEC standards. Rev.1 has been developed to comply with the agreed format.

2. Engineering background for technical basis and rationale

Format for references to Industry standards

Format:
[Standard Designation], [version/revision, if applicable], [year of publication] (examples: API Spec 2F, 6th Edition, 1997; ISO 4624, 2002), where [version/revision, if applicable] and/or [year of publication] are decided by IACS and are not necessarily to be the current/latest version.

3. Source / derivation of the proposed IACS Resolution

None

4. Summary of Changes intended for the revised Resolution:

UR E17 has been updated to specify the revision/version of the IEC standards as follows:

IEC standards	Replaced by
60092-201	60092-201:2019
60092-301	60092-301:1980/AMD2:1995

5. Points of discussions or possible discussions

IEC 60092-201:1994 was replaced by the new edition of September 2019.

In the edition of 1994, paragraph 6.2.3 is as follow:

6.2.3 The arrangements of the ship's main source of electrical power shall be such that the services referred to in 6.1.1 can be maintained regardless of the speed and direction of rotation of the main propulsion machinery or shafting.

Generators driven from the propulsion plant may be accepted as generators forming the main source of electrical power if in all sailing and manoeuvring conditions, including the propeller being stopped, the arrangement is such that the generating capacity of these generators is sufficient to provide the electrical power to comply with 6.2.2 and fulfil all further requirements, especially those of 6.2.4. They shall be not less effective and reliable than the independent generating sets.

NOTE – Following the wording of Amendment 4 (1988) the word "ship" has been replaced by the word "propeller".

Generators driven from the propulsion plant which do not comply with this sub-clause may be used as additional source(s) of electrical power with respect to the power balance, but attention should be given to a quick restoration of electrical power to all auxiliaries necessary for maintaining the ship in operational and safe condition after an electrical power interruption, for example, due to a sudden stop of the propulsion plant. The time involved for restoring the above-mentioned services should be not longer than 45 s.

The edition of 2019 had been greatly changed. The similar provision as IEC 60092-201:1994 paragraph 6.2.3 should be paragraph 8.1.1 as follow:

A generator or generator system, having the ship's main propulsion machinery as its prime mover, may be accepted as main sources of electrical power, provided that it can be used in all operating modes for the propulsion plant, including standstill of the vessel (with the propeller stopped). When there are several main propulsion engines, each of these could be the driver of a main source of power. One propulsion engine can only be the driver of one main source of electric power.

Technical Background (TB) document for UR E18 (New, July 2003)

1 Scope and objectives

To formulate IACS requirements for the recording of the type, location and maintenance cycle of batteries.

2 Engineering background for technical basis and rationale

In view of the increasing use of electronic and computer based systems and electrical equipment that operate at low voltage, e.g. 12 or 24 volts d.c, there has been the associated increasing use of locally installed batteries around the ship. Examples of such batteries include those fitted within equipment for memory power supply back up, in the event of the failure of the normal electrical power supply and those for the transitional emergency supply for low location lighting systems and other emergency services. Failure of such batteries as the result of poor maintenance or ageing may cause the loss of essential or emergency services. Because of the quantity of such batteries and the variety of equipment and locations in which they may be installed it is considered necessary to require that a schedule of such batteries be compiled and kept.

3 Source/derivation of the proposed IACS Resolution

In-house expertise

4 Summary of Changes intended for the revised Resolution

N/A

5 Points of discussions or possible discussions

An increasing number of items of SCADA (supervisory control and acquisition) equipment are now low power and voltage as the result of advanced technology. Because of the difficulty of providing such equipment with an alternative/emergency source of power, where required, at low voltage from a central source without prohibitive voltage loss, the use of UPS (uninterruptible power source) units has increased dramatically. The batteries in the UPS units require maintenance and also replacement after a specified lifetime. Failure of such batteries as the result of poor maintenance or ageing may cause the loss of essential or emergency services.

Most of the modern batteries fitted are of the valve- regulated sealed type[1] requiring reduced ventilation. Where vented type[2] batteries replace valve-regulated sealed types, it is to be ensured that there is adequate ventilation and that Society's requirements relevant to the location and installation of vented types batteries are complied with.

During discussion it was noted that developing a listing of batteries and keeping it on board each ship is supported, provided it is used during the subsequent class surveys. This task is to ensure that the location of batteries is known and that they are safe and maintained in a correct manner. The full text of the UR agreed by WG was forwarded to GPG for consideration attached to the 32nd WP/EL Progress Report.

1 A valve-regulated battery is one in which cells are closed but have an arrangement (valve) that allows the escape of gas if the internal pressure exceeds a predetermined value.

2 A vented battery is one in which the cells have a cover provided with an opening through which products of electrolysis and evaporation are allowed to escape freely from the cells to the atmosphere.

Technical Background (TB) document for UR E18 (Rev. 1, Dec 2014)

1 Scope and objectives

Clarify when the review of the battery schedule is to be done, i.e. during plan approval and/or onboard survey.

2 Engineering background for technical basis and rationale

A review of members' current practice revealed different approaches towards the review of the battery schedule. It is the intention of Rev. 1 to clarify the requirement.

3 Source / derivation of the proposed IACS Resolution

Members' current practice and experience in the application.

4 Summary of Changes intended for the revised Resolution

Adding clarification that the battery schedule is to be reviewed by the Society during plan approval or the new building survey.

5 Points of discussions or possible discussions

The proposed clarification was agreed unanimously.

Annex 2.1

Technical Background Document

E 19 Ambient temperatures for electrical equipment
(New, July 2003) in areas other than machinery spaces.

IACS WP/EL Task 54 "Ambient temperatures for electrical equipment in areas other than machinery spaces"

1. Objective and scope:
To formulate an IACS requirements for ambient temperatures for electrical equipment in areas other than machinery spaces

2. Source of proposed requirements.
WP/EL XXIII meeting, St.Petersburg 2001

3. Résumé:

The current ambient temperatures specified for electrical equipment is the same as that for mechanical equipment as exemplified in UR M28, i.e. 45°C. Whilst this acceptable for electrical equipment located in machinery spaces and on open deck there is a considerable amount of electrical equipment, including cables, that is fitted in locations which never experience these elevated temperatures. Examples of these areas are machinery control rooms and switchboard rooms that are generally fitted with air conditioning units and passenger accommodation on passenger ships, which again have air conditioning.

Along with the increased generating capacity now installed is the associated increase in the capacity and size of the main switchboard and, for high voltage systems, the associated section-board(s). Switchboard manufacturers advise that for a 5°C reduction in ambient temperature can result in smaller frame sizes of circuit breakers and a reduction in the size of the switchboard(s)/section-board(s).

Electrical systems in passenger accommodation are now being designed using industrial practices
except that heat producing equipment, such as fluorescent lights, are currently required to specially built for a 45°C ambient temperature which they are very unlikely to experience.

5. Points of discussion

The current ambient temperatures specified for electrical equipment is the same as that for mechanical equipment as exemplified in UR M 28, i.e. 45°C. Whilst this acceptable for electrical equipment located in machinery spaces and on open deck there is a considerable amount of electrical equipment, including cables, that is fitted in locations which never experience these elevated temperatures. Examples of these areas are machinery control rooms and switchboard rooms that are generally fitted with air conditioning units and passenger accommodation on passenger ships, which again have air conditioning.

Technical Background Document

UR E19(Rev.1, August 2005)

IACS WP/EL AOB 5.8 "To modify the UR E19 "Ambient Temperatures for Electrical Equipment in Areas other than Machinery Spaces" with regard to definition of machinery spaces."

Objective and scope:
To modify the UR E19 "Ambient Temperatures for Electrical Equipment in Areas other than Machinery Spaces" with regard to definition of machinery spaces.

Source of proposed requirements.

UR E19 background.

Points of discussion

According to SOLAS, Machinery Control Rooms are categorized as Machinery Spaces. Thus, the current UR E19 seems not to be applicable to the equipment installed in Machinery Control Rooms because of its title; however, the "Technical Background" of UR E19 allows such application.

Since the UR E19 and its technical background are discrepant each other the modifications of title of the UR E19 and para.1 of UR E19 were made.

Technical Background

UR E 20 (New, 2004)

IACS WP/EL Task 52 "Influence of fixed water-based local application fire-fighting systems (FWBLAFFS) in engine rooms to electrical equipment"

Objective and scope:
To develop UR for the electrical safety of electrical and electronic equipment within engine rooms, in areas protected by FWBLAFFS, and adjacent areas where water may extend.

Source of proposed requirements.
SOLAS Ch. II-2 / 10.5.6.2
MSC Circ. 913
MSC Circ. 1082

Points of discussion
Increasingly, water-based fire-fighting systems are being used in engine rooms, control rooms and other spaces, as well as for local application, which when activated may have an extremely destructive effect on electrical equipment.
In this context an essential requirements contained in IMO document MSC Circ. 913, clause 3.2, should be noted: "The activation of the fire-fighting systems should not result in loss of electrical power or reduction of the maneuverability of the ship".
WG considered the possibility of damage to some electrical equipment due to the operation of FWBLAFFS. The potential for damage depends upon a number of factors, which include:

1. Various types of available FWBLAFFS and their potential effects on electrical equipment within their vicinity.
2. Requirements for the installation of FWBLAFFS in machinery spaces in respect to adjacent electrical equipment.
3. Degree of ingress protection for electrical equipment in these areas with regard to the type of FWBLAFFS used. (e.g. low and/or high pressure systems etc.)
4. Voltage at which the equipment operates (low voltage vs. high voltage systems).
5. Location of the electrical equipment and enclosure inlets relative to the water mist nozzles.
6. Mist droplet size and droplet density (which can vary substantially from manufacturer to manufacturer depending upon their particular nozzle design).

Each of the above items directly impact the potential for damage to electrical equipment, and it would therefore appear that all such items must be adequately quantified before establishing any reasonable conclusions regarding the potential damage to electrical equipment. Beyond the potential damage to electrical equipment, it would appear that the potential danger of shock would also be of significant concern.
During the XXV WP/EL Meeting it was decided to make some definitions concerning with areas protected by FWBLAFFS where electrical equipment are installed.
Taking into account the aforesaid WP/EL developed this Unified Requirement, which was agreed by WG and forwarded to GPG for consideration attached to the 33rd WP/EL Progress Report.

Technical Background

UR E20, Rev.1 (June 2009)

Machinery Panel Task PM5403 *"Develop an alternative text for the Interpretation to Paragraph 3.2 in MSC/Circ. 1082 and review the need for the IP44 requirement in UR E20"*

1. Clause 3.2 of the Annex to the MSC/Circ. 913 "Guidelines for the Approval of Fixed Water Based Local Application Fire-Fighting Systems for Use in Category-A Machinery Spaces" reads as follows.
   "The activation of the fire-fighting systems should not result in the loss of electrical power or the reduction of maneuverability of the ship."

2. MSC/Circ.1082 gives an interpretation for the paragraph 3.2 of the MSC/Circ. 913 as follows.
   "The activation of the system should not require engine shutdown, closing fuel oil tank outlet valves, evacuation of personnel and sealing of the space. Any of these actions would lead to loss of electrical power or reduction of maneuverability. Paragraph 3.2 is not intended to place requirements on electrical equipment."

3. While noting the above interpretation, the Machinery Panel concluded that the classification requirements of URE20 are necessary and appropriate to address the safety of ships and personnel in the event of FWBLAFFS activation.

4. Based on service experience since the introduction of SOLAS Ch II-2/C, Reg.10.5.6 and cases where the appropriateness of the UR E20 requirement for electrical and electronic equipment enclosures in protected or adjacent areas exposed to direct spray to have a degree of protection of at least IP44 has been challenged, Rev. 1 introduces the possibility of evidence of suitability for lower degrees of protection to be submitted for consideration by the Society.

5. This may involve adequate testing or submission of satisfactory test evidence and/or analysis that is relevant to the particular installation of FWBLAFFS (including nozzle type), equipment and machinery that is found on board a given ship. The use of enclosures with a lower degree of protection than IP 44 will be subject to the approval of the Society in each case.

6. Updating of the requirements of IEC 60092-201, *Electrical installations in ships – System design – General*, Section 7: *Degree of protection* will be considered when issued to assess whether there is any impact on UR E20.

Submitted by Machinery Panel Chairman
27 May 2009

Permanent Secretariat note (June 2009):
Rev.1 of UR E20 was approved by GPG on 22 June 2009 (ref. 6014_IGi).

UR E21 "Requirements for uninterruptible power (UPS) units"

Summary

In Rev.2 of this Resolution, the requirements for UPS are extended to other cases than alternative and transitional power, recognizing widely used practice and existing usage that UPS is often utilized for continuous and uninterruptible services in the application of essential services like DP control system, AMS, BMS, etc.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev.2 (Feb 2024)	23 February 2024	1 July 2025
Corr.1 (June 2022)	25 June 2022	-
Rev.1 (Feb 2021)	12 February 2021	1 July 2022
New (Aug 2005)	August 2005	-

- **Rev.2 (Feb 2024)**

1 Origin for Change:

☑ Suggestion by IACS Member

2 Main Reason for Change:

It was found that the requirements in UR E21 are now limited to alternative and/or transitional power to emergency services as defined in SOLAS II-1/42 and SOLAS II-1/43, although it is well recognized that UPS has been and will be commonly used as a means of continuous and uninterruptible power supply to essential services such as UPS for DP control system, AMS and BMS, etc.

It was also observed that the requirements in UR E21 were already reflected in the Rules of certain member Societies.

In order to resolve above findings, it is suggested to extend the applicability of UR E21 to other cases than alternative and transitional power, dividing the application whether mandatory or voluntary, specifying more in detail the requirement for location and service duration, also reflecting the latest edition of IEC standards.

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None

4 History of Decisions Made:

The suggestion was discussed in 37th MP Meeting, and the majority shared the necessity and agreed to continue discussions in succeeding rounds of correspondence. The draft Rev.2 was presented to SuP before finalization. The SuP comments and MP responses were recorded for future reference.

5 Other Resolutions Changes:

None

6 Any hinderance to MASS, including any other new technologies:

None

7 Dates:

Original Proposal	: 02 February 2023	(Ref: PM20906tRIc)
Panel Approval	: 12 January 2024	(Ref: PM20906tIMj)
GPG Approval	: 23 February 2024	(Ref: 24012_IGb)

- **Corr.1 (June 2022)**

1 Origin for Change:

☑ Suggestion by IACS Member

2 Main Reason for Change:

To delete or replace the term “cable”, which is not related to the content of this UR, in Notes 1 and 3.

To take this opportunity, references to IMO instruments have been slightly modified, taking into account the latest Format according to IACS Procedures Volume 1 (Rev.16).

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None

4 History of Decisions Made:

Corr.1 of Rev.1 of UR E21 was discussed by correspondence and reached a unanimous agreement of Machinery Panel Members.

5 Other Resolutions Changes:

None

6 Any hinderance to MASS, including any other new technologies:

None

7 Dates:

Original Proposal	: 15 July 2021	(Ref: PM20906mIMa)
Panel Approval	: 03 June 2022	(Ref: PM20906mIMf)
GPG Approval	: 25 June 2022	(Ref: 20206cIGh)

- **Rev.1 (Feb 2021)**

1 Origin of Change:

☑ Other (Update to comply with the required format when industry standards are referred to)

2 Main Reason for Change:

There was a need to update this UR to comply with the following format when industry standards are referred to:

[Standard Designation], [version/revision, if applicable], [year of publication] (examples: API Spec 2F, 6th Edition, 1997; ISO 4624, 2002), where [version/revision, if applicable] and/or [year of publication] are decided by IACS and are not necessarily to be the current/latest version.

To take this opportunity, references to IMO instruments have been specified in the following format based upon confirmation of amendments up to the latest one:

regulation/paragraph x.x.x of SOLAS Chapter X/MARPOL Annex X/the XXX Code, as amended by IMO resolutions up to MSC.xx(xx)/MEPC.xx(xx)

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None

4 History of Decisions Made:

None

5 Other Resolutions Changes:

None

6 Any hinderance to MASS, including any other new technologies:

None

7 Dates:

Original Proposal	: 28 October 2019	(Ref: PM18939_IMd)
Panel Approval	: 09 November 2020	(Ref: PM20906_IMf)
GPG Approval	: 12 February 2021	(Ref: 20206cIGb)

Technical Background Document
UR E21 (New, August 2005)

IACS WP/EL Task 53

Unified requirements for the use of Uninterruptible Power Supply (UPS) units as alternative and/or transitional sources of electrical power in lieu of centralized arrangements.

Objective and scope:
To formulate an IACS requirement for the acceptance of the use of uninterruptible Power Supply (UPS) units as alternative and/or transitional sources of electrical power in lieu of centralized arrangements.

Source of proposed requirements.
SOLAS Ch. II-1 / 42 and 43
SOLAS Ch. II-1 / 42.2.3 or 43.2.4.
IEC 62040

Points of discussion
A increasing number of items of SCADA equipment and alike, are now low power and voltage as the result of advanced technology. Because of the difficulty of providing such equipment with an alternative/emergency source of power, where required, at low voltage from a central source without prohibitive voltage loss and because of the convenience and design advantages of using a UPS unit, the use UPS units has increased dramatically.

UPS units are also now being proposed, fitted and being accepted as an alternative to supplying emergency electrical equipment from the transitional source of electrical power as required by SOLAS. Whilst such arrangements do not meet the wording of SOLAS they meet and in some cases exceed the intent.

The purpose of the UR is to clarify the acceptable arrangements and to propose to IMO amendments considered necessary to the applicable SOLAS requirements

During the XXVI WP/EL Meeting it was decided to make some definitions concerning with UPS type and also:

To specify a minimum UPS capacity subjected to survey
To specify a battery charger capacity
To place the definitions given in the footnote up into beginning of the document

Taking into account the aforesaid WP/EL developed this Unified Requirement, which was agreed by WG and forwarded to GPG for consideration attached to the 34rd WP/EL Progress Report.

Submitted by WP/EL Chair
31/01/2005

Technical Background (TB) document for UR E21 (Rev.1 Feb 2021)

1. Scope and objectives

UR E21 (Original version) does not reflect the agreed format for referencing the IEC standards. Rev.1 has been developed to comply with the agreed format.

2. Engineering background for technical basis and rationale

A) Format for references to Industry standards

Format:
[Standard Designation], [version/revision, if applicable], [year of publication] (examples: API Spec 2F, 6th Edition, 1997; ISO 4624, 2002), where [version/revision, if applicable] and/or [year of publication] are decided by IACS and are not necessarily to be the current/latest version.

B) Format for references to IMO instruments (where the number of amendments is large)

Format:
regulation/paragraph x.x.x of SOLAS Chapter X/MARPOL Annex X/the XXX Code, as amended by IMO resolutions up to MSC.xx(xx)/MEPC.xx(xx)

3. Source/derivation of the proposed IACS Resolution

N/A

4. Summary of Changes intended for the revised Resolution

UR E21 has been updated to specify the revision/version of the IEC standards as follows:

IEC standards	Replaced by
IEC 62040:1999	IEC 62040-3:2011
IEC 62040	IEC 62040-3:2011 (for definition)
IEC 62040	IEC 62040 IEC 62040-1:2017, IEC 62040-2:2016, IEC 62040-3:2011, IEC 62040-4:2013 and/or IEC 62040-5-3:2016, as applicable (for requirements)

5. Points of discussions or possible discussions

None

6. Attachments if any

None

Technical Background (TB) document for UR E21 (Rev.2 Feb. 2024)

1. Scope and objectives

This revision revisits the application of UPS in services (mandatory or voluntary) and addresses the location and duration requirements depending on the services (e.g. emergency services, essential services) in consideration with the base standards (IEC 62040 series)

2. Engineering background for technical basis and rationale

The requirements for UPS need to be extended to other cases than alternative and transitional power for emergency services, taking into account that UPS has been widely used for continuous and uninterruptible services in the application of essential services like DP control system, AMS, BMS, etc.

2a. Specification of the data utilised in the development/revision of the proposed IACS Resolution, if any

N/A.

3. Source/derivation of the proposed IACS Resolution

SOLAS II-1/42 and SOLAS II-1/43,
FSS Code Chapter 9, 2.2.2 to 2.2.4,
MSC.1/Circ.1580, 3.4.1.8,
IACS UI SC134,
IEC 62040 series.

4. Summary of Changes intended for the revised Resolution:

A. **The subject of UR E21**: now that the requirements will also be applicable to other cases than emergency services, the phrase "as alternative and/or transitional power" has been deleted in wary of confusion or conflict.

B. **Scope/Application**: the wording "Scope" is rephrased as "Application", in consideration of revision on applicability whether mandatory (1.1 strict application) or voluntary (1.2 case by case application at the discretion of Society). Essential services as per UI SC134 and FSS Code Ch. 9, 2.2.2 to 2.2.4 are added.

C. **Definitions**: UPS definition and topologies, with supportive figures and associated terminologies, are updated in view of the latest IEC 62040-3.

D. **External bypass**: requirements for external bypass are revisited and clarified.

5. Points of discussions or possible discussions

In the last item of para. 3.5 of UR E21 rev.2, "any other fault and abnormal conditions of the UPS unit" should indicate~~s~~ para. 4.2 of IEC 62040-1:2017.

However, para. 4.2 of IEC 62040-1:2017 refers to the withdrawn IEC62477-1:2012 which is a standard for power electric converters. In the light of above, it is understood that this requirement should be applied on a case-by-case basis, and it is agreed to add “as applicable” at the end of the requirement.

The duration of UPS performance is briefly mentioned in para. 5.1 which is only applicable to emergency services, and thus it was suggested to give guidance in the UR for other services. This suggestion got the simple majority support but did not achieve qualified majority. For the reference of readers, the proposed guidance is given here.

5.1 The output power is to be maintained for the duration required for the connected equipment and in consideration of paragraph 1, as follows, for instance but not limited to:

> *.1 alternative power UPS: for a period of 36h or 18h as stated in SOLAS II-1/42 or SOLAS II-1/43,*
>
> *.2 transitional power UPS: for half an hour (30minutes) as stated in SOLAS II-1/42 or SOLAS II-1/43,*
>
> *.3 supplemental power UPS: for minimum 30minutes as stated in FSS Code Chapter 9, 2.2.4,*
>
> *.4 DP control system UPS: for minimum 30minutes as stated in MSC.1/Circ.1580, paragraph 3.4.1.8, and*
>
> *.5 essential services UPS: for minimum 30minutes when used for essential services as defined in IACS UI SC134.*

The SuP comments on Testing requirement of 6.2 was discussed among MP. While there was suggestion to further revise the testing requirement, but it was acknowledged that the comments are not included in the scope of this revision and it is impractical to thoroughly investigate the testing requirement and improve at this stage.

There was another comment from SuP on application of the UR whether mandatory or voluntary, and it was confirmed that voluntary means at the discretion of the Society, i.e. 1.1 is mandatory and 1.2 is up to the decision of each Society.

The SuP comments and MP responses are recorded as follow for future reference and possible update at the next revision process.

Item 4	**Survey Panel members comments**
4.1	**SuP XXX comment**
4.1.1	Section 3.5. Section is header is Design / Construction. Lends the reader to infer that the testing is only at the manufacturer. Consider clarifying if testing is also necessary at the initial and annual machinery surveys on only manufacture.
MP1	For the design and construction part, the wording is existing; in 3.5 the expression “normally attended location” has been replaced by the expression

	"continuously manned station(s)". MP1 understands that part 3 relates to tests at the manufacturer, while the requirements of 3.5 can be verified during the initial survey
MP2	The proposed comments are acceptable to MP2
MP3	It's suggested to make it clear that functional tests will be carried out at preliminary inspection and annual survey, and other required tests are all product tests performed in the workshop or factory
MP4	MP4 is of the view that Section 3.5.(header is Design / Construction) is related to design requirement and not directly related to testing at the manufacturer
MP5	MP5 does not understand the comment as section 3.5 is not related to testing
MP6	MP6 can accept all three comments made.
MP7	MP7 has no objection to the SuP ABS comments.
MP8	MP8 understands that it is basically required for testing at the manufacturer, but as it is also part of "6. Testing and survey" (first bullet of paragraph 6.2 is updated as "functionality, including operation of alarms in paragraph 3.5") and thus it is to be verified after installation on board.
Proposed Action	The comment is beyond the scope of this revision work and impractical to complete at the very final stage. Section 3.5 will be retained as is.
4.1.2	Section 6.1 Section is a bit ambiguous, suggest additional clarity as to surveyed at "manufacturing and testing". Unclear which testing (manufacture only, initial onboard, annually).
MP1	MP1 suggests the following addition in underlined font: 6.1 UPS units of 50 kVA and over are to be surveyed by the Society during manufacturing and testing<u>, in accordance with 6.2</u>.
MP2	The proposed comments are acceptable to MP2
MP3	It's suggested to make it clear that functional tests will be carried out at preliminary inspection and annual survey, and other required tests are all product tests performed in the workshop or factory
MP4	MP4 share comment
MP5	MP5 agrees with the SuP comment
MP6	MP6 can accept all three comments made.
MP7	MP7 has no objection to the SuP comments.
MP8	MP8 understands that it is the requirement for witness of surveyor, i.e. in case of UPS of 50kVA and over, it is to be witnessed by the Surveyor.
Proposed Action	The comment is beyond the scope of this revision work and impractical to complete at the very final stage. 6.1 will be updated as suggested by MP1.
4.1.3	Section 6.2 Suggest that standards / criteria are noted for surveyors to apply during testing. Temperature rise (what is acceptable criteria) Ventilation (appropriate flow based on KVA?) Batter Capacity, not clear if this is discharging rate, etc..
MP1	With regard to temperature rise, MP1 notes that IEC 62040-1 refers to the temperature rise tests of IEC 62477-1 , which in 5.2.3.10 for type tests reads: The test is intended to ensure that parts and accessible surfaces of the PECS (power electronic converter systems) do not exceed the temperature limits specified in 4.6.4 and the component manufacturer's temperature limits of safety-relevant parts. With regard to battery and ventilation rate, MP1 understands that section 5.4.2 "Battery" of IEC 62040-3 applies, which states in 5.4.2.1 reads A battery

	intended to serve as an energy storage device for a UPS complying with this document shall comply with the IEC 62040-1 requirements for location, ventilation, marking and protection of a battery (Annex CC of IEC 62040-1 contains guidance similar to that one of UR E18). In this regard MP1 understands that temperature rise type test and battery/ventilation may relate to design and construction and not to testing.
MP2	The proposed comments are acceptable to MP2
MP3	It's suggested to make it clear that functional tests will be carried out at preliminary inspection and annual survey, and other required tests are all product tests performed in the workshop or factory
MP4	MP4 share comment
MP5	MP5 agrees with the SuP comment and would suggest referring to relevant tests in IEC 62040-3. It may in this respect be necessary to reconsider the required tests
MP6	MP6 can accept all three comments made.
MP7	The SuP commented on the test items on 6.2 of draft UR E21. In this regard, MP7 suggests deleting all items that can be changeable depending on design and arrangement excluding the first item «Functionality, (...) in paragraph 3.5». MP7 has no objection to the other SuP comments on 6.3 of draft UR E21.
MP8	MP8 wishes to remind that the said items (temperature rise, ventilation rate, battery capacity) are not the scope of this revision, and it is understood that each Society has applied this requirement at its own right so far.
Proposed Action	Please note that the said items (temperature rise, ventilation rate, battery capacity) are not the scope of this revision, and it is understood that each Society has applied this requirement at its own right so far. Also it is impractical to thoroughly review the testing requirement and revise at this stage. 6.2 will be retained as is and HF&TB be updated describing the comment and discussion.
4.2	**SuP XXX comment** See attached file Att.3
MP1	In light of the above, MP1 agrees with the SuP member comment for removal of the three items under testing. The last two suggestions for the addition of tests are not considered necessary at this stage.
MP2	MP2 prefers the current wording of the UR.
MP3	it's suggested to identify type approval tests and factory acceptance tests following the way as in Table 1 of UR E13
MP4	MP4 share comments
MP5	MP5 agrees in general with the SuP comments and would suggest a review of the tests for alignment with, or reference to, the tests in IEC 62040-3, which also specifies whether the tests are type tests or routine tests.
MP6	MP6 does not accept the comments made within Att.3 and suggests that the UR remains as worded.
MP7	The SuP commented on the test items on 6.2 of draft UR E21. In this regard, MP7 suggests deleting all items that can be changeable depending on design and arrangement excluding the first item «Functionality, (...) in paragraph 3.5». MP7 has no objection to the other SuP comments on 6.3 of draft UR E21.
MP8	MP8 wishes to remind that the LR comments are not the scope of this revision, and it is understood that each Society has applied this requirement at its own right so far.
Proposed	See PA for 4.1.3

Action	
4.3	**SuP XXX comment**
4.3.1	It is our opinion that the title should not be amended as proposed; the UPS remains an alternative and or transitional source of power and the system to which the UPS is applied are expected to return to be feeded by the main or the emergency souce of power. In case the new paragraph 1.1.3 of UR E21 applies then the definition of Uninterruptible Power System (UPS) should not consider the failuire of the of the AC input power.
MP1	SuP member comment is not very clear to us. In this regard we can accept the revised title**.**
MP2	The proposed comment is not acceptable to MP2
MP3	MP3 does not agree to the comment, because UPS in this UR is an emergency source of power not a transitional one
MP4	MP4 does not share SuP comment
MP5	MP5 does not agree with the SuP comment. The terms “alternative” and “transitional” are used in relation to power supply requirements for emergency services in SOLAS regulations 42 and 43 and are not representative for power supplies to essential services required during a main power blackout condition.
MP6	MP6 does not accept comment made.
MP7	MP7 prefers the updated title.
MP8	MP8 does not share the SuP member opinion.
Proposed Action	The comment does not achieve support. Title is retained.
4.3.2	It is not clear the intention expressed under paragraph 2 of the HF “Main Reason for Change” that reads inter alia: ...Omissis....*dividing the application whether mandatory <u>or voluntary</u>*.... Omissis Being an UR, it should be mandatory and voluntary application should be left to the policy of each individual Class Society as specified in UR E21 paragraph 1.2.; the latter could be deleted.
MP1	MP1 feels that the expression can be retained, however if the word “voluntary” creates confusion, then “optional” can be a replacement, while the expression “dividing the application whether” can be deleted together with the expression “strict application”.
MP2	The proposed comment is acceptable to MP2
MP3	MP3 agrees to the comment, and further suggests to delete Paragraph 1.2 of UR E21
MP4	MP4 share SuP comment
MP5	MP5 agrees with the SuP comment.
MP6	MP6 can accept the comment made.
MP7	MP7 agrees to the SuP comment for HF. And if accepted, part 1 of TB file will be updated too.
MP8	MP8 understands that each member can exercise its own discretion for voluntary items only which is already said in paragraph 1.2.
Proposed Action	Please note that UPS has been widely used for other services than 1.1 and each member can exercise its own discretion for voluntary items. HF&TB is updated as per MP7 pointed out and 1.2 will be retained as is.

As to the location of UPS units for other services than emergency supply, there was a proposal to further elaborate paragraph 4.1, such as "The UPS unit for other services may be installed near to the load equipment", "Location of UPS unit for other services is at the discretion of the Society", "The UPS unit for other services may be installed near to the load equipment, or in other locations at the discretion of the Society", but did not achieve the majority support.

Paragraph 1.1.4 was rephrased at the final moment. The intent of the paragraph is to describe the supplemental power supply which prevents momentary loss of power and permits the continued operation and is capable of operating all connected visual and audible fire alarm for a period of 30 minutes as required by FSS Code Chapter 9, 2.2.2 to 2.2.4.

UR E22 "Computer-based systems"

Summary

This UR provides requirements for Computer-based Systems. This revision is intended to improve and clarify the requirements for computer-based system during design, construction, commissioning and maintenance, including better clarification of the system integrator. Objective of this revision is to ensure that UR E22 provides a minimum set of requirements to suppliers and system integrators of software-based automation that ensures that both individual systems and the total integrated functionality is of high quality and safe for use.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev.3 (June 2023)	13 June 2023	1 July 2024
Rev.2 (June 2016)	10 June 2016	1 July 2017
Rev.1 (Sept 2010)	02 Sept 2010	1 Jan 2012
Corr.1 (Oct 2007)	05 Oct 2007	-
New (Dec 2006)	17 Dec 2006	1 Jan 2008

- **Rev.3 (June 2023)**

1 Origin for Change:

Other (Specify: A general desire to update E22 to bring it in line with the current technologies and methods for development of computer-based systems. Concerns related to the role of the system integrator)

2 Main Reason for Change:

During the evaluation at the panel meeting (April 1st, 2020) of the current UR E22 in general, and with specific focus on DNV reservation to the current UR, all societies agreed that at an update of the UR is necessary.

a. Focus on the activities required for development, installation and updates of cyber physical systems and clarify the requirements from this holistic view.
b. Clarify the role division between the systems integrator and the supplier of the individual system.
c. Consider best practices from other industries than the maritime industry and put emphasis on the different verification methods/steps (including use of simulators)
d. Change management for the system (hardware, software and parameters)
e. Survey requirements

3 List of non-IACS Member Classification Societies contributing through the TC Forum and/or participating in IACS Working Group:

IACS Joint working group members that contributed with review comments:

4 History of Decisions Made:

Forms A and 1 agreed by GPG under 20063aIGp dated 05 May 2023.

5 Other Resolutions Changes:

- IACS UR E26 Cyber resilience of ships
- IACS UR E27 Cyber resilience of on-board systems and equipment

These two URs where development in parallel with the update to version 3, and they are referenced from E22 as normative standards.

6 Any hinderance to MASS, including any other new technologies:

None.

7 Dates:

Original Proposal:	14 June 2021	(Made by: Cyber Systems Panel)
Panel Approval:	22 May 2023	(Ref: PC20005_ICze)
GPG Approval:	13 June 2023	(Ref: 20063aIGr)

- **Rev.2 (June 2016)**

1 Origin for Change:

Other *(Specify: Concerns related to the increasing complexity and fragmentation of on-board systems and man-machine interfaces were raised by Industry)*

2 Main Reason for Change:

IACS council C69, Action Plan Item K-18 and EG/COSDI (Complex On-board Systems with Dependability Issues) propose the creation of a project team in order to modify IACS Unified requirement E22 focusing on:

a. dedicated software dependent systems installed onboard ships like Power Management Systems, Steering Control, Safety systems
b. service systems installed onboard specific ship types like dynamic positioning systems, lifting appliances
c. minimum elements to be taken into account in risk analysis including software items during the whole life cycle of system. This analysis should also take into account security aspect involved in use of software and data links
d. tests undertaken on software dependent systems during life cycle and intervention of different actors including Class Societies
e. list of reference documents and standards likely to be selected for these activities

3 List of non-IACS Member Classification Societies contributing through the TC Forum and/or participating in IACS Working Group:

None.

4 History of Decisions Made:

Forms A and 1 agreed by GPG under 14119_IGs dated 26 February 2015.

5 Other Resolutions Changes:

None.

6 Dates:

Original Proposal: 9 February 2015 Made by Machinery Panel Panel
Approval: 14 April 2015 (Ref: PM14917b)
GPG Approval: 10 June 2016 (Ref: 14119_IGw)

- **Rev.1 (Sept 2010)**

1 Origin of Change:

Suggestion by an IACS member

2 Main Reason for Change:

Suppliers are proposing wireless communication links in safety related class installations, including that for propulsion and steering arrangements. There is a need to address the possible development of requirements for short range wireless communications, for example using Bluetooth, and IEEE 802.11 (WiFi) protocols.

3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None.

4 History of Decisions Made:

The project team attempted to follow a holistic approach to the development of requirements by conducting a safety assessment of potential wireless technologies used in classed safety related application.

Relevant best practices applied by Member Societies and related industries and existing standards were considered. A variety of industry stakeholders were consulted to provide feedback that was acted upon.

UR E22 defines system categories for programmable electronic systems that have been used to differentiate wireless technology in different applications.

5 Other Resolutions Changes:

UR E10 (Rev.5 Dec 2006) "Test Specification for Type Approval" is under revision.

This revision will introduce additional requirements for the assessment of:

a. Electromagnetic field for equipment within the transmission range of the wireless data communication devices.
b. Radiated Emission of wireless data communication devices above 1GHz.

6 Dates:

Original Proposal: *October 2008 Made by the Machinery Panel*
Panel Approval: *June 2010*
GPG Approval: *02 September 2010 (Ref: 8672_IGe)*

- **Corr.1 (Oct 2007)**

Standard footnote for the explanation of the "contracted for construction" date added. (ref. 7546a)

No TB document available.

- **New (Dec 2006)**

Task No.31 of WP/EL.

See TB in Part B.

Part B. Technical Background

List of Technical Background (TB) documents for UR E22:

Annex 1 **TB for New (Dec 2006)**

See separate TB document in Annex 1.

Annex 2 **TB for Rev.1 (Sept 2010)**

See separate TB document in Annex 2.

See separate TB document in Annex 4.

Note: *There is no separate Technical Background (TB) document available for Corr.1 (Oct 2007).*

UR E22 UNIFIED RQUIREMENTS FOR THE ON BOARD USE AND APPLICATION OF PROGRAMMABLE ELECTRONIC SYSTEMS

Technical Background

1. Scope and objectives

UR E22 complements the existing UR E10 for hardware test standards with requirements for software. Reliable operation of programmable electronic systems and consequently of the systems functionality and safety requires suitable software. The new requirements for the assessment of software relate to quality assurance, testing at module and system level, and to integration and failure simulation.

UR E22 relates to the "GUIDELINES FOR THE ONBOARD APPLICATION AND USE OF COMPUTERS" as prepared by IACS and the NMD at the request of IMO. At the 39th session of the Sub-Committee on Ship Design and Equipment Norway and IACS were invited to prepare "GUIDELINES FOR THE ONBOARD APPLICATION AND USE OF COMPUTERS". The IACS/NMD proposal was adopted as a MSC/Circ. 891 dated 21.12.1998. These Guidelines have been developed to provide an international standard for design, approval and testing of such systems and are additional to the regulation of the SOLAS Convention.

2. Source/ derivation of requirements

Related international standard: IEC 60092-504

Technical Background for UR E22 (Rev.1, Sept. 2010)

1. Scope and objectives

To consider the suitability of wireless technologies in Classed installations and to introduce suitable Unified Requirements that support an effective unified approach to the assessment of wireless technologies where permitted by Member Societies.

- To assess where wireless technologies are suitable for use in classed installations.
- To development a Unified Requirement that will allow a unified assessment approach to the use of wireless technology onboard ships that:
  - If necessary, states clearly any restriction of use for safety related applications with reasoning for restriction;
  - covers both performance, testing and assessment requirements;
  - addresses relevant hazards to contribute to overall safety;
  - reflects current technologies and best practice;
  - allows for application to future technology by considering the services affected; and
  - ensures consistency with UR E10, Test Specification for Type Approval.

2. Engineering background for technical basis and rationale

There is a need to address the possible development of requirements for short range wireless communications typically using Bluetooth, and IEEE 802.11 (WiFi) protocols. This is becoming an issue as suppliers are providing such communication links as part of their products in classed installations.

3. Source/derivation of the proposed IACS Resolution

Developed by IACS Project Team.

4. Summary of Changes intended for the revised Resolution:

The following section of UR E22 has been updated to give consideration of wireless technologies.

Section 2. Requirements applicable to programmable electronic systems
Section 3. Documents to be submitted
Section 4. Tests and Evidence
Appendix 1, Section 7. On-board tests

The following text has either been changed or added.

Rationale for new 2.1.2:
To provide for consideration of alternative design arrangements, potentially including the use of wireless data communications links, in safety critical applications which do not conventionally comply with the requirements of UR E22.

Rationale for new 2.3.6:

To make clear that data link communications are to be arranged to cause systems to 'fail to safe' upon loss of data communications.

Rationale for new 2.3.7:
To make clear that data link communications capacity should avoid the possible effects of data link congestion and provide adequate data transmission times as required by the application. This requirement aligns with IEC 60092-504, sub-Clause 10.6.3.

Rationale for new Subsection 2.4 Additional requirements for wireless data links: Additional requirements governing the use of wireless data links in applications covered by Classification are grouped together to assist users.

Rationale for new 2.4.1:
Through application of a holistic approach to the development of requirements, and use of the existing UR E22 categorising of programmable electronic systems based on the application, it was observed that:

- the likelihood of failure of a category III system leading to an accident with catastrophic severity needs to be minimised. As such, the use of unconventional technology for such applications will only be permitted exceptionally in cases where evidence can be presented that demonstrates acceptable system performance to the satisfaction of the Society;
- failure of a category II system may lead to accidents and Classification requirements are to be provided to assist in reducing the likelihood of failure as a consequence of design, construction or installation;
- the failure of category I systems may be tolerated by mitigation other than classification requirements. The requirements may optionally be used for category 1 systems.

Rationale for new 2.4.2:
Recognising that wireless technology may be subject to denial of service, either intentionally or unintentionally, an alternative means of control for essential services independent of a wireless data communication link is to be provided so that systems are designed and arranged such that essential services provision is not dependant on a wireless data communication link.

Rationale for new 2.4.3:
Requirements are introduced to address attributes considered to be specifically required for wireless data communication links in Category II system applications. It is considered appropriate to apply proven internationally recognised protocols to achieve compliance under most circumstances and it is recognised that application of alternative protocols will likely necessitate closer scrutiny of evidence provided to the Society to verify compliance.

Rationale for new 2.4.3(a):
Data integrity is considered essential for the reliability of Category II system applications.

Rationale for new 2.4.3(b):
To address security, systems designs are to be defined and limited in terms of the-------- total planned devices (including planned devices that are not always present and/or connected, e.g. planned arrangements for manufacturer representative access). Device authentication is to be utilised to prevent connection of devices that that are not part of the system design.

Rationale for new 2.4.3(c) and (d):
Measures considered necessary to address security.

Rationale for new 2.4.4:
It is recognised that frequency spectrum usage and power levels should be restricted to that permitted internationally and, where such exist, the requirements of the Flag State to ensure the wireless data communication link operation will be allowed.

The note recognises that the actual operation and control of systems and the areas visited globally by a ship are not addressed by Classification, noting that different local restrictions globally could potentially prove difficult for ship operators in practice in cases. In such cases, ship operators are responsible for assessment in advance so that safe system operation is achieved, noting the requirements of 2.4.2.

Rationale for new 3.4:
Provision of evidence of compliance with UR E22 for systems incorporating wireless data communication.

Rationale for new Table III entry:
On board testing under operational conditions to demonstrate system operation as planned is considered necessary to verify compliance and safe operation.

Rationale for new Appendix I, 7.3:
Specification of testing to be conducted. This includes the need to consider different expected operating conditions onboard. It should be recognised that testing may need to be conducted to demonstrate that systems coexist without mutual interference under expected operating conditions

5. Points of discussions or possible discussions

Short-range wireless data communication technologies for systems covered by Classification are not yet considered to have a significant record of service experience for reference.

Specifying of 'wired' back-ups for wireless data communication links is not considered a pragmatic option.

Wireless technology should be as safe as a 'wired' equivalent so far as is reasonable and practicable.

The introduction of wireless technology to applications covered by Classification introduces a number of concerns including the possibility of unauthorised access and manipulation of systems and 'jamming' as a deliberate act or as a consequence of EM interference

Category III applications dependant on wireless data communication to operate should only be considered at this time if a body of evidence demonstrating acceptable performance to the satisfaction of the Society is prepared. This may exclude the use of wireless technology in an application due to cost and availability of technology.

Some countries and locations (e.g. ports) have different restrictions from those internationally agreed on frequency spectrum usage and transmission power levels. Some states may also enforce legislation related to accessibility of transmitted data for state security purposes. Ship operators should consider and adapt to these effects.
Classification approval will be based upon the whole system, including wireless technology, operating as presented.

It is recognised that the use of wireless systems in non-classed and category I systems may cause interference with other classed systems, immunity requirements have been introduced accordingly.

Mitigation of Safety, health and environmental risks is provided for with the use of internationally accepted power levels and frequencies.

None.

Technical Background (TB) document for UR E22 (Rev.2 June 2016)

1. Scope and objectives

Updating of UR E22 focused on introducing top down analysis of systems including programmable code and life cycle approach of these systems.
Several work items were considered in order to prepare drafting of modified UR E22:

Work Item 1: Scope of requirement

- definition of dedicated software dependent systems installed onboard ships which would need to be covered by mandatory requirements (like Power Management Systems, Steering Control, Safety systems…).
- definition of service systems installed onboard specific types of ships which would need to be covered by additional requirements (like dynamic positioning systems, lifting appliances…).

Work Item 2: Risk analysis minimum requirements

Definition of minimum elements to be taken into account in risk analysis including software items during the whole life cycle of system, including security aspect involved in use of software and data links.

Work Item 3: Testing requirements

Definition of minimum tests that shall be undertaken on software dependent systems during life cycle and intervention of different actors including Class Societies.

Work item 4: External references list

Definition of a list of external references that can be used for such activities.

2. Engineering background for technical basis and rationale

Taking into account life cycle approach at the level of a system as described in various dedicated standards commonly used (as IEC 61508 "Functional safety of electrical/electronic/programmable electronic safety-related systems", IEC/ISO 31010 "Risk Management - Risk assessments techniques") in specification, design and verification of programmable systems seemed necessary in order to promote a global approach based on a risk analysis of programmable systems.

3. Source/derivation of the proposed IACS Resolution

- IEC 61508: Functional safety of electrical/electronic/programmable electronic safety-related systems
- ISO/IEC 12207: Systems and software engineering - Software life cycle processes

- ISO 9001:2008 Quality Management Systems - Requirements
- ISO/IEC 90003: Software engineering - Guidelines for the application of ISO 9001:2008 to computer software
- IEC 60092-504: Electrical installations in ships - Part 504: Special features - Control and instrumentation
- ISO/IEC 25000 - Systems and software engineering - Systems and software Quality Requirements and Evaluation (SQuaRE) - Guide to SQuaRE
- ISO/IEC 25041 - Systems and software engineering - Systems and software Quality Requirements and Evaluation (SQuaRE) - Evaluation guide for developers, acquirers and independent evaluators
- IEC 61511: Functional safety - Safety instrumented systems for the process industry sector
- ISO/IEC 15288: Systems and software engineering - system life cycle process

4. Summary of Changes intended for the revised Resolution:

The following section of UR E22 will provide new requirements compared to previous revision of UR E22:

- Section 1.4 for references has been created and some standards dealing in particular with software lifecycle added.
- Section 2 has been created in order to provide definitions for stakeholders and system hierarchy.
- Section 2.3 is showing examples for category II and III systems.
- Section 2.4 is defining Simulation Tests.
- Section 3.1 is providing requirements for life cycle approach.
- Section 3.2 is providing requirements for limited approval of sub-systems and programmable devices not integrated yet into a system.
- Section 3.3 is dealing with modification during operation. The notion of software registry was introduced in order to track versions of software and security scans during software updating.
- Section 3.4 is providing minimum requirements for system security related to software.
- Section 4 is referring to UR E10 about requirements regarding environment.
- Section 5 is dealing with wireless data links minimum requirements. It is considered risk analysis will cover risks connected to data links inside computer-based systems.

5. Points of discussions or possible discussions

Paragraph 1.3 "References": Content of this paragraph was debated. It has been clearly mentioned that the use of these standards is not compulsory, but just given as a possibility. The extent of the list was also questioned: in some existing Class Rules dealing with software, the list of references is much more extensive. This list might be updated in the future, the texts listed now seemed to be a good compromise in order to cover the topics apprehended in this Unified Requirement and having together a limited list of references.

Paragraph 2.1 "Stakeholders": The definitions mentioned here have the ambition to be limited in number (Owner, System Integrator, and Supplier) and to define what the stakeholders are doing. It was also included how these responsibilities could be modulated during the different phases of the project and according to the level(s) of integration required by the project.

Paragraph 3.1.2.1 "Risk assessment of system": reference text to be used regarding risk assessment was debated, it was agreed to introduce IEC/ISO 31010 in order to determine the method of risk management. Possibility of omission of this risk assessment was also debated and made possible in case of such following justifications for a computer-based system:

- How the risks are known
- The equivalence of the context of use of the current computer-based system and the computer-based system initially used to determine the risks
- The adequacy of existing control measures in the current context of use.

An opinion was expressed that a requirement for a risk assessment had the potential to be unclear in terms of the content, scope, level of detail, methodology etc. and thus a general requirement for a risk assessment without further guidance would be inappropriate. In particular, the following rationale was provided:

> *"A risk assessment is in general not part of maritime new-building projects today, and when such assessment is not part of the general process/machinery/system design, a risk assessment of the control system may be considered a bit out of context. Further, if a risk assessment is required (both from system suppliers and system integrators), the method, scope/coverage and the criteria for the assessment must be defined clearly to enable a consistent practice in the industry. A risk assessment may be very relevant for certain systems in certain types of vessels, but for a traditional bulk carrier with proven-in-use systems, it may be unnecessary. As an alternative to the general requirement for a risk assessment, maybe a failure mode analysis for integrated systems could be a more achievable measure."*

Paragraphs 3.1.3 and 3.1.5: The way the "integration" issue was dealt with has been evolving during the elaboration of the modified UR E22. At the beginning, COSDI group outputs were mentioning the creation of an additional Unified Requirement dealing with integration. After GPG stated not to go through this achievement, it was decided to include what was integration of software inside the system in itself (Paragraph 3.1.3) and also a more global integration of the computer-based systems with other systems inside the ship (Paragraph 3.1.5).

Paragraph 3.2 "Limited approval": The situation of programmable devices not being specifically assigned to a computer-based system in particular but that could be tested on a limited scope was debated. It was decided to provide them with a "limited approval".

Paragraphs 3.3 and 3.4: "Security" aspects were included in UR E22 as it seemed to many Class Societies to be an important item to implement and that traceability was together a way to keep reliability and security present during the system life cycle.
This is why the "Software Registry" was introduced in order to keep the

records of software revision and security checks.

Paragraph 5.2 "Specific requirements for wireless data links": maintaining these requirements inside UR E22 about Computer-based systems about wireless data links was debated.

6. Attachments if any

None.

Technical Background (TB) document for UR E22 (Rev.3 June 2023)

1. Scope and objectives

Evolution of UR E22 focused on tidying up the requirements described in the document and to clarify the responsibilities of the different roles.

Several work items were considered to prepare drafting of modified UR E22:

Work Item 1: Restructuring of the existing information (requirements)
A detailed review of E22 V2 revealed that the document structure in some cases made it hard to distinguish between the different process steps and also some inconsistencies and contradictions. The document structure was updated to be based on a process structure with further breakdown into the responsibilities of the different roles. Also the class societies verification and survey activities have been made clearer by describing this per activity requirement.

Work Item 2: The process of defining a system's category
The initial plan was to make a specific mapping between different systems and their category, but after lengthy discussion both in the PT and the cyber panel (CP) it was decided that this is not possible, and that a system's category can only be correctly defined in the context of its application in a specific vessel.

Work Item 3: Differentiation of the system categories (CAT I, CAT II, CAT III)
The desire to make more distinct differentiation to the requirements for the different categories ended up with the clarification that there are no mandatory requirements on category 1 systems, and that the process requirements on category II and Category II systems should be identical because a system that is defined as category II on a specific vessel, may be defined as category III in another vessel. It was still opted to keep the category II and III separate, as there are technical requirements that differ between them.

Work Item 4: The responsibilities of the systems integrator
The role of the systems integrator has been clarified and strengthened by the addition of explicit requirements on activities and artifacts. As default of the Yard and the Owner shall take on the role of systems integrator unless another organization or person is explicitly appointed.

Work item 5: Management of change
Management of change is a process that spans throughout the whole lifecycle of a vessel and its systems, in order to reflect this without having to repeat a number of activity descriptions several times, the management of change has been described in a separate section in the UR (paragraph 6). The described management of change process is a simple high-level process inspired by several standards. It may be implemented using several specific standards, methods, and tools.

Work item 6: Resolving member's reservations towards UR E22 V2
Panel members had three reservations towards UR E22 Revision 2. In order to resolve these, the following steps where implemented:

1) The “quality plan” has changed from being mandatory to be submitted on request of the Class society. Alternatively, the quality plan may be inspected at a relevant test activity witnessed by the class society (FAT/SAT/SOST).
2) The “risk assessment” for each system has changed from being mandatory to be provided upon request of the class society.
3) The requirement on the owner to maintain a “software registry” during operation has been changed to require a change record to be kept up to date.

2. Engineering background for technical basis and rationale

Having evaluated the current reference list in E22 the Project team (PT) found that the listed standards still are valid, and that only a few additions where needed for e.g. cyber security. The reference list has however been split into a normative and an informative section.

2a. Specification of the data utilised in the development/revision of the proposed IACS Resolution, if any

None.

3. Source/derivation of the proposed IACS Resolution

Developed by IACS Project Team.

4. Summary of Changes intended for the revised Resolution:

Restructuring:
The document has been restructured to better communicate the requirements of the different roles involved. Most of the requirements are connected to the process of creating a computer-based system while a few technical requirements are still present. These technical requirements have been organised into a separate paragraph.

The structure of the document is now as follows:

- Paragraph 1.3 for references has been divided into a normative and an informative part and some IACS URs dealing with cyber security have been added along with a standard for automatic reporting on software status.
- Paragraph 2 clarifies how systems and components are to be approved
- Paragraph 3 gives the definition of the system categories and some examples of typical systems for the different categories
- Paragraph 4 gives the requirements on the development and delivery of computer-based systems
- Paragraph 5 gives the requirements on the maintenance of computer-based systems
- Paragraph 6 gives an overview of the required management of change process
- Paragraph 7 gives the technical requirements in the systems

Mapping of paragraphs between revision 2 and revision 3:
Below is a mapping of how revision 2 has transformed into revision 3.

Revision 2 paragraph:	Revision 3 paragraph(s):	Comment:
Title	Title	The title of the UR E22 has been changed from “On Board Use and Application of Computer-based systems” to “Computer-based systems” to better reflect its content and scope
1. Introduction	1 Introduction	The introduction paragraph now contains the “terms and abbreviations” along with a new paragraph (1.4) which describes the structure of the UR. This is done to improve the usability of the UR.
1.1 Scope	1.1 Scope	The scope description has been shortened by removing some wording about “focus on functionality of the software and hardware” as the focus of E22 is on the system- and software-lifecycle process.
1.2 Exclusion	1.2 Exclusion	The text has been updated to describe in more general terms which systems that are not in scope of the UR. The scope itself has not changed, and the old text from revision 2 which references different SOLAS chapters is kept as a guidance note.
1.3 References	1.3.1, 1.3.2	- The reference list has been split into two: 1.3.1 Normative and 1.3.2 Informative standards - IACS URs for cyber security are added as Normative standards - The applicable revision has been added to each reference document

2. Definitions	1.5 Definition of abbreviations and terminology	The definitions paragraph has been included in the “introduction” paragraph and restructured into a “terms” part and an “abbreviations” part. The entries are listed in alphabetically order to make it easier to find a specific term. Some definitions have been rewritten in order to avoid that actual requirements are included in the definition text. The definition of the three categories has been moved to a separate paragraph.
2.1 Stakeholders	Removed	-
2.1.1 Owner	Included in 1.5.2 Terminology	-
2.1.2 System integrator	Included in 1.5.2 Terminology	The term has been changed to “systems integrator” in order to put emphasis on that several systems are being integrated into a “system of systems”
2.1.3 Supplier	Included in 1.5.2 Terminology	-
2.2 Objects	Removed	This was only a grouping of some terms
2.2.1 Object definitions	Removed	This was only a grouping of some terms
2.2.1.x Each defined term is a separate paragraph	Included in 1.5.2 Terminology	-

2.3 System categories	3.1 System category definitions	The definitions of category I and category II are unchanged. Category III has been slightly updated to also include systems which failure may cause "catastrophic situations". The introductory text and table heading have been updated to focus on that the is the effect of these system's failure which drives the classification. Also see the discussion in "paragraph 3.1 system category definitions" in part 4 below
2.4 Other terminology	Removed	This was only a grouping of some terms
2.4.x Each defined term is a separate paragraph	Included in 1.5.2 Terminology	-
3. requirements for software and supporting hardware	4 requirements on development and certification of computer-based systems	Most of the content of paragraph 3 in revision 2 is included in paragraph 4 in revision 4, but technical requirements on the systems have been moved to a separate paragraph 7
3.1 Life cycle approach	4.1.1 Life cycle approach with appropriate standards	This heading and the text directly under it have been reformulated to a separate requirement

3.1.1 Quality system	4.1.2 Quality system	In order to clarify requirements and make the document structure more consistent, the requirements on quality systems and the Society's follow-up of this has been consolidated into one paragraph. The requirements on the quality system have been made more explicit, better related to the activity requirements and are clearly defined in table-format.
3.1.1.1 Relevant procedures regarding responsibilities, system documentation, configuration management and competent staff.	4.1.2 Quality system	The requirements on quality systems and the Society's follow-up of this has been consolidated into paragraph 4.1.2
3.1.1.2 Relevant procedures regarding software lifecycle and associated hardware:	4.1.2 Quality system	The requirements on quality systems and the Society's follow-up of this has been consolidated into paragraph 4.1.2
3.1.1.3 Minimum requirements for approval of Quality system:	4.1.2 Quality system	The requirements on quality systems and the Society's follow-up of this has been consolidated into paragraph 4.1.2 Because both the system supplier and the systems integrator are required to follow a defined quality system, this paragraph is now placed under paragraph 4.1 General requirements
3.1.1.4 Quality Plan	4.2.1 and 4.3.2 Define and follow a quality plan	The paragraph has been split into two parts: one as a requirement on the system supplier, one on the systems integrator. The actual requirement to define and follow a quality plan has not changed

3.1.2 Design phase	4.2 Requirements on the system supplier *and* 4.3 Requirements on the systems integrator	The content has in general been split in two parts; one where the system supplier is responsible, and one where the systems integrator is responsible. Changes to the individual sub paragraphs are described below, and in general the responsibilities of the systems integrator have been clarified and somewhat increased.
3.1.2.1 Risk assessment of system	4.3.4 Risk assessment of the system	The requirement to do a risk analysis of the system is now only applicable if requested by the Society. The responsibility now lies on the systems integrator, while it earlier could be done either by the systems integrator or the system supplier. The reason for this change is that a system's category must be decided in the context of the vessel in question. The part about submitting a justification for not doing a risk analysis if "the associated risks are well understood" has been removed, because it is superfluous when the risk analysis shall only be submitted when requested by the Society.
3.1.2.2 Code production and testing	4.2.5 Software code creation, parameterization, and testing	The revision 2 text only describes the documentation to be submitted and only indirectly put other requirements on the system supplier. The requirement is rewritten to explicitly require the system supplier to perform certain activities and to document this.

3.1.3 Integration testing before installation on board	4.2.6 Internal system testing before FAT and 4.2.7 Factory acceptance testing (FAT) before installation on board	The revision 2 text requires that intra-system integration shall be performed, and then goes on to describe documentation requirements for FAT. The requirement has been rewritten and split into two paragraphs to reflect that this is in fact two different activities; one where the system supplier performs an internal test of the system to be delivered, and one FAT event where the Society approves the test-program and witness the test execution. For the internal testing (4.2.6) it is now specified that this activity shall take place before the FAT, and there is a more explicit list of which aspects of the system that shall be tested. Use of simulators and other test-tools are encouraged and shall be documented. Documentation of the internal testing shall be made available to the Society during the FAT or submitted upon request. For the FAT (4.2.7) It is now specified that the expectation is that this test is performed "…with the project specific software operating on the actual hardware components to be installed on board…", and that other solutions must be agreed with the Society. There is now an explicit requirement that test records with pass/fail

		results and software versions are documented. Some of the documentation requirements for the system have been moved to the activity “System description” (4.2.3), but the overall documentation requirements are generally unchanged.
3.1.4 Approval of programmable devices for Category II and III systems	2 Approval of systems and components	This paragraph has been rewritten to clarify the difference between “vessel-specific certifications” and “type approval of computer-based systems” based on the current practice of Class Societies
3.1.5 Final integration and on board testing	4.3.6 System acceptance test (SAT) onboard the vessel *and* 4.3.7 Testing of integrated systems on vessel-level	Most of the requirements in this paragraph are now included in “System acceptance test (SAT) onboard the vessel”. in addition it is now an explicit requirement that test records with pass/fail results and software versions are documented. In order to put more emphasis on the testing of whole functions across systems a separate “Testing of integrated systems on vessel-level” activity has been added. It is now explicitly stated that it is the systems integrator that is responsible for these tests. The requirement for the Society to approve test plans and witness the tests is mandatory for both test activities

3.2 Limited approval	Removed	The reason for removal of this paragraph was that it was not clear what the "limited approval" constituted. Instead, the mechanisms for approval of computer-based systems are described in paragraph 2
3.3 Modifications during operation	5 Requirements on maintenance of computer-based systems	The content has in general been split in three parts in order to clarify the responsibilities of the different roles; one where the system supplier is responsible, and one where the systems integrator is responsible and one where the owner is responsible
3.3.1 Responsibilities	5.1.1 Responsibilities (partly)	The requirement on the owner to define who shall act as systems integrator during operations is unchanged. The requirements regarding a software registry have been rewritten and moved to paragraph 6.11 because it describes one of many activities required by a defined "management of change" process
3.3.2 Change management	6 Management of change and 4.2.8 and 4.3.8 and 5.2.1 and 5.3.1	The description and requirements regarding change management is substantially extended and a management of change process based on industry good practices is now expected to be followed. The requirements for the change management process are described in paragraph 6, and other paragraphs require the individual roles to follow relevant parts of the described management of change process

3.4 System security	Removed	Replaced by reference to IACS UR E26 and E27 as normative standards
4. Requirements for hardware regarding environment	4.2.4 Environmental compliance of hardware components	The requirement is basically unchanged, but there is now a clarification that it is the responsibility of the system supplier to provide this information, and that the "Reference to Type approval certificate or other evidence of type testing" shall be submitted "for information" (not for approval) for category II and category III systems
5. Requirements for data links for Category II and III systems	7.2 Data links	The requirements on datalinks have been grouped together with other technical system requirements in a new paragraph named "7. Technical requirements on computer-based systems" The Society's verification of the technical requirements has been clarified
5.1 General requirements	7.2.1 General requirements for category II and III systems	-
5.1.x Each technical requirement is a described as a paragraph heading	7.2.1 bullet #1 through bullet #5	The requirements for datalinks are essentially unchanged except for a change to the requirement regarding "single failure" (rev. 2: 5.1.2) which has been spitted in two (rev. 3: 7.2.1 bullet#1 and 7.2.1 bullet#2) and reworded to focus on the "fail-to safe" principle and the need for local means to compensate for loss of remote control
5.2 Specific requirements for wireless data links	7.2.2 Specific requirements for wireless data links	The requirements regarding wireless data links have been slightly reorganized to achieve a better structure in the document, but the requirements have not changed.

5.2.1 Category III systems shall not use wireless data links unless specifically considered by the Class Society on the basis of an engineering analysis carried out in accordance with an International or National Standard acceptable to the Society.	7.2.2 bullet #1	-
5.2.2 Other categories of systems may use wireless data links with following requirements:	7.2.2 bullet #1	-
5.2.2.x Each technical requirement is a described as a paragraph heading	7.2.2 bullet #2 through bullet #5	-
Annex: Documents for Class Society and test attendance	Annex A, Annex B	The information in the previous Annex has been divided into two lists: Annex A which summarizes the documentation to be submitted to the Class Society, and Annex B which lists the activities the Class Society will be witnessing. The Annexes does not introduce any requirements, they only serve as a quick overview and summary of the requirements defined in the main part of the UR. For each of the items in the annexes there is a reference to the paragraph in which the requirement is defined and detailed.

Deleted paragraphs:

Some items have been removed as a part of the restructuring. These include:

- Paragraph 3.1.2.1 Risk assessment of system (partly): The part about submitting a "justification for the omission" of the risk analysis has been removed.
- Paragraph 3.2, Limited approval. The reason for removal of this paragraph was that it was not clear what the "limited approval" constituted. Instead, the mechanisms for approval of computer-based

systems are described in paragraph 2.
- Paragraph 3.4 system security. The IACS UR E26 Cyber resilience of ships and UR E27 Cyber resilience of on-board systems and equipment are both listed as Normative standards that shall be used for computer-based systems. The inclusion of these makes the description of system security in E22 superfluous, and it has thus been removed.

Added requirements:
Some items have been added because of the restructuring and evolution of E22, most noticeably:

4.3.3	Determining the category of the system in question
4.3.5	Define the vessel's system-architecture
4.3.6	Testing of integrated systems on vessel-level
5.	Requirements on maintenance of computer-based systems
7.1	Reporting of system and software identification and version

5. Points of discussions or possible discussions

Paragraph 3.1 "System category definitions": Despite hard work and long discussion, it was not possible for the PT to agree upon a definite mapping between a system name and a category. It turns out that the criticality of a specific system may differ from vessel to vessel, and that the determination of the category for a specific system thus must be done per vessel. Some may argue that this creates a challenge for suppliers that want to type approve their system before the vessel in question is known, but with the elimination of all requirements for CAT I systems and the fact that all process requirements are identical between CAT II and CAT III, this should not pose a big problem for the system suppliers.

Paragraph 3.2 "Class societies' scope": The lack of requirements on category I systems (except in special cases) lead to some discussions and review comments. It is however current practise for most class societies not to include these systems into the scope of the verification.

Paragraph 3.3.3 " Determining the category of the system in question": As a result of the discussion described in paragraph 3.1 above, the category of a system must be determined in the context of its installation onboard a specific vessel. In order to facilitate this, the categorization needs to be performed by the shipyard (which per default is the systems integrator during newbuilding) based on the category definitions in paragraph 3.1.
If the class society determines that there is a need to analyse or document the categorization, a documented risk-assessment may be requested (as described in paragraph 3.3.4).

Paragraph 4.3.5 "Define the vessel's system-architecture": There was some concerns that some yards may not easily be able to create the requested "system architecture" and that in some cases there might be some "buyer equipped systems" that are out of the control of the yard. The PT however thinks that even if the provided system-architecture is not complete or perfect, it will still be beneficial as a starting point for the scope and functionality discussions that must take place before the test plans for the "system of systems test" (SOTS) are created.

Paragraph 4.3.5 "Testing of integrated systems on vessel-level (SOST)": This activity is maybe the biggest change to E22 in this version. This activity represents the core of the strengthening the systems integrator role and requires the systems integrator to make sure that the different systems are working well together before the handover to the owner. There were some discussions regarding to what degree this kind of testing already takes place, but no clear patterns were discovered, and the current practice is most likely varying not only from yard to yard, but also from project to project.

Paragraph 7.1.1 "System identification": There was some discussions regarding how hard the UR should "push" the concept of automated collection of the identity and revision of the onboard system software. We do think this will become standard in the future, but for now it is only a recommendation to follow ISO 24060 for a ship software logging system.

Application of UR E22 to Maritime Autonomous Surface Ships (MASS): There was some discussions if the UR should be updated to address aspects of systems and software used for monitoring and controlling systems of autonomous ships. Such systems are expected to be especially reliant on computer and software, and typically also contain elements of machine learning, which requires quite specialized processes for development and verification. It was decided that the requirements for such computer-based systems where out of scope for this update. It is however evident that the focus on the processes and quality control that the UR provides will serve as a good basis also for computer-based systems used in context of autonomy and remote control.

❖ Impact on the different roles between revision 2 and revision 3

The table below provides a detailed mapping between revision 2 and revision 3 of IACS UR E22 and which of the defined roles that are impacted by the changes.

IACS UR E22 Rev. 3 (paragraph and name)		**Rev. 2 (paragraph)**	**Summary of changes**	**Reason for change**	**System supplier**	**Systems integrator**	**Owner**
General	Document structure	Document structure	Changed: Restructured the document to clarify the requirements on the different roles and to make the use of chapters and headings consistent	Improvement. To clarify the content and improve readability	X	X	X
General	Title	Title	Changed: new title: Computer-based systems	Improvement. To better reflect the scope and content of the UR	---	---	---
General	Class Societies verification activities	Class Societies verification activities	Changed and added: For each of the requirements, it is specified how the class society is going to follow-up the requirement	Clarification of the class society's verification activities	X	X	X
1.1	Scope	1.1	Equivalent	---	---	---	---

IACS UR E22 Rev. 3 (paragraph and name)		Rev. 2 (paragraph)	Summary of changes	Reason for change	System supplier	Systems integrator	Owner
1.2	Exclusion	1.2	Rewritten, but equivalent	A more general formulation is applied to potentially cover systems not explicitly mentioned	---	---	---
1.3.1	Normative standards	New	Added: UR E10, E26, E27	Improvement. To clarify which standards are mandatory and which are voluntary to follow	X	---	---
1.3.2	Informative standards	1.3	Added: ISO 90007 and ISO 24060	Improvement. To make the reference list consistent with the content of the rest of the document	X	X	---
1.4	Structure	New	Added: a description of the structure of E22	Improvement. To describe the structure of the E22	---	---	---
1.5.1	Abbreviations	New	Added: table with abbreviations	Improvement, it is normal to define abbreviations used in a document	---	---	---

IACS UR E22 Rev. 3 (paragraph and name)		Rev. 2 (paragraph)	Summary of changes	Reason for change	System supplier	Systems integrator	Owner
1.5.2	Terminology	2 (except for 2.3)	Changed: owner, supplier, system, and systems integrator Added: 12 items Deleted: software module	- The system category definitions have been moved to a separate chapter in order to describe the context and examples better. - Owner, supplier and systems integrator definitions are shortened because all actual requirements on these roles are described elsewhere in the UR - Some terms are added because they are used in the more detailed descriptions of the requirements.	X	X	X

IACS UR E22 Rev. 3 (paragraph and name)		Rev. 2 (paragraph)	Summary of changes	Reason for change	System supplier	Systems integrator	Owner
2.1	System certification	3.1.4	Rewritten, equivalent	A clear definition of that is needed for a ship-specific certification is described. The old text in 3.1.4 has been rewritten because it contained some strange formulations. The description has been moved to a separate paragraph (2) where it is put in context with the type approval of computer-based systems	X	X	---

IACS UR E22 Rev. 3 (paragraph and name)		Rev. 2 (paragraph)	Summary of changes	Reason for change	System supplier	Systems integrator	Owner
2.2	Type approval	3.1.4	Rewritten, but largely equivalent to current practice. The concept of "limited approval", described in old paragraph 3.2 has been removed because it was not being used.	A clear definition of that is needed for a type approval is described. The old text in 3.1.4 has been expanded upon in order to better define the concept of type approval. The description has been moved to a separate paragraph (2) where it is put in context with the ship-specific certification	X	---	---
3.1	System category definitions	2.3, Table 1	Category III now also includes systems which failure may lead to catastrophic situations. Slightly rephrased "typical system functionality"	Clarification about the importance of category III systems	X	X	X

IACS UR E22 Rev. 3 (paragraph and name)		Rev. 2 (paragraph)	Summary of changes	Reason for change	System supplier	Systems integrator	Owner
3.2	Class Societies' scope	NEW	Added: how to deal with category I systems	To clarify the Class societies' scope	X	X	X
3.3	System category examples	2.3, below Table 1	Changed: from typical ones to examples always to be evaluated in the context of a specific vessel Added: examples of category I systems	Categorization of systems may vary for each ship	X	X	X
4.1.1	Life cycle approach with appropriate standards	3.1	Clarification that hardware is also a part of a system.	Clarification	X	X	X
4.1.2 para 1	Quality system	3.1.1 para 1	Rewritten and amended. Added: information about the different expectations on the quality system of a systems integrator and a system supplier	Clarifications on the expected content of the quality system. Clearer connection between the requirements on the quality system and the detailed requirements in the UR	---	---	---

IACS UR E22 Rev. 3 (paragraph and name)		Rev. 2 (paragraph)	Summary of changes	Reason for change	System supplier	Systems integrator	Owner
4.1.2 para 2	Quality system	New	Added: Information that this is only valid for category II and III.	Clearer connection between the requirements on the quality system and the detailed requirements in the UR			
para 2 and Table 4	#1	3.1.1.1	Changed: indicated it is required for supplier and systems integrator	clarification	X	X	---
	#2	New	Added: complete life cycle	Consistency with detailed requirements in the UR	X	X	---
	#3	New	Added: procedures for unique identification	Consistency with detailed requirements in the UR	X	---	---
	#4	New	Added: system architecture	Consistency with detailed requirements in the UR	---	X	---

IACS UR E22 Rev. 3 (paragraph and name)		Rev. 2 (paragraph)	Summary of changes	Reason for change	System supplier	Systems integrator	Owner
	#5	3.1.1.2 1st bullet	Changed: indicated it is required for supplier and systems integrator	clarification	X	X	---
	#6	3.1.1.2 2nd bullet	changed: indicated it is required for supplier	clarification	X	---	---
	#7	3.1.1.2 3rd bullet	changed: indicated it is required for supplier	clarification	X	---	---
	#8	New	added: procedures for FAT and SAT	Consistency with detailed requirements in the UR	X	X	---
	#9	3.1.1.1	changed: indicated it is required for supplier	clarification	X	---	---
	#10	3.1.1.3 3rd bullet	added: yard changed: indicated it is required for supplier and systems integrator	Consistency with detailed requirements in the UR	X	X	---

IACS UR E22 Rev. 3 (paragraph and name)		**Rev. 2 (paragraph)**	**Summary of changes**	**Reason for change**	**System supplier**	**Systems integrator**	**Owner**
	#11	3.1.1.3 1st bullet	changed: indicated it is required for supplier	clarification	X	---	---
	#12	same to the above	Changed: indicated it is required for supplier and systems integrator	clarification	X	X	---
	#13	3.1.1.1	changed: indicated it is required for supplier	clarification	X	---	---
	#14	same to the above	changed: indicated it is required for supplier and systems integrator	clarification	X	X	---
	#15	3.1.1.3 2nd bullet	changed: indicated it is required for supplier and systems integrator	clarification	X	X	---
below Table 4	---	3.1.1 para 2	equivalent	---	---	---	---
(supplier) 4.2.1	Define and follow a quality plan	3.1.1.4	Rewritten, but equivalent. Split into 4.2.1 and 4.3.2	clarification	X	---	---

IACS UR E22 Rev. 3 (paragraph and name)		**Rev. 2 (paragraph)**	**Summary of changes**	**Reason for change**	**System supplier**	**Systems integrator**	**Owner**
4.2.2	Unique identification of systems and software	New	Added: method for unique identification of systems and software	This is a foundation needed for good management of change	X	---	---
4.2.3	System description	3.1.3 documentation	Changed: The requirement to describe the system has been moved to a separate paragraph	To clarify the requirements on system documentation	X	---	---
4.2.4	Environmental compliance of hardware components	4	equivalent	---	---	---	---

IACS UR E22 Rev. 3 (paragraph and name)		Rev. 2 (paragraph)	Summary of changes	Reason for change	System supplier	Systems integrator	Owner
4.2.5	Software code creation, parameterization, and testing	3.1.1.2 2nd bullet	Changed: clarifications on the expected scope and extend of quality assurance of software code and parameters	As software is becoming a more and more critical and important part of systems, the quality assurance needs to follow suit. Quality assurance of individual software components before they are integrated into a larger system is considered a good practice	X	---	---
4.2.6	Internal system testing before FAT	3.1.1.2 3rd bullet	Changed: clarifications on the expected scope and extend of quality assurance of by the system supplier on the system	There is a need to verify as much as possible of the system before it is being installed onboard.	X	---	---

IACS UR E22 Rev. 3 (paragraph and name)		Rev. 2 (paragraph)	Summary of changes	Reason for change	System supplier	Systems integrator	Owner
4.2.7	Factory acceptance testing (FAT) before installation on board	3.1.3	Rewritten, but largely equivalent: clarifications on the expected scope and extend of the FAT	There was a need to position the FAT related to the internal system test and the system acceptance test	X	---	---
4.2.8	Secure and controlled software installation on the vessel	New	Added: requirement for the supplier and system's integrator to agree on a "management of change" procedure for onboard installations	Increased focus on the management of change for systems and software	X	X	---
(integrator) 4.3.1	Responsibilities	beginning of 2.1.2	Equivalent	---	---	---	---
4.3.2	Define and follow a quality plan	3.1.1.4	Rewritten, but equivalent: clarified that the systems integrator shall have a quality plan	clarification	---	X	---

IACS UR E22 Rev. 3 (paragraph and name)		Rev. 2 (paragraph)	Summary of changes	Reason for change	System supplier	Systems integrator	Owner
4.3.3	Determining the category of the system in question	New	Added: explicitly decide the category of a system in the context of the specific vessel in question	The category must be decided in the context of the vessel where the system is being installed	---	X	---
4.3.4	Risk assessment of the system	3.1.2.1 1st half	Added: Risk assessment is only required if requested by the class society. Rewritten, but equivalent when requested	Clarification that risk assessment is not always needed	---	X	---
4.3.5	Define the vessel's system-architecture	New	Added: system architecture	Needed in order for the systems integrator to be able to plan, prepare and execute the testing of integrated systems on vessel-level. It also gives the systems integrator a clearer role in the design of the system of systems	---	X	---

IACS UR E22 Rev. 3 (paragraph and name)		Rev. 2 (paragraph)	Summary of changes	Reason for change	System supplier	Systems integrator	Owner
4.3.6	System acceptance test (SAT) onboard the vessel	3.1.5	Rewritten, but equivalent: clarified the expectations on the system acceptance test	Aligning the system acceptance test with the FAT and the testing of integrated systems on vessel level	---	X	---
4.3.7	Testing of integrated systems on vessel-level (SOST)	New	Added: The systems integrator is responsible for performing a test of the integrated system of systems onboard the vessel	To ensure that the integrated systems are verified to work together, and to strengthen the role of the systems integrator	---	X	---
4.3.8	Change management	3.3.1	Rewritten, but largely equivalent: The responsibilities of the systems integrator have been mapped to the requirements in the new chapter on management of change	More focus on the management of change process to secure that changes are being managed in a good way	---	X	---

IACS UR E22 Rev. 3 (paragraph and name)		Rev. 2 (paragraph)	Summary of changes	Reason for change	System supplier	Systems integrator	Owner
(Owner) 5.1.1	Responsibilities	3.3.1	Rewritten, but largely equivalent: The owner is considered the systems integrator during operations if the role is not explicitly delegated	More focus on the management of change process in order to secure that changes are being managed in a good way	---	X	X
(Integrator) 5.2.1	Change management	3.3.1	Rewritten, but largely equivalent: The responsibilities of the systems integrator have been mapped to the requirements in the new chapter on management of change	More focus on the management of change process in order to secure that changes are being managed in a good way	---	X	---

IACS UR E22 Rev. 3 (paragraph and name)		Rev. 2 (paragraph)	Summary of changes	Reason for change	System supplier	Systems integrator	Owner
(Supplier) 5.3.1	Change management	New	Added: The responsibilities of the system supplier have been mapped to the requirements in the new chapter on management of change	More focus on the management of change process in order to secure that changes are being managed in a good way	X	---	---
5.3.2	Testing of changes before installation onboard	New	Added: requirement on the system supplier to perform inhouse tests of changes to a system before it is installed onboard	More focus on the management of change process to secure that changes are being managed in a good way	X	---	---
6	MANAGEMENT OF CHANGE	New / 3.3.2	Expanded and added: 11 requirements on different parts of the management of change process are added	More focus on the management of change process to secure that changes are being managed in a good way	X	X	X

IACS UR E22 Rev. 3 (paragraph and name)		Rev. 2 (paragraph)	Summary of changes	Reason for change	System supplier	Systems integrator	Owner

Technical Background (internal)

UR E23 (NEW Feb 2007)

UR for the choice of circuit breakers (PM5405)

Objective and scope:

To develop unified requirements for selection of low voltage circuit breakers with relation to point of installation, services fed, and short circuit conditions.

Source of proposed requirements:

The proposed requirements have been based on the present Rule requirements of IACS members and IEC Standard 60947 Low-voltage switchgear and controlgear.

Background:

As a consequence of feedback from switchboard makers indicating confusion about selection of circuit breakers due to different practise from the different societies, IACS established a project team with the aim to establish unified requirements for selection of low voltage circuit breakers restricted to consideration of short-circuit capacity and co-ordination in service. Other factors, i.e. environmental testing, location and construction of enclosures, are not covered here.

Content:

Based on definitions and test methods for breaker data laid down in IEC 60947, the UR establish requirement for choice of low voltage circuit breakers short-circuit capacity and co-ordination in service ensuring the safety and reliability of the electrical installation with a clear description of how breaker data should be evaluated for specific distribution systems on board ships.

Points of discussion:

The Project Team proposed to base requirements to breaking capacity on the short circuit current's value at the instant of contact separation, in line with IEC 61363 section 9.2 b). However, after discussions in the Machinery Panel, it has been decided to base the requirements to breaking capacity on the short circuit current's value after the first half cycle (t = T/2) in order to keep today's practise, and in order to make the societies' verification more simple.
No decisions have been based on voting.

Submitted by Machinery Panel Chair
20 December 2006

Discussion at GPG level:
RINA in 6214_RIa suggested to replace the word 'after' with 'at', although only one member (DNV) supported this proposal at the first round discussion, considering the importance and it being a specific technical comment, GPG Chairman tasked the Machinery Panel to consider it. The Machinery Panel reported that they had no objections to replacing the word 'after' with 'at' in sections 3 and 4 of the new UR. CCS and RS only agreed this proposal to be taken in section 3 (excluding section 4). Further CCS and RINA provided more detailed technical comments to back their views respectively. As those

messages were received at late stage, unfortunately no other members' comments were available before the deadline.
Since those discussions between RINA and CCS are related to specific technical matter which is not appropriated to be discussed at GPG level, and CCS suggested to seek the opinions of the major circuit breakers manufacturers about the proposed changes to the draft UR (section 4) by RINA to make sure that there is no difficulty in the implementation of the UR, while RINA had no objection on this suggestion and RS supported it, in addition, RS suggested that Machinery Panel should be tasked to seek the opinions of manufacturers. In order to implement this new UR E23 unanimously, GPG Chairman suggested that Machinery Panel be tasked to select the major circuit breakers manufacturers to seek their opinions on this matter, and feedback the result as early as possible, so further rectified action may be taken if necessary.

All members agreed to extend the implementation date on 1st of July 2008 suggested by LR.

Appendix A:

Supporting guidance for the application of IACS UR E23

1. For definition of terms used in this UR, refer to IEC 60092 and IEC 60947.
2. Figure 1 below shows an example of the application of Clause 3 of UR E23 to a power distribution system.
3. Figure 2 below shows continuity of supply and continuity of service as referred to in Clauses 5 and 6 of UR E23.

Technical Background for UR E23 Delete, Mar 2011

Machinery panel reported to GPG70 that:

Panel had been tasked to review the UR E23 (Subject Number: PM5405 (6214a)) which had been withdrawn by IACS following the negative feedback from the industry. The Panel has since been trying to gather evidence from members' experience, which will help in justifying the need to review the UR further or may be for re-issuing it. However gathering evidence was proving difficult because once the fire had been extinguished, it was too difficult to find out whether the fire was initiated by the circuit breakers or not. Due to the lack of evidence the Panel decided to permanently delete UR E23. After agreement in GPG the Permanent Secretariat is kindly requested to publish/update the UR E23 from withdrawn to deleted.

On receiving the machinery panel report (10158bPMa), PermSec updated the status of UR E23 to 'Deleted'.

IACS PermSec

UR E24 "Harmonic Distortion for Ship Electrical Distribution System including Harmonic Filters"

Summary

This UR provides requirements for the monitoring of the harmonic distortion levels and the mitigation of the effects of harmonic filter failure.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev.1 (Dec 2018)	17 December 2018	1 January 2020
New (June 2016)	2 June 2016	1 July 2017

- **Rev 1 (Nov 2018)**

.1 Origin of Change:

☑ Suggestion by IACS member

.2 Main Reason for Change:

To introduce the scope of application of the current UR E24 in order to clarify that the requirements are applicable only to ships where harmonic filters are installed onboard. To compare the total harmonic distortion limits of current UR with those of international standards to verify if an update is necessary.

.3 List of non-IACS Member Classification Societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

The matter was offered by a Machinery Panel Member and discussed at 27th Machinery Panel Meeting (27 Feb to 02 March 2018) and agreed by correspondence.

.5 Other Resolutions Changes

None

.6 Dates:

Original Proposal: February 2018
Panel Approval: 28 November 2018 (Ref:PM18908_IMg)
GPG Approval: 17 December 2018 (Ref:18141_IGe)

New (June 2016)

.1 Origin for Change:

☑ Other (Recommendation by MAIB)

.2 Main Reason for Change:

Recommendation was made to introduce requirements for survey of harmonic filters and harmonic distortion levels by an MAIB investigation following the catastrophic failure of a harmonic filter installed on board a UK flag passenger vessel.

.3 List of non-IACS Member Classification Societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

The Machinery Panel commented on proposed draft by correspondence and at regularly scheduled meetings. In the process of development, the draft UR approved by Machinery Panel was sent to Survey Panel for review and concurrence on the survey requirements in Section 2.

The form A was approved 05 October 2012.

.5 Other Resolutions Changes

None

.6 Dates:

Original Proposal: 2 March 2012 Made by a Member
Panel Approval: 1 April 2016 (Ref: PM12405)
GPG Approval: 2 June 2016 (Ref: 12165_IGd)

Part B. Technical Background

Technical Background (TB) document for UR E24 (New June 2016)

1. Scope and objectives

In September 2010, while approaching Barcelona, the UK flag cruise vessel RMS Queen Mary 2 experienced a catastrophic failure of a harmonic filter installed as part of the high voltage electrical distribution system. This failure resulted in a blackout of the vessel. No one was injured and the vessel was able to resume passage following isolation of the harmonic filter and part of the main switchboard.

The subsequent investigation carried out by the Marine Accident Investigation Branch (MAIB) concluded that the failure occurred following deterioration over time of the capacitors within the harmonic filter.

In order to reduce the risk of a similar failure occurring in the future the report recommended that harmonic distortion levels on board vessels should be monitored in order to detect any deterioration of harmonic mitigation equipment at an early stage. The report further recommended that guidance should be available to ship's personnel to enable the operation of the ship while maintaining an acceptable level of harmonic distortion following degradation or failure of harmonic mitigation equipment.

The root cause of the failure that occurred on the Queen Mary 2 was not identified.

The intent of this Unified Requirement is to:

- Address the MAIB recommendations.
- Consider the need to require online monitoring of harmonic distortion.
- To mitigate against the issues of harmonic filter failure.

2. Engineering background for technical basis and rationale

<u>QM2 catastrophic failure of harmonic filter: MAIB Recommendations</u>

Improve the standards of protection that are required against harmonic distortion and component failure in vessels operating high voltage networks, to provide:

- a requirement in all new-build vessels that may be affected by harmonic distortion of current and voltage that:

    - In the event that all harmonic mitigation systems fail, information is provided on board to describe the maximum extent of harmonic distortion that can be expected.

    - Guidance is provided so that crew can take effective action to keep power and propulsion equipment operating (at an appropriate power output) if harmonic mitigation equipment degrades or fails.

    - On-line monitoring of harmonic distortion of voltage is required for new build vessels and, for existing vessels, there is periodic monitoring to detect change or degradation of harmonic distortion levels.

    - Specific requirements are developed to detect and mitigate against the failure of high-energy storage devices such as capacitors.

Review the requirements for the enclosure of high voltage systems to confirm that the degree of protection is consistent for all equipment where crew intervention could be required and the hazard from arc-flash exists.

Introduce a specific requirement specifying that where the failure of equipment or machinery may lead to serious damage to the vessel, or injury to personnel, its protection system is to be of a 'fail safe' type.

3. Source / derivation of the proposed IACS Resolution

The root cause of the QM2 harmonic filter failure catastrophe was not identified and therefore requirements were developed through IACS Machinery Panel discussion and required a panel majority for a Resolution to become realised. Requirements have been derived from the following sources:

- MAIB Report 28/2011 December 2011 – "Report on the investigation of the catastrophic failure of a capacitor in the aft harmonic filter room on board RMS Queen Mary 2 while approaching Barcelona 23 September 2010".
- IEC60092-501: Special features – Electric propulsion plant, date: 22th October 2013.
- IACS Unified Requirements.
- Member classification society's Rules.

4. Summary of Changes intended for the revised Resolution:

N/A

5. Points of discussions or possible discussions

Paragraph	Summarised comments from industry and other IACS Members
General comments	
	C. The requirement for arc flash hazard calculations as part of the UR had been proposed. A. There is no substantial evidence that arc flash was the cause for the Queen Mary II incident, and any arc flash hazards should be more generally applied rather than for this specific case.
Specific comments	
Section 1	C. Concern that problems may occur regarding the application of the UR because Total Harmonic Distortion (THD) limits are different among each society. Therefore, it was proposed that it is necessary to specify THD limits in the UR. A. The 8% limit is used because it does not have any conflict with power quality in UR E5 as it only covers voltage and frequency. The UR makes exceptions to this limit in cases where all installed equipment and systems have been designed for higher THD levels.

	"harmonic distortion calculation report" was used to prove the system is designed to operate at higher THD levels, but validation testing is required. The 8% THD limit is already stated in member classification society's rules.
Section 2	C. What frequency should the harmonic distortion levels be measured on existing ships? A. Considering the specialist equipment and access to interiors of switchboards that may be required to perform the measurements on existing installations where the monitoring system is not provided, for high voltage installations in particular, it is impractical to require harmonic distortion measurements to be made more frequently than annually.
	C. It has been clarified that the guidance documentation produced should include permitted modes of operation following any combination of harmonic filter failures. It has further been clarified that the validity of the guidance documentation is to be verified by testing during sea trials. A. Reference to propulsion has not been made as harmonic filters may be included in systems containing other large electrical consumers, or even large numbers of small consumers fed by frequency converting equipment. It should be noted that full verification of the calculation or practical testing of the effect of failure could result in inducing high levels of harmonic distortion onto the system, albeit for a short period of time during testing, which should ideally be avoided. It is therefore proposed that the calculation should be carried out and then verified by testing up to a point where the harmonic distortion levels observed are moving beyond certain limits. The current wording leaves it to the interpretation of the individual classification society as to exactly how far the verification of the calculation by testing will need to be carried out.
	C. Should the UR be applied only for the ships which have the potential risks of harmonic distortion failure, such as electric propulsion ships having high capacity power electronics. Because, considering the experience that vessels complying with current Class requirements of 6-8% THD without the harmonic filters, a catastrophic failure does not happen. . A. Problems with harmonics on low voltage high powered vessels have being experienced, and therefore members proposed that the UR should not be restricted to high voltage filters but the same requirements applicable to low voltage ones too. Recently industry has seen increased numbers of variable speed drives connected to LV services, and consequently use of harmonic filters will increase.
	C. Should the UR require "Continuously monitor the levels of harmonic distortion" or would an "annual testing" be sufficient.

	<u>A. New building ships</u> The UR should require the harmonic distortion to be continuously monitored as it will provide early warning and also fault finding capabilities in event of a failure. Additionally following a failure or loss of equipment on board, the effect on harmonics can be immediately determined. <u>B. Existing ships</u> An annual testing of harmonic distortion level would be sufficient for monitoring of harmonic distortion on board. Assuming that the filter has been designed properly and its operation been verified during initial testing, and a failure in the harmonic filter is alarmed by its protection, then annual testing should suffice.
	C. A suggestion to add in the Note that the UR also applies to new harmonic filters fitted to existing ships A. The phrase "Where the electrical distribution system on board a ship includes harmonic filters," is understood to cover new harmonic filters fitted to existing ships. Therefore, an additional note is not necessary.
Section 3	C. It is not acceptable determining the effect of a failure of a harmonic filter on the level of harmonic distortion on the basis of a calculation. A. Calculations are to be verified by tests during sea trials. However, it should be noted that full verification of the calculation or practical testing of the effect of failure could result in inducing high levels of harmonic distortion onto the system, albeit for a short period of time during testing, which should ideally be avoided. It is therefore proposed that the calculation should be carried out and then verified by testing up to a point where the harmonic distortion levels observed are moving beyond certain limits. The current wording leaves it to the interpretation of the individual classification society as to exactly how far the verification of the calculation by testing will need to be carried out.
Section 4	C. The explosion may have been a result of pressure build up within the hermetically sealed capacitors. A member proposed a requirement for pressure relief valves to be fitted on capacitors over 2 litres. Justification of the 2 litres threshold was requested. A. Based on the recommendation received from an independent Electrical and Electronic Manufacturer, the proposal for relief valves or overpressure disconnectors were rephrased. The wording also considers alternative cell protection technologies.

Paragraph	Comments received from the Survey Panel
Section 2	Comment 1: for E.R. provided with automation systems (unmanned machinery spaces) the alert for level of harmonic distortion outside of acceptable limits should be recorded by the system together with that one for activation of the protection of a harmonic filter circuit (Exx4).

	Review of print out of automation system to be carried out at annual survey. For ship not fitted with automation system official records should be logged in the engine log book. Records shall be available to the surveyor.
Section 2	Comment 2: It should be specified that the annual measurement should be carried out close to the annual machinery survey.
Section 2	Comment 3: Acceptable limit should be clearly documented (harmonic distortion calculation report) based on system design calculation and/or trial; availability on board to be checked at annual survey. The operating conditions under which the test are to be clearly stated – with/without filters, all equipment running, etc.
Section 2	Comment 4: It would be better to specify that measurements are to be carried out with the filters connected to the net. The operating conditions under which the measurements are to be carried out needs to be clearly stated: e.g. with/without filters, all equipment running, etc.
Section 2	Comment 5: the seagoing conditions should also specify that the conditions should be those where the harmonic level is the higher.
Section 2	Comment 6: that the responsible party for Harmonic distortion levels measurements needs to be clarified: crews or authorized person of manufacture?
Section 3	Comment 7: it is proposed to add "by class surveyor" after word "verified".

Technical Background (TB) document for UR E24 (Rev.1 Dec 2018)

1 Scope and objectives

To introduce the scope of application of the current UR E24 in order to clarify that the requirements are applicable only to ships where harmonic filters are installed onboard.
To compare the total harmonic distortion (THD) limits of current UR with those of international standards to verify if an update is necessary.

2 Engineering background for technical basis and rationale

- The issue was triggered by an IACS Member having a reservation regarding the total harmonic distortion limits of the current UR E24 (June 2016).

- It was observed that the requirements of the current UR E24 (June 2016) may be misinterpreted as to be applicable to all the existing ships due to an absence of clear scope, even though the UR was developed to apply to ships where harmonic filters are installed onboard, as expressed in the title.

- It was also considered necessary to compare the total harmonic distortion limits required in the current UR E24 (June 2016) with those required by international standards (IEC60092-101 and IEC60092-501).

3 Source / derivation of the proposed IACS Resolution

None

4 Summary of Changes intended for the revised Resolution

- A new paragraph "**1. Scope**" was introduced and the existing paragraphs renumbered.

- In the existing paragraph 2.1 (renumbered as 3.1 in Rev.1) the first sentence "Where the electrical distribution system on board a ship includes harmonic filters, such" and the last sentence "However, harmonic filters installed for single application frequency drives such as pump motors may be excluded from these requirements, i.e. Sections 1 to 4." have been deleted as no more necessary given the clarifications in the new paragraph "**1. Scope**".

- The implementation statement has been updated

5 Points of discussions or possible discussions

The IACS Member having the reservation on the total harmonic distortion limits proposed to revise from 8% to 10% the THD limit specified in paragraph 1 "General" of the IACS UR E24 (June 2016) for the reason that the proposed value (i.e. 10%) correspond to that of the International Standard IEC 60092-501 "Electric Propulsion Plant"; the proposal was not accepted by the qualified majority of Machinery Panel Members.

As a compromise solution in order to solve the reservation the IACS Member propose to modify paragraph 1 "General" of the IACS UR E24 (June 2016) to read as follow:

> **"**The total harmonic distortion (THD) of electrical distribution systems is not to exceed 8%. The THD value for the propulsion network not directly connected to the ship's network is not to exceed 10%.
>
> Those limits may be exceeded where all installed equipment and systems have been designed for a higher specified limit and this relaxation on limits is documented (harmonic distortion calculation report) and made available on board as a reference for the surveyor at each periodical survey.**"**

Also this compromise proposal was not accepted by the qualified majority of Machinery Panel Members sharing in general the opinion that the last part of the "General" paragraph already offers the possibility to derogate and accept a higher THD, when systems have been designed for this higher THD.

The IACS Member having the reservation also highlighted that the requirements of paragraph 2 in general and specifically those of sub-paragraph 2.2 of UR E24 (June 2016), the latter being provided for retrospective application to existing ships, are rather vague regarding the measurement procedure and proposed to establish a PT for the development of such procedures; the proposal was not accepted by the qualified majority of Machinery Panel Members.

UR E25 "Failure detection and response of all types of steering control systems"

Summary

Revision 2 of this UR adds an application statement as paragraph E25.1, deletes the item of "Hydraulic locking" from the failure list in paragraph E25.2.1 (renumbered) and provides amendment in paragraph E25.3.1 (renumbered) to clarify that the system response is not mandatory for mechanical failures.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev.2 (Mar 2022)	03 March 2022	1 July 2023
Rev.1 (Dec 2019)	7 December 2019	1 January 2021
New (June 2016)	21 June 2016	1 July 2017

Note: Added on 01 March 2023 (Ref: 22013_IGm) Rev.2 of UR E25 was less stringent compared with Rev.1 because of deleting Hydraulic locking from list of failures in UR E25 Rev.1 and then accordingly Hydraulic locking removed from requirement of 2.1 in UR E25 Rev.1. Early implementation of UR E25 Rev.2 was agreed by GPG on case-by-case basis as per Par 2.1 of 22013_IGh message dated 17 January 2023.

- **Rev.2 (Mar 2022)**

.1 Origin for Change:

☑ Suggestion by IACS Member

.2 Main Reason for Change:

To clarify that the system response is not mandatory for such as sticking valves, including hydraulic locking.

.3 List of non-IACS Member Classification Societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

The Revision 2 was discussed by correspondence and agreed at the 34th Panel Meeting (from 31th August to 2th September 2021)

.5 Other Resolutions Changes

.6 Any hinderance to MASS, including any other new technologies:

None

.7 Dates:

Original Proposal	: 11 May 2020	(Ref: PM20801_IMa)
Panel Approval	: 20 January 2022	(Ref: PM20801_IMl)
GPG Approval	: 03 March 2022	(Ref: 22013_IGc)

- **Rev.1 (Dec 2019)**

.1 Origin for Change:

☑ Suggestion by IACS Member

.2 Main Reason for Change:

To amend paragraph E25.2.1 in order to clarify the intention and the requirements of this paragraph.

.3 List of non-IACS Member Classification Societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

The Revision 1 was discussed by correspondence and agreed at the 29th Panel Meeting (from 26th to 28th of March) and finally on 13/11/2019 (Ref: PM19801_IMi)

.5 Other Resolutions Changes

None

.6 Any hinderance to MASS, including any other new technologies:

None

.7 Dates:

Original Proposal: 9 January 2019 (Ref: PM19801_IMa)
Panel Approval: 13 November 2019 (Ref: PM19801_IMi)
GPG Approval: 7 December 2019 (Ref: 19139_IGe)

- **New (June 2016)**

.1 Origin for Change:

☑ Suggestion by IACS member

.2 Main Reason for Change:

Section 4 in UI SC94 was introduced in revision 1. The Machinery Panel considered that the content is more suitable for a UR rather than a UI. It was hence agreed to review Section 4 of UI SC94 and move the contents to a new UR. Subsequently a new task was opened to revise UI SC94 accordingly.

.3 List of non-IACS Member Classification Societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

Form A agreed in December 2012.
Draft UR E25 agreed by Machinery Panel in June 2015.

.5 Other Resolutions Changes

UI SC94: Section 4 to be removed and document to be re-numbered in a new task

.6 Dates:

Original Proposal: 30 March 2012 Made by a Machinery Panel Member
Panel Approval: 12 May 2016 (Ref: PM11919) GPG
Approval: 21 June 2016 (Ref: 12222_IGf)

Technical Background (TB) document for UR E25 (New June 2016)

1. Scope and objectives

To clarify the requirements for failure detection in steering gear control and monitoring systems and what is considered an acceptable response to such. Develop a new UR with agreed requirements.

2. Engineering background for technical basis and rationale

Rev.1 of UI SC94 describes under section 4 "failure detection and response of control systems". The need for unified requirements for steering gear control systems is acknowledged by all members, and that such should be made through a UR rather than a UI SC.

Failure in the steering gear control system shall be detected and provide the operator with sufficient information to decide what action is required for the different failure scenarios. The UR provides more details on which failures shall be alarmed.

3. Source / derivation of the proposed IACS Resolution

Basis for the new UR is Section 4 of UI SC94 (Rev.1). This was developed further based on experience in the application of UI SC94 and on engineering judgment.

4. Summary of Changes intended for the revised Resolution:

N/A

5. Points of discussions or possible discussions

- Deviation alarm is now required, not as an alternative to, but in addition to basic failure detection. The deviation alarm is used to alarm in situations where the rudder does not reach its setpoint (SP) within a specified time after SP change. Mechanical block of the rudder blade and failure in the control valve are examples of failures resulting in a deviation. The Panel acknowledged that a deviation alarm is useful for notifying the operator of failures resulting in inability to actuate the rudder to the given command. However, as the alarm is on a very high level and does not indicates the cause of failure or which system is affected, the deviation alarm cannot substitute loop monitoring or any of the alarms referred to in 1.1. Moreover, it is noted that a deviation alarm is required by the USCG.

- Earth fault detection is required on AC and DC circuits. Earth fault detection is moved to a separate bullet point as the requirement is somewhat different in detection and rectification than a pure power supply failure and "on AC and DC circuits" is explicitly stated to remove ambiguity.

- Loop failure detection is required in closed loop systems, both command and feedback loops signals.

- Industry review was carried out to get feedback on the new UR E25 and two (2) SGCS manufacturers provided their interpretations and comments as follows, mostly concerning about the definition of the listed alarms.

Industry comments to UR E25	Proposed answers
1. Failure detection *1.1 The most probable failures that may cause reduced or erroneous system performance shall be automatically detected and at least the following failure scenarios shall be considered:* Comment: Well noted in general	
a) Power supply failure Comment: Definition of *Power supply failure* is not clearly shown. We manufacturers need to refer to commonly defined standards and understand that the IEC requirements and test specifications covers this requirement. If IACS has any specific requirement to be applied, please inform us. * Refer to item 7 Power supply in IEC 60945 Maritime navigation and radio communication equipment and system - General requirements – Methods and required test results.	It is anticipated that a SGCS has passed the tests concerning power supply in UR E10 / IEC 60945. The "power supply failure" referred to in the draft UR concerns loss of power to any part of the SGCS as defined in SOLAS Regulation II-1/3.1.
(b) Earth fault on AC and DC circuits Comment: Definition of *Earth fault on AC and DC circuit* is not clearly shown. IEC60945 has no specific description or requirement on this Earth fault. If IACS or a classification society (hereinafter referred to as Class) has any specific requirement which covers the fault definition and conditions, please inform us. If such a test requirement requires covering all power supply of the systems which are connected to SGCS, the signal lines and other factors, it may be out of scope of SGCS performance. E.g. an earth failure in the other system which is connected to SGCS and its secondary earth failure if initiated in SGCS is quite difficult to monitor what is being failed in that system. It also should be defined to exclude the SGCS which has the own power supply system isolated from main power supply as well as the signal line earth failure.	Item (b) "Earth fault on AC and DC circuits" was included on the list of potential failure scenarios to ensure that it is considered for all designs, it was not expected that it would be applicable to all designs. The wording of the UR should be noted, the items listed under item 1.1 are to be "considered". There is no intent to require all the items to be included in the control system if they are not applicable. For example: If the control system is an insulated supply fed via a transformer, we would need to know if that supply has an earth fault on one of the conductors. If it is fed direct from the main supply (which already has earth fault detection or is an earthed system) this would not be required. Any earth fault detection (if required) should result in an alarm to alert the crew and then the cause would be investigated, it would not be expected to have an immediate impact on the operation of the steering gear.
(c) Loop failures in closed loop systems, both command and feedback loops (normally short circuit, broken connections and earth faults) Comment: Definition of *closed loop systems* is not clearly shown. Title of this proposed UR says ***Failure detection and response of all types of steering control systems.***	The wording "all types" in the title of the proposed UR is intended to highlight that the requirements not only relate to traditional steering gear systems, but also to thruster arrangement, Voith Schneider etc. By "closed loop control" in the context of the UR, one considers mainly the closed loop

Industry comments to UR E25	Proposed answers
SGCS controls two types of steering gear hydraulic system e.g. one is like direct control of steering gear directional solenoid valves and it senses the actual rudder position for its servo loop control. Another is a control system to actuate a floating lever which mechanically controls the swash-plate of a steering gear pump. SGCS has a small control loop with its own pump units and performs actuator stroke control with the signal between the steering order and the repeatback signal from the actuator. Then it has NO direct feedback of the rudder position. SGCS for the latter system does not make a control loop with the rudder position or provide the main loop control alarm. Is this system excluded?	controller loop acting on the rudder. The requirements also apply to other closed loop control in a SG control system. If it is documented however (e.g. in an FMEA) that failures have no impact on the steering function, failure detection as specified in the UR may not be required.
(d) Data communication errors Comment: Definition of data communication coverage is not clearly shown. We understand that the data communication error in this section (d) is somewhere between SGCS and other equipment connected. Data communication errors inside SGCS are covered in (e) below as hardware or software failures.	Communication failure can occur between internal components in the SG control system, but also between the SG control system and external systems (such as the autopilot and alarm panel).
(e) Programmable system failures (Hardware and software failures) Comment: Well noted in general Tests for SGCS system has been carried out based upon IEC60945 and some Class environmental requirements like the vibration test up to 4G. Test procedure of this failure should be clearly defined for shop test or onboard test.	The SG control system shall comply with the environmental requirements in IACS UR E10. HW and SW failures in the context of this UR are not related to environmental compliance. The HW in a programmable system is often built up by a CPU module, power module, I/O modules, communication modules, etc.. Failure in such (e.g. failure in I/O module) shall initiate an alarm. SW failure is typically detected by check-sum and watch-dog. Failure is to initiate alarm.
(f) Hydraulic locking HLA : Comment: Hydraulic lock alarm is clearly defined as an alarm of steering gear itself in Classes rule. It is available to provide the hydraulic lock alarm in SGCS once such alarm information is supplied from a steering gear alarm managing system. Sensing the HLA condition is out of scope of SGCS.	The HY lock alarm (HLA) shall be in the same alarm panel as the other required SG alarms.
*(g) Deviation between rudder order and feedback** ** Deviation alarm shall be initiated if <u>the rudder's actual position</u> does not reach the set point within acceptable time limits. Deviation alarm may be caused by mechanical, hydraulic or electrical failures.* Comment: Well noted in general but the definition of this alarm is not clearly shown. Please refer to the comment in (c) above. Some current	**AA**: Applicable for closed loop rudder control. **BB**: The deviation alarm required in this UR shall be through the alarm panel used for the other required SG alarms. It is acceptable to generate this alarm through the HW used in the SG controls system based on deviation between the command from the helm and the rudder feedback. The deviation alarm in this UR is

Industry comments to UR E25	Proposed answers
SGCS does not sense <u>*the rudder's actual position*</u> to satisfy this alarm requirement. UR E25(new 2015) HF& TB mentioned as; "it is noted that a deviation alarm is required by the USCG." We understand that the deviation alarm by the USCG is referred to; USA 46CFR 113.43 Steering Failure Alarm Systems (hereinafter referred to as SFA) SFA defines very specific requirements. It has to be independent alarm system from the main steering gear control systems mechanically and electrically as much as practicable. SFA requires an independent steering wheel turning censor, a separate alarm managing system and a rudder transmitter with separate wiring arrangements between a wheel house and steering gear room. SFA works only at steering wheel control mode, not at other steering modes and it can cover all type steering gear control systems independently. We supply the SFA system as an option for US vessels or with a specific purchase order. For this (g) alarm, followings should be defined. AA: Application coverage of SGCS, all SGCS or specific SGCS control type BB: Whether it must be independent from SGCS same as SFA or the embedded alarm as a standard feature. CC: Whether operating steering mode is only at steering wheel mode, or it covers all follow-up steering modes	independent of the USCG requirements. Deviation alarm in line with USCG is considered complying with the requirements in this UR. Arrangements in line with the requirements in this UR may NOT comply with the USCG. **CC**: Deviation alarm as required in this UR should apply to any position where the operator can perform closed loop steering control.
1.2 All failures detected shall initiate audible and individual visual alarm on the navigation bridge. Comment: Well noted in general	
2. System response upon failure *2.1 The failures (as defined but not limited to those in 1.1) likely to cause uncontrolled movements of rudder are to be clearly identified. In the event of detection of such failure, the rudder should stop in the current position. Alternatively the rudder can be set to return to the midship/neutral position in the event of a failure. This is subject to the discretion of each Classification Society.* Comment: We do not understand how to control a steering gear by SGCS when providing steering gear vital alarms as HLA or Deviation alarm which is caused by steering gear main construction failures like hydraulic control line trouble or steering gear power supplies. SGCS system response to the alarms as shown above must be conditional, not available in all alarm cases. There has been much discussion in MSC or IEC related committees on which is better for safety ship control as to stop the rudder in the current position or to return to the	We fully acknowledge the comment concerning control of the rudder in case of deviation alarm and or HLA. Comparing these two alarms ("Hydraulic locking" and "deviation between rudder order and feedback") with the first five faults listed in the UR, (f) and (g) are <u>effects of failure</u> rather than failures. Please note the wording in the proposed UR: *"<u>likely</u> to cause uncontrolled movements of rudder…"* The rationale for the requirement ("zero or freeze in case of failure") is to prevent uncontrolled movement of the rudder. Freeze, e.g. through stopping the power units, is considered the only realistic action during HLA. One could imagine many different failures

Industry comments to UR E25	Proposed answers
midship/neutral position in the event of a failure. At the moment, it is defined to stop the rudder in the current position as with the requirement of TCS performance standard. Our SGCS stops or holds the rudder order from a steering stand to the steering gear control system in a steering gear room.	that could cause deviation alarm (f). Deviation alarm should hence generate alarm only (no action), unless the system identifies the deviation as an uncontrolled movement of the rudder.

Technical Background (TB) document for UR E25 (Rev.1 Dec 2019)

1. Scope and objectives

To develop amendments to UR E25.2.1 (June 2016) to clarify the intention and requirements.

2. Engineering background for technical basis and rationale

- Regarding the 2nd and 3rd sentence of UR E25.2.1 (June 2016):
  it was observed that the rudder is requested to be stopped in the current position or returned to the midship/neutral position when vessels face with uncontrolled movements by failures (as defined but not limited to those in the 1.1 of UR E25); however the expression "In the event of..., the rudder should stop ... . Alternatively the rudder can be set to return ... a failure." was evaluated to be unclear for the reasons that recommendatory wordings such as "should" or "can be", which are not appropriate for a mandatory IACS Resolution, are used and such expression do not clarify if an automatic response may be required to satisfy the requirement.

- Regarding the last sentence of UR E25.2.1 (June 2016)
  The wording ".This is subject to the discretion of each Classification Society" was evaluated to be unclear as it may be interpreted to apply to both the 2nd and 3rd sentence of the UR (i.e. the Classification Society may evaluate not to apply the requirements for rudder positioning as stated in the 2nd and 3rd sentence) or it may be interpreted that the Classification Society need to choose between stopping the rudder in the current position (as per the 2nd sentence) or returning the rudder to the midship/neutral position (as per the 3rd sentence).

After consideration of the above matters:

1) it was decided to modify the 2nd and 3rd sentence of UR E25.2.1 (June 2016) (as per paragraph 4. below) to make clear that the Classification Society need to choose between stopping the rudder in the current position or returning the rudder to the midship/neutral position.

2) the Panel discussed on the need to add the following sentence at the end of paragraph 2.1 in order to allow in case of failure, as an alternative, an automatic change-over to stand-by steering gear power unit and control system:

   Alternatively, an automatic change-over to stand-by steering gear power unit and control system may be considered"

   This proposal was however not supported by the qualified majority for the reason that, in case of failures (as defined but not limited to those in paragraph 1.1), there is the risk that the change over to stand-by power unit and control system might not impede further uncontrolled rudder movements; the change-over to stand by steering gear was therefore not considered an alternative to stop the rudder in the current position or return it to the midship/neutral position.

   In this regard one Members Society proposed to modify the above sentence as follow for the reason that in their understanding a "stand-by control system" is required by SOLAS Regulation II-1 / 29.7.2 only for steering gears arranged in accordance with SOLAS Regulation II-1 / 29.6.1:

"Alternatively, for steering gears arranged in accordance with SOLAS regulation II-1 / 29.6.1, an automatic change-over to stand-by steering gear power unit and control system may be considered."

The proposal was however not supported by the qualified majority

3) An IACS Members proposed to add the following note at the end of paragraph E25.2.1 for the reason that, with regards to the hydraulic locking failure (item (f) of the failure list in UR E25.1.1), in their understanding of UR M42.12.2 and 42.13, in case of hydraulic locking of a steering gear designed to operate with 2 power units running simultaneously, the steering control is to be regained by stopping each pump in turn; accordingly, rudder stop in the current position or return to the midship / neutral position is not deemed sufficient:

   "*Note: For hydraulic locking failure, refer also to UR M42.12.2 and 42.13.*"

   The proposal was supported by the qualified majority

3. Source / derivation of the proposed IACS Resolution

N/A

4. Summary of Changes intended for the revised Resolution:

Paragraph 2.1 has been modified as follow:

"2.1 The failures (as defined but not limited to those in 1.1) likely to cause uncontrolled movements of rudder are to be clearly identified. In the event of detection of such failure, the ~~rudder should stop in the current position. Alternatively the rudder can be set to return to the midship/neutral position in the event of a failure. This is subject to the discretion of each Classification Society~~ rudder is to stop in the current position without manual intervention or, subject to the discretion of the Classification Society, is to return to the midship/neutral position.

Note: For hydraulic locking failure, refer also to UR M42.12.2 and 42.13."

5. Points of discussions or possible discussions

The amendments to the UR have been agreed by correspondence.

Regarding paragraph 2.1 the following comments/proposals have been received:

- One Members Society requested the Panel Members confirmation regarding the following their understanding:

  "Regarding the requirement "*the rudder is to stop in the current position without manual interventions*", it only apply to control systems (that is, to be achieved by interrupting control over the rudder by a control system which has failed so as not to allow the rudder to move), and is not to be interpreted as a requirement for the provision of additional gears in order to actually physically prevent the rudder from moving."

The above understanding was shared by the unanimity of Panel Members.

- One Members Society proposed to modify paragraph 2.1 as follow to improve the readability:

  "2.1 Failures (as defined but not limited to those in 1.1) likely to cause uncontrolled movements of rudder are to be clearly identified. In the event of the detection of such failure;
  .1 the rudder is to stop in the current position without manual intervention; or,
  .2 the rudder is subject to the discretion of the Classification Society, to return to the midship/neutral position; or,
  .3 the steering gear is to automatically change-over to the stand-by steering gear power unit and control system."

  The proposal was not supported by the qualified majority

Technical Background (TB) document for UR E25 (Rev.2 Mar 2022)

1. Scope and objectives

To clarify the necessity of a system response for mechanical failures, including hydraulic locking.

2. Engineering background for technical basis and rationale

According to UR E25 (Rev.1), it is required to stop the rudder without manual operation in the event of detection of failure that is identified as likely to cause uncontrolled movements of the rudder (system response). Hydraulic locking is included in the failure list to be considered for alarm and system response. When hydraulic locking occurs, it may cause uncontrolled rudder. In addition, a failure of a sticking valve that is a cause of hydraulic locking can also lead to uncontrolled rudder movement on a case-by-case basis. Therefore, according to UR E25 (Rev.1), it is interpreted that even mechanical failures such as sticking valves, including hydraulic locking, are subject to the system response.

On the other hand, for electrical failures in the system (e.g., data communication errors), the rudder can be stopped simply by an electrical signal from the steering control system, but the above-mentioned failure due to sticking valve is kind of a mechanical failure and cannot be stopped by an electrical signal from the steering control system. As stated in the IACS "proposed answer" in terms of "2. System response upon failure" in the table of TB of URE25(NEW), the only practical way to stop the rudder when hydraulic locking occurs is to stop the power unit. However, since it is difficult to implement the stopping of the power unit without manual operation (e.g., automatically stopping the pumps), the necessity of system response in the event of mechanical failure including hydraulic locking was reconsidered.

In addition, the Panel discussed that hydraulic locking is overlapped with 'deviation between rudder order and feedback' in the list of failures in UR E25. Also, a hydraulic locking alarm is already required in UR M42.

Based on the above, hydraulic locking is deleted from the list of failures in UR E25, and an exemption is added to the effect that mechanical failures are not subject to the system response.

3. Source/derivation of the proposed IACS Resolution

None

4. Summary of Changes intended for the revised Resolution:

To clarify that the subject of UR E25 is for the steering gear control system defined in UR M42 Appendix 1, an application statement is added to paragraph 1. In addition, the title of the UR is changed to steering gear control system from steering control system.

Upon the 34th IACS Machinery Panel Meeting, the following updates to UR E25 were agreed by the Panel:

i) removal of "Hydraulic locking" from Requirement 2.1;
ii) making references to UR M42.13 in Requirement 3.1; and
iii) modifications on the wording of the added last sentence of Requirement 3.1.

5. Points of discussions or possible discussions

During the discussion, a Panel Member proposed the following two issues about failure scenarios in the E25.1.1. Regarding these two issues, the qualified majority agreed and finally concluded to amend as specified in item 4 of this TB.

Deletion of «(f) Hydraulic locking» or «(g) Deviation between rudder order and feedback»

a. The failure scenarios '(f) Hydraulic locking' is overlapped with '(g) Deviation between rudder order and feedback'. And Hydraulic locking(f) is detected by the (g) failure.

b. According to the HF of UR E25, the requirements came from 4 of the Rev.1 of UI SC94. The «Hydraulic locking considering order given by steering wheel or lever» had been listed on a kind of failure in 4.1.1 of the Rev.1 of UI SC94.

Scope of mechanical failures stating on the asterisk note(*) for '(g) Deviation between rudder order and feedback'

a. Steering Gear Control System cannot take an actions against kinds of mechanical failures without manual intervention, even if the failures cause uncontrolled movements of rudder.

b. In this regard, the current UR E25 may lead to excessive requirement for all vessels. As a similar requirement to system response in UR E25.2.1(renumbered to 3.1), automatic isolation is required to a tanker, chemical tanker, or gas carrier of 10,000 GT and upwards in accordance with SOLAS II-1/Reg.29.1.6.2.

c. Therefore, it is suggested stating on the UR E25 that mechanical failures such as sticking valves and failure of static components(pipes, cylinders) can waive system response in UR E25.2.1 (renumbered to 3.1) .

6. Attachments if any

None

UR E26 “Cyber resilience of ships”

Summary

UR E26 aims to ensure the secure integration of both operational technology and information technology equipment into the vessel’s network during the design, construction, commissioning, and operational life of the ship. This UR targets the ship as a collective entity for cyber resilience and covers five key aspects: equipment identification, protection, attack detection, response, and recovery. This revision includes requirements for the suppliers to demonstrate compliance with the requirements in this UR.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev.1 (Nov 2023)	15 November 2023	01 July 2024
New (Apr 2022)	11 April 2022	01 January 2024*

*New UR E26 was withdrawn in September 2023 before coming into force on 1 January 2024 (Ref: 22094_IGm)

- **Rev.1 (Nov 2023)**

1 Origin of Change:

☑ Other *(12th IACS Cyber Systems Panel meeting)*

2 Main Reason for Change:

Develop IACS unified requirements for verification and survey in newbuilding and operational phase of cyber physical systems and vessels to ensure compliance with IACS UR E26.

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

JWG/Cyber systems

4 History of Decisions Made:

During the 12th meeting of the IACS Cyber Systems Panel held September 21-23, 2021, following former discussions and request from GPG, the Cyber Panel agreed to form PTPC07 to develop requirements for verification, survey and audit in newbuilding and operational phase of cyber physical systems and vessels to ensure compliance with IACS UR E26 and UR E27. Executive summary of the history, such as internal decisions made, meeting minutes, reference to Form A or Form 1.

The objectives for PTPC07 have been defined in Form A as follows: "Establish common requirements for verification activities to ensure a harmonized practice for compliance with UR E26 and UR E27."

Further, it was decided by the Cyber Systems Panel in January 2023 that PTPC07 shall propose resolution of industry feedback to UR E26 and UR E27 ("pilot phase comments").

5 Other Resolutions Changes:

UR E22 and UR E27 may be impacted, for cross-reference purposes.

6 Any hinderance to MASS, including any other new technologies:

In the development of this UR, consideration has been given so as not to hinder the development of new or improved technologies providing an equivalent or higher level of safety.

7 Dates:

4 History of Decisions Made:

During the 9th meeting of the IACS Cyber Systems Panel held in March 22-25, 2020, following former discussions and request from GPG, the Cyber Panel agreed to form a PT for the task of translating appropriate portions of Recommendation 166 on cyber resilience of ships into an IACS UR. Executive summary of the history, such as internal decisions made, meeting minutes, reference to Form A or Form 1.

The objectives for this PT have been defined in Form A as follows:

1. Starting from the experience and knowledge acquired in the development of Recommendation 166 on cyber resilience of ships, produce an UR with minimum goal-based requirements for cyber resilience of new ships. The focus will be set on OT systems and cyber incidents resulting from any type of offensive maneuver that targets such systems, excluding system failures. The extent of requirements will be limited to the most common and effective cyber security barriers, feasible for a smooth implementation on all new ships. Such requirements will be mandatory for OT systems that, if compromised, could immediately lead to dangerous situations for human safety, safety of the vessel and/or threat to the environment.

2. Organize the UR to make it possible to implement the requirements therein contained uniformly and smoothly by class societies and industry and make it applicable to all types of vessels, in such a way that the requirements enable a minimum level of security and apply to all classed vessels/units regardless of operational risks and complexity of OT-systems.

3. Organize the UR to encourage its evolution and improvement to continuously provide answers to industry expectations e.g. on systems connectivity,

digitalization and smart shipping, anticipating the needs of autonomous ships (MASS) and supporting the effort of national and international authorities on cyber risk management.

IACS officially released the unified requirements UR E26 "Cyber Resilience in Ships", and UR E27, "Cyber Resilience Equipment and Systems", in the month of April in the year 2022, with scheduled implementation date of 01 January 2024.

Given the relatively nascent nature of the subject matter in maritime sector, an imperative need to establish a standardized approach to survey requirements was envisaged and the aforementioned unified requirements underwent a meticulous revision, to incorporate survey requirements. Industry feedback on published URs were also suitably addressed in revised URs (now referred to as Rev1) slated to come into effect on 01 July 2024.

During the course of development of revised URs, considering the challenges in implementation of the new cyber requirements in smaller vessels, falling under IACS's scope of applicability as delineated in "IACS General Procedures Volume 1 Chapter A Introduction- para 2 IACS’s scope of interest," the applicability of these unified requirements was bifurcated as mandatory compliance for one category of vessels and non mandatory compliance for another category, in accordance with reference GPG mail 18197b.

Recognizing the intrinsic interrelationship between IACS UR E27 and UR E26, the scope of applicability of both URs and to eliminate any potential confusion which could arise within the industry, due to availability of two versions of same UR with different implementation date a strategic decision was taken to withdraw the original (new) version of UR E26 and UR E27, as initially published in the year 2022 which requires mandatory application to all ships contracted for construction from 01 January 2024.

This strategic approach also eliminates any conceivable perplexity in Industry that might arise from having two distinct versions/revisions of the same URs, characterized by a six-month variance in their implementation dates, divergent scopes of applicability, and supplementary survey information available through the official IACS website.

5 Other Resolutions Changes

UR E22 and UR E27 may be impacted, for cross-reference purposes.

6 Any hinderance to MASS, including any other new technologies:

In the development of this UR, consideration has been given so as not to hinder the development of new or improved technologies providing an equivalent or higher level of safety.

7 Dates:

Original Proposal:	December 2019
Panel Approval:	September 2021
GPG Approval:	11 April 2022 (Ref: 18197aIGz)

Part B. Technical Background

Technical Background (TB) document for UR E26 (New Apr 2022)

1. Scope and objectives

The aim of this resolution is to provide a minimum set of requirements for cyber resilience of ships, with the purpose of providing technical means to stakeholders which would lead to cyber resilient ships.

This resolution targets the ship as a collective entity for cyber resilience and is intended as complementary to other URs and industry standards addressing cyber resilience of onboard systems, equipment and components.

IACS Recommendation 166 on Cyber Resilience is intended for ships contracted for construction after its publication and may be used as a reference for ships already in service prior to its publication. For ships to which this resolution applies as mandatory instrument, when both this resolution and Recommendation 166 are used, should any difference in requirements addressing the same topic be found between the two instruments, the requirements in this resolution shall prevail.

2. Engineering background for technical basis and rationale

Interconnection of computer systems on ships, together with the widespread use onboard of commercial-off-the-shelf (COTS) products, open the possibility for attacks to affect personnel data, human safety, the safety of the ship, and threaten the marine environment.

Attackers may target any combination of people and technology to achieve their aim, wherever there is a network connection or any other interface between onboard systems and the external world. Safeguarding ships and shipping in general from current and emerging threats involves a range of measures that are continually evolving.

It is then necessary to establish a common set of minimum functional and performance criteria to deliver a ship that can indeed be described as cyber resilient.

IACS considers that minimum requirements applied consistently to the full threat surface using a goal-based approach are necessary to make cyber resilient ships.

3. Source/derivation of the proposed IACS Resolution

The development of this resolution starts from the experience and knowledge acquired in the development of Recommendation 166 on cyber resilience of ships (IACS Recommendation 166), with the aim to produce an UR with minimum goal-based requirements for cyber resilience of new ships.

The focus is set on OT systems and cyber incidents resulting from any type of offensive manoeuvre that targets such systems, excluding system failures.

The extent of requirements is limited to the most common and effective cyber security barriers, feasible for a smooth implementation on all new ships. Such requirements will be mandatory for OT systems that, if compromised, could immediately lead to dangerous situations for human safety, safety of the vessel and/or threat to the environment.

Recommendation 166 will remain in force, whereas only some of the content in this document is lifted over to this resolution, which aims to be small and focus on the most important cyber security barriers.

This resolution is not concerned about hw/sw failures, but considers only cyber incidents, i.e. events like intentional or accidental unauthorized access, misuse, modification, destruction or improper disclosure of the information generated, archived or used in onboard computer-based systems of interest, or transported by the networks connecting such systems.

Taking into account the organization and layout of contents adopted in other authoritative and widely accepted guidelines (IMO MSC-FAL.1/Circ.3, BIMCO Guidelines...) the organization of contents is inspired by the so-called NIST Cybersecurity Framework, however maintaining a goal-based approach.

In order to evaluate the topics to be translated into this resolution from Recommendation 166, an excel sheets which contains the items extracted from the latest consolidated version of Recommendation 166 has been used. For each item, CS Panel Members and IACS Joint Working Group/Cyber Systems (JWG) Members have been asked to vote on the need for a translation into an UR.

An "experience-building phase" has also been considered to clarify and define the scope of Recommendation 166 to be made mandatory. Discussions have been carried out inside the Panel on how to implement the experience building phase in order to agree a common way adopted by all Members and collect feedback in a consistent format so as to ensure an effective experience capable of providing results concretely useful for the finalization of the UR.

At the time of discussion, there was very limited experience in Class Societies and their clients in the actual application of Rec. 166 and a more extensive experience on its application in the near future seemed not realistic.

It was also noted that a conventional EBP was not possible since Rec.166 is not established as mandatory requirements. Consequently, it was not possible to gain experience from its implementation. It was then agreed to start the drafting of a UR and seek to gather feedback from relevant parts of the industry in the process of making the UR (i.e. from IACS members and JWG).

The experience building phase relied strongly on JWG inputs, by way of regular meetings with JWG members to collect comments about the progression of the UR, comments sent by JWG members to the JWG Chairman through the dedicated email threads and specific expectations sent by members to the JWG Chairman.

This resolution has been designed to be open to future developments, to meet possible future evolution and improvements and continuously provide more and more appropriate answers to industry expectations e.g. on systems connectivity, digitalization and smart shipping, anticipating the needs of autonomous ships (MASS).

4. Summary of Changes intended for the revised Resolution:

None

5. Points of discussions or possible discussions

Organization of the UR:

This resolution follows a goal-based approach and contains minimum goal-based requirements for cyber resilience of new ships.
The primary goal is to support safe and secure shipping, which is operationally resilient to cyber risks.

Whereas safe and secure shipping can be achieved through effective cyber risk management, to achieve the above, sub-goals for the management of cyber risk are defined for the five functional elements listed below:

1. Identify: Develop an organizational understanding to manage cybersecurity risk to onboard systems, people, assets, data, and capabilities.

2. Protect: Develop and implement appropriate safeguards to protect the ship against cyber incidents and maximize continuity of shipping operations.

3. Detect: Develop and implement appropriate measures to detect and identify the occurrence of a cyber incident onboard.

4. Respond: Develop and implement appropriate measures and activities to take action regarding a detected cyber incident onboard.

5. Recover: Develop and implement appropriate measures and activities to restore any capabilities or services necessary for shipping operations that were impaired due to a cyber incident

These sub-goals and relevant functional elements should be concurrent and considered as parts of a single comprehensive risk management framework.

Functional/technical requirements are given for the achievement of specific sub-goals of each functional element.

While it is generally recognized that in the cyber risk management operational aspects are fundamental elements to achieve the target goals and subsequently the sub-goals, it has been pointed out by the JWG that these elements should be ensured by other guidelines specifically directed for ship owners (BIMCO Guidelines etc.) and reference to the operational requirements should be avoided. This point of view has been taken in high consideration in this UR.

The requirements are intended to allow a uniform implementation by stakeholders and to make them applicable to all types of vessels, in such a way as to enable an acceptable level of resilience and apply to all classed vessels/units regardless of operational risks and complexity of OT systems.

For each requirement, a rationale is given.

A summary of actions to be carried out and documentation to be made available is also given for each phase of the ship's life and relevant stakeholders participating to such phase. Criteria for performance evaluation and testing are also given.

Scope of application

This resolution applies to:

a) Operational Technology (OT) systems onboard ships, i.e. those computer-based systems (CBS) using data to control or monitor physical processes that can be vulnerable to cyber incidents and, if compromised, could lead to dangerous situations for human safety, safety of the vessel and/or threat to the environment. In addition, navigational systems required by statutory regulations and internal and external communication systems required by class rules and statutory regulations are included in the scope of applicability of this resolution,

and

b) Any IP-based communication interface from CBSs in scope of this UR to other systems

The cyber incidents considered in this resolution are events resulting from any offensive manoeuvre that targets OT systems onboard ships.

Concerning inclusion of IT systems in the scope of applicability, a discussion has been carried out about the possibility to require a-priori segregation between IT and OT systems to avoid inclusion of IT systems in the scope of applicability.

Another approach to inclusion of IT systems in scope of applicability has been discussed, based on the impact of a possible impairment of an IT system on the safe operation of the ship, leading to a categorization of IT systems connected to OT systems essentially according to E22 Cat.I, II, III.

Both approaches have been considered as feasible, however none has been selected as exclusively applicable, also taking into account the variety of real-world cases.

IT systems connected to OT systems are not considered in the scope of applicability of this resolution, however the interface in-between is considered in scope and should be the same level of security as required to the CBS in scope.

The Scope of Applicability has been defined also taking into account the absence of a requirement for Risk Assessment and is intended to clarify which CBSs belong to which E22 Category.

Having a unique Scope of Applicability among all URs on cyber resilience, including E22 has been proposed, to be referenced by other URs. This unique scope of applicability should provide a sufficiently exhaustive and clear list of CBS and criteria to assign CBS to Cat.I, II or III to novel technologies, new devices etc. To this purpose, the list provided in this resolution can be considered as a starting point.

Risk Assessment

An assumption of this resolution is that a preliminary risk assessment is already done by IACS, resulting in a defined minimum set of requirements and a defined set of computer-based systems (indicated in the Scope of Applicability) to be considered for the safety of the ship.

This assumption implies that an initial risk assessment to establish appropriate level of protection is not needed since this is implied by the pre-selected minimum goal-based requirements in this resolution.

However, there could be systems on board for which the cyber risk is negligible and may be exempted from some or all requirements. Criteria for such exemption are not precisely defined in this resolution, due to the possible variety of real-world cases.

To avoid diverging practice among shipyards and classification societies, it would be necessary to develop a more prescriptive methodology for such risk assessment and its acceptance criteria. It may be feasible to focus on attack surfaces such as network connections, physical access to the equipment, portable devices, software updates, etc.

This resolution allows for a system-oriented risk assessment in the design phase. The purpose of this would be to determine if any of the required systems are "so simple" that they by design represent low risk. The requirements to such systems could then be less. The system-oriented risk assessment in the design phase is aimed to establish if any requirements are not applicable for certain systems or vessels. E.g. requirement for secure remote access is not applicable if there is no system providing remote access.

Exclusion of a Computer Based System falling under the scope of applicability of this resolution from the application of relevant requirements needs to be duly justified and documented. Such exclusion can be accepted by the Classification Society only if evidence is given that the risk level associated to the operation of the CBS is under an acceptable threshold by means of specific risk assessment.

The risk assessment shall be based on available knowledge bases and experience on similar designs, if any, taking into account the CBS category and its connectivity. Cyber threat information from internal and external sources may be used to gain a better understanding of the likelihood and impact of cybersecurity events.

In the risk assessment, the following elements shall be considered:

1. Asset vulnerabilities;

2. Threats, both internal and external;

3. Potential impacts of cyber incidents affecting the asset on human safety, safety of the vessel and/or threat to the environment;

4. Possible effects related to integration of systems, or interfaces among systems, including systems not onboard (e.g. if remote access to onboard systems is provided).

The risk model may be developed using one of the well-established methods such as fault tree analyses, event tree analyses, Markov models, Bayesian networks, structural reliability analyses, etc.

There may be different approaches to approval of the risk assessment for exclusion of CBS from the application of requirements, depending on how challenging the proposed set of excluded requirements is for the CBS of interest.

One approach to the approval is to compare the safety performance of the CBS to existing designs to demonstrate that an equivalent level of safety is guaranteed. In order to demonstrate an equivalent level of safety, evaluation criteria should be established. Safety objectives and functional requirements should be taken into consideration when developing the evaluation criteria.

To allow verification of safety equivalence, the risk assessment shall be complemented with a test plan where specific tests addressing the excluded requirements are described and relevant results documented.

By means of execution of these tests, the CBS of interest is to demonstrate that it will perform its intended safety related functions in a manner that is equivalent to or better than the prescriptive requirement it is deviating from.

Upon positive verification of test results and analysis of the risk assessment documentation, the risk assessment can be approved.

Verification activities by the classification societies

In section 5 (Test plan for performance evaluation and testing) and in the appendix (Summary of actions and documents) E26 indicates expected activities to be carried out by the relevant stakeholders.

It is worth noting that Section 5 "Test plan for performance evaluation and Testing" is mainly about design, implementation, execution and maintenance of a Test Plan, which is the essential instrument intended to support and ground the verification of the effective implementation of measures adopted for the fulfilment of requirements. It does not indicate how to test or how to conduct surveys, rather it prescribes how the essential instrument intended to support and ground testing and verification (the Test Plan) shall be done: how it shall be designed, implemented and maintained in the different phases of the ship's life, also indicating responsibility related to these actions.

Definition of specific survey requirements is delegated to a different document in the Z series and is not in scope of this UR.

When the new Z-series document will be established, it will probably be necessary to revise section 5 of this resolution in order to align and harmonize the contents of the two documents. This revision will probably also affect the documentation to be provided to Class societies.

Security Levels

While ISA/IEC 62443 and other popular standards have a robust, articulated and target-based definition of security levels (SLs), using SLs in this resolution in the same way and based on the same principles appears to be not compatible as the UR is set to provide minimum requirements.

Form A states that minimum security requirements for all new vessels shall be defined: this implies that multiple security levels are not relevant for this resolution.

On the other hand, UR E22 already has a concept of SLs implied with the definition of Cat.I, II and III. So, having a common approach followed by this resolution and E22 has been considered more important and consistent.

Categories defined in E22 (Cat.I, II, III), even if based essentially on the impact or consequences of possible impairment of CBS functionality due to a cyber incident, are very familiar to most stakeholders (UR E22 has been in force for very long time) and provide a well-understood view of CBS's criticality.

Other subdivisions or categorizations such as 62443-like security levels have been avoided in this resolution.

For the sake of clarity, the word "category" has been reserved to E22 categories and not used anywhere else.

Requirements to be fulfilled during the ship's operational life

Requirements to be fulfilled during the ship's operational life have been considered in this resolution. This will be further addressed in the Z-series document that will be developed describing survey procedures and activities.

Based on feedback from JWG, it was decided to exclude verification activities by the classification societies during the operational phase of the vessel, except verification of required documentation. This conclusion should be considered a point for discussion since it is widely recognized that cyber security relies on continuous management of cyber risks, policies, procedures, roles and responsibilities, physical access control, awareness training, monitoring of cyber events, management of change, security patching, incident response, business continuity, etc.

E26 currently includes some requirements to the shipowner related to the operational phase, but no verification activities by the classification societies, except verification of required documentation.

Technical Background (TB) document for UR E26 (Rev.1 Nov 2023) - Survey requirements

1. Scope and objectives

Form A specified four work items, summarized as follows:

a) Specify verification activities of cyber physical systems delivered by product suppliers.
b) Specify verification activities of integration, architecture and implementation by shipyards or system integrators.
c) Specify verification activities of cyber security management during operation.
d) Establish guidance for acceptance criteria, compensating countermeasures, test methods and application of alternative standards.

2. Engineering background for technical basis and rationale

Since UR E26 specifies requirements for the installation, integration and management of cyber physical systems onboard, it was decided that UR E26 Rev.1 should address item II, III and IV in Form A.

Furthermore, it was decided that UR E26 Rev.1 should specify requirements to how system integrators and shipowners shall demonstrate compliance with the requirements of UR E26. Hence, it should not specify how the classification societies shall carry out verification activities.

It was considered important to ensure the classification process specified in UR E26 is not in contradiction with UR E22.

Finally, it was considered important to rectify any faults or inconsistencies that may have been overlooked in the development of the original version of UR E26.

2a. Specification of the data utilised in the development/revision of the proposed IACS Resolution, if any

None

3. Source/derivation of the proposed IACS Resolution

None

4. Summary of Changes intended for the revised Resolution:

None

5. Points of discussions or possible discussions

5.1 Management of cyber security

During development of UR E26 Rev.1 it was discussed how requirements in E26 related to management of cyber security may be demonstrated by the stakeholder and how these requirements may be verified by the classification societies.

It was recognized that these requirements are generally not prescriptive, enabling verification by testing or conventional inspection/survey, but that they are goal-based and relies on processes implemented in the organization responsible for operation of the vessel.

It was also recognized that these requirements may be considered broadly addressed by IMO resolution MSC.428(98) and may be partly covered by the Flag's statutory requirements. E.g. "*Administrations to ensure that cyber risks are appropriately addressed in safety management systems*".

Since these requirements are considered important to ensure cyber resilience in the operational phase of the vessel, it was decided to keep the requirements in E26 and verify compliance by the following survey schemes:

1) Verify in the first annual survey that Shipowner's documented processes (i.e. policies, procedures, manuals, instructions, etc.) address the requirements in E26

2) Verify in subsequent annual surveys that Shipowner organization follows the documented processes that are submitted and verified in the implementation survey.

    a) It was discussed if the verification to be carried out in the annual surveys is considered an "audit" activity and if such activities shall be required by classification societies.

       Since the annual survey requirements in UR E26 are quite prescriptive, and refer to specific technical requirements in E26, it was found that these verification activities are to be considered "survey items". The classification surveyor shall verify that relevant records or other artifacts have been produced demonstrating that the required technical security countermeasures in UR E26 are maintained and demonstrating that the required processes/management activities in UR E26 are implemented on board.

    b) It was discussed if the scope of annual survey is the same as invoked by MSC.428(98) and IACS Procedural Requirements No.9 (*Procedural Requirements for ISM Code Certification*).

       The security-related requirements invoked by MSC.428(98) are general and nonspecific. The ISM Audit is required by the Administration (not classification societies) and intends to verify that the objectives of the ISM Code are met (i.e., "*that SMS takes into account cyber risk management*" and "*that cyber risks are appropriately addressed in the SMS*"). Based on this, the ISM Audit cannot be considered to cover the prescribed requirements in UR E26.

The documented processes were summarized in Appendix I and Appendix II, and the survey items/acceptance criteria are specified in each subsection "Operation phase".

See also Definition of audit in UR E27 HF_TB (Rev.1 Apr 2023) Annex 3 item 5.1.

5.2 Alignment of requirements with UR E27

During the development of the new unified requirements E26 and E27 in 2022, efforts were made to ensure that there two documents were aligned. This alignment was continued in the development of the revised E26 and E27 in 2023.

The objective was to ensure that CBSs approved in accordance with UR E27 would have all necessary security capabilities to meet the requirements of E26.

5.3 Content of documentation to be submitted by System integrator

Based on the process specified in UR E27 Rev.1, all CBSs in the scope of applicability shall be verified to meet all applicable requirements of UR E27 before delivery to the System integrator (shipyard).

If the System integrator supplies equipment in scope of applicability, the System integrator is considered a Supplier, and UR E27 applies also for the System integrator.

The process in UR E27 includes assessment of documentation and survey by the classification society with factory acceptance test. CBSs that are type approved in accordance with UR E27 may be subject to a lesser verification process.

Based on the above process, it was decided that E26 shall not require the System integrator to document the security capabilities required by UR E27 (since this is the responsibility of the Suppliers).

It was also decided that E26 shall not require testing of these security capabilities in the commissioning phase on board (since this is done in FATs or type approval testing).

Consequently, it was decided to focus requirements to the System integrator on issues related to integration (e.g. security zones, physical access controls, security zone boundaries, etc.)

The requirements for documentation by the System integrator are specified in section 5.1 and in each subsection "Design phase".

The requirements for testing during commissioning on board are specified in section 5.2 and in each subsection "Commissioning phase".

5.4 Scope of testing in the commissioning phase

The extent of required testing in the commissioning phase was subject to discussions during the development of UR E26 Rev.1.

It was concluded that the Ship cyber resilience test procedure shall include all tests specified in the subsections "Commissioning phase". This will ensure that the shipowner will receive a complete test procedure upon delivery of the ship.

However, since most of the requirements in UR E26 are fulfilled by security capabilities specified in UR E27 and since all CBSs in the scope of applicability are required to be certified in accordance with UR E27, it was agreed that some tests may be omitted from the Commissioning phase (such tests are specifically identified in the respective subsection "Commissioning phase"). This concept is further justified as follows:

- Since the certification process in UR E27 includes, for each CBS and equipment in the scope of applicability, verification and testing of the required inherent security capabilities and configuration thereof, it will not add significant value to repeat the test onboard. Examples are the capability to respond safely to DoS events (section 4.2.2) and the capability to be restored in the event of cyber events (section 4.5.2).

- Tests associated with physical installation or integration of the CBSs onboard may not be omitted in the commissioning phase. Examples are Dos attacks from external networks (section 4.2.2) and physical access control (section 4.2.4).

- The surveyor's decision to allow for omitting the specified tests shall be based on the certification process of the respective CBS or equipment having been carried out without any comments, compensating countermeasures, or subsequent modifications of the CBS.

- In the decision of this concept, it was also recognised that the process of testing all requirements for each component in each CBS in the scope of applicability will normally take several weeks. It was therefore found feasible to credit the testing required by UR E27 as relevant and specified in the respective subsections.

Technical Background (TB) document for UR E26 (Rev.1 Nov 2023)- Pilot phase Comments

1. Scope and objectives

When IACS UR E26 and UR E27 were published in April of 2022, it was decided that the period until mandatory implementation should be considered a "pilot phase" and consequently that feedback from the industry should be considered in a possible revision of the URs.

2. Engineering background for technical basis and rationale

To allow classification societies sufficient time for implementation of the revised UR E26 and UR E27 it was decided that cutoff date for considering feedback from the industry should be set to December 1st. 2022.

In the evaluation of the feedback from the industry it was decided to categorize the consolidated result of each comment as follows:

- Clarification (no change)
- Suggestion for improvement

2a. Specification of the data utilised in the development/revision of the proposed IACS Resolution, if any

None

3. Source/derivation of the proposed IACS Resolution

None

4. Summary of Changes intended for the revised Resolution:

None

5. Points of discussions or possible discussions

5.1 Applicability of UR E26 and E27 (vessel types)

UR E26 Rev.1 was updated to specify vessel types for which the URs apply considering the following:

- IMO resolution MSC.428(98) encouraging Administrations to ensure that cyber risks are appropriately addressed in safety management systems required by ISM Code which applies to ships and units specified by SOLAS I/3 and SOLAS IX/2.

Mandatory requirements for:

a) Passenger ships (including passenger high-speed craft) engaged in international voyages

b) Cargo ships of 500 GT and upwards engaged in international voyages

c) High speed craft of 500 GT and upwards engaged in international voyage

d) Mobile offshore drilling units of 500 GT and upwards

e) Self-propelled mobile offshore units engaged in construction (ie wind turbine installation maintenance and repair, crane units, drilling tenders, accommodation, etc)

Non-mandatory guidance to:

a) Ships of war and troopships

b) Cargo ships less than 500 gross tonnage

c) Vessels not propelled by mechanical means

d) Wooden ships of primitive build

e) Passenger yachts (passengers not more than 12).

f) Pleasure yachts not engaged in trade

g) Fishing vessels

h) Site specific offshore installations (ie FPSOs, FSUs, etc)

5.2 Applicability of UR E26 and E27 (CBSs)

During the pilot phase, classification societies received many questions from shipyards and suppliers about the scope of applicability.

Suppliers were asking which CBSs will be required to have the security capabilities specified in UR E27.

Shipyards were asking which CBSs will be required grouped into security zones and meet the requirements in UR E26.

Consequently, it was decided to revise section 1.3 and specify more precisely the scope of applicability of UR E26 and E27.

5.3 Illustration of “Physical network segment” and “logical network segment”

“Physical network segment” and “logical network segment” defined in UR E26 are illustrated below to help the readers understand.

The examples below are arranged in accordance with section 4.2.1; the network in each security zone is a separate broadcast domain (separate network segment) and communication between the security zones is controlled by a firewall.

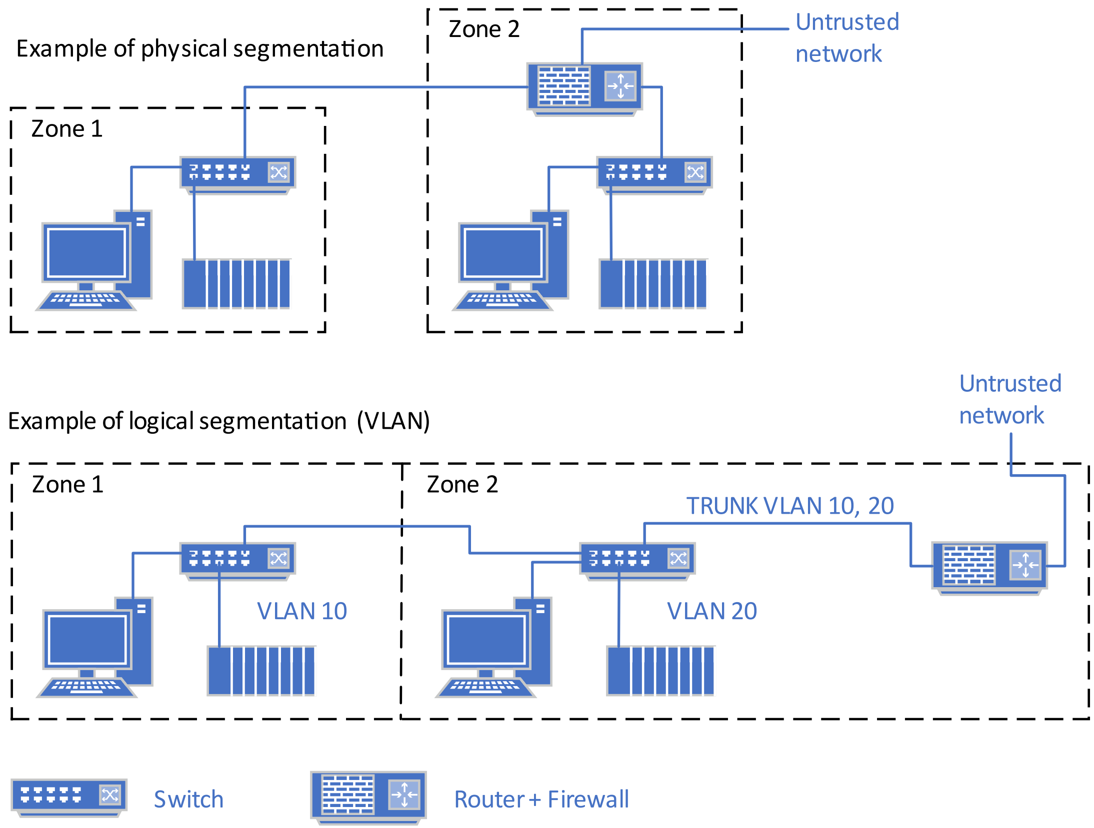
Required safety systems must be grouped in one or more dedicated security zones, and that these zones must be physically segmented from other zones.

Physical segmentation is also required if a CBS shall communicate with untrusted networks (outside scope of applicability).

Logical segmentation may be applied if other security zones shall communicate with each other (e.g., navigation systems and control systems).

The examples below are also arranged in accordance with section 4.4.3 (Network isolation), i.e., the connection between each zone may be disconnected in the event of a security incident.

Note that there may be multiple CBSs within a security zone. These CBSs may be isolated or connected to each other. Network segmentation and packet filtering (control of traffic) is not required for communication between CBSs within the same security zone.



5.4 Interpretation of roll-back

The requirement in section 4.5.3 for CBSs to have the capability to roll-back was commented in the pilot phase. It was agreed to interpret "roll-back" in a similar way as "restore", i.e., that roll-back may be achieved by manual actions.

None

UR E27 "Cyber resilience of on-board systems and equipment"

Summary

In this revision, UR E27 aims to ensure system integrity is secured and hardened by third-party equipment suppliers. This UR provides requirements for cyber resilience of onboard systems and equipment and provides additional requirements relating to the interface between users and computer-based systems onboard, as well as product design and development requirements for new devices before their implementation onboard ships. This revision includes requirements for the suppliers to demonstrate compliance with the requirements in this UR.

Part A. Revision History

1 Origin of Change:

☑ Other *(12th IACS Cyber Systems Panel meeting)*

2 Main Reason for Change:

Develop IACS unified requirements for verification and survey of cyber physical systems to ensure compliance with IACS UR E27.

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

JWG/Cyber systems

4 History of Decisions Made:

During the 12th meeting of the IACS Cyber Systems Panel held September 21-23, 2021, following former discussions and request from GPG, the Cyber Panel agreed to form PTPC07 to develop requirements for verification, survey and audit in newbuilding and operational phase of cyber physical systems and vessels to ensure compliance with IACS UR E26 and UR E27. Executive summary of the history, such as internal decisions made, meeting minutes, reference to Form A or Form 1.

The objectives for PTPC07 have been defined in Form A as follows: "Establish common requirements for verification activities to ensure a harmonized practice for compliance with UR E26 and UR E27."

Further, it was decided by the Cyber Systems Panel in January 2023 that PTPC07 shall propose resolution of industry feedback to UR E26 and UR E27 ("pilot phase comments").

IACS officially released the unified requirements UR E26 "Cyber Resilience in Ships", and UR E27, "Cyber Resilience Equipment and Systems", in the month of April in the year 2022, with scheduled implementation date of 01 January 2024.

Given the relatively nascent nature of the subject matter in maritime sector, an imperative need to establish a standardized approach to survey requirements was envisaged and the aforementioned unified requirements underwent a meticulous revision, to incorporate survey requirements. Industry feedback on URs were also suitably addressed in revised URs (now referred to as Rev1) slated to come into effect on 01 July 2024.

During the course of development of UR Rev1, considering the challenges in implementation of the new cyber requirements in smaller vessels, falling under IACS's scope of applicability as delineated in "IACS General Procedures Volume 1 Chapter A Introduction- para 2 IACS's scope of interest," the applicability of these unified requirements was bifurcated as mandatory compliance for one category of vessels and non mandatory compliance for another category, in accordance with reference GPG mail 18197b.

Recognizing the intrinsic interrelationship between IACS UR E27 and UR E26, the scope of applicability of both URs and to eliminate any potential confusion which could arise within the industry, due to availability of two versions of same UR with different implementation date a strategic decision was taken to withdraw the original (new) version of UR E26 and UR E27, as initially published in the year 2022 which requires mandatory application to all ships contracted for construction from 01 January 2024.

This strategic approach also eliminates any conceivable perplexity in Industry that might arise from having two distinct versions/revisions of the same URs, characterized by a six-month variance in their implementation dates, divergent scopes of applicability, and supplementary survey information available through the official IACS website.

5 Other Resolutions Changes:

UR E26 may be impacted, for cross-reference purposes.

6 Any hinderance to MASS, including any other new technologies:

In the development of this UR, consideration has been given so as not to hinder the development of new or improved technologies providing an equivalent or higher level of safety.

Part B. Technical Background

List of Technical Background (TB) documents for UR E27:

Annex 1. **TB for New (Apr 2022)**

See separate TB document in Annex 1.

Annex 2. **TB for Rev.1 (Sep 2023) – Survey requirements**

See separate TB document in Annex 2.

Annex 3. **TB for Rev.1 (Sep 2023) – Pilot phase Comments**

See separate TB document in Annex 3.

Technical Background (TB) document for UR E27 (New Apr 2022)

1. Scope and objectives

The aim of this resolution is to establish cyber resilience unified requirements for onboard systems and equipment. The requirements specified in this UR are applicable to computer-based systems as defined in IACS UR E26.

This UR does not cover environmental performance for the system hardware and the functionality of the software. In addition to this UR, following URs shall be applied:

- UR E10 for environmental performance for the system hardware
- UR E22 for safety of equipment for the functionality of the software

2. Engineering background for technical basis and rationale

The evolving technology of surface vessels, container terminals, etc. and increased reliance upon Operational Technology (OT) and Information Technology (IT) convergence has created an increased possibility for attacks to affect personnel data, human safety, the safety of the ship, and to threaten the marine environment.

Attackers may target any combination of people and technology to achieve their aim, wherever there is a network connection or any other interface between onboard systems and the external world. Safeguarding shipping from current and emerging threats involves a range of measures that are continually evolving.

Currently the computer-based systems (CBS) are required to be tested according to UR E10 for Category II and Category III systems. However, as UR E10 specifies only environmental test requirements, the cyber security performance is not addressed.

It is then necessary to establish set requirements for cyber resilience of systems and equipment to be used on-board.

The cyber incidents considered in this resolution are events resulting from any offensive manoeuvre that targets OT systems onboard ships.

3. Source/derivation of the proposed IACS Resolution

The development of this resolution starts from the experience and knowledge acquired in the development of Recommendation 166 on cyber resilience of ships (IACS Recommendation 166).

IEC 62443-3-3 and IEC 62443-4-2 standards have been referred for development of this UR. The 62443 series of standards aim to improve the safety, availability, integrity and confidentiality of systems or components used for industrial automation and control and to provide criteria for procuring and implementing secure industrial automation and control systems.

IEC 62443-3-3 standard is part of IEC 62443 series to describe the System security requirements and security levels. The principal audience for this standard is intended to be asset owners, system integrators, product suppliers, service providers and, where appropriate, compliance authorities.
The requirements defined in this UR are derived from foundational requirements (FR) and subsequent system requirements (SR) described in IEC 62443-3-3 and IEC 62443-4-2 standards.

Whereas ISA/IEC 62443-3-3 standard have a robust, articulated and target-based definition of security levels (SLs), using SLs in this resolution in the same way and based on the same principles appear to be not compatible as the UR is set to provide minimum requirements. In this light, minimum set of requirements are extracted from IEC 62443-3-3 and defined in this UR. However, as the cyber attack surface has major impact on system/component cyber security, this aspect has been considered while identifying the requirements as detailed in this document. IACS UR E22 is referred for basic system categorization. It has been clarified that navigation and communication requirements will continue to follow existing IEC 61162-460 Standards.

This resolution has been designed to be open to future developments, to meet possible future evolution and improvements and continuously provide more and more appropriate answers to industry expectations e.g. on systems connectivity, digitalization and smart shipping.

Technical Background (TB) document for UR E27 (Rev.1 Sep 2023)

Survey requirements

1. Scope and objectives

Form A specified four work items, summarized as follows:

a) Specify verification activities of cyber physical systems delivered by product suppliers.
b) Specify verification activities of integration, architecture and implementation by shipyards or system integrators.
c) Specify verification activities of cyber security management during operation.
d) Establish guidance for acceptance criteria, compensating countermeasures, test methods and application of alternative standards.

2. Engineering background for technical basis and rationale

Since UR E27 specifies requirements for cyber physical systems delivered by product suppliers, it was decided that UR E27 Rev.1 should address item I and IV in Form A.

Furthermore, it was decided that UR E27 Rev.1 should specify requirements to how product suppliers shall demonstrate compliance with the requirements of UR E27. Hence, it should not specify how the classification societies shall carry out verification activities.

It was considered important to ensure the classification process specified in UR E27 is not in contradiction with UR E22.

Finally, it was considered important to rectify any faults or inconsistencies that may have been overlooked in the development of the original version of UR E27.

None

3. Source/derivation of the proposed IACS Resolution

None

4. Summary of Changes intended for the revised Resolution:

None

5. Points of discussions or possible discussions

5.1 IEC 63154 as alternative standard for navigation and radiocommunication systems
The application of alternative standards in lieu of UR E27 was discussed. An inconsistency was found in that UR E26 referred to IEC 61162-460 or IEC 63154 as alternative standards, whereas UR E27 referred to only IEC 61162-460. During the development of UR E27 Rev.1 it was understood that IEC 63154 refers to IEC 61162-460 as a normative standard, and consequently it would have been more appropriate to specify both IEC 61162-460 and IEC 63154 as an alternative to UR E27. However, this was considered too excessive, and it was decided to not mention IEC 63154 as an alternative standard.

5.2 IEC 61162-460 as alternative standard for navigation and radiocommunication systems.
It was proposed by PTPC07 that UR E26/UR E27 should be "agnostic" with respect to application of alternative standards, and the following text was accepted by the CS Panel:

> "*For navigation and radiocommunication systems, the application of other equivalent standards in lieu of the required security capabilities in UR E27 section 4 may be accepted by the Society, on the condition that requirements in UR E26 are complied with.*"

However, it was then learned that IEC TC80 was in progress of updating IEC 61162-460 with the aim to meet the requirements of UR E26 chapter 4. To acknowledge this work, the following text was decided:

> "*For navigation and radiocommunication systems, the application of IEC 61162-460 or other equivalent standards in lieu of the required security capabilities in UR E27 section 4 may be accepted by the Society, on the condition that requirements in IACS UR E26 are complied with*."

5.3 Additional security capabilities
The requirements in UR E27 section 4.2 applies for computer-based systems that will communicate with systems or networks outside the scope of UR E26 (untrusted networks).

Given that the technical requirements in UR E27 are derived from IEC 62443-3-3, it was questioned why UR E27 does not include relevant requirements in FR5 of IEC 62443-3-3 (segmentation of security zones and conduits traversing zone boundaries).

It was assumed that such requirements were omitted from UR E27 since these are specified in UR E26 section 4.2.1 and are primarily under the responsibility of the shipyard/system integrator.

However, for product suppliers delivering systems with e.g. remote support capabilities, UR E27 would not specify all required security capabilities. Therefore, it was decided to add the following sentence after the first paragraph of section 4.2:

"*CBSs with communication traversing the boundaries of security zones shall also meet requirements for network segmentation and zone boundary protection in UR E26 section 4.2.1 and 4.2.2*."

5.4 Documentation requirements

The original version of UR E27 specified in section 3 the documents to be submitted by the supplier.

The revised UR E27 includes a more detailed description of this documentation. To minimize changes to the original version of UR E27, this detailed description was added in the new section 6.2 (Plan approval) and referred to section 3, for consistency.

It was commented that this cross referencing is difficult to read and therefore it was decided that the new detailed description is moved to- and merged with section 3.

6. Attachments if any

None

Technical Background (TB) document for UR E27 (Rev.1 Sep 2023)

Pilot phase

1. Scope and objectives

When IACS UR E26 and UR E27 were published in April of 2022, it was decided that the period until mandatory implementation should be considered a "pilot phase" and consequently that feedback from the industry should be considered in a possible revision of the URs.

2. Engineering background for technical basis and rationale

To allow classification societies sufficient time for implementation of the revised UR E26 and UR E27 it was decided that cutoff date for considering feedback from the industry should be set to December 1st. 2022.

In the evaluation of the feedback from the industry it was decided to categorize the consolidated result of each comment as follows:

- Clarification (no change)
- Suggestion for improvement

2a. Specification of the data utilised in the development/revision of the proposed IACS Resolution, if any

None

3. Source/derivation of the proposed IACS Resolution

None

4. Summary of Changes intended for the revised Resolution:

None

5. Points of discussions or possible discussions

5.1 Definition of audit

It was suggested to add definition of Audit in UR E27 to ensure the reader will understand that terms such as "audit records" and "auditable events" in UR E27 have different meaning than "audit" required by the ISM Code. It was decided to not add the definition in UR E27, but instead clarify possible uses of the term "audit" in this TB:

<u>IACS Procedural Requirements for ISM Code Certification</u>: "Audit" means a

process of systematic and independent verification, through the collection of objective evidence, to determine whether the SMS complies with the requirements of the ISM Code and whether the Safety Management System (SMS) is implemented effectively to achieve the Code's objectives.

IEC 62443-3-3:2013 "Auditable events": The purpose of this requirement is to record the occurrence of important events which need to be audited as significant and relevant to the security of the control system.

IEC 62443-4-1:2018 "audit log": event log that requires a higher level of integrity protection than provided by typical event logs.

IEC 62443-1-1: 2009 "security audit": independent review and examination of a system's records and activities to determine the adequacy of system controls, ensure compliance with established security policy and procedures, detect breaches in security services, and recommend any changes that are indicated for countermeasures [8].

5.2 Relationship with IEC 62443-3-3

It was decided in the 14th CS panel meeting that the relationship between the requirements in UR E27 section 4 should be clarified by applying one of the following options:

- Change the text in UR E27 to align with the text in IEC 62443-3-3
- Add a note in UR E27 to clarify the relationship

The second alternative was decided during the development and hearing process of UR E27, and it was decided to add the following note to section 4:

> "*The requirements in this section are based on the selected requirements in IEC 62443-3-3. To determine the full content, rationale and relevant guidance for each requirement, the reader should consult the referenced standard*."

The classification societies may choose to enforce the requirement text as specified in UR E27 (taking into consideration the rationale in the IEC standard), or they may choose to follow the text in IEC 62443. This should make a significant difference. The following main differences were identified:

- Item 10 / SR 2.3: The note in UR E27 allows for compliance based only on physical port blockers. If the IEC 62443-3-3 is followed, the system itself should have capabilities to disable such ports, prevent use by unauthorized users, or prevent/restrict transfer of data to/from such devices. If these requirements cannot be met, it is fully possible to accept non-compliance based on compensating countermeasures such as physical port blockers. This should then be documented and informed to the Shipowner so that this can be incorporated into the policy and procedure for handling mobile and portable devices.

- Item 13 / SR 2.8: The following events are not listed in E27: request errors, control system events, potential reconnaissance events, audit log events. Also, E27 does not specify the content of the audit records (timestamp, source, category, type, event ID, event result.)

- Item 17 / SR 3.1: E27 includes "Note: Cryptographic mechanisms shall be employed for wireless networks". This is possibly quite OK since such encryption is believed to be part of "commonly accepted industry practices" in SR 2.2.

- Item 21 / SR 4.1: E27 includes "Note: Cryptographic mechanisms shall be employed for wireless networks". This is possibly quite OK since such encryption is believed to be part of "commonly accepted industry practices" in SR 2.2.

5.3 Secure development lifecycle (SDL) requirements

It was questioned how the classification societies would apply the SDL requirements for computer-based systems that are developed before the SDL requirements became mandatory.

Some of the requirements are not specifically related to the development process whereas other requirements may be enforced following a reasonable and practicable approach.

It may be noted that the seven SDL requirements in UR E27 are to some extent lacking the complete context since the majority of the requirements in IEC 62443-4-1 are not implemented in UR E27.

5.4 Definition of computer-based network

The definition of computer-based network was discussed in the 14th CS Panel meeting.
It was agreed to use the same definition in UR E26 and E27:

> "*Computer Network: A connection between two or more computers for the purpose of communicating data electronically by means of agreed communication protocols*."

It was also proposed to add the following sentence:

> "*Networks within a computer are not necessarily dealt with as computer network*."

The reason for the amended sentence was to allow for unmanaged network switches to be used within CBSs delivered by suppliers, even if such switches do not support many of the requirements in UR E26 and UR E27 (e.g. item 1 in Table 1).
It was decided in the 15th CS panel meeting that the amended sentence is not needed due to the following reasons:

- If a device in a CBS does not have human user interface, then the requirements related to human user interface is not applicable (e.g. item 1 in table 1), hence such requirements would not prevent the use of an unmanaged switch.
- An unmanaged network switch cannot provide functionality to protect against excessive network traffic. Ref. UR E26 section 4.2.2.1/4.3.1.3 and UR E27 item 24. However, if such protection functions can be implemented in the endpoints of the network (e.g. in the PLCs and HMI-devices), then it would be acceptable to use unmanaged switch in a CBS.
- An unmanaged network switch cannot provide functionality to prevent connection of mobile/portable devices to the network. Ref. UR E26 section 4.2.7 and UR E27 item 10. However, this should be acceptable if the network switch and all its connected devices are installed in a locked cabinet and/or in an area with control of physical access. In addition, unused ports should be physically blocked.

UR F2 "Aluminium Coatings on Board Oil Tanker and Chemical Tankers"

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev.2 (Nov 2012)	21 November 2012	1 January 2014
Corr.1 (March 1999)	04 March 2012	-
Rev.1 (May 1998)	28 May 1998	-
NEW (May 1971)	*No records*	-

- **Rev.2 (Nov 2012)**

.1 Origin for Change:

☑ Suggestion by IACS Member/ CSR PT2

.2 Main Reason for Change:

- To align UR F2 with CSR-DHOT, per KC695.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

At 12th Hull Panel Meeting, it was agreed by the Hull Panel to amend UR F2 to align it with CSR-DHOT.

For Technical Background, see Annex 1.

.5 Other Resolutions Changes

None

.6 Dates:

Original proposal: *20 September 2011* *Made by: Hull Panel Chair*
Panel Approval: *01 October 2012* *by: Hull Panel*
GPG Approval: *21 November 2012 (12172_IGc)*

- **Corr.1 (March 1999)**

It was found that the text of UR F2 Rev.1 in clean version was not the same of the underlined version. As the UL version of UR F2 Rev.1 was adopted by Council the clean version must have the same text. Therefore the clean version was corrected accordingly.

- **Rev.1 (May 1998)**

Addressed a use of aluminium pipes in hazardous areas on open deck, inerted cargo tanks and ballast tanks.

Adopted by C37.

- **NEW (1971)**

No history available.

Part B. Technical Background

List of Technical Background (TB) documents for UR F2:

Annex 1. **TB for Rev.2 (Nov 2012)**

See separate TB document in Annex 1.

◄▼►

Note: *There are no Technical Background (TB) documents available for the original resolution (1971), Rev.1 (May 1998), or Corr.1 (March 1999).*

TECHNICAL BACKGROUND DOCUMENT
IACS UR F2 (REV.2, Nov 2012)

1. Scope and objective

To align UR F2 with CSR-DHOT.

2. Background

Knowledge Center Item 695 was created to clarify the differences between CSR-DHOT and UR F2 regarding aluminum coatings. In June 2008, an answer was approved for KC 695, indicating that there was in fact inconsistency between the documents and that one or the other would be updated to ensure consistency. At the suggestion of the CSR PT2 at the 12th Hull Panel Meeting, the Hull Panel agreed that UR F2 should be amended to align with CSR-DHOT.

3. Points of discussions or possible discussions

- Aluminum limit and testing procedure
  - CSR-H DHOT allows for coatings with greater than 10% Al, if "it has been shown by appropriate tests that the paint to be used does not increase the incendiary sparking hazard."
  - However, this clause was not included in this revision of UR F2 because the Hull Panel Members had limited experience with coatings with greater than 10% Al and the testing procedures for such coatings. In the absence of an Industry Standard test procedures, the Hull Panel preferred to set a strict upper limit of 10% Al limit.

4. Source / derivation of proposed requirements

- CSR-DHOT, Section 6 2.1.3.1

Submitted by Hull Panel Chairman
[01 Oct 2012]

UR F7 "Portable instruments for measuring oxygen and flammable vapour concentrations"

Summary

UR F7 has been corrected to clarify the application statement so that it clearly only applies to new construction.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Corr.1 (Nov 2020)	20 November 2020	-
Rev.3 (June 2020)	13 June 2020	1 July 2021
Rev.2 (May 1999)	May 1999	-
Rev.1 (1989)	1989	-
New (1971)	1971	-

- ### Corr.1 (Nov 2020)

1 Origin of Change:

☑ Suggestion by IACS member

2 Main Reason for Change:

To clarify that there was no intention to retroactively apply the Rev.3 to existing ships.

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None

4 History of Decisions Made:

The application statement was updated to included the phrase "on ships contracted for construction on or after 1 July 2021".

5 Other Resolutions Changes:

None

6 Any hinderance to MASS, including any other new technologies:

None

7 Dates:

Original Proposal: 04 August 2020
Panel Approval: 09 November 2020 (Ref: 20080_PSb)
GPG Approval: 20 November 2020 (Ref: 20080_IGf)

- **Rev.3 (June 2020)**

1 Origin of Change:

☑ Suggestion by IACS member

2 Main Reason for Change:

To distinguish between portable gas detectors capable of measuring flammable vapour concentrations in air and it capable of flammable vapour concentrations in inerted atmosphere.

To incorporate the content of UI SC149.

3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

4 History of Decisions Made:

More clear distinction between gas detectors described in UR F7 was proposed within the Safety Panel by a member. After some discussion it was agreed to revise the UR F7. It was also agreed to incorporate the content of UI SC149 into UR F7.

5 Other Resolutions Changes:

None

6 Any hinderance to MASS, including any other new technologies:

None

UR F7 Rev. 2

- Objective and scope

Upgrade this UR to adequately cover oil tankers with IGS.
Take into account SOLAS 1996 amendments to Reg. II-2/59.

- Sources of proposed requirements

UR F7
Reg. II-2/59

- Unanimous agreement achieved.

Date of submission: 21 May 1999
By BV

Technical Background (TB) document for UR F7 (Rev.3 June 2020)

1. Scope and objectives

This revision is intended to make more clear distinction between portable gas detectors capable of measuring flammable vapour concentrations in air and it capable of flammable vapour concentrations in inerted atmosphere. This revision also intended to incorporate relevant IACS UI.

2. Engineering background for technical basis and rationale

The main purpose of measuring flammable vapour concentrations in air is considered to determine what percentage of gas is present relative to lower explosive limit (LEL).

Regarding measuring flammable vapour concentrations in inerted atmosphere, determining % LEL rather than % gas by volume in an atmosphere without oxygen does not make sense.

3. Source/derivation of the proposed IACS Resolution

UR F7 is related to SOLAS Reg. II-2/4.5.7.1.

"5.7.1 Portable instrument
Tankers shall be equipped with at least one portable instrument for measuring oxygen and one for measuring flammable vapour concentrations, together with a sufficient set of spares. Suitable means shall be provided for the calibration of such instruments."

4. Summary of Changes intended for the revised Resolution:

More clear distinction between portable gas detectors capable of measuring flammable vapour concentrations in air and it capable of flammable vapour concentrations in inerted atmosphere has been made

Content of UI SC149 which is the interpretation for SOLAS Reg. II-2/4.5.7.1 has been incorporated

5. Points of discussions or possible discussions

Regarding changes for distinction between portable gas detectors, see 2. above.

Members understand that the original intent of UI SC 149 is to make a link between UR F7 and SOLAS II-2/4.5.7.1. Thus, UR F7 has been revised to incorporate UI SC149.

UR F15
"Reinforced thickness of ballast and cargo oil piping"

Summary

In Rev.7, the words "not glands" is deleted and two definitions of "expansion bends" and "heavy flanges joints" are added so as to eliminate possible mis-understanding or confusion.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev.7 (Sep 2023)	12 September 2023	01 January 2025
Corr.1 (Feb 2021)	07 February 2021	-
Rev.6 (Feb 2021)	15 February 2021	1 July 2022
Rev.5 (1996)	1996	-
Rev.4 (1989)	1989	-
Rev.3	No record	-
Rev.2	No record	-
Rev.1	No record	-
New (1982)	1982	-

- **Rev.7 (Sep 2023)**

1 Origin of Change:

☑ Suggestion by IACS Member

2 Main Reason for Change:

In F15.1.1, it reads "*Expansion bends only (not glands) are permitted in these lines within cargo tanks for serving the ballast tanks and within the ballast tanks for serving the cargo tanks.*". But except for "shaft gland", "stern gland", "inboard gland" used in SOLAS and "gas-tight gland" in IACS UR M24.4, the word "gland" is not found in any other IMO documentations or IACS documentation. Also, in the above-mentioned circumstances in SOLAS and IACS UR M24, the word "gland" does not have the meaning of expansion. This situation has caused some misunderstanding and confusion.

During discussion, one IACS Member also suggested, and was agreed by other members, to provide definitions of "heavy flanged joints" and "expansion bends" used in this UR.

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None

4 History of Decisions Made:

None

5 Other Resolutions Changes:

None

6 Any hinderance to MASS, including any other new technologies:

None

7 Dates:

Original Proposal:	05 July 2022 (Ref: PM22302_IMa)
Panel Approval:	29 August 2023 (Ref: PM22302_IMe)
GPG Approval:	12 September 2023 (Ref: 23158_IGb)

• Corr.1 (Feb 2021)

1 Origin of Change:

☑ Suggestion by IACS Member

2 Main Reason for Change:

References to the latest MARPOL Regulation needed corrections and unpreferable phrase "as amended by IMO resolutions up to MEPC.314(74)" needed removal as agreed by Machinery Panel.

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None

4 History of Decisions Made:

None

5 Other Resolutions Changes:

None

6 Any hinderance to MASS, including any other new technologies:

None

7 Dates:

Original Proposal:	5 October 2021 (Ref: PM20906oIMa)
Panel Approval:	12 November 2021 (Ref: PM20906oIMb)
GPG Approval:	07 February 2021 (Ref: 20206aIGf)

- **Rev.6 (Feb 2021)**

1 Origin of Change:

☑ Other (Periodical review to reflect the latest IMO Resolutions)

2 Main Reason for Change:

There was a need to update this UR to reflect the latest IMO Resolutions related to MARPOL Annex I.

To take this opportunity, references to IMO instruments have been specified in the following format based upon confirmation of amendments up to the latest one:

regulation/paragraph x.x.x of SOLAS/MARPOL/the XXX Code, as amended by resolutions MSC/MEPC.xx(xx), (...) and MSC/MEPC.xx(xx)

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

Technical Background (TB) document for UR F15 (Rev.6 Feb 2021)

1. Scope and objectives

UR F15 (Rev.5) does not reflect the latest IMO Resolutions related to MARPOL Annex I. Rev.6 has been developed to correct references to the regulation of MARPOL Annex I.

2. Engineering background for technical basis and rationale

Format for references to IMO instruments (where the number of amendments is large)

> ***Format:***
> *regulation/paragraph x.x.x of SOLAS Chapter X/MARPOL Annex X/the XXX Code, as amended by IMO resolutions up to MSC.xx(xx)/MEPC.xx(xx)*

The change of the title of UR F15

It was agreed that the title of UR F15 "Piping passing through dangerous zones" should be modified to "Reinforced thickness of ballast and cargo oil piping".

3. Source/derivation of the proposed IACS Resolution

None

4. Summary of Changes intended for the revised Resolution:

UR F15 has been updated to reflect the latest IMO Resolutions related to MARPOL Annex I as follows:

Regulations of MARPOL Annex I before the amendment adopted by Resolution MEPC.117(52)	Replaced by regulations of MARPOL Annex I as amended by IMO resolutions up to MEPC.314(74)
MARPOL Annex 1 Reg. 13F	Regulation 19.6.3.6 of MARPOL Annex I
Unified Interpretation to Regulation 1(17)	Unified Interpretation to Regulation 1.18

5. Points of discussions or possible discussions

None

6. Attachments if any

None

Technical Background (TB) document for UR F15 (Corr.1 Feb 2022)

1. Scope and objectives
To correct an editorial error (reference to the latest MARPOL Regulation) and to remove an unpreferable phrase for references to IMO instruments.

2. Engineering background for technical basis and rationale
None

3. Source/derivation of the proposed IACS Resolution
None

4. Summary of Changes intended for the revised Resolution:
UR F15 has been corrected to fix the reference to MARPOL Regulation and to remove an unpreferable phrase "*as amended by Resolutions up to [...]*" as follows:

UR F15 Rev.6	**UR F15 Rev.6 Corr.1**
Regulation 19.6.3.6 of MARPOL Annex I as amended by IMO resolutions up to MEPC.314(74)	Regulation 19.3.6 of MARPOL Annex I
Unified Interpretation to Regulation 1.18 of MARPOL Annex I as amended by IMO resolutions up to MEPC.314(74)	Unified Interpretation to Regulation 1.18 of MARPOL Annex I

5. Points of discussions or possible discussions

None

6. Attachments if any

None

Technical Background (TB) document for UR F15 (Rev.7 Sep 2023)

1. Scope and objectives

In Rev.7, the words "not glands" is deleted and two definitions of "expansion bends" and "heavy flanges joints" are added so as to eliminate possible mis-understanding or confusion.

2. Engineering background for technical basis and rationale

In F15.1.1, it reads "*Expansion bends only (not glands) are permitted in these lines within cargo tanks for serving the ballast tanks and within the ballast tanks for serving the cargo tanks.*". But except for "shaft gland", "stern gland", "inboard gland" used in SOLAS and "gas-tight gland" in IACS UR M24.4, the word "gland" is not found in any other IMO documentations or IACS documentation. Also, in the above mentioned circumstances in SOLAS and IACS UR M24, the word "gland" does not have the meaning of expansion. This situation has caused some mis-understanding and confusion.

During discussion, one IACS Member also suggested, and was agreed by other members, to provide definition of "heavy flanged joints" used in this UR.

3. Source/derivation of the proposed IACS Resolution

None

4. Summary of Changes intended for the revised Resolution:

UR F15.1.1 was modified as follows:
"
F15.1.1 The pipes are to be of heavy gauge steel of minimum wall thickness according to the table hereunder with welded or heavy flanged joints[1] the number of which is to be kept to a minimum.

Expansion bends[2] only are permitted in these lines within cargo tanks for serving the ballast tanks and within the ballast tanks for serving the cargo tanks.

Nominal diameter (mm)	Minimum wall thickness (mm)
50	6.3
100	8.6
125	9.5
150	11.0
200 and above	12.5

[1]*Heavy flanges joints means welded flange joints rated at least PN10 or one pressure rating higher than required design pressure, whichever is greater.*

[2]*Expansion bends means expansion loops such as an omega bend (' Ω ') in piping system to counteract excessive stresses or displacement caused by thermal expansion or hull deformation which could be fabricated from straight lengths of pipe.*
"

5. Points of discussions or possible discussions
None

6. Attachments if any

.1 Origin for Change:

☑ Base on IMO Resolution MSC.367(93)

.2 Main Reason for Change:

To harmonize the UR with the amended FSS Code as per MSC.367(93).

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

The amended FSS Code Chapter 15 as per MSC.367(93) is applied to tankers, including chemical tankers, constructed on or after 1 January 2016, therefore it was necessary to harmonize the UR with the amended FSS Code. Machinery Panel approved Rev.7 of the UR during its 21st Meeting in March 2015, and approved its technical background on 2 Apr 2015.

.5 Other Resolutions Changes

None

.6 Dates:

Original proposal: 15 December 2014 made by: Machinery Panel
Panel Approval: the 21st Meeting held from 3rd to 6th March 15 March 2015
by: Machinery Panel
GPG Approval: 17 May 2015 (Ref. 11043_IGf)

- **Rev.6 (May 2012)**

.1 Origin for Change:

☑ Request by non-IACS entity (Wilhelmsen Technical Solutions)

.2 Main Reason for Change:

To clarify the term "safe location" in F20.4.10.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

IACS Statutory Panel considered the query on IACS UR F20 forwarded by the IACS PermSec under the long-standing Task 8 “Maintenance of IACS Resolutions” and developed an IACS common understanding on the term "safe location" in F20.4.10. It was unanimously decided to revise IACS UR F20 as per the agreed IACS common understanding. Final version of the revised UR and technical background documents were approved by the Statutory Panel on 25th February 2012.

Rev.6 proposed by the Statutory Panel was supported by the Machinery Panel.

.5 Other Resolutions Changes

None

.6 Dates:

Original proposal: *25 August 2011 made by: Statutory Panel*
Panel Approval: *15 April 2012 by: Statutory panel*

Part B. Technical Background

List of Technical Background (TB) documents for UR F20:

Annex 1. **TB for Rev.5 (November 2005)**

See separate TB document in Annex 1.

◄▼►

Annex 2. **TB for Rev.6 (May 2012)**

See separate TB document in Annex 2.

◄▼►

Note: There are no separate Technical Background (TB) documents for Original resolution (1974), Rev.1 (1983), Rev.2 (1987), Rev.3 (May 1998), Corr.1 (Sept 2001), Rev.4 (May 2004) and Rev.7 (May 2015).

Technical background
UR F20 (Rev.5, Nov 2005)

The text of the existing paragraph F20.4.15, applicable to Nitrogen Generation Systems (NGS), contains a requirement for the number of oxygen recording devices that is more stringent than the correspondent requirement applicable to other kind of Inert Gas System (IGS) as explained in the following:

1. The requirements set out in both the Fire Safety System Code and UR F20 regarding the display and recording of the oxygen content of inert gas are equivalent for IGS based on boiler flue gas and oil fired inert gas generators, i.e. display in the Cargo Control Room (CCR) and Machinery Control Room (MCR) or Machinery Space (MS) while recording is only required in the CCR, where provided, or in a position easily accessible for the officer in charge of cargo operations;

2. Paragraph F20.4.15 requires display and recording of the oxygen content of the inert gas downstream of the NGS to be placed in the CCR and MCR or MS. This requirement implies that two records on paper are maintained onboard in two different locations.

3. It should be noted that the recording device mentioned in the above is fitted with the purpose of continuously recording the oxygen content in the Nitrogen flow. This is aimed to provide with an evidence for compliance with the requirements (maximum content of Oxygen: 5% as per paragraph F20.4.6) during the operation. The purpose to indicate continuously the Oxygen content in the Nitrogen flow to the crew is assured by the display devices, placed in both the CCR and MCR or MS.

4. There is no reason for such requiring the duplication of the recording of oxygen content for the NGS only; and, therefore, it was proposed that the text of paragraph F20.4.15 should be changed and put in line with the requirement of FSS Code Chapter 15, paragraph 2.4.2.2.

Submitted by Statutory Panel
7 Nov 2005
(s/n 5030e)

Note by Permsec:
GPG/Council agreed that no implementation date was needed for this revision.

Technical Background for UR F20 Rev.6, May 2012

1. Scope and objectives

This revision of UR F20 is done to clarify the term "safe location" in F20.4.10 for its uniform application as per the agreed IACS common understanding.

2. Engineering background for technical basis and rationale

Keeping in mind that the understanding/interpretation proposed by Wilhelmsen Technical Solutions has received no strong support from the Statutory Panel Member, it was decided to develop an IACS common understanding to clarify the term "safe location" in F20.4.10 based on Members' practical experience on application of UR F20.

3. Source/derivation of the proposed IACS Resolution

IACS Common understanding prepared in reply to Wilhelmsen Technical Solutions' query on IACS UR F20 forwarded by the IACS PermSec.

4. Summary of Changes intended for the revised Resolution:

The following footnote was added to clarify the term "safe location" in F20.4.10:

*) "safe location" needs to address the two types of discharges separately:

1. oxygen-enriched air from the nitrogen generator - safe locations on the open deck are:
- outside of hazardous area;
- not within 3m of areas traversed by personnel; and
- not within 6m of air intakes for machinery (engines and boilers) and all ventilation inlets.

2. nitrogen-product enriched gas from the protective devices of the nitrogen receiver - safe locations on the open deck are:
- not within 3m of areas traversed by personnel; and
- not within 6m of air intakes for machinery (engines and boilers) and all ventilation inlets/outlets.

5. Points of discussions or possible discussions

The UR was reviewed and discussed within IACS Statutory and Machinery Panels via email correspondence.

6. Attachments if any

None

Annex 1 :
Technical background documents

UR F 16 - Bow and stern loading and unloading arrangements on oil tankers

- Scope and objectives

To take into account MSC/Circ. 474 which also deals with this subject.

- Points of discussion

The title has been changed to be in line with the circular and be restricted to oil tankers, as chemical and gas tankers have detailed requirements in the codes.

The acceptable segregation requirements have been extended to include those of the circular.

The location of the segregation device has been harmonized with the circular.

To be noted : the UR deals with segregation, while the circular recommendations deal with many other aspects.

UR F 26 - Safety aspects of double bottoms and duct keels under cargo oil tanks

- Scope and objectives

To link the UR with SOLAS Reg. II-2/56.9 which also deals with duct keels.

Technical Background Document

UR F29 (Rev.6 June 2005)

Non sparking fans

Protection screens are required to prevent the entrance of foreign objects into the fan housings. The largest probabilities of origin for these foreign objects are from the open areas and the UR is amended to reflect this.

Submitted by WP/FP&S Chair
14/01/2005

Technical Background
To

DELETION OF F 30

&

NEW UR M 62 (Feb. 2002)

In the WP/FP+S Progress Report No.34 (March 2001), the WP/FP+S proposed to transfer three parts of F30 as interpretations (three UI SCs) and to drop the rest, as they were adequately covered by SOLAS and other interpretations.
(Task No.31: To re-formulate F30, F34 and F35 into UIs or RECs as appropriate)

The following steps have been taken:

1. GPG agreed to completely delete F30 from the Blue Book at its 50th meeting (Tokyo, March 2001);

2. GPG approved the three UI SCs 162, 163, and 164, as proposed by WP/FP+S, which were not covered by the Convention;

3. After GPG 50, LR confirmed that the WP/MCH's proposed amendment to F30.2.7 (The rooms where the pump mover…) was not contained in the Convention, however, it was already contained in LR Rules. LR had no objection to it being a UR on Machinery. Finally, GPG agreed that the proposed amendment to F30.2.7 should be classified as UR M 62 "Rooms for em'cy fire pumps in cargo ships".

- Outcome
  1. Deletion of F30.
  2. Creation of new UR M62.
  3. Creation of three UI SCs 162, 163, and 164.

- Information
  GPG agreed that F30.4.1 should be formulated as a UI if it is not dealt with in the SOLAS text.
  The text was prepared by WP/MCH with due consideration to practical difficulty for larger ships in meeting M 46 inclination requirements. However, having identified a need to define "lightest seagoing condition" in the draft UI SC zzz, GPG tasked WP/FP+S to consider Members' experience of plan approval work and performance test after installation of em'cy fire pump systems in consultation with CG/LSA (Refer to the outcome of WP/FP+S Task 39).

Prepared by the Permanent Secretariat

(submitted on 30 August 2001)

UR F35 Rev. 6

- Objective and scope

Solve reservations on various paragraphs.
Take into account SOLAS 1994 amendments to Reg. II-2/15.

- Sources of proposed requirements

UR F35
Reg. II-2/15

- Unanimous agreement achieved.

Date of submission: 21 May 1999
By BV

Technical Background
F 35 (Rev.7, July 2003)

1. Background

WP/FP&S undertook Task 31 "to reformulate F35 into a UI or REC as appropriate"

2. Points of discussion

WP/FP+S submitted a draft UI for SOLAS II-2 concerning fire protection of machinery spaces. At the same time, WP submitted a revised Recommendation No.58 "Fire Protection of Machinery Spaces".

GPG noted that the draft UI together with the revised REC 58 resulted in deletion of UR F35. However, GPG further noted that IMO has just adopted temporary measures pending adoption of SOLAS amendments at a later stage, referring directly to UR F35 and deletion of F35 from the IACS Blue Book would cause confusion.

Finally, the proposed UI was provisionally adopted as UR F35 (Rev.7) and retained as such IMO amends SOLAS.

ABS' proposal to retain in F35 only reg.II-2/4.2.2.4 and issue all the remaining interpretations as UIs was not supported.

*****

UR F39 Rev. 3

- Objective and scope

Solve reservations.
Take into account WP/EL work.

- Sources of proposed requirements

WP/EL

- Unanimous agreement achieved

Footnote concerning item 2, which reads "the individual Society may introduce into their Rules only one of these two options, instead of both", to be noted.

Date of submission: 21 May 1999
By BV

F 39 Measures to prevent explosion in cargo pump rooms on oil tankers

(Rev.4 May 2001 + Deletion on 30 June 2002)

Technical Background

a) Objective/Scope

The objective was to have F39 aligned with the SOLAS II-2/Reg.4.5.10.1 (Res MSC.99(73)).

b) History

1) AHG/FSA submitted the results of FSA case study for evaluation and effectiveness of F 39 to GPG 46 (March 1999). This study did not suggest any amendment to F 39 and indicated that there would be little improvement of safety to be gained by interlocking the pump room lighting with the ventilation.

However, WP/EL proposed an alternative approach for F 39.2, by adding "an alarm is given ...". This was further elaborated by WP/FP+S. Draft of Rev.3 F 39 was modified by GPG during GPG 46 with addition of the Note. Council approved it in July 1999.

2) After adoption of F 39(Rev.3), IACS communicated with OCIMF, Intertanko and ICS to explain them about the content of F 39.2(ii).

3) Having taken actions under GPG 47 FUA 40 & 41 (October 1999), GPG finally submitted a document to MSC 72 (MSC 72/8/1) on 1 February 2000, proposing an alternative to the draft amendment to SOLAS II-2/63.3, which will stand from 1 July 2002 as II-2/Reg.4.5.10.1.

4) MSC 72 Report (MSC 72/23, para. 8.3): The Committee noted IACS document MSC 72/8/1........ did not agree to the proposal by IACS. IACS Observer's Recommendation No.8 was to amend UR F 39 accordingly.
The revised SOLAS Ch.II-2 was adopted at MSC 73 (5 December 2000) as Res. MSC.99(73). It will brought into force from 1 July 2002.

c) Points of Discussion

GPG noted that F 39 would be covered by the SOLAS II-2/Reg.4.5.10.1, however, F39.2.(ii) would be contradictory to the aforesaid SOLAS II-2 requirement and the two sentences in F39.3 were not covered by SOLAS II-2. To overcome this discrepancy between F39 and SOLAS, GPG decided that F39 be deleted from Blue Book as of 1 July 2002 and WP/FP&S consider transforming the 3rd and 4th sentences in F39.3 into UIs, as appropriate. See UI SC 172(August 2002).

Decision/action were taken on 18 May 2001.

* * * * *

 Prepared by the Permanent Secretariat (9 May 2001)

UR F42 "Fire testing of flexible pipes"

Summary

This IACS Resolution addresses the fire testing of flexible pipes and specifies test requirements for the fire test. UR F42 has been deleted as all requirements are considered by UR P2 section 12 Flexible Hoses.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Del (Nov 2023)	24 November 2023	-
Original version	1995	-

- **Del (Nov 2023)**

1 Origin of Change:

☐ Based on IACS Requirement *(Periodic review of IACS Resolutions)*

2 Main Reason for Change:

UR P2 considers all requirements of UR F42.

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None

4 History of Decisions Made:

Discussed by correspondence in the Safety Panel.

Members compared the requirements of UR P2.12 and UR F42 and agreed that UR P2.12 covers all requirements of UR F42, e.g.

- P2.12.3.5 Flexible hose assemblies constructed of non-metallic materials intended for installation in piping systems for flammable media and sea water systems where failure may result in flooding, are to be of fire-resistant type […]. Fire resistance is to be demonstrated by testing to ISO 15540 :2016 and ISO 15541 :2016.

- Comparison of relevant requirements summarised below

UR F42	UR P2.12/ISO 15540:2016
30 min fire test	duration 30 min
Flame temperature of 800°C	temperature of flame 800 ±50°C
Flowing water at maximum service pressure or at 5 bar and subsequent pressure test to twice the design pressure	pressure during test: at least (5 ±0.2) bar or the maximum allowable working pressure (M.A.W.P.) as identified on the product
Temperature of the water at the outlet > 80°C	temperature of flowing water in: 80 ±2°C; out: max 85°C
	pressure test after fire test: hose assemblies normally two times the M.A.W.P.; compensators 1.5 times the M.A.W.P.
No leak during or after the test	test is considered as passed when the test specimen remains tight when subjected to proof pressure after flame application

5 Other Resolutions Changes:

None

6 Any hinderance to MASS, including any other new technologies:

Part B. Technical Background

Note: *There is no separate Technical Background (TB) document available for Del (Nov 2023) and Original version.*

UR F43 "Installation requirements for analysing units for continuous monitoring of flammable vapours"

Summary

UR F43 is deleted because all the requirements have been included into FSS CODE CHAPTER 16 FIXED HYDROCARBON GAS DETECTION SYSTEMS, as amended by resolution MSC.292(87), and relating SOLAS provisions.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Deleted	31 January 2025	-
Rev.2 (June 2002)		
Rev.1 (July 1999)		
New (1997)		

- **Deletion (Jan 2025)**

1 Origin of Change:

Select a relevant option and delete the rest.

✓ Suggestion by IACS member

2 Main Reason for Change:

Resolution MSC.292(87) adopted the contents in UR F43 into a new Chapter 16 in FSS Code, also the requirements for "bulkhead penetrations of sample pipes between safe and dangerous areas shall be of approved type and have same fire integrity as the division penetrated" are included in relating SOLAS provisions.

3 Surveyability review of UR and Auditability review of PR

Not applicable.

4 Human Element issues assessment

Not applicable.

5 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None.

6 History of Decisions Made:

1. An IACS member proposed to delete UR F43.

2. A member pointed out that the sentence in UR F43 "bulkhead penetrations of sample pipes between safe and dangerous areas shall be of approved type and have same fire integrity as the division penetrated" is not in FSS CODE CHAPTER 16 FIXED HYDROCARBON GAS DETECTION SYSTEMS, as amended by resolution MSC.292(87), so it's preferred not to delete UR F43, but to modify UR F43 and keep this sentence in the new version UR F43.

3. But other members pointed out that this above requirement is included in the relating SOLAS provisions as well as FTP Code.

7 Other Resolutions Changes:

None.

8 Any hinderance to MASS, including any other new technologies:

None.

9 Dates:

Original Proposal:	Date: 07 November 2024	Made by: PM24027_IMa
Panel Approval:	Date: 12 December 2024	Made by: PM24027_IMb
GPG Approval:	Date: 31 January 2025	Made by: (24216_IGd)

- **Revision No.2 (June 2002)**

No HF/TB document available.

- **Revision No.1 (July 1999)**

See Annex.1

- **New (1997)**

No HF/TB document available.

Part B. Technical Background

List of Technical Background (TB) documents for UR F43:

Annex 1. **TB for Rev.1 (July 1999)**

See separate TB document in Annex 1.

Annex 2. **TB for Deletion (Jan 2025)**

See separate TB document in Annex 2.

Technical Background (TB) document for UR F43 Rev.1

1. Scope and objectives
Removing the undefined expression “gas tight”.

2. Sources of proposed requirements
F43

3. Member’s proposals
A unanimous agreement was achieved.

Technical Background (TB) document for Deletion of UR F43 (Del Jan 2025)

1. Scope and objectives

UR F43 is deleted because all the requirements have been included into FSS CODE CHAPTER 16 FIXED HYDROCARBON GAS DETECTION SYSTEMS, as amended by resolution MSC.292(87), and relating SOLAS provisions.

2. Engineering background for technical basis and rationale

Resolution MSC.292(87) adopted the contents in UR F43 into a new Chapter 16 in FSS Code, also the requirements for "bulkhead penetrations of sample pipes between safe and dangerous areas shall be of approved type and have same fire integrity as the division penetrated" are included in relating SOLAS provisions.

3. Source/derivation of the proposed IACS Resolution

- SOLAS II-2/9
- FSS CODE CHAPTER 16 FIXED HYDROCARBON GAS DETECTION SYSTEMS, as amended by resolution MSC.292(87)

4. Summary of Changes intended for the revised Resolution:

UR F43 is deleted.

5. Points of discussions or possible discussions

During the discussion the main discussion points were

- whether the whole UR F43 is to be deleted?

- whether UR F43 is to be modified so as to keep the requirements "bulkhead penetrations of sample pipes between safe and dangerous areas shall be of approved type and have same fire integrity as the division penetrated"?.

6. Attachments if any

None.

UR F44 "Fore peak ballast tanks and space arrangements on oil & chemical tankers"

Summary

UR F44 contains requirements for fore peak ballast tanks and forward space arrangements for oil tankers and chemical tankers
In Rev.3 amendments were made to extend the application of UR F44 to chemical tankers.
Correction 1 corrected an error in the operational requirements in all sample figures in relation to the required air exchange rate.

Part A. Revision History

☐ Suggestion by IACS member

2 Main Reason for Change:

The UR F44 was issued in June 2000 and was at that time not made applicable to chemical tankers, only to oil tankers. The entry into force of the Ballast Water Management Convention and consequently the required installation of ballast water treatment systems has actualized the need to reconsider the strict understanding of IBC Code Reg. 3.5 and consequently consider enlarging the application of this UR also to chemical tankers.

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None

4 History of Decisions Made:

Based on the proposal by an IACS Member it was agreed to enlarge the application of this UR to chemical tankers. In order to consider the additional issue regarding the access to the FPT (hazardous zone) from the enclosed space (considered gas safe), the formation of a Project Team was agreed in order to align the approach in UR F 44 with the IEC 60092 and with the UI SC 274. The PT considered the following objectives:
- To review associated risks and evaluate consequences of alignment of access requirements to FPT for both oil- and chemical tankers.
- To develop an updated UR F44 based on a common understanding and interpretation of the input from IACS-members.
- To review associated risks and evaluate consequences of defining compartment built on top of compartment adjacent to cargo tank, to not be defined as part of cargo area. To avoid bosun store being defined as being within cargo area, in line with multiple vessel’s being built.
- To develop an updated UI SC 211 based on a common understanding and

interpretation of the input from IACS-members.

Draft Rev. 3 was provided for an industry hearing. Comments received were considered.

5 Other Resolutions Changes:

IACS Unified Interpretation SC211 has been amended in accordance with the revision of UR F44, i.e. a new interpretation 2 regarding the spaces referred to in SOLAS II-2/3.6 and IBC Code 1.3.6.

6 Any hinderance to MASS, including any other new technologies:

UR F44 (New) Fore peak ballast system on oil tankers

- Scope and objectives

To harmonize the practices of IACS Societies with respect to:

- connection of fore peak tanks to the ballast system of the cargo area
- access to fore peak tanks

- Points of discussion

SOLAS does not deal with ballast systems of tankers nor with hazardous areas. It only deals with access to ballast tanks adjacent to cargo tanks. It was then agreed to draft a UR rather than a UI.

The WP also agreed to make this UR applicable only to oil tankers for the time being but agreed as a second step to advise the group MP-BC-GT to further consider it.

The main discussion was on the location of the access manhole in an enclosed space.

The UR as is proposed take into account the fact that, for fore peaks separated by a cofferdam from the cargo tanks, the risk to have it hazardous is remote and the opening of a bolted manhole is infrequent. However that risk is there and means to take measurements and to gas free the peak through this manhole are included in the UR.

TECHNICAL BACKGROUND OF UR F44

Fore peak ballast system on oil tankers

- *Scope and objectives*

To harmonize the practices of IACS Societies with respect to :

- connection of fore peak tanks to the ballast system of the cargo area
- access to fore peak tanks

- *Points of discussion – Rev.0 (June 2000)*

1. SOLAS does not deal with ballast systems of tankers nor with hazardous areas. It only deals with access to ballast tanks adjacent to cargo tanks. It was then agreed to draft a UR rather than a UI.
2. The WP also agreed to make this UR applicable only to oil tankers for the time being but agreed as a second step to advise the group MP-BC-GT to further consider it.
3. The main discussion was on the location of the access manhole in an enclosed space.
4. The UR as is proposed take into account the fact that, for fore peaks separated by a cofferdam from the cargo tanks, the risk to have it hazardous is remote and the opening of a bolted manhole is unfrequent. However that risk is there and means to take measurements and to gas free the peak through this manhole are included in the UR.

- *Points of discussion – Rev.1 (Aug 2008)*

1. This revision takes into account the two scenarios where the FPT is adjacent to, or separated from, the cargo tanks as per the opening statement of Rev.0 which already qualifies the FPT as being hazardous since the ballast system serving other tanks within the cargo area is connected to the FPT.
2. The essential aspect of F44 is the entry to the FPT (which is hazardous regardless of its location relative to the cargo tanks) from an enclosed space which can be hazardous (if adjacent to the cargo tanks) or non-hazardous (if separated from the cargo tanks by a cofferdam).
3. "Other" has been introduced in the opening text to take into account that a FPT which is adjacent to a cargo tank is by definition part of the cargo area.

Submitted by Statutory Panel Chair

22 July 2008

Permanent Secretariat note (August 2008):

GPG approved UR F44 Rev.1 on 11 August 2008 (ref. 8628_IGb).

Technical Background for UR F44 Rev.2, Oct 2010

1. Scope and objectives

To establish unified interpretations taking into the zoning concept for hazardous areas and eliminating vague expressions in the governing documents.

2. Engineering background for technical basis and rationale

IACS has agreed to accept the IEC standard 60092-502 with regard to the installation of electrical equipment in tankers. The standard introduces a zoning concept for hazardous areas and has new requirements to the electrical installations in line with generic principles laid down in the IEC 60079-series of standards for electrical installations in hazardous areas.

It has been identified that there exists several differences between SOLAS and the IEC requirements especially with the introduction of hazardous area zoning and the location of vent pipes. The intention of Revision 2 was to align both the terminology and requirements between the two documents.

3. Source/derivation of the proposed IACS Resolution

SOLAS
IEC 60092-502

4. Summary of Changes intended for the revised Resolution:

The term hazardous was replaced with hazardous area to align with the terminology used within the IEC document.

The distance between vent pipe openings and sources of ignition have now been referenced to the IEC 60092-502 standard so that the hazardous area zoning classification is completed as specified within this document.

5. Points of discussions or possible discussions

There was discussion on removing the requirement altogether based on one member's consideration of the likelihood of significant fuel oil leakage from an adjacent tank. However, it was observed that the same piping may be used for a ballast tank within the cargo tank area and the fore peak tank and could contain significant quantities of oil and high levels of hazardous vapour and therefore the area around the vent outlet shall be considered hazardous for a distance specified within the IEC 60092-502.

None

Technical Background for UR F44 Rev.3, Sep 2024

1. Scope and objectives

To establish a unified interpretation of IACS UR F44 so that it is applicable for both oil tankers and chemical tankers and that it simultaneously considers the access requirements and take into consideration that chemical tankers carry cargoes with other additional hazards such as toxicity.

2. Engineering background for technical basis and rationale

The present UR F44 was issued in June 2000 and at that time it was not made applicable to chemical tankers. This was based on the understanding of the IACS Working group that drafted UR F44 at the time that it would be in conflict with the understanding of the requirements in IBC Code Reg. 3.5.1 and 3.5.3.

The entry into force of the Ballast Water Management Convention and consequently the required installation of ballast water treatment systems has actualized the need to reconsider the strict understanding of IBC Code Reg. 3.5 and consequently consider to enlarge the application of this UR also to chemical tankers.

Simultaneously the UR F44 should be reconsidered with respect to access requirements and consideration should also be done taking into account industry standards and relevant IACS UIs and URs.

IACS expressly decided to **not apply this UR to chemical tankers but only to oil tankers** as mentioned in its title (see attached background TB1). This decision was taken based on the fact that this UR would conflict with the understanding (at that time, of the Working Party that drafted it) of the requirements in IBC Ch 3.5.1 and 3.5.3:

1. **IBC Code Reg. 3.5.1 and 3.5.3**

   3.5.1 *Pumps, ballast lines, vent lines and other similar equipment serving permanent ballast tanks shall be independent of similar equipment serving cargo tanks and of cargo tanks themselves. Discharge arrangements for permanent ballast tanks sited immediately adjacent to cargo tanks shall be outside machinery spaces and accommodation spaces. Filling arrangements may be in the machinery spaces provided that such arrangements ensure filling from tank deck level and non-return valves are fitted.*

   3.5.3 *Bilge pumping arrangements for cargo pump-rooms, pump-rooms, void spaces, slop tanks, double-bottom tanks and similar spaces shall be situated entirely within the cargo area except for void spaces, double-bottom tanks and ballast tanks where such spaces are separated from tanks containing cargo or residues of cargo by a double bulkhead.*

Strict application of this UR (i.e. to oil tankers) may become a "hot topic" in relation the installation of BWTS on tankers. The following information is affecting the end result and is therefore listed as information;

2. **M74 specifies in 3.2.2**

3.2.2 *For tankers carrying flammable liquids having a flashpoint not exceeding 60 ° C or products listed in the IBC Code having a flashpoint not exceeding 60 ° C or cargoes heated to temperature above their flashpoint and cargoes heated to temperature within 15°C of their flashpoint. In general, two independent BWMS may be required – i.e. one for ballast tanks in hazardous areas and the other for ballast tanks in non-hazardous areas.*
UR M74 addresses, in para 3.2.3, the interconnection of ballast piping between hazardous areas.

3. **IBC Code Reg. 3.4.1:**

3.4.1 *Access to cofferdams, ballast tanks, cargo tanks and other spaces in the cargo area shall be* ***direct from the open deck*** *and such as to ensure their complete inspection. Access to double bottom spaces may be through a cargo pump room, pump room, deep cofferdam, pipe tunnel or similar compartments,* ***subject to consideration of ventilation aspects***.

4. SOLAS Ch II-1 Part A-1 Regulation 3-6:

3 Safe access to cargo holds, cargo tanks, ballast tanks and other spaces
3.1 *Safe access* to cargo holds, cofferdams, ballast tanks, cargo tanks and other spaces in the cargo area shall be direct from the open deck and such as to ensure their complete inspection. Safe access * to double bottom spaces or to forward ballast tanks may be from a pump-room, deep cofferdam, pipe tunnel, cargo hold, double hull space or similar compartment not intended for the carriage of oil or hazardous cargoes.*
* Refer to the Recommendations for entering enclosed spaces aboard ships, adopted by the Organization by resolution A.864(20).

5. Access requirements as per present UR F44

The access to the fore peak tank is direct from open deck. Alternatively, indirect access from the open deck to the fore peak tank through an enclosed space may be accepted provided that:

1. In case the enclosed space is separated from the cargo tanks by cofferdams, the access is through a gas tight bolted manhole located in the enclosed space and a warning sign is to be provided at the manhole stating that the fore peak tank may only be opened after:
- *it has been proven to be gas free; or*
- *any electrical equipment which is not certified safe in the enclosed space is isolated.*

2. In case the enclosed space has a common boundary with the cargo tanks and is therefore a hazardous area, the enclosed space can be well ventilated.

6. IBC Code equivalents

The premise for the requirement is to a certain extent obsolete as it does not take into account that modern tanker designs have a **divided forepeak tank**, where a large dry void is constructed between the FPT and the bosun store. As the UR only covers the FPT, one cannot readily apply it to the upper void.

IBC Code Reg. 1.4
Equivalents
1.4.1 *Where the Code requires that a particular fitting, material, appliance, apparatus, item of equipment or type thereof shall be fitted or carried in a ship, or that any particular provision shall be made, or any procedure or arrangement shall be complied with, the Administration may allow any other fitting, material, appliance, apparatus, item of equipment or type thereof to be fitted or carried, or any other provision, procedure or arrangement to be made in that ship, if it is satisfied by trial thereof or otherwise that such fitting, material, appliance, apparatus, item of equipment or type thereof or that any particular provision, procedure or arrangement is at least as effective as that required by the Code. However, the* ***Administration may not allow operational methods or procedures to be made an alternative to a particular fitting, material, appliance, apparatus, item of equipment, or type thereof****, which are prescribed by the Code, unless such substitution is specifically allowed by the Code.*

7. Scenarios for FPT & Void considered in the draft;

In the event of a structural leak, gas freeing and access from a hazardous zone 1 to a non-hazardous space cannot be permitted for any tanker, regardless of whether the non-hazardous space is being entered or not. Initial background for F44 was that the FPT was served by cargo area ballast pumps and not only when located adjacent to cargo tanks. I.e. the FPT/void was initially considered “gas dangerous”. As per IEC 60092-502 it’s assumed this would be equivalent to zone 2.

A. If the **upper void is protected by a cofferdam**, the upper void would be **non-hazardous.** If the FPT is protected by a cofferdam, then the only reason it is hazardous is in case of leaks via the ballast piping (i.e. structural leak from a cargo tank into a ballast tank and from there leaks via the ballast system into the FPT). As this is considered to have a low probability, the **FPT is considered as a hazardous zone 2**. In such cases an access can be arranged from bosun store, provided the FPT is confirmed gas free or any electrical equipment which is not certified safe in the enclosed space is isolated.

B. If the **upper void** or **FPT is located adjacent to a cargo tank** it is **hazardous zone 1**. However, the criteria in F44 do not distinguish between whether the FPT/upper void is non-hazardous or hazardous zone 1. According to the project team's opinion this is wrong. According to the team's opinion, access from a non-hazardous space to an enclosed hazardous zone 1 is clearly prohibited and in the event of gas freeing of the space in case of cargo leaks (flammable or toxic) clearly not acceptable, I.e., they shall only have access for direct gas freeing on open deck. Although one can argue that gas-freeing from open deck is possible for FPT's through emptying and filling the ballast tank (with discharge to slop tank and not overboard due to MARPOL pollution issues), this method of efficient gas freeing is not available for upper voids I.e., as a minimum all upper voids must have access directly to open deck for gas freeing purposes.

8. FPT is not considered as part of cargo area

The FPT and **forepeak void** is not considered as part of the cargo area. The reason being that the contrary would formally imply that the bosun store above is formally within the cargo area, something which is unacceptable as per SOLAS II-2/Reg.4.5.1.2. and IBC 3.2.1).

9. Applicable scenarios covering different designs included.

Through the process of updating the UR, it was agreed by the IACS members to include 6 scenarios reflecting the current arrangement onboard tankers. Reference is given to Scenario 1~6.
For these scenarios, operational requirements have been listed and considered towards IMO resolution A.1050(27), IMO Resolution MSC.1/Circ.1401, IBC Code & SOLAS II-2.

3. Source/derivation of the proposed IACS Resolution

SOLAS
IEC 60092-502
IBC code
IACS UR M74, IACS UI SC211

4. Summary of Changes intended for the revised Resolution:

The following has been amended since Revision 2 (2010) in order to include IBC code requirements:

- Definition of "hazardous area" has been included.
- Definition of "cargo area" has been included.
- Detailed requirement applicable for Fore peak ballast systems on tankers for oil/chemicals has been included in section 1;
  - Clarification that sounding pipes are not considered as a source of hazardous zone.
  - Clarification how a indirect access may be arranged
  - Clarification that pipes passing bow thruster rooms will be required to have only fully welded pipes through the non-hazardous space. Possible consequence of this is that the FPT valve will have to be positioned in the forepeak tank itself.
  - Clarification that continuous ventilation would be required while accessing the forepeak tank.
  - Clarification regarding how gas freeing of the forepeak tank is done towards open deck and how this shall be arranged.

- Clarification of the use of portable gas detection devices considering cargoes on previous voyage and subsequently specific procedures to follow in case gas detectors are not available for the specific gas.
- Clarification of additional requirements for forward spaces that are not defined as a ballast tank.
- Clarification of recommended operational practice when a chemical tanker does not have the required gas detection equipment as per IBC code 13.2 is given in figure 1~6. As per IBC code 13.2.3, the administration may exempt a vessel from having the required vapour detection equipment onboard in case such equipment is not available in the market. If, during such voyage, a tank entry into the forepeak tank is deemed required at the same time a cargo leakage is suspected in the same space, the tank entry procedure onboard must consider additional ventilation by dilution method. IMO resolution A.1050(27) and the additional safety equipment to be used as per IBC code 13.2.3 and as part of the operational requirements, it has been specified that a mechanical fan, providing minimum of 6 air changes for 24hrs may be done prior to actual tank entry. It shall also be highlighted that when the expected gas is known, considering the cargo carried onboard, the actual ventilation rate may also be calculated for the space itself.

5. Points of discussions or possible discussions

The Group identified the need for clarification and agreed to include self-describing scenarios that would identify acceptable arrangement for oil and chemical tankers. Two scenarios were also included specifically for oil tankers only. Reference is given to Scenario 1 to 6 in the UR.

UR F45 "Installation of BWMS on-board ships"

Summary

This UR details relevant safety measures for the installation of BWMS on-board ships. This UR comes as a complement to UR M74 and focuses on the fire safety and personnel protection issues.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev.1 (Mar 2025)	03 March 2025	01 January 2027
Original version	08 June 2021	01 July 2022

- **Rev.1 (Mar 2025)**

1 Origin of Change:

☒ Suggestion by IACS member

2 Main Reason for Change:

UR M74 was reviewed by the Machinery Panel, which included the transfer of the section 6 text from UR F45.

The Safety Panel identified some ambiguities in relation to the categorisation of an engine room used for the storage of chemicals for the ballast water management system (§2.3.2). Additional changes were made to paragraphs 2.1 and 2.3.1 of UR F45 to improve the clarity.

3 Surveyability review of UR and Auditability review of PR

NA

4 Human Element issues assessment

NA

5 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None

6 History of Decisions Made:

The Safety Panel discussed §2.3.2 and noted that the categorisation of an engine room used for the storage of chemicals for the ballast water management system needs to be clarified. It was agreed to amend the text to clarify that a machinery space used also the storage of BWMS chemicals is generally considered both as store-room and machinery space in line with the categorisation in §2.1b), unless it is a machinery space of category A. In addition, the special case of storing chemicals in a tanker cargo pump-room was taken into consideration.

When discussing the amendments in §2.3.2, further paragraphs were identified that could benefit from textual improvements and these have been amended accordingly:

- §2.1 inclusion of additional text explaining the relevant categories (as defined in SOLAS II-2/9.2) of BWMR containing oil-fired inter gas generators for the ship types passenger ship and cargo ship;

- §2.3 replacing "store rooms" by "spaces" as not all of the listed spaces are store rooms.

In addition:

- All references to UR M74 have been updated;
- Renumbering of section 7 due to the transfer of section 6 to UR M74
- Change of the word "or" to "and" in the implementation note.

7 Other Resolutions Changes:

UR F45 section 6 has been moved to UR M74.

8 Any hinderance to MASS, including any other new technologies:

NA

9 Dates:

Original Proposal	: 17 May 2023	(Made by: IACS member)
Panel Approval	: 10 Jan 2025	(Ref: PS23029_ISl)
GPG Approval	: 3 Mar 2025	(Ref: 17162_IGze)

- **New (June 2021)**

1 Origin of Change:

☒ Based on IACS Requirement: UR M74
☒ Other: Need identified at IMO SSE4 and MSC 98

2 Main Reason for Change:

Many ships are currently installing BWMS on-board in line with the requirements of the BWM Convention which has entered into force on 8 September 2017.

However, BWMS are not covered by SOLAS II-2 and the relevant fire safety measures for such systems have never been clarified, leading to non-uniform safety level onboard ships. The purpose of this UR is to detail the relevant fire safety and personnel protection measures for the installation of BWMS on-board ships, in order to ensure a uniform and satisfactory safety level on-board IACS ships equipped with BWMS.

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None

Part B. Technical Background

List of Technical Background (TB) documents for UR F45:

Annex 1. **TB for New (June 2021)**

See separate TB document in Annex 1.

Annex 2. **TB for Rev.1 (March 2025)**

See separate TB document in Annex 2.

Technical Background (TB) document for UR F45 (New June 2021)

1 Scope and objectives

1.1 Context:

Many ships are currently installing BWMS on-board in line with the requirements of the BWM Convention which has entered into force on 8 September 2017.

However, BWMS are not covered by SOLAS II-2 and the relevant fire safety measures for such systems are therefore unclear in the currently available regulations. The purpose of this UR is to detail the relevant fire safety and personnel protection measures for the installation of BWMS on-board ships, in order to ensure a uniform and satisfactory safety level on-board IACS ships equipped with BWMS.

1.2 Scope

This UR specifies fire safety and personnel protection measures for BWMS installations on-board all kinds of ships, i.e. existing ships and newbuilt ships, passenger ships, ro-ro ships, general cargo, tankers, dry bulk carriers etc.

NB: Ships not designed or constructed to carry ballast water or ships carrying permanent ballast water in sealed tanks that is not subject to discharge are not subject to the BWM Convention and will therefore fall out of the scope of this UR since no BWMS will be installed on board.

This UR comes as a complement to:

- IACS UR M74 which details piping and segregation measures for BWMS installed on-board ships, covering especially the case of tankers

- SOLAS II-2: For practical purposes, SOLAS II-2 applies to any BWMR / BWMS-related space, requiring fire-detection, active and passive fire protection in line with the fire category detailed in clause 2. This UR and especially clauses 3, 4, 5, 6, 7 and 8 are meant to detail only the relevant *additional* safety measures. It is to be noted that safety measures additional to minimum SOLAS requirements are not needed for all BWMS technologies.

1.3 Methodology

An initial risk assessment has been carried out by PT PM42/2017 in order to revise IACS UR M74. A number of the risks that have been identified then are covered by UR M74, the remainder – understood to be related to fire safety and personnel protection - was transmitted to PT PS41/2018. This PT has then carried out a complementary risk analysis considering each kind of BWT technologies as outlined in Table 1 of the UR and focusing on fire safety and personnel protection.

In general, it was assumed that maximum one person would be present in the BWT room during normal operation while the system is running and that two to three persons could be present in the BWT room for maintenance purposes, i.e. when the system is not running.

1.4 Definitions and abbreviations

BWMS	Ballast Water Management System
Cargo ship	Any ship which is not a passenger ship

FSS IMO Code for Fire Safety Systems, IMO Resolution MSC.98(73) as amended
IMO International Maritime organization
Passenger ship Ship which carries more than twelve passengers
Tanker Cargo ship constructed or adapted for the carriage in bulk of liquid cargoes of an inflammable nature
SOLAS International Convention for the Safety Of Life At Sea

2 Engineering background for technical basis and rationale

2.1 Technology analysis

2.1.1 Group 1 - In line UV

No active substance: expected problems are out of the scope of this PT, reliability (UV bulb reliability) rather than safety.
Identified risks:

- High power, to be shut down in case of fire and release of the fixed fire-extinguishing system.

- Citric Acid used to wash UV lamps: to be kept away from heat as per Safety Datasheet

- Ions that may be generated by this technology are very short-lived, no specific risk expected

2.1.2 Group 2 – In-line flocculation

Known flocculants are triiron tetraoxide, PAC (PolyAluminium Chloride) and PASA (Poly Acrylamide Sodium Acrylate). MEPC 59/2/5 says "The chemicals used in this system are the same as those used in drinking water purification process, and have been extensively cited in literatures relating to human health and the environment (including World Health Organization (WHO) guidelines), so there is plenty of evidence to show that they are safe."

PAC is reckoned to be corrosive to metals => coatings needed

No risk of fire (ignitability or self-reaction) identified as per MEPC 59/2/5.

Note: IMO G9 report is taken as reference rather than general REACH datasheets that are produced for other purposes, considering that IMO G9 takes into account specific technology & actual quantities and concentrations.

All 3 substances are identified as irritating and possibly harmful to human health. Contact with eyes is the most dangerous aspect.

Note: MEPC 59/2/5 "The manufacturer is therefore requested to describe separately the potential human health risks associated with each major component of the system and to describe the measures necessary to prevent human exposure for each such component."

2.1.3 Group 3 – De-oxygenation

In general, these technologies include an inert gas generator or a nitrogen generator, which fall under SOLAS and FSS Code requirements for inert gas systems. As a consequence:

- BWMS room containing inert gas generators are cat.A machinery spaces as per SOLAS II-2/3.31

- The requirements of FSS Code Ch.15 are to be followed as relevant

2.1.4 Group 4 - In-line full flow electrolysis

Limited risk is associated with the electrolysis unit (no or very low emission of H_2). Neutralizers such as sodium bisulfite, sodium thiosulfate are low hazard substances.

2.1.5 Group 5 – In-line side stream electrolysis (Electro chlorinization)

Risk of H_2 build-up is to be really considered for this system, since higher intensity is needed for side-stream electrolysis, thus leading to higher H_2 generation.
UR M74 defines hazardous areas in §3.2.1 (reference is made to IEC 60092-502 and IACS UI SC274.

2.1.6 Group 6 – Chemical injection

Actual hazards will depend on the concerned chemicals, to be determined on a case-by-case basis. Consider:
- Stored chemicals & neutralizers
- Active substances that may be produced on-demand (risk is different because these substances will not be stored in significant quantity)

Expected risks to be checked (based on MSDS and adequate risk analysis):
- Toxicity (gas / irritation through breathing system)
- Toxicity (liquid / irritation through skin or eye contact)
- Toxicity through ingestion
- Fire (combustible material)
- Chemical reaction with water => possible hazard for the ship & crew
- Chemical ageing => possible hazard for the ship & crew
- Chemical reaction when exposed to high temperature => possible hazard for the ship & crew
- Reaction between several chemicals stored on board => possible hazard for the ship & crew
- Impact of chemical on steel
- ….

2.1.7 Group 7 – In-line side-stream ozone injection

2.1.7.1 Ozone destruction

Investigated risks associated with technologies used for ozone destruction (apart from ozone leakage)

Ozone destruction can be either catalytic or thermal oxidation, i.e. degradation of ozone into oxygen. In general, no specific risk is associated with ozone destruction, except for one (not very much used) solution based on catalytic destruction of ozone through activated carbon, in case of high ozone concentration : this situation is associated with an increased risk of fire

Ozone itself being already associated with an increased risk of fire, this is already taken into account in the analysis.

2.1.7.2 Ozone

The presence of Ozone is the main risk associated with those technologies as ozone is toxic and will increase the risk of fire

Ozone itself is not flammable but it may accelerate or initiate combustion (very strong oxidant)

Sodium thiosulfate is used as a neutralizer. It is a liquid chemical with limited hazard, which is also used for electrolysis technologies.

2.1.8 Group 8 – In-tank pasteurization and de-oxygenation with N2 generator

In addition to N2 injection, it is noted that this system includes heat exchangers / heaters, intended to raise the temperature of the ballast water to 72°C for 75s for pasteurization purposes. The heat exchangers themselves are not considered a significant fire risk, however, the heat source (e.g. boiler or steam generator) is a significant fire risk and is to be located in a cat.A machinery space. Assumption is that the heat source (to be adequate to meet the heating capacity requirements) is another/existing ship equipment, already covered by SOLAS / FSS Code.

It is understood that, if installed in a non-dedicated machinery space (e.g. engine room), the hot piping will be shielded from fuel projection etc. Similarly, thermal insulation of hot surfaces (for crew safety) is already required on a standard basis.

2.2 Risk assessment – Outcome of expert workshop

The outcome of the risk assessment performed during the expert workshop is detailed in Table 1 below. For ease of reading:

- Grey background refers to safety measures that are already properly specified in SOLAS, FSS Code or UR M74 and which, as a consequence, are not repeated in the present UR F

- Note (1) means "depending on the analysis of the chemicals"

In addition to the safety measures specific for each BWMS technology, the following general principles have been identified:

- In case a foam or gas fixed fire extinguishing system is installed, it must be compatible with seawater (in case of leakage in the ballast water piping, sea water will enter the compartment)

- Automatic BWMS shutdown upon release of the fire extinguishing system (any requirement for cooldown necessary for safe shutdown to be considered in the shutdown sequence).

- In case the BWMS is located in a space covered by a fixed gas fire-extinguishing system, air or O2 storage is to be included in the gas capacity calculation.

Table 1: Outcome of the expert workshop

BWMS's Technology category →	**1**	**2.1**	**2.2**	**3a**	**3b**	**3c**	**4**	**5**	**6.1**	**6.2**	**7a**	**7b**	**8**
Identification of specific hazards ↓	In-line UV including UV + Advanced Oxidation Technology (AOT) or UV + TiO2 or UV + Plasma	In-line Flocculation (ex. Clearballast™) **BWT machinery**	In-line Flocculation (ex. Clearballast™) **BWT polymer storage**	In-line membrane separation and de-oxygenation (injection of N2 from a N2 Generator) ex. Ni-Ballast™	In-line de-oxygenation (injection of Inert Gas from Inert Gas Generator) ex. VOS™	In-tank de-oxygenation with Inert Gas Generator ex. GLD™	In-line full flow electrolysis (ex. Electroclean™)	In-line side stream electrolysis (ex. HiBallast™)	In-line (stored) chemical injection (ex. JFE BallastAce® with NeoChlor Marine® or TG Ballast Cleaner®) : **BWT machinery**	In-line (stored) chemical injection (ex. JFE BallastAce® with NeoChlor Marine® or TG Ballast Cleaner®): **BWT chemical storage**	In-line side-stream ozone injection without gas/liquid separation tank and without Discharge treatment tank (ex. NK-O3 BlueBallast)	In-line side-stream ozone injection with gas/liquid separation tank and Discharge water treatment tank (ex. FineBallast®OZ)	In-tank pasteurization and de-oxygenation with N2 Generator ex. BAWAT™
Fire growth potential: acceptable spaces outside cargo area for the location of the BWMS (accommodation spaces, service spaces, control stations, machinery spaces of category A, other machinery spaces, Ro-Ro spaces, etc)	No restriction		Not to be located in accommodation area, if identified as toxic or flammable as per IMO G9 report	No restriction					Depending on the chemicals (i.e. toxic or flammable products): Not to be located in the accommodation area Depending on the chemicals, minimum distance from the accommodation to be defined		Separate / dedicated compartment with gastight boundaries Room-in-room (=only one access through ER + ER alarm repeated in the BWMR) in ER could be OK (airlock required)		No restriction
Containment of fire: fire categorization of the BWMS room and fire integrity of the boundaries with adjacent spaces	Auxiliary machinery space having little or no fire risk on PAX >36 Other machinery space on other kinds of ships		To be considered as a store-room (category will then depend on whether they contain flammable liquids and on the size of the space)	Auxiliary machinery space having little or no fire risk on PAX >36 Other machinery space on other kinds of ships	Cat.A machinery space		Auxiliary machinery space having little or no fire risk on PAX >36 Other machinery space on other kinds of ships		Auxiliary machinery space having little or no fire risk on PAX >36 Other machinery space on other kinds of ships	To be considered as a store-room (category will then depend on whether they contain flammable liquids and on the size of the space)	Auxiliary machinery space having little or no fire risk on PAX >36 Other machinery space on other kinds of ships		Auxiliary machinery space having little or no fire risk on PAX >36 Other machinery space on other kinds of ships
Fire categorization and fire integrity when located in the cargo area of tankers	Cat. (8)				Not allowed		Cat. (8) NB: This equipment would have to be certified safe		Cat. (8)	Cat (8) if allowed in the cargo area (For products are covered by the IBC Code, check compatibility and possible interactions with the cargo)	Not allowed		Cat.(8)
Prevention against fire: Fire detection	Not required		As per SOLAS	Not required	In line with FSS Code Ch.9 Smoke and flame or smoke and heat		Not required			As per SOLAS	Fire detection Combined smoke and flame or smoke and heat		Not required
Fire fighting: fixed fire fighting system in the BWMS room	Not required		Required by SOLAS	Not required	Fixed fire ext. system for Cat.A machinery space		Not required			As per SOLAS	Require a fixed fire-extinguishing system (manual)		Not required
Fire fighting: portable fire fighting equipment in the BWMS room	Portable fire extinguisher suitable for electrical fire	Nothing specific	Required by SOLAS	Nothing specific	Portable foam applicator 2 portable foam extinguishers Sand box		Nothing specific			As per SOLAS	Nothing specific (We don't want to send somebody inside in case of a fire)		Nothing specific
Contamination from BWMS room to other enclosed spaces: direct access to other enclosed spaces	Nothing specific			No direct access to service space, accommodation space or control station Access from the open deck if a nitrogen receiver is fitted in a dedicated compartment. Independent mechanical ventilation, extraction type	No direct access to service space, accommodation space or control station		No specific requirement		*See first line of the table*		Access through an airlock, except in case of access from the open deck Ozone detection in the space giving access to the BWM room Ozone detection repeater close to the entrance & out of the room + proper instruction on the door to prevent people from entering a room where ozone has leaked		No direct access to service space, accommodation space or control station Access from the open deck if a nitrogen receiver is fitted in a dedicated compartment. Independent mechanical ventilation, the extraction type

BWMS's Technology category →	1	2.1	2.2	3a	3b	3c	4	5	6.1	6.2	7a	7b	8
Contamination from BWMS room to other enclosed spaces: gas-tight and self-closing door	Not required	Gastight and self-closing door		- (Not really relevant because access only from the open deck in case of N2 storage)	Gastight and self-closing door		Gastight and self-closing door, depending on the chemicals		Gastight and self-closing door		Gastight and self-closing door Gas tight boundaries		- (Not really relevant because access only from the open deck in case of N2 storage)
Contamination from BWMS room to other spaces: Independent ventilation + outlet arranged at a safe location on the open deck (refer to the definitions proposed UR M74 2.7)	Nothing specific	Independent ventilation, except that the machinery and storage room can be ventilated together (Irritation and toxicity) (1)		X The oxygen-enriched air from the nitrogen generator and the nitrogen-product enriched gas from the protective devices of the nitrogen receiver are to be discharged to a safe location (See UR M74) on the open deck. Independent ventilation with automatic fire dampers Low level exhaust in the BWMR	X		X Independent ventilation with exhaust located so as to take out any toxic gas	X Independent ventilation with exhaust located so as to take out hydrogen	X Independent ventilation required if toxic chemicals or if toxic gas may be generated	Independent ventilation required if toxic chemicals or if toxic gas may be generated (storage and BWT machinery room may be ventilated together)	X Independent ventilation with reinforced thickness exhaust ducts (in order to ensure exhaust availability after a fire for atmosphere purging purposes)		X The oxygen-enriched air from the nitrogen generator and the nitrogen-product enriched gas from the protective devices of the nitrogen receiver are to be discharged to a safe location* on the open deck. **[Covered by UR M74]** Independent ventilation with automatic fire dampers Low level exhaust in the BWMR
Ventilation of the BWMS room: minimum air changes per hour, mechanical extraction type, etc.	Nothing specific	Min. 6	Stay with 6 air changes per hour by default since PAC is not identified as a specific risk as per G9 analysis	Min. 6 (extraction type) The compartment shall be fitted with an independent mechanical extraction ventilation system providing six air changes per hour. If a nitrogen receiver is fitted in a dedicated compartment, independent mechanical ventilation, of the extraction type shall be provided	Min. 6 (positive pressure type)		Min. 6	Min 20 (risk of H_2)	Min. 6 To be adjusted depending on the gases that may be generated (toxic gases, explosive gases)		Interlock btw BWMS & ventilation of the BWM room and space providing access (system to shutdown / no start without ventilation) Alarm in case of loss of ventilation Min. 20 air changes per hour+ alarm + shutdown		Min. 6 (extraction type) The compartment shall be fitted with an independent mechanical extraction ventilation system providing six air changes per hour. If a nitrogen receiver is fitted in a dedicated compartment, independent mechanical ventilation, of the extraction type shall be provided
Chemical reactivity: potential reactivity with the performance of the type of the foam in case the BWMS is located in a space protected by a fixed foam fire extinguishing system	-	-	-				(1)	(1)	(1)	(1)	-	-	-

BWMS's Technology category →	1	2.1	2.2	3a	3b	3c	4	5	6.1	6.2	7a	7b	8
Chemical or physical reactivity with water: potential reactivity with water spraying system (example exothermic reactivity from Sulfuric acid tank of Ecochlor)	-	-	-	-			- (The electrolysis reactor is to be provided with a pressure relief valve. Vent of this valve to be led to a safe location on the open deck => Risk of reaction btw hot water and free radicals in case of hot water)		(1)	(1)			-
O_3 leakage inside the BWMS room: air breathing apparatus	NA								EEBD to be provided depending on the specific risk assessment for the chemicals		EEBD to be provided		
Chemical leakage inside the BWMS room : Emergency eye wash, shower	NA	X	X	NA			X	NA	(1)		NA		
Routing of piping (To be discussed whether it is really worth mentioning, or whether there will be no piping out of the BWMS room)	NA	-	-	Inert gas piping systems shall not pass through accommodation, service and control station spaces			(Already covered in UR M74 rev.2 3.3.2.5)		Minimum pipe length (Already covered in UR M74 rev.2 3.3.2.2)		O_3 piping shall not pass through accommodation, service spaces or control stations, unless fully welded & reinforced thickness (same as CO2 pipes)		Inert gas piping systems shall not pass through accommodation, service and control station spaces
Means of escape	As per SOLAS II-2/13 for auxiliary machinery spaces				As per SOLAS II-2/13 for cat.A machinery spaces		As per SOLAS II-2/13 for auxiliary machinery spaces		Crew training taking into account the risks of the chemicals as laid down by the manufacturer safety sheet Safety instructions to be displayed in the room Correct PPE (as defined by manufacturer or MSDS) As per SOLAS II-2/13 for auxiliary machinery spaces		As per SOLAS II-2/13 for auxiliary machinery spaces		

3 Source / derivation of the proposed IACS Resolution

N/A

4 Summary of Changes intended for the revised Resolution:

N/A

5 Points of discussions or possible discussions

5.1 Application of the UR

1.1.2 – Application conditions are the same as UR M74 for general coherence of IACS requirements.

During development work, it has been considered whether the present UR should be merged with UR M74. This was finally declined because of the amount of work involved, which was expected to significantly delay the publication of both UR M74 rev.2 and this UR while the industry is actually installing ballast water treatment systems.

5.2 Fire categories BWMR

2.1 and 2.2 – The following fire categories are to be applied to BWMR for the purpose of applying SOLAS II-2, in line with the outcome of the discussion at IMO SSE4:

- As a general rule, BWMR are considered to be similar to auxiliary machinery spaces, hence assimilated to "other machinery spaces", i.e. cat.(7) on passenger ships carrying not more than 36 passengers or cargo ships, or cat.(10) or (11) on passenger ships carrying more than 36 passengers

- BWMR containing oil-fired inert gas generators, however, are reckoned to represent a significant fire risk and fall under SOLAS definition II-2/3.31 of machinery spaces of category A. Therefore such spaces are to be considered as machinery spaces of category A

- BWMR located in the cargo area of tankers are to be categorised (8) – Cargo pump-rooms. When allowed in the cargo area, BWMR are considered similar to ballast pump room and therefore categorized (8), in line with the principles given in SOLAS II-2/4.5.1 and IGC §3.1 to 3.5. It is to be noted that not all ballast water management technologies are allowed in the cargo area of a tanker, those technologies that create a significant fire or explosion risk are not allowed in the cargo area as per UR M74 rev.2.

5.3 3m distance

The 3m distance mentioned in 3.1.1 was chosen by reference to:

- the 3 m distance specified in SOLAS Reg II-2/5.2.1

- the definition of "Gas-dangerous space or zone" , which is defined in IGC Code as: "a zone on the open deck, or semi-enclosed space on the open deck, within 3 m of any cargo tank outlet, gas or vapour outlet, cargo pipe flange or cargo valve or of entrances and ventilation openings to cargo pump rooms and cargo compressor rooms"

5.4 Fire categories for storage spaces for chemicals used by the BWMS

2.3 – The spaces where the storage of liquid or solid chemicals or additives for BWMS is intended are categorized similarly to any other store-room onboard – although complementary safety requirements are then provided in the UR. Then, depending on whether they contain flammable chemicals, those storage spaces will be considered as standard store-rooms or as store-rooms that may contain flammable liquids.

In case this storage space in located in the cargo area of a tanker, the philosophy explained above for the BWMR applies and this room is to be categorised (8).

5.5 Ventilation arrangement for BWMS using chemical substances

3.1 - The 3m distance between ventilation outlets or other openings from the BWMR and openings to the accommodation spaces was chosen by reference to:

- the 3 m distance specified in SOLAS Reg II-2/5.2.1

- the definition of "Gas-dangerous space or zone" , which is defined in IGC Code as: "a zone on the open deck, or semi-enclosed space on the open deck, within 3 m of any cargo tank outlet, gas or vapour outlet, cargo pipe flange or cargo valve or of entrances and ventilation openings to cargo pump rooms and cargo compressor rooms"

5.6 Ventilation arrangement for ozone-based BWMS

6.1.4 – The requirement for reinforced thickness steel duct is applicable when ventilation ducts serving a BWMR containing an ozone-based BWMS cross other spaces. It was discussed whether "The part of the ducts located outside of the BWMR shall be made of steel" should be changed as "The part of the ducts located outside of the BWMR, where passing through other compartments/spaces, shall be made of steel", and finally decided that the indication “where passing through other compartments/spaces” need not be included, and the following points were made:

- SOLAS II-2/9.7.1.1 requires ventilation ducts to be of steel or equivalent material

- the purpose of the subject sentence is to request the construction of ducts, when crossing other spaces, in reinforced thickness steel, not merely steel ducts, thus not contradicting SOLAS requirements.

5.7 In-tank pasteurization and de-oxygenation

It was decided not to include any specific requirement regarding the space containing type 8 BWMS i.e. in-tank pasteurization and de-oxygenation because:

- Compartment with no direct access to service space, accommodation space or control station is already required by FSS Code §2.4.1.4

- Requirement for a gastight boundary was not deemed relevant during risk assessment, because FSS Code will allow only access from the open deck in case there is N2 storage

5.8 Ventilation in case the BWMS is located in the engine room

In case of BWMS installed in E/R and provided no division, the E/R has to be considered as BWMR. In that case, taking into account of current arrangement of E/R, it is deemed difficult to satisfy 3.1, therefore engine rooms have been excluded from this requirement.

However, it is noted that:

- 7.1.1 remains applicable: According to the requirements of SOLAS II-2/9.7.2.1, it is understood that the ventilation system for the engine room is already separated from the ventilation system for any other spaces. Therefore, this requirement is not considered particularly stringent for engine rooms.

- 7.2.3 also remains applicable: Ventilation in engine rooms is expected to provide more than 20 air changes per hour, so that this requirement is not understood to be a constraint for engine rooms.

Technical Background (TB) document for UR F45 (Rev.1 Mar 2025)

1. Scope and objectives

See Technical Background (TB) document for UR F45 (New June 2021)

2. Engineering background for technical basis and rationale

See Technical Background (TB) document for UR F45 (New June 2021)

2a. Specification of the data utilised in the development/revision of the proposed IACS Resolution, if any

NA

3. Source/derivation of the proposed IACS Resolution

See Technical Background (TB) document for UR F45 (New June 2021)

4. Summary of Changes intended for the revised Resolution:

Changes made:

2.1 General

BWMR shall be classified as follows for the purpose of applying the requirements of SOLAS Chapter II-2:

a) BWMR containing oil-fired inert gas generators (i.e. BWMS cat.3b and 3c as per Table 1) shall be categorized as machinery spaces, depending on the ship type as category (12) according to SOLAS II-2/9.2.2.3 or category (6) according to SOLAS II-2/9.2.2.4, II-2/9.2.3 and II-2/9.2.4.

b) Other BWMR shall be considered as other machinery spaces and shall be categorized, depending on the ship type as category (10) or (11) according to SOLAS II-2/9.2.2.3 or category (7) according to SOLAS II-2/9.2.2.4, II-2/9.2.3 and II-2/9.2.4.

2.3 Storage of chemicals

2.3.1 Spaces where the storage of liquid or solid chemicals for BWMS is intended shall be categorized as the following spaces for the purpose of applying the requirements of SOLAS Chapter II-2, i.e.:

2.3.2 Where the storage of chemicals is foreseen in the same space as the ballast water management machinery, this space shall be considered both as a store-room and as a machinery space in line with 2.1b or cargo pump room in line with 2.2. However, if the storage of chemicals and the ballast water management machinery are located in a machinery space of category A, then the space is to be considered only as a machinery space of category A. When chemicals are stored in a room with BWMS in the cargo area of a tanker this room will be categorized as cargo pump room in accordance with 2.2 above.

5. Points of discussions or possible discussions

Nothing additional to the above.

UR F46 "Low pressure CO_2 piping system"

Summary

This UR provides requirement for the minimum pressure at the nozzles for low pressure CO_2 systems.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
New (Aug 2021)	02 August 2021	01 July 2022

- **New (Aug 2021)**

1 Origin of Change:

☑ Based on IACS Requirement

2 Main Reason for Change:

To address the remaining requirement from UI SC170 about minimum pressure requirement at the nozzles for CO_2 systems which has not been included in the amendments to the FSS Code MSC.206(81).

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None

4 History of Decisions Made:

During the maintenance of IACS Resolutions which have not been updated for the last ten years, the Safety Panel, after asking Machinery panel's view, agreed to develop a new UR in order to maintain the requirement of the minimum CO_2 pressure at the nozzles initially requested in UI SC170.

5 Other Resolutions Changes:

UI SC170 should be deleted after this UR Takes effect because the only requirement not incorporated in amendments of FSS code Ch.5.2.2. (Res.MSC.206(81)) has been included in this UR.

6 Any hinderance to MASS, including any other new technologies

None

7 Dates:

Original Proposal: June 2021 (Made by Safety Panel)
Panel Approval: 29 June 2021 (Ref: PS19002o)
GPG Approval: 02 August 2021 (Ref: 21114_IGd)

****

Part B. Technical Background

List of Technical Background (TB) documents:

Annex 1. **TB for New (Aug 2021)**

See separate TB document in Annex 1.

◄▲►

Technical Background (TB) document for UR F46 (New Aug 2021)

1. Scope and objectives

The purpose of this UR is to include a requirement for the minimum pressure at the nozzles for low pressure CO_2 systems.

2. Engineering background for technical basis and rationale

After asking Machinery panel's view, the Panel majority agreed that the requirement about minimum pressure at nozzles for low pressure CO_2 systems initially described in UI SC170 is to be kept and transferred in a unified requirement.

3. Source/derivation of the proposed IACS Resolution

IACS UI SC170

History Files (HF) and Technical Background (TB) documents for URs concerning Gas Tankers (UR G)

Res. No.	Title	Current Rev.	HF/TB?
UR G1	Vessels with cargo containment system for liquefied gas	Corr.3 Sep 2023	HF
UR G2	Liquified gas cargo tanks and process pressure vessels	Rev.3 May 2023	HF
UR G3	Liquified gas cargo and process piping	Rev.8 Oct 2023	HF
UR G4	Periodical surveys of cargo installations on ships carrying on liquefied gases in bulk	Deleted (Jun 1999) *Re-categorised as Z16*	TB
UR G5	Fail-close action of Emergency Shut Down (ESD) valve	New (Dec 2022)	HF

UR G1 "Vessels with cargo containment system for liquefied gas"

Summary

Rev.3 Corr.3 of UR G1 is made in order to modify editorial errors on formulas in Table 1 and appendix 1.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Corr.3 (Sep 2023)	05 September 2023	-
Corr.2 (Oct 2021)	18 October 2021	-
Corr.1 (May 2018)	30 May 2018	-
Rev.3 (June 2016)	21 June 2016	1 July 2016
Corr.1 (Sept 2003)	05 September 2003	-
Rev.2 (1997)	12 May 1997	-
Rev.1 (1979)	No record	-
New (1974)	No record	-

- **Corr.3 (Sep 2023)**

1 Origin for Change:

☑ Suggestion by HP Members

2 Main Reason for Change:

Editorial errors are identified by HP Members with respect to "tb > −55°C, −10°C < tb ≥ −55°C, tb > −10°C" in Table 1 as well as "L < 50m" in appendix 1.

3 List of non-IACS Member Classification Societies contributing or participating in IACS Working Group:

None

4 History of Decisions Made:

Editorial errors are checked in comparison with the corresponding requirements of IGC Code (4.5 & 4.28.2) and modified into the correct formulas of "tb < −55°C, −55°C ≤ tb < −10°C, tb ≥ −10°C" in Table 1 as well as "L > 50m" in appendix 1.

5 Other Resolutions Changes

None

6 Any hinderance to MASS, including any other new technologies:

None

7 Dates:

Original Proposal:	19 June 2023	(Ref: PH17013_IHbi)
Panel Approval:	21 August 2023	(Ref: PH17013_IHbn)
GPG Approval:	05 September 2023	(Ref: 21086_IGi)

- **Corr.2 (Oct 2021)**

1 Origin for Change:

☑ Suggestion by HP Chair

2 Main Reason for Change:

Due to the revised UR W1 (UR W1 Rev.4 Mar 2021) an update of the references to UR W1 was necessary.

3 List of non-IACS Member Classification Societies contributing through the TC Forum and/or participating in IACS Working Group:

None

4 History of Decisions Made:

Following GPG message 19083_IGc HP Chair reviewed G1 and proposed an update of the references. Proposal was discussed and agreed by the Panel and forwarded to GPG for final approval. The title of this UR has been updated in order to better reflect the scope of these requirements, i.e. unified requirements for vessels which the IGC code is not mandatory.

5 Other Resolutions Changes

None

6 Any hinderance to MASS, including any other new technologies:

None

7 Dates:

Original Proposal	: 07 May 2021	
Panel Approval	: 07 September 2021	(Ref: PH21009_IHf)
GPG Approval	: 18 October 2021	(Ref: 21086_IGg)

- **Corr.1 (May 2018)**

.1 Origin for Change:

☑ Suggestion by IACS member

.2 Main Reason for Change:

UR updated to correct inconsistency found.

.3 List of non-IACS Member Classification Societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

IACS Members identified an inconsistency in the requirement of integral tanks presented in UR G1 paragraph 1.2.1and in IGC Code (ref 4.2.1.2). Indeed, the design vapour pressure P0 should be taken less than 0.07 N/mm^2 as integral tanks, like membrane, semi-membrane, independent tanks (type A/B) primarily constructed of plane surfaces (gravity tanks) etc., are not regarded as pressure tanks.

The corrected text for G1.2.1 should be as follows:
"If, however, the hull scantlings are increased accordingly, P0 may be increased to a higher value but ~~not~~ less than 0,07 N/mm^2 (0.7 bar)."

.5 Other Resolutions Changes

None

.6 Dates:

Original Proposal: 26 March 2018
Panel Approval: 09 May 2018 (Ref: PH14029)
GPG Approval: 30 May 2018 (Ref: 15042_IGx)

- **Rev.3 (June 2016)**

.1 Origin for Change:

☑ Suggestion by IACS member

.2 Main Reason for Change:

The IMO International Code for the Construction and Equipment of Ships Carrying Liquified Gases in Bulk has been updated to include the content of the UR and as a result the UR is not applicable to ships which will comply with the new Gas Code.

.3 List of non-IACS Member Classification Societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

The Hull Panel carried out a review of the updates to the Gas Code in order to determine what changes needed to be made to UR G1. It was concluded that the entire content of UR G1 has been included in the amendments made to the Gas Code. Hence, UR G1 is only applicable to vessels which do not have to comply with the requirements of the new Gas Code.

.5 Other Resolutions Changes

None

.6 Dates:

Original Proposal: 8 September 2015 Made by: An IACS Member
Panel Approval: January 2016 (Ref: PH14029)
GPG Approval: 21 June 2016 (Ref: 15042_IGo)

- **Corr.1 (2003)**

.1 Origin for Change:

☑ Suggestion by IACS member

.2 Main Reason for Change:

UR updated to correct errors found.

.3 List of non-IACS Member Classification Societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

None

.5 Other Resolutions Changes

None

.6 Dates:

No records available.

- ## Rev.2 (1997)

.1 Origin for Change:

☑ Suggestion by IACS member

.2 Main Reason for Change:

UR updated to include cover latest developments in cargo containment system technology.

.3 List of non-IACS Member Classification Societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

None

.5 Other Resolutions Changes

None

.6 Dates:

No records available.

- ## Rev.1 (1979)

.1 Origin for Change:

☑ Suggestion by IACS member

.2 Main Reason for Change:

UR updated to include cover latest developments in cargo containment system technology.

.3 List of non-IACS Member Classification Societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

None

.5 Other Resolutions Changes

None

.6 Dates:

No records available.

- ## New (1986)

.1 Origin for Change:

☑ Suggestion by IACS member

.2 Main Reason for Change:

The IMO International Code for the Construction and Equipment of Ships Carrying Liquified Gases in Bulk does not include complete requirements for the cargo containment systems of gas carriers. The purpose of this UR is to ensure that all IACS Members apply certain minimum standards when assessing such systems.

.3 List of non-IACS Member Classification Societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

None

.5 Other Resolutions Changes

None

.6 Dates:

No records available.

Part B. Technical Background

List of Technical Background (TB) documents for UR G1:

Annex 1. **TB for Rev.3 (June 2016)**

See separate TB document in Annex 1.

◄▲►

Note: *There are no separate Technical Background (TB) documents available for New (1986), Rev.1 (1979), Rev.2 (1997), Corr.1 (Sept 2003), Corr.1 (May 2018), Corr.2 (Oct 2021) and Corr.3 (Sep 2023).*

Technical Background (TB) document for UR G1 (Rev.3 June 2016)

1. Scope and objectives

The purpose of this revision to the UR is to align it with the latest version of the Gas Code.

2. Engineering background for technical basis and rationale

The content of the UR has been included in the amendments to the Gas Code and so it is not necessary to apply the UR to vessels which will be complying with the requirements of the new Gas Code.

3. Source/derivation of the proposed IACS Resolution

IMO International Code for the Construction and Equipment of Ships Carrying Liquified Gases in Bulk.

4. Summary of Changes intended for the revised Resolution:

An application statement has been included which states the following:

"This UR does not apply to vessels which must comply with the requirements of IMO Resolution MSC.370(93) *Amendments to the International Code for the Construction and Equipment of Ships Carrying Liquified Gases in Bulk (IGC Code)."*

The reason the contracted for construction date is not used (as is typical of IACS URs) is because the Gas Code has fairly convoluted criteria. Namely, the amendments apply to the following vessels:

> *"1.1.1 The Code applies to ships regardless of their size, including those of less than 500 gross tonnage, engaged in the carriage of liquefied gases having a vapour pressure exceeding 0.28 MPa absolute at a temperature of 37.8°C and other products, as shown in chapter 19, when carried in bulk.*
> *1.1.2.1 Unless expressly provided otherwise, the Code applies to ships whose keels are laid, or which are at a similar stage of construction where:*
> *.1 construction identifiable with the ship begins; and*
> *.2 assembly of that ship has commenced, comprising at least 50 tonnes or 1% of the estimated mass of all structural material, whichever is less,*
> *on or after 1 July 2016.*
> *1.1.2.2 For the purpose of the Code, the expression "ships constructed" means ships the keels of which are laid or which are at a similar stage of construction."*

Hence, it is simpler to apply the UR to vessels where it is has already been established that the amendments to the Gas Code are applicable.

UR G2 "Liquefied gas cargo tanks and process pressure vessels"

Summary

The Rev.3 of UR G2 provides requirements regarding the new IGC Code (MSC 370(93) Corr.1 and Revised UR W1.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev.3 (May 2023)	7 May 2023	1 July 2024
Rev.2 (Dec 2018)	21 December 2018	1 January 2020
Rev.1 (1979)	No records	-
New (1974)	No records	-

- **Rev 3 (May 2023)**

1 Origin of Change:

☑ Suggestion by GPG and IACS Hull Panel

2 Main Reason for Change:

The IMO International Code for the Construction and Equipment of Ships Carrying Liquified Gases in Bulk has been updated to include the content of the UR G2 and as a result the UR G2 (Rev.2, 2018) is not applicable to ships which will comply with the new IGC Code (Res.MSC.370(93) Corr.1 and W1 as amended).

3 List of non-IACS Member Classification Societies contributing through the TC Forum and/or participating in IACS Working Group:

None

4 History of Decisions Made:

The Machinery Panel carried out a review of the updates to the Gas Code in order to determine what changes needed to be made to UR G2. It was decided to review the UR G2 (Rev.2, 2018) in order to make it applicable to ships complying with the new IGC (Res.MSC.370(93) Corr.1 and W1 as amended).

5 Other Resolutions Changes

UR G3

6 Dates:

Original Proposal:	May 2021	(GPG 19083_IGe)
Panel Approval:	April 2023	(via PM20304kIMd)
GPG Approval:	07 May 2023	(Ref: 19083_IGh)

- **Rev 2 (Dec 2018)**

1 Origin of Change:

☑ Suggestion by IACS member

2 Main Reason for Change:

The IMO International Code for the Construction and Equipment of Ships Carrying Liquified Gases in Bulk has been updated to include the content of the UR G2 and as a result the UR G2 (Rev.1, 1979) is not applicable to ships which will comply with the new IGC Code (Res.MSC.370(93) as amended).

3 List of non-IACS Member Classification Societies contributing through the TC Forum and/or participating in IACS Working Group:

None

4 History of Decisions Made:

The Machinery Panel carried out a review of the updates to the Gas Code in order to determine what changes needed to be made to UR G2. It was decided to review the UR G2 (Rev.1, 1979) in order to make it applicable to ships complying with the new IGC (Res.MSC.370(93) as amended).

5 Other Resolutions Changes

UR G3

6 Dates:

Original Proposal: September 2015 (22nd Machinery Panel Meeting)
Panel Approval: September 2018 (28th Machinery panel meeting)
GPG Approval: 21 December 2018 (Ref: 15042_IGzd)

- **Rev.1 (1979)**

No records available.

- **New (1974)**

No records available.

Part B. Technical Background

List of Technical Background (TB) documents for UR G2:

Annex 1. **TB for Rev.2 (Dec 2018)**

See separate TB document in Annex 1.

Annex 2. **TB for Rev.3 (May 2023)**

See separate TB document in Annex 2.

Note: There are no Technical Background (TB) documents available for New (1974) and Rev.1 (1979).

Technical Background (TB) document for UR G2 (Rev.2 Dec 2018)

1. Scope and objectives

The purpose is to revise UR G2 (Rev.1 1979), applicable to ships complying with the old IGC Code (pre-2016 editions), in order to make it applicable to ships complying with the new IGC Code (Res.MSC.370(93) as amended).

2. Engineering background for technical basis and rationale

The requirements of UR G2 (Rev.1 1979) correspond to the requirements of the old IGC code (pre-2016 editions); in the revision process those requirements of UR G2 which were found different to those of the new IGC Code have been modified to conform to the requirements of the new IGC code and these modifications are reflected in the Rev.2 of the UR G2.

3. Source/derivation of the proposed IACS Resolution

IMO International Code for the Construction and Equipment of Ships Carrying Liquified Gases in Bulk, Res.MSC.370(93) as amended.

4. Summary of Changes intended for the revised Resolution

The Rev.2 of the UR G2 was developed to apply to ships for which the new IGC Code is applicable.

5. Points of discussions or possible discussions

Direct references to the IGC Code are made in some parts of the UR instead of repeating the Code text.

6. Attachments if any

None

Technical Background (TB) document for UR G2 (Rev.3 May 2023)

1. Scope and objectives

The purpose is to revise UR G2 (Rev.2 2018), applicable to ships complying with the old IGC Code (2016 editions), in order to make it applicable to ships complying with the new IGC Code (Res.MSC.370(93) Corr.1 and UR W1 as amended).

2. Engineering background for technical basis and rationale

The requirements of UR G2 (Rev.2 2018) correspond to the requirements of the old IGC code (2016 editions); in the revision process those requirements of UR G2 which were found different to those of the new IGC Code have been modified to conform to the requirements of the new IGC code and these modifications are reflected in the Rev.3 of the UR G2.

3. Source/derivation of the proposed IACS Resolution

IMO International Code for the Construction and Equipment of Ships Carrying Liquified Gases in Bulk, Res.MSC.370(93) Corr.1 as amended.

4. Summary of Changes intended for the revised Resolution

The Rev.3 of the UR G2 was developed to apply to ships for which the new IGC Code is applicable.

5. Points of discussions or possible discussions

Direct references to the IGC Code are made in some parts of the UR instead of repeating the Code text.

Note that detailed welding requirements are no longer within UR W1.

UR W1 is only applicable to material for thickness from 40-50mm (which are currently beyond the Code's requirements).

For NdT techniques and requirement, G2.9 referred to recognized standards acceptable to the Classification Societies.

Reference on UR W1 mentioned in G2.2 for the material of process pressure vessel (when thickness is beyond the Code).

Rev.3 (Dec 2008)	19 December 2008	1 January 2010
Rev.2 (1997)	12 May 1997	-
Rev.1 (1979)	No record	-
NEW (1974)	No record	-

- ### Rev.8 (Oct 2023)

.1 Origin for Change:

☑ Suggestion by IACS member

.2 Main Reason for Change:

Regarding various discussions for alignment of IGC Code with IGF Code A-1, it was agreed that UR G3 needs revision to expand G3.6.3 to address liquefied gas carrier gas/liquefaction/refrigeration compressors in addition to cargo pumps.

.3 List of non-IACS Member Classification Societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

With reference to SOLAS Reg. II-1 26.6: Main propulsion machinery and all auxiliary machinery essential to the propulsion and the safety of the ship shall, as fitted in the ship, be designed to operate when the ship is upright and when inclined at any angle of list up to and including 15° either way under static conditions and 22.5° under dynamic conditions (rolling) either way and simultaneously inclined dynamically (pitching) 7.5° by bow or stern. The Administration may permit deviation from these angles, taking into consideration the type, size, and service conditions of the ship.

and to IGF Code in A-1, 9.9.2: Compressors and pumps shall be suitable for their intended purpose. All equipment and machinery should be adequately tested to ensure suitability for use within a marine environment. Such items to be considered would include, but not be limited to .1 environmental; .2 shipboard vibrations and accelerations; .3 effects of pitch, heave, and roll motions, etc.; and .4 gas composition.

it was decided to revise UR G3 (in conjunction with a revision of UR M46) to ensure clarity that cargo pumps and gas/reliquefication/refrigeration compressors are expected to demonstrate compliance with criteria set for design assessment and testing or prior satisfactory service experience.

- **Rev.7 (Dec 2019)**

.1 Origin for Change:

☑ Suggestion by IACS member

.2 Main Reason for Change:

The IMO International Code for the Construction and Equipment of Ships Carrying Liquified Gases in Bulk (IGC Code) has been updated to include the content of the UR G3 and as a result the UR G3 (Rev.6, Jan 2016) is not applicable to ships which will comply with the new IGC Code (Res.MSC.370(93) as amended).

.3 List of non-IACS Member Classification Societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

The Machinery Panel carried out a review of the updates to the IGC Code in order to determine what changes needed to be made to UR G3. It was decided to review the UR G3 (Rev.6, Jan 2016) in order to make it applicable to ships complying with the new IGC (Res.MSC.370(93) as amended).

.5 Other Resolutions Changes

UR G2

.6 Any hinderance to MASS, including any other new technologies:

None

.7 Dates:

Original Proposal:	September 2015 (22nd Machinery Panel Meeting)
Panel Approval:	September 2019 (30th Machinery Panel Meeting) and 30 October 2019 (Ref. PM5901eIMt)
GPG Approval:	13 December 2019 (Ref: 15042_IGzm)

- **Rev.6 (Jan 2016)**

.1 Origin for Change:

☐ Based on the proposal of an IACS Member

.2 Main Reason for Change:

To reconsider the prototype testing and the unit production testing for valves used for isolation of instruments.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

Survey Panel discussed under the task PSU15008 the proposal of the Member for reconsidering the test procedures of valves used for isolating instruments in piping having diameter not greater than 25 mm.
The proposal was supported by the consideration that valves in instrumentation piping, which only serve to isolate a gauge or other instrumentation, are usually left open.
Therefore it has been evaluated that the prototype test and unit production test of these valves can be deemed acceptable as follows:

- Prototype testing: it may be witnessed by an Independent Certification Body

- Unit production testing: the witnessing by part of the surveyor may be dispensed.

- In both cases records of the testing activities are to be available for review.

Panel at the 21st Meeting concurred with the proposal and agreed to the modification of the paragraphs G3.6.1.1 and G3.6.1.2 of Unified Requirement G3.

The draft of revision 6 was subsequently submitted to the examination of the Machinery Panel which is the responsible of the UR.

Machinery Panel Members provided their comments on the proposal: these have been dealt with by the Survey Panel Members during the 22ndmeeting. As outcome of the discussion Panel concluded that the proposed modification of the paragraph G3.6.1.1 does not need to be applied since the presence of the Classification Society surveyor at the prototype tests of the cryogenic valves having diameter less than 25 mm is necessary.

In the light of above Panel decided to finalize the revision 6 of the UR by modifying only the paragraph G3.6.1.2

Technical Background, recording the Machinery Panel advice and the Survey Panel technical justifications, is provided in Annex 4.

.5 Other Resolutions Changes

None

.6 Dates:

Original proposal: 22 January 2015 by IACS Member
Panel Approval: December 2015 by Survey Panel (Ref: PSU15008) GPG Approval: 29 January 2016 (Ref: 15204_IGb)

- **Rev.5 (Jan 2013)**

.1 Origin for Change:

☐ Request by non-IACS entity (LESER)

.2 Main Reason for Change:

To reflect the test procedures for prototype and production tests of safety valves intended to be used at a working temperature lower than -55°C.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

Survey Panel discussed the proposal of LESER for reconsidering the test procedures of safety valves. The panel discussed and revised the provisions of test procedure for safety valves required by Para G3.6.1.1 and G3.6.1.2. Conclusion of Survey Panel was further reviewed and supported by Machinery Panel.

Technical Background

UR G3 (Rev.3, Dec 2008)

Survey Panel Task 57: Consider amending UR G 3 “Liquefied gas cargo and process piping” to reflect the common survey practices of the Members on testing of cryogenic valves and adding in test requirements for valves intended to be used at a working temperature not lower than -55°C and for new LNG and LPG pumps.

1. Objective

Consider amending the present survey tightness test requirements contained in UR G3, section 3.6.1, which is only each size and each type of valve intended to be used at a working temperature below -55°C to take into account the present best practices of the members. Also consider adding in new sections containing survey test requirements based on best practices of Members for valves intended to be used at a working temperature not lower than -55°C and new LNG and LPG cargo pumps as presently there are no requirements.

2. Background

ABS Panel member initially requested clarification on testing of cryogenic valves and requirements for testing of new LNG pumps based on email correspondence dated 28 Nov 2007. NK Panel member requested that survey requirements for valves intended to be used at a working temperature not lower than -55°C be considered based on email dated 14 Dec 2007.

3. Methodology of Work

The Survey Panel has progressed its work through meetings as well as a Survey Panel Project Team consisting of ABS (Chair), BV, DNV, KR and NK. The proposed scope of work as well as the draft recommendation by the Project Team was circulated to all Members for comment and agreement.

4. Discussion

- **Valves**

The Project Team first discussed the survey practices of the members on testing of cryogenic valves for temperatures lower than -55°C. The use of the term “type testing” caused considerable confusion due to current type approval programs offered by the societies. After lengthy discussion, in order to eliminate confusion, the members decided to use the terms “prototype” testing and “unit production” testing.

All members stated that prototype testing was carried out for each type and size of valve and that surveyor attendance was required during these tests. However, for unit certification, the practices differed. The members also reported that it was common practice to carry out cryogenic testing of 10 percent of the valves.

For prototype testing, all members agreed that the required minimum tests in the presence of a surveyor include hydrostatic test of the valve body at a pressure equal to 1.5 times the design pressure, seat and stem leakage test at a pressure equal to 1.1 times the design pressure, and cryogenic testing consisting of valve operation and leakage verification. They also agreed that testing is to be carried out at the minimum design temperature or lower and to a pressure not lower than the maximum design pressure foreseen for the valves.

For unit production testing, the members agreed there should be two options for testing of the valves based on current practices. The first option required surveyor attendance for all valve testing. The second option allowed the manufacturer to carry out the testing if they had a recognized quality system which had been assessed by the society and is subject to periodic audits.

All members agreed that the required minimum tests for both options include hydrostatic test of the valve body at a pressure equal to 1.5 times the design pressure, seat and stem leakage test at a pressure equal to 1.1 times the design pressure. It was also decided to include the industry standard of requiring cryogenic testing consisting of valve operation and leakage verification for a minimum of 10% of each type and size of valve for valves intended to be used at a working temperature below -55°C. The cryogenic tests are to be carried out in the presence of a surveyor for both of the above options.

The members then discussed the requirements for valves intended to be used at a working temperatures above -55°C. Based upon service experience, and that there is no testing medium for -55°C, it was decided that prototype testing was not required for these valves.

- **Cargo Pumps**

The members decided to use the same methodology for cargo pumps as was used for valves. All members reported their procedures followed the prototype and unit production testing similar to valves.

Again, the members decided that surveyor attendance was required for prototype testing and that two options be available for unit production testing. The first option required surveyor attendance for all pump testing. The second option allowed the manufacturer to carry out the testing if they had a recognized quality system which had been assessed by the society and is subject to periodic audits.

For prototype and unit production testing, all members agreed the required minimum tests include hydrostatic test of the pump body equal to 1.5 times the design pressure and a capacity test. For pumps intended to be used at a working temperature below -55°C, the capacity test is to be carried out at the minimum working temperature. After completion of tests, the pump is to be opened out for examination. Based upon service experience, and that there is no testing medium for -55°C, it was decided pumps intended to be used at temperatures above -55°C, could be tested at ambient temperature.

- **IACS UR G3**

The members also decided to change the title of G3.6 to indicate these tests were to be carried out prior to installation onboard and differentiate it from G3.8. It was also decided to revise the title of G3.8 to "Test onboard".

In order to differentiate between prototype testing and type testing, the members also recommend the proposed change to G3.6.2. It is further recommended that this section be revised to incorporate the same methodology used for the valves and pumps. Since this was not included in the task, the project team took no action at this time.

During the discussions on the task, the team noted that UR G3 may require updating to reflect current practices. This is probably due to the fact that UR G3 was written in 1974 and revised in 1979 and 1997.

Submitted by Survey Panel Chairman

12 November 2008

Permanent Secretariat note (January 2009):

UR G3 (Rev.3) was approved by GPG on 19 December 2008 (ref. 8508aIGd) with the following implementation statement:

"The requirements of G3.6 Rev.3 are to be uniformly implemented by IACS Societies for piping components and pumps:

i) when an application for testing is dated on or after 1 January 2010; or

ii) which are installed in new ships for which the date of contract for construction is on or after 1 January 2010."

Technical Background for UR G3, Rev.4 (Mar 2011)

1. Scope and objectives

Consider amending the present prototype test and unit production test requirements contained in UR G3, section G.3.6.3.1 and G.3.6.3.2, for pumps intended to be used at a working temperature below -55°C to take into account the present best practices of the members and the comments from the Industry. Also consider adding in new sections containing survey test requirements based on best practices of Members for pumps intended to be used at a working temperature not lower than -55°C and new LNG and LPG cargo pumps as presently there are no requirements.

2. Engineering background for technical basis and rationale

For prototype testing, all members agreed the required minimum tests include hydrostatic test of the pump body equal to 1.5 times the design pressure and a capacity test. Although capacity tests are not safety related, this test demonstrates the overall performance of the pump prior to being installed onboard.

Since this is a new requirement and there are pumps currently in service which have years of satisfactory service, an option was provided to allow the manufacturer to submit data proving the in-service experience rather than requiring them to carry out the prototype test which would be required for a new design of pump.

For submerged electric motor driven pumps the capacity test is to be carried out in the design medium or below minimum working temperature. The reason two conditions was added is that some manufacturers may test with LNG and others may use liquid nitrogen which has a temperature of -196 C. When testing with the design medium, LNG, it is difficult to keep the temperature constant and there is a possibility that air may be introduced. Therefore, the test is usually carried out between -160 and -150 C in order to keep the suction line a little above atmospheric pressure.

The shaft driven deep well pumps are now being used on gas vessels that are capable of pumping LPG, Ethylene and LNG. Since it is not practical and could be dangerous to perform a capacity test of shaft driven deep well pumps at the minimum working temperature, this test may be carried out with water. However, in order to prove the pump will be able to operate at the minimum working temperature, a spin test to demonstrate satisfactory operation of bearing clearances, wear rings and sealing arrangements should be carried out prior to the pump being installed onboard. This test would most likely be done using liquid nitrogen so the pump would have to be designed for the lower temperature.

After completion of tests, the pump is to be opened out for examination.

3. Source / derivation of the proposed IACS Resolution

Current industry practice.

4. Summary of Changes intended for the revised Resolution:

G3.6.3 Cargo Pumps

G3.6.3.1 Prototype Testing

Each size and type of pump is to be approved through design assessment and prototype testing. Prototype testing is to be witnessed in the presence of the Society's representative. In lieu of prototype testing, satisfactory in-service experience, of an existing pump design approved by a Society, submitted by the manufacturer may be considered.

Prototype testing is to include a hydrostatic test of the pump body equal to 1.5 times the design pressure and a capacity test. For submerged electric motor driven pumps, the capacity test is to be carried out with the design medium or with a medium below the minimum working temperature. For shaft driven deep well pumps, the capacity test may be carried out with water. In addition, for shaft driven deep well pumps, a spin test to demonstrate satisfactory operation of bearing clearances, wear rings and sealing arrangements is to be carried out at the minimum design temperature. The full length of shafting is not required for the spin test, but must be of sufficient length to include at least one bearing and sealing arrangements. After completion of tests, the pump is to be opened out for examination.

G3.6.3.2 Unit Production Testing

All pumps are to be tested at the plant of manufacturer in the presence of the Society's representative. Testing is to include hydrostatic test of the pump body equal to 1.5 times the design pressure and a capacity test. For submerged electric motor driven pumps, the capacity test is to be carried out with the design medium or with a medium below the minimum working temperature. For shaft driven deep well pumps, the capacity test may be carried out with water.

As an alternative to the above, if so requested by the relevant Manufacturer, the certification of a pump may be issued subject to the following:

- The pump has been ~~prototype tested~~ approved as required by 3.6.3.1, and
- The manufacturer has a recognized quality system that has been assessed and certified by the Society subject to periodic audits, and
- The quality control plan contains a provision to subject each pump to a hydrostatic test of the pump body equal to 1.5 times the design pressure and a capacity test. The manufacturer is to maintain records of such tests.

5. Points of discussions or possible discussions

G3.6.3.1 Prototype Testing

In lieu of prototype testing, satisfactory in-service experience, of an existing pump design approved by a Society, submitted by the manufacturer may be considered.

Since this is a new requirement and there are pumps currently in service which have years of satisfactory service, an option was provided to allow the manufacturer to submit data proving the in-service experience rather than requiring them to carry out the prototype test which would be required for a new design of pump.

…For submerged electric motor driven pumps, the capacity test is to be carried out with the design medium or with a medium below the minimum working temperature. For shaft driven deep well pumps, the capacity test may be carried out with water. In addition, for shaft driven deep well pumps, a spin test to demonstrate satisfactory operation of bearing clearances, wear rings and sealing arrangements is to be carried out at the minimum design temperature. The full length of shafting is not required for the spin test, but must be of sufficient length to include at least one bearing and sealing arrangements.

For submerged electric motor driven pumps the capacity test is to be carried out in the design medium or below minimum working temperature. The reason two conditions was added is that some manufacturers may test with LNG and others may use liquid nitrogen which has a temperature of -196 C. When testing with the design medium, LNG, it is difficult to keep the temperature constant and there is a possibility that air may be introduced. Therefore, the test is usually carried out between -160 and -150 C in order to keep the suction line a little above atmospheric pressure.

The shaft driven deep well pumps are now being used on gas vessels that are capable of pumping LPG, Ethylene and LNG. Since it is not practical and could be dangerous to perform a capacity test of shaft driven deep well pumps at the minimum working temperature, this test may be carried out with water. However, in order to prove the pump will be able to operate at the minimum working temperature, a spin test to demonstrate satisfactory operation of bearing clearances, wear rings and sealing arrangements should be carried out prior to the pump being installed onboard. This test would most likely be done using liquid nitrogen so the pump would have to be designed for the lower temperature.

G3.6.3.2 Unit Production Testing

…. For submerged electric motor driven pumps, the capacity test is to be carried out with the design medium or with a medium below the minimum working temperature. For shaft driven deep well pumps, the capacity test may be carried out with water.

Same reasoning as prototype testing.

- The pump has been ~~prototype tested~~ approved as required by 3.6.3.1, and

To clarify that all the requirements of 3.6.3.1 must be completed and not just the testing.

Technical Background for UR G3 Rev.5 Jan 2013

1. Scope and objectives

To consider the comments and proposals submitted by non-IACS entity (LESER) for revision of the requirements regarding prototype and production tests of safety valves intended to be used at a working temperature lower than -55°C.

2. Engineering background for technical basis and rationale

- Survey Panel reviewed the comment of a non-IACS entity that the requirements of UR G3 Para G3.6.1.1 and G3.6.1.2 are not possible to satisfy for safety valves because of the different design from shut off valves.

- Panel discussed the above issue and revised the requirements of UR G3 for prototype and production tests of safety valves.

3. Source / derivation of the proposed IACS Resolution

None

4. Summary of Changes intended for the revised Resolution

G3.6.1.1 Prototype Testing

Each size and type of valve intended to be used at a working temperature below -55°C is to be approved through design assessment and prototype testing. Prototype testing to the minimum design temperature or lower and to a pressure not lower than the maximum design pressure foreseen for the valves is to be witnessed in the presence of the Society’s representative. Prototype testing for all valves, is to include hydrostatic test of the valve body at a pressure equal to 1.5 times the design pressure, and cryogenic testing consisting of valve operation or safety valve set pressure, and leakage verification. In addition, for valves other than safety valves, a seat and stem leakage test at a pressure equal to 1.1 times the design pressure.

For valves intended to be used at a working temperature above -55°C, prototype testing is not required.

G3.6.1.2 Unit Production Testing

All valves are to be tested at the plant of manufacturer in the presence of the Society’s representative. Testing is to include hydrostatic test of the valve body at a pressure equal to 1.5 times the design pressure for all valves, and seat and stem leakage test at a pressure equal to 1.1 times the design pressure for valves other than safety valves. In addition, cryogenic testing consisting of valve operation and leakage verification for a minimum of 10% of each type and size of valve for valves other than safety valves intended to be used at a working temperature below -55°C. The set pressure of safety valves is to be tested at ambient temperature.

As an alternative to the above, if so requested by the relevant Manufacturer, the certification of a valve may be issued subject to the following:

- The valve has been approved as required by 3.6.1.1 for valves intended to be used at a working temperature below -55°C, and
- The manufacturer has a recognized quality system that has been assessed and certified by the Society subject to periodic audits, and
- The quality control plan contains a provision to subject each valve to a hydrostatic test of the valve body at a pressure equal to 1.5 times the design pressure for all valves and seat and stem leakage test at a pressure equal to 1.1 times the design pressure for valves other than safety valves. The set pressure of safety valves is to be tested at ambient temperature. The manufacturer is to maintain records of such tests, and
- Cryogenic testing consisting of valve operation and leakage verification for a minimum of 10% of each type and size of valve, for valves other than safety valves, intended to be used at a working temperature below -55°C in the presence of the Society's representative.

G3.8.3 Functional tests

All piping systems including all valves, fittings and associated equipment for handling cargo or vapours are to be tested under normal operating conditions not later than at the first loading operation.

5. Points of discussions or possible discussions

Prototype and production tests of safety valves

6. Attachments if any

None

Technical Background (TB) document for UR G3 (Rev.6 Jan 2016)

1. Scope and objectives

Analyse the Machinery Panel comments to the draft revision 6 of UR G3 and verify the possibility to address them.

2. Engineering background for technical basis and rationale

With the revision 6 of UR G3 it has been scheduled to introduce new requirements relevant the witnessing, by part of the Classification Society, of the prototype and production testing for the valves used for insulation of instrumentation piping not greater than 25 mm (outside diameter).

3. Source / derivation of the proposed IACS Resolution

Survey Panel Member

4. Summary of Changes intended for the revised Resolution:

Revision of the criteria to apply to the prototype and production testing of the valves to be fitted on pipes having outside diameter of 25mm and used in order to isolate the instrumentations. Paragraphs to be modified inside the UR: G3.6.1.1 and G3.6.1.2

5. Points of discussions or possible discussions

The draft revision 6 of UR G3 as agreed by Survey Panel during the 21st meeting has been sent to the Machinery Panel, who is the responsible for the captioned UR, for review and possible advices.

The Machinery Panel provided the following comments:

Paragraph	Text	Machinery Panel Comments
G3.6.1.2	"For valves used for isolation of instrumentation in piping not greater than 25mm, unit production testing need not be witnessed by the surveyor. Records of testing are to be available for review."	**Comment 1:** Member society considers further that cryogenic testing for production units is impractical, costly and of limited value and should be deleted. Hydraulic testing of individual valves including tightness testing to 1.1 design pressure at ambient conditions is regarded an appropriate measure to reveal production deficiencies.

Paragraph	Text	Machinery Panel Comments
G3.6.1.1 **G3.6.1.2**	"For valves used for isolation of instrumentation in piping not greater than 25mm, prototype testing may be witnessed by an independent certification body. Records of testing are to be submitted for review." "For valves used for isolation of instrumentation in piping not greater than 25mm, unit production testing need not be witnessed by the surveyor. Records of testing are to be available for review."	**Comment 2:** Member society thinks that the modifications should not apply to valves used for the isolation of instrumentation directly connected to type C cargo vessel at pressure above 4 bar, which should be tested using the same procedure applied to valves having diameter greater than 25 mm.
G3.6.1.1 **G3.6.1.2**	"For valves used for isolation of instrumentation in piping not greater than 25mm, prototype testing may be witnessed by an independent certification body. Records of testing are to be submitted for review." "For valves used for isolation of instrumentation in piping not greater than 25mm, unit production testing need not be witnessed by the surveyor. Records of testing are to be available for review."	**Comment 3:** The proposed revisions to IACS G3 have been noted and the following observations are offered: a. It is noted that the relaxations are only to allow; prototype testing witnessed by an independent certification body and, production testing need not be witnessed by a surveyor, it does not negate the need for the valves to be prototype and production tested. b. The relaxation will only be applicable when the valves are below 25 mm diameter and be installed for instrumentation applications. c. The relaxations would be acceptable provided: i. The lines served by these valves are fitted with orifices in order to restrict the flow as required by Chapter 5, paragraph 5.5.5 of the Revised IGC Code, and ii. A more detailed technical and safety justification is provided in the HF&TB for the relaxation. d. If these relaxations are to be allowed then the wording used in; G3.6.1.1 Prototype Testing and G3.6.1.2 Unit Production Testing also needs to be amended because they currently refer to all valves. e. As SIGTTO have produced a document titled; 'The Selection and Testing of Valves for LNG Applications' it is proposed that they might be consulted on this proposed relaxation to allow their document to be updated. f. It is noted that the items proposed for amendment originally raised in prior message and then with the survey panel are to be separately addressed when UR G3 is revised to align with the new IGC Code.
HF&TB		**Editorial comment:** It is understood that the sub-header of Part A of the HF "Rev.5 (Jan 2013)" will be modified to read "Rev.6 (xxx 2015)".

During the 22nd Survey Panel meeting the comments to revision 6 have been examined and technically dealt with as follows:

- For what concern the comment 1, Panel Members concurred that a modification of the testing criteria of the cryogenic valves (working at temperature below -55°C) does not need to be modified by relaxing them. Moreover, since the current practice is not subject any critics or complaints by part of the industry, Panel consider the actual requirements feasible and accepted by the interested parties.
- Paragraph G3.6.1.1 – following the revisions of the comments no. 2 and no. 3d, the Panel Members re-examined the proposal and concurred that since the prototype test is carried out only (at the time that a new product is submitted to the type approval procedure) the witnessing of the Classification Society Surveyor is a fundamental part of the process. Thus Panel reviewed its previous decision and concurred that the proposed modification to paragraph G3.6.1.1 has not to be considered.
- Paragraph G3.6.1.2 - following the revisions of the comments no. 2 and no. 3c, the Members agreed that the modification introduced does not have the scope to avoid the testing of valves but rather, to allows an alternative scheme of testing. Therefore any valve will be always tested (by the manufacturer at least) and records of the testing will be available.
- Comment no. 3e: Panel Members noted that IACS requirements already have differences; however IACS may notify this last modification to UR G3 to SIGTTO.

Comment on HF/TB: the clerical error has been corrected.

Technical Background (TB) document for UR G3 (Rev.7 Dec 2019)

1. Scope and objectives

The purpose is to revise the UR G3 (Rev.6, Jan 2016), applicable to ships complying with the old IGC Code (pre-2016 editions), in order to make it applicable to ships complying with the new IGC Code (Res.MSC.370(93) as amended.

2. Engineering background for technical basis and rationale

The requirements of UR G3 (Rev.6, Jan 2016) correspond to the requirements of the old IGC Code. In the revision process those requirements of UR G3 which were found different to those of the new IGC Code have been modified to conform to the requirements of the new IGC Code and these modifications are reflected in the Revision 7 of the UR G3.

3. Source / derivation of the proposed IACS Resolution

- IMO International Code for the Construction and Equipment of Ships Carrying Liquified Gases in Bulk, Res.MSC.370(93) as amended.

4. Summary of Changes intended for the revised Resolution:

The Revision 7 of the UR G3 was developed to apply to ships for which the new IGC Code is applicable.

5. Points of discussions or possible discussions

- Direct references to the IGC Code are made in some parts of the UR instead of repeating the Code text.

6. Attachments if any

None

Technical Background (TB) document for UR G3 (Rev.8 Oct 2023)

1. Scope and objectives

The purpose is to develop or revise requirements for cargo pumps and gas/liquefaction/refrigeration compressors in conjunction with a parallel revision of UR M46.

2. Engineering background for technical basis and rationale

- The IGF Code in A-1, 9.9.2 reads: Compressors and pumps shall be suitable for their intended purpose. All equipment and machinery should be adequately tested to ensure suitability for use within a marine environment. Such items to be considered would include, but not be limited to .1 environmental .2 shipboard vibrations and accelerations .3 effects of pitch, heave, and roll motions, etc. and .4 gas composition.

- The IGC Code does not contain a similar requirement.

- Due to vibration problems on piston rods of piston type BOG compressor units on LNG ships during navigation at heavy sea conditions, a proposal was made for a revision of the UR to address vibration issues in the design and prototype testing of cargo pumps and gas/liquefaction/refrigeration compressors.

- Additional items such as satisfactory service history and boundary components needed further discussion.

3. Source/derivation of the proposed IACS Resolution

- IMO International Code for the Construction and Equipment of Ships Carrying Liquified Gases in Bulk, Res.MSC.370(93) as amended.

- IMO International Code of Safety for Ships Using Gases or Other Low-Flashpoint Fuels, Res. MSC.391(95) as amended.

- UR M46 Rev. 3 (Draft) Ambient conditions – Inclinations and Ship Motions (PM19923)

4. Summary of Changes intended for the revised Resolution:

- A new paragraph G3.1.3 has been introduced referring to the IGC Code, thus any reference in the previous text to “Resolution MSC.370(93)” has been removed.

- Previous section 3.6.3 “Cargo Pumps” has been revised to address “Cargo Pumps and Gas/Reliquefication/Refrigeration Compressors”. The section has been restructured to include separate subsections for Cargo pumps and Gas/Reliquefication/Refrigeration Compressors with subparagraphs on material testing, prototype testing, unit production testing and installation testing.

- In the prototype testing sections, subparagraphs containing vibration criteria have been introduced.

- The satisfactory in-service experience as an alternative to design assessment and prototype testing has been revisited, and qualified majority agreed to remove from new revision of UR.

- Notes for the expression "boundary components" for Cargo Pumps (G3.6.3.1(a)) and Gas/Reliquefication/Refrigeration Compressors (G3.6.3.2(a)) have been added for guidance purposes only.

- The reference to UR W1 in G3.7.6 has been replaced by a reference to the IGC Code and to the society's requirements.

- A list of standards has been inserted at the end of the document for reference.

5. Points of discussions or possible discussions

- A discussion was held on whether a detailed listing of boundary components needed to be inserted in the UR or such components are subject to the society's decision. The listing has been retained for guidance purposes.

- The origin of the listed vibration criteria has been discussed.

  - A specific vibration numerical limit of 12 mm/s overall RMS was initially proposed for the pump prototype test section, based on Internationally recognized standards such as VDI3836 and ISO 10816-1, however this was not finally agreed for insertion in the UR.

  - The numerical limit of 25 mm/s overall RMS, quoted in G3.6.3.2(b) is based on ISO 10816 -6, while the limit of 11.2 mm/s overall RMS in same subsection is based on ISO 10816-1, (ISO 20816-1:2016) Table B.1 (table C.1). As the relevant standards do not quote a single "value" as a limit due to the various power variations, installation requirements (e.g., rigid, flexible), etc., it has been suggested that the most representative of these limits are stated, based on typical such machinery units installed onboard such typical vessels, in terms of power and installation arrangements.

- Regarding the vibration limits, it has been clarified that the wording in the UR indicates that the proposed limits apply only in the absence of any applicable recognized standards by the maker or pertinent fatigue calculations,

  - For reciprocating machinery to be used for continuous operation, the vibration in all directions is to be less than 25 mm/sec overall RMS vibrational velocity on the machinery casing or on the structure in the area of bearings, from 4 to 200 Hz.

  - For rotating machinery to be used for continuous operation, the vibration in all directions is to be less than 11.2 mm/sec overall RMS vibrational velocity on the machinery casing or on the structure in the area of bearings, from 1 to 1000 Hz.

but further discussed in the Panel that;

about whether the limits of vibration criteria such as 25 mm/s and 11.2 mm/s are 'based on' ISO 10816-6 and ISO 10816-1 respectively. Regarding reciprocating machinery, the frequency range in i.e. 4 to 200 Hz, is different from ISO 10816-6 as 2 to 1000 Hz and there is no limitation in ISO 10816-6.

Regarding rotating machinery, perhaps 9.3 mm/s (RMS) is more suitable for vibration criterion.

Therefore, the panel decided to delete criteria and replace it with the text "justification is to be submitted for criteria used as reference in terms of overall root mean square (RMS) vibrational velocity value for normal operation conditions".

- Suggestions for the removal of the option of satisfactory in-service history (as an alternative to design assessment and testing) discussed within the panel did reach the qualified majority. The thought and reason behind are as LNG-Gas fuel system will be more and more trend to use in maritime shipping then IACS MP aim is encouraging manufactures to obtain approval (design approval and witnessing tests) from societies for such crucial equipment. It's understood that some IACS members may have confidence on certain reputable manufactures & product but having such sentence in UR will open door for other manufactures to claim for obtain acceptance without necessary intervention from class societies (design approval and witnessing tests) while in other hand IACS don't has unified criteria about proven in service satisfactory experience.

- One member raised the point that above may impose the cost of type approval on existing products of reputable manufacturer that their products already are in service with satisfactory.

- The various suggestions have not been reflected in the UR.

- A detailed procedure for the leak test of G3.6.3.2(d), suggested by a member (leak test procedure under operating condition at 20%, 40%, 60%, 80% and 95% of design pressure with holding time of minimum 10 minutes), did not receive the qualified majority's acceptance.

- On a query for the conditions for the performance testing of compressors whether they should correspond to the actual & design temperature of compressor (medium) or not required when not specified in the relevant standards, although there was no unform approach as regards the test temperature (operating or design temperature), no society expressed support for the option "not required when not specified in the relevant standards". The various replies are stated below for reference:

    - ...compressors performance tests to be performed, as a minimum, at full load, rated pressure, temperature, and speed.

    - …performance testing of compressor should be carried out under the operating conditions for which they are designed.

- …performance testing conditions to match the design temperature, alternative medium that is like the actual medium is acceptable. Test parameters normally are specified (For example, air compressors).

- …performance testing of compressors should correspond to the actual & design temperature of compressor (medium).

- …performance testing should be performed under design temperature.

- …performance test for intended service is necessary in operating pressure and temperature conditions.

- … in cases where the test medium and temperature are not specified in the standard, the test medium does not necessarily have to be the same as the actual cargo, however the test temperature should be the lowest design temperature.

UR G5 "Fail-close action of Emergency Shut Down (ESD) valve"

Summary

This UR provides requirements to ensure fail-close action of the emergency shutdown valve.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
New (Dec 2022)	28 December 2022	1 January 2024

- **New (Dec 2022)**

1 Origin of Change:

☑ Suggestion by IACS Member

2 Main Reason for Change:

To ensure the fail-close action of ESD valve, by giving specific requirements for the actuating system as well as alarm systems.

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None

4 History of Decisions Made:

Developed by correspondence

5 Other Resolutions Changes:

None

6 Any hinderance to MASS, including any other new technologies:

None

7 Dates:

Original Proposal	: 06 August 2022	(Ref: PM20304cIMc)
Panel Approval	: 25 November 2022	(Ref: PM20304cIMo)
GPG Approval	: 28 December 2022	(Ref: 22060_IGd)

Part B. Technical Background

List of Technical Background (TB) documents for UR G5:

Annex 1. **TB for New (Dec 2022)**

See separate TB document in Annex 1.

Technical Background (TB) document for UR G5 (New Dec 2022)

1. Scope and objectives

The objective is to provide requirements to ensure the fail-close action of ESD valve for the actuating system as well as alarm systems in association with the requirement in 18.10.2.1.2 of the IGC Code, as amended by IMO Resolutions MSC.370(93), MSC.411(97) and MSC.441(99).

2. Engineering background for technical basis and rationale

It was found that there are various requirements and arrangements for fail-close action of emergency shutdown valves (ESD valve, ref. IGC code 18.10.2), especially when such valves are actuated by hydraulic or pneumatic system. And the Machinery Panel decided to develop a Unified Requirements to ensure the fail-close action of ESD valve, setting out provisions for the actuating system and alarm systems.

3. Source/derivation of the proposed IACS Resolution

This UR was initially proposed and discussed by correspondence among Members. After the development of the draft UR, it was further reviewed and confirmed by SIGTTO (a representative of industry).

4. Summary of Changes intended for the revised Resolution:

None

5. Points of discussions or possible discussions

There were two opinions with respect to requirements for alarm in 2.1 of the UR G5 as follows in square bracket:

> *Audible and visible alarm shall be given [in any of both the events of loss of pressure or activation of fail-close action]/[in the event of loss of pressure that causes activation of fail-close action]. The alarm shall be provided in a normally manned control station (e.g. Cargo Control Room and/or the navigation bridge, etc.).*

Now that both options are a matter of expression on the same requirement, it was agreed to include the issue in the Industry Hearing (SIGTTO) and it has been decided to adopt the second option taking into account the Industry Response:

> *We are content with the proposed recommendation and suggest the second option in paragraph 2.1.1 would be most appropriate i.e. alarm on loss of pressure*

Res. No.	Title	Current Rev.	HF/TB?
UR H1	Control of Ammonia releases in Ammonia fuelled vessels	Withdrawn Nov 2024	HF

UR H1 "Control of Ammonia releases in Ammonia fuelled vessels"

Summary

This UR provides requirements for releases of ammonia from the onboard systems for bunkering, storing, preparing and using ammonia as fuel. It addresses normal operation as well as abnormal and emergency scenarios.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Withdrawn (Nov 2024)	11 November 2024	-
New (Jan 2024)	16 January 2024	01 January 2025*

- **Withdrawn (Nov 2024)**

1 Origin of Change:

- Request by non-IACS entity
- Suggestion by IACS member

2 Main Reason for Change:

Potential confusion which could arise within the industry due to the differences between the IACS UR H1 and the IMO Draft Interim Guidelines for Ships Using Ammonia as Fuel finalised at CCC10 in September 2024 and expected to be approved by MSC109 in December 2024.

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None

4 History of Decisions Made:

Recognizing the potential confusion which could arise within the industry due to the differences between the IACS UR H1 and the IMO Interim Guidelines, a strategic decision was taken to withdraw the UR H1 before its coming into force date of 1st January 2025, in view of publication of a revised version, aligned with the IMO Guidelines.

5 Other Resolutions Changes:

None

6 Any hinderance to MASS, including any other new technologies:

None

7 Dates:

Original Proposal:	25 September 2024	(CCC10 PA7)
Panel Approval:	10 October 2024	(Ref: PD24022_PDa)
GPG Approval:	22 November 2024	(Ref: 24159_IGe)

- **New (Jan 2024)**

***New UR H1 was withdrawn in November 2024 before coming into force on 1 January 2025 (Ref: 24159_IGe).**

1 Origin of Change:

☑ Request by non-IACS entity
☑ Suggestion by IACS member

2 Main Reason for Change:

Considering the variety of exposure threshold levels related to the toxicity of Ammonia, there is a need for IACS to unify exposure levels on board ships, and establish basic safety principles relevant to releases of ammonia.

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None

4 History of Decisions Made:

It was considered that different condition/scenarios (normal/abnormal/emergency) are to be addressed by separate requirements.

5 Other Resolutions Changes:

None

6 Any hinderance to MASS, including any other new technologies:

The basic principles relating to MASS have been taken into account while developing new and revised IACS Resolutions; reconsideration of some requirements may be needed in case of fully automated and unmanned ships, because the risk of ammonia toxicity on such ships is be mitigated by the absence of people, but special consideration is to be given to specific operational scenarios (e.g. ammonia bunkering, maintenance) where personnel might be present even on a fully autonomous ship.

7 Dates:

Original Proposal:	25 October 2022	(Made by: Machinery Panel)
Panel Approval:	20 December 2023	(Ref: PD22019_IDo)
GPG Approval:	16 January 2024	(Ref: 22044aIGq)

****

Part B. Technical Background

List of Technical Background (TB) documents for UR H1:

Annex 1. **TB for New (Jan 2024)**

See separate TB document in Annex 1.

Annex 2. **TB for Withdrawn (Nov 2024)**

See separate TB document in Annex 2.

Technical Background (TB) document for UR H1 (New, Jan 2024)

1. Scope and objectives

Considering the variety of exposure threshold levels related to the toxicity of Ammonia, there is a need for IACS to propose unified exposure levels on board ships, and establish basic safety principles relevant to releases of ammonia.

The term "ammonia" means anhydrous or nearly anhydrous ammonia, having suitable composition and quality to be stored and used onboard as marine fuel.

2. Engineering background for technical basis and rationale

2.1 Ammonia is recognised as being toxic to human life and to aquatic life. Therefore, in normal conditions, contact with ammonia, exposure to ammonia vapours and discharge of ammonia-containing effluents is to be avoided. The best method to mitigate risks is to require that the systems for its containment are designed such that they do not release ammonia, at least in normal conditions.

2.2 Acknowledging that even in normal conditions there are special cases where ammonia cannot be fully contained (e.g. small amounts of ammonia vapours trapped in the coupling could be released when disconnecting bunkering hoses), it is considered necessary to identify these cases in a risk assessment and arrange the systems so that released ammonia getting to spaces where people normally have access will have a concentration below a specific threshold level. With reference to normal operations, the concentration threshold was selected as a concentration which may be tolerated for long periods (25 ppm corresponding to the NIOSH REL-TWA (Recommended Exposure Level – Time Weighted Average).

2.3 Considering that it is presently not possible to establish the actual behaviour of an ammonia vapour plume (also depending on the quantity of the ammonia being released and boundary conditions such as wind speed and obstructions in the area), it was agreed that the expected concentration of ammonia in way of spaces where people normally have access is to be demonstrated by gas dispersion analysis, however IACS acknowledges that when more experience will be gained, typical separation distances might be applied instead of gas dispersion analysis for each case; when the need and opportunity arises, this will be accommodated by a revision of the UR.

2.4 Taking into account that ammonia will be stored in a liquefied phase, obtained either by refrigeration or compression or a combination of both, it was acknowledged that there could be both abnormal scenarios (e.g. in case of malfunction of equipment or off-design conditions), and emergency scenarios (e.g. collision, fire) in which ammonia cannot be contained (either for impossibility or for safety concerns like excessive pressure) and is to/will be released. Such cases are to be identified in a risk assessment and a gas dispersion analysis is to be carried out. Depending on the results of these analyses, necessary measures are to be taken to prevent all persons onboard being exposed to hazardous ammonia concentrations (in the context of abnormal/emergency scenarios, dangerous ammonia concentration for short term exposure is defined as a concentration of 300 ppm or more).

The necessary actions or mitigation measures are not established by the UR, and a variety of them depending on the specific scenario may be considered (e.g. availability or use of specific PPE when entering specific spaces or areas, installation of ammonia treatment systems, arranging of spaces on the ship as “safe heavens” with special life support arrangements).

2.5 In order to warn the people on board of possible hazards, the points at which ammonia is typically released (vent mast) are to be equipped with gas detectors giving audible and visual alarms when ammonia is released at a concentration exceeding 300 ppm, so that people may readily avoid/abandon the resulting toxic area and take refuge.

2.6 Spaces which have reasonably foreseeable ammonia leak points (secondary enclosure, fuel preparation room), are required to be equipped with gas detection, monitoring and alarm system. These are typically not manned spaces and the systems should be capable of preventing release, but in order to prevent escalation, when the concentration reaches 300 ppm the safety action of shutting down the source of release is to be taken (e.g. by closing the tank valve or, depending on the location of the detected leak, the master valve).

2a. Specification of the data utilised in the development/revision of the proposed IACS Resolution, if any

Ammonia boiling point at atmospheric pressure (100 kPa) : -32 °C
Ammonia vapour saturation pressure at 25°C : 1003 kPa
Ammonia vapour saturation pressure at 45°C : 1781 kPa
IMO CCC9-3-2 (Republic of Korea): “Study on Safety Assessment of Ammonia Toxicity”

3. Source/derivation of the proposed IACS Resolution

IMO CCC9-3-1 (ITF and Republic of Korea): “Proposal for Safety Principles and Draft Safety Provision against Toxicity for Development of Guidelines for Ships Using Ammonia as Fuel”

4. Summary of Changes intended for the revised Resolution:

NEW

5. Points of discussions or possible discussions

5.1 There was discussion about definitions of normal operation, abnormal scenario and emergency scenario; the agreed definitions are based on the assumption that:

- abnormal scenario is a predictable condition where systems are operating outside of the intended condition, but due to the predictability of the condition and the countermeasures taken the scenario does not present hazard(s)

- an emergency scenario is a condition which is not predictable and/or there are not available sufficient countermeasures to mitigate the hazard(s).

5.2 there was a proposal to add "condition" beside the wording "scenario" in Para. 3.1, 3.2, and 4.3.2, but this was dropped due to the wording "scenario" was used to give the idea of a wider picture, in which the condition of some systems or equipment is only one part, therefore the addition of "condition" beside the wording "scenario" was considered not suitable.

5.3 There was discussion about possibility of requiring specific separation distance between point of release and spaces where people are normally present (instead or requiring gas dispersion analysis), but it was finally agreed that there is not enough experience so far to establish the correct figure, and that these may depend on many factors; also the option of introducing a compromise text referring to "equivalent method" to gas dispersion analysis, thus opening to future experience-based alternatives was considered, but finally dropped in consideration of the need of clarity and uniformity of application

5.4 There was discussion about inclusion in 4.3.1 of additional examples of cases of normal operations where release of ammonia is unavoidable (and that are to be identified in the risk assessment):

- "during storage"
- "fuel preparation"
- "Ventilation out of Fuel preparation Room and TCS"
- "purging, venting and bleeding of fuel supply piping"

These were finally not accepted because:

- "during storage" is unclear in its meaning during bunkering or during idle periods or all cases that ammonia is kept stored in the tank, and also gives the idea that releases from storage tank are unavoidable, but this should not be the case.

- "fuel preparation" is unclear, in that "fuel preparation" is a specific action that is carried out for using the fuel but does not identify a specific condition; also, releases during fuel processing should be avoided, as required in Paragraph 4.1 of the UR

- "Ventilation out of Fuel preparation Room and TCS" is not a condition that implies release of ammonia, unless ammonia is leaking, but this case qualifies as an abnormal scenario

- "purging, venting and bleeding of fuel supply piping" gives the idea that these are normal operations implying unavoidable release of ammonia, which instead should be avoided by design, as required in Paragraph 4.1 of the UR.

5.5 There was discussion about inclusion in 4.3.2 of additional examples of cases of abnormal scenarios where possible releases of ammonia could occur (and that are to be identified in the risk assessment):

- “Gas purging after gas detection at annular space or other process room”
- “PRV open to protect BOG compressor or fuel pump”
- “Forced ventilation from FPR after ammonia release“

The outcome of the discussion was that:

- “Gas purging after gas detection at annular space or other process room” was included because it describes a scenario where a leak occurred and was collected in the double piping or other process room and there is the need of purging.

- “PRV open to protect BOG compressor or fuel pump” was not accepted because in case a PRV fitted downstream of a BOG Compressor, releasing ammonia to atmosphere may be avoided by ducting the PRV outlet to the intake of the Compressor or pump.

- “Forced ventilation from FPR after ammonia release” was combined with the case of “Gas purging after gas detection at annular space or other process room”, thus reading “Gas purging or ventilation after gas detection at annular space or other process room”.

Technical Background (TB) document for UR H1 (Withdrawn, Nov 2024)

1. Scope and objectives

Recognizing the potential confusion which could arise within the industry due to the differences between the IACS UR H1 and the IMO Interim Guidelines, a strategic decision was taken to withdraw the UR H1 before its coming into force date of 1st January 2025, in view of publication of a revised version, aligned with the IMO Guidelines.

2. Engineering background for technical basis and rationale

IACS noted the following differences between the Requirements in UR H1 and the IMO Draft Interim Guidelines for Ships Using Ammonia as Fuel finalised at CCC10 in September 2024 (Annex 1 to CCC10/WP.6 and [CCC 10/16]) and expected to be approved by MSC109 in December 2024.

i. **Hazardous concentration of ammonia**
   a. UR H1 gives a definition of hazardous concentration of ammonia as 300 ppm or more (NIOSH IDHL), or 25 ppm if the exposure is longer than 8 hours (NIOSH REL-TWA), and highlights that other concentrations between 25 ppm and 300 ppm, may be dangerous depending on the exposure time.
   b. The Guidelines do not define hazardous concentration of ammonia, due to the different national occupational regulations in place, however appear to consider 220 ppm of (AEGL 2) as criterion for acute exposure.

ii. **Abnormal scenario**
   a. UR H1 gives a definition of "abnormal scenario" as : "A condition under which one or more systems or equipment are operating outside of the intended conditions and does not present a threat to human and/or aquatic life."
   b. The Guidelines do not define "abnormal scenario" but use that term 3 times, 2 of which in the form "controllable abnormal scenario".

iii. **Releases of ammonia**
   a. UR H1 requires to avoid direct release of ammonia fuel to atmosphere during normal operation e.g. during fuel bunkering, fuel processing, purging of equipment, ventilation system discharges etc, and when possible during any foreseeable abnormal scenario
   b. The Guidelines require to avoid direct release of ammonia into the atmosphere during normal operation and during any foreseeable and controllable abnormal scenario. The Guidelines require operational gas releases to be collected and handled by a suitable ammonia release mitigation system (ARMS). (In this context, it is understood that some member states will consider as not controllable the releases resulting from leakages, and this implies, contrary to UR H1, not requiring treatment/abatement of releases from ventilation of tank connection space, fuel preparation room and double walled piping, but this is not clarified by the Guidelines and thus is left to interpretation).

iv. **Concentration limits in manned spaces**
   a. UR H1, for unavoidable releases, requires the resulting concentration at locations of the ship where persons normally have access not to exceed 25

ppm, to be demonstrated by gas dispersion analysis, but does not specify a clear bound as to the size of the toxic area.

b. The Guidelines establishes definite toxic areas and spaces, and in addition requires gas dispersion analysis to demonstrate that ammonia concentrations exceeding 220 ppm do not reach: air intakes, outlets and other openings to accommodation, machinery, service, control and other non-toxic spaces. The gas dispersion analysis to address discharges from the pressure relief valves protecting the tank containment system, discharges from secondary barriers around fuel tanks and discharges from secondary enclosures around ammonia leakage sources. (This means that concentrations up to 220 ppm may be existing in non-toxic areas).

v. Alarm at the point of release

a. UR H1 requires an alarm when the ammonia concentration at the point of release (vent mast) exceeds 300 ppm, but provides that lower threshold may need to be applied to allow effective warning of people and/or activation of the necessary mitigation measures.

b. The Guidelines requires the outlet from ARMS not to exceed 110 ppm, and have an alarm for ammonia concentration from discharge of ARMS at 110 ppm.

vi. Alarms and shutdown in case of detection of ammonia within spaces

a. UR H1 requires monitoring the spaces where all reasonably foreseeable ammonia leaks may occur, and shutdown of the source of release when a concentration of 300 ppm is detected, but provides that lower threshold may need to be applied to allow activation of the necessary mitigation measures.

b. The Guidelines require an alarm at 110 ppm and shutdown at 220 ppm, and in addition, at an ammonia vapour concentration 25 ppm, a visual local indication at all entrances to enclosed spaces affected.

2a. Specification of the data utilised in the development/revision of the proposed IACS Resolution, if any

None

3. Source/derivation of the proposed IACS Resolution

Draft Interim Guidelines for Ships Using Ammonia as Fuel finalised at CCC10 in September 2024 (Annex 1 to CCC10/WP.6 and [CCC 10/16])

4. Summary of Changes intended for the revised Resolution:

Recognizing the potential confusion which could arise within the industry due to the differences between the IACS UR H1 and the IMO Interim Guidelines, a strategic decision was taken to withdraw the UR H1 before its coming into force date of 1st January 2025.

5. Points of discussions or possible discussions

IACS consider that the IMO Draft Interim Guidelines for Ships Using Ammonia as Fuel were drafted without sufficient discussion time, therefore some elements were removed due to a lack of agreement between member states and there are standards without clear technical justification but just averaging.

IACS considers that it would be advisable:

- to develop URs based on the draft interim guidelines, addressing unclear/ambiguous areas and those not covered or not detailed but needed by the industry
- investigate lacking technical background and submit documents to the IMO accordingly

IACS AHG/PSR

IACS UR I1 - Polar Class Descriptions and Application

- Technical Background -

1.0 Historical Development

An international effort has been made in the development of a uniquely integrated package of measures aimed at protecting life, property and the environment in polar waters. This so-called "harmonisation" process began when several nations recognised the benefits of aligning existing safety and pollution control standards for marine operations in polar waters, and of giving these more general applicability. Germany and Russia made proposals to IMO in the early 1990's, and these resulted in discussions amongst various interested governments who formed a working group to develop an appropriate approach. This Outside Working Group (OWG) reported its formation and aims to IMO in 1993, and was subsequently expanded to include members from industry, academic and research communities and representatives from classification societies. The efforts of the OWG culminated in the development of the IMO *Guidelines for Ships Operating in Arctic Ice-Covered Waters*, which was promulgated in December 2002 as a joint MSC/MEPC circular (MSC/Circ.1056, MEPC/Circ.399).

The structure and format of the IMO *Guidelines* are divided into construction, equipment, operational and environmental protection sections, although the *Guidelines* themselves include only a minimal set of direct technical requirements for construction. Instead, they outline performance standards and reference compliance with IACS Unified Requirements for Polar Ships as demonstrating adequate performance. Accordingly, in May of 1996, IACS GPG established a "non-permanent" Ad-Hoc Group to establish Unified Requirements for Polar Ships (AHG/PSR), with one working group for structural requirements and one for machinery requirements. Notably, the AHG/PSR also includes non-IACS working members who have expertise and knowledge to assist in the development of requirements for this specialised subject. The efforts of AHG/PSR have resulted in three sets of unified requirements for Polar Ships; UR I1 (Polar Class Descriptions and Application); UR I2 (Structural Requirements for Polar Class Ships); UR I3 (Machinery Requirements for Polar Class Ships).

2.0 Scope and Objectives

The scope of UR I1 includes neither structural nor machinery requirements. The objective of UR I1 is simply to specify the application of the structural and machinery requirements for polar ships (UR I2 and UR I3), and to provide descriptions of the various polar classes used throughout these requirements to convey differences with respect to operational capability and strength.

3.0 Points of Discussions or Possible Discussions

3.1 Application

The unified requirements for polar ships are to be applied to any ships constructed of steel and navigating in ice-infested polar waters, except for icebreakers. Icebreakers are defined as any ship (1) having an operational profile that includes escort or ice management functions, (2) having powering and dimensions that allow it to undertake aggressive operations in ice-covered waters, and (3) having a class certificate endorsed with this notation.

3.2 Polar Classes

A total of seven polar classes are described in UR I1 in terms of nominal ice conditions based on WMO sea ice nomenclature. It should be noted that these descriptions are very general, due to the considerable variability of ice conditions in polar waters. The overall intent in defining the technical requirements for each class has been to provide a relatively smooth increase in requirements (and cost) to assist owners in matching the requirements for the ship with its intended voyage or service. It will still be possible to damage any polar class ship by careless operation, accounting for the emphasis placed on operational issues in the IMO *Guidelines* which, of course, have the same polar class descriptions.

One possible point of future discussion concerns the two lowest IACS polar classes PC6 and PC7. These classes are recognised in the IMO Guidelines as nominally equivalent to the Finnish-Swedish ice classes 1AS and 1A. To minimise the cost and design efforts required for ships that are to operate in the Baltic Sea during the winter season and in Arctic waters during the summer season, official recognition of these equivalencies by the Finnish and Swedish Maritime Administrations has been obtained. Due to future rule development on both sides, co-ordination between IACS and the Baltic Administrations are required to maintain these equivalencies.

4.0 Source/Derivation of Proposed Requirements

As noted in the foregoing, UR I1 is a consequence of the international effort to harmonise standards for marine operations in polar waters, and is directly connected with the IMO *Guidelines for Ships Operating in Arctic Ice-Covered Waters* (MSC/Circ.1056, MEPC/Circ.399).

5.0 Appendices

Attachment: *PT 49 – Technical background to UR I1 and UR I2 revision proposals.*

PT 49 – Technical background to UR I1 and UR I2 revision proposals

IACS Hull Panel Project team 49

03 March 2016

Introduction

This document describes the rationale and background for the Rule proposal developed by PT 49 on the revision of IACS Unified Requirements for Polar Class Ships, UR I2.

The proposal covers the following aspects:

- Design loads for non-icebreaking bows
- Requirements for icebreaker notation
- Strength evaluation of web frames and stringers

The proposal includes changes in I1 which are related to the introduction of the specific icebreaker requirements. As a consequence of specifying the application of blunt and bulbous bows, some requirements or assumptions to the hull form, performance, and operational limitations are included as well. This is discussed in more detail below.

A proposal originating from the I3 working group related to propeller submergence has been included in I1.

In the original scope of work, design requirements for rudders as well as evaluation of ice compression loads were included. Due to time and budgetary constraints, these tasks have not been prioritized at this stage. These items should be reassessed in the next revision phase.

Some proposals developed as part of this revision work did not reach agreement within the group, and are hence been left out from the final UR I revision proposal. Some references to these proposals are however included and discussed for possible use in later revisions.

General acceptance criteria for direct calculations for web frames and girders have been included in the rule proposal, and it is opened up for both linear and non-linear calculation methods. However, detailed procedures for how these structures are to be evaluated is not included, and it is considered crucial that a common approach is developed to ensure consistent practice and interpretation among the classification societies. Hence, it is advised that that a separate group is tasked to develop a detailed guidance describing suitable evaluation procedures for web frames and stringers.

A general clean-up of the rule text has been carried out to correct typos, inconsistencies etc.

Task 1 – Design loads for non-icebreaking bows

Introduction

The rule design load formulation for dimensioning of the bow structure is according to IACS URI2 only valid for vessels with icebreaking forms. The definition of *icebreaking form* is however non-existent, but it is reasonable to assume that the term excludes vessels with bulbous bows, or vessels with extreme blunt or vertical bow forms. The aim of the current revision has been to clarify the applicability of the existing load formulation, and specify alternative methods, or limitations, for other bow forms not covered by the existing formulation. In addition, other relevant requirements which depend on the bow form are addressed, including longitudinal strength requirements and design accelerations as given in I3.

Background and summary of the new rule proposal

The Polar Class requirements do not give any explicit limitations with regard to hull form for any ice class. It is however evident that the rule requirements are developed with traditional icebreaking designs in mind, on which also most of the operational experience and validations have been based. The rules are seen to be less applicable for unconventional designs, with one of the most apparent deficiencies being the definitions of the design loads.

In the new revision proposal, the text in I1 is amended to emphasize that the Polar Class notations are developed for ships intended for independent operation in ice-infested polar waters. This has clearly been the basis for the development, and should be stated explicitly stated in the Rules.

Although intended for independent operation and customized for traditional icebreaking forms, the Polar Class notations have been applied on vessels with alternative designs. These include traditional commercial vessels with hull shapes optimized for open water, for which the (two) lower Polar Classes are considered to be a possible alternative to the (two) highest Baltic classes. In addition, ship-shaped offshore units have been assigned higher Polar Class notations without being designed for independent operation in ice. Increased focus on energy efficiency and multi-functional vessels calls for innovative solutions which will not necessary be covered by the hull families considered during the initial development of the rules. Hence, in the new revision proposal, design procedures for alternative designs have been addressed.

The load formulation which is basis for the Polar Class strength requirements is based on a set of ship/ice interaction scenarios, which are considered to be the most demanding design cases for "standard" polar class vessels. During the development of the Rules, dozens of different ship/ice interaction scenarios were identified and considered potentially relevant for structural design. Preferably the governing design scenario for any part of the hull should be chosen from a "library" of relevant scenarios, depending on ship size, type, shape, class etc. However, in the current rules, two selected scenarios are considered to be governing, namely:

- Ramming scenario
- Glancing impact scenario

The ramming scenario is considered to be governing for the longitudinal strength, while the glancing impact scenario is considered to be dimensioning for the structural design of the bow (and used as basis for the remaining part of the hull structure). During the development of the rules, the ice compression scenario was also considered as potentially governing for the transverse strength of the midship structure, but have until now not been addressed explicitly in the Rules.

The reasons for imposing limitations with regard to bow form to the original design load formulation are not explicitly explained in the available background documentation. One reason may be the fact that alternative designs were not considered during the development of the rules, and that the limitation is a simple consequence of insufficient validation and verification. In any case it is reasonable to assume that possible limitations are related to the validity of the assumption that the glancing impact actually is the governing scenario, and/or the validity of the derivation of the load formulation itself. These will be discussed in more detail below.

When it comes to the derivation of the load formulation, several assumptions which potentially could limit the applicability of the formulation are discussed below. Extremities lie typically within this category, and are often not covered by any validation or calibration against available full scale and model test data. As mentioned above, the main focus during the development was on traditional icebreaking bows, and other bow shapes including bulbous bows were not part of the evaluation. Consequently, no validations or calibrations of such hull shapes are found. However, if the applicability of the load formulation should be limited to the bow forms considered during the development of the Rules, many bow forms which easily can be classified as “icebreaking” will be excluded. Other aspects limiting the applicability are discussed below, including approximations introduced by the simplified hull shape coefficient fa, the limitations introduced with regard to the patch aspect ratio, and the relevancy of the assumed shape of the ice footprint area.

In the current Rule proposal, the term *icebreaking form* has been removed. Instead, the validity of the existing load formulation has been defined by introducing limitations on bow angles.

Certain limitations to the hull form have been introduced for ice classes PC1-PC5. These vessels are normally purpose-built for operation in difficult ice conditions, and bow forms which are not considered effective for ice operation should generally be avoided. For the higher ice classes, bows with vertical sides and bulbous bows are examples which are not considered effective.

A paragraph addressing the expectation that Polar Class vessels should be able to operate independently in ice conditions representative for the ice class have been added in I1. However, requirements to hull form and performance should not restrict the application of new, innovative or other purpose-built designs which do not fit directly into the formulations, but these should be subject to special consideration by each Society.

For PC6 and PC7, open water bows including bows with vertical sides and bulbous bows may be accepted, and alternative load formulations have been developed for these cases. In general, bulbs should be treated as a structural appendage, i.e. the own structural requirements should not drive those of the overall structure.

The longitudinal strength requirements and the design accelerations given in URI3.6 are derived based on the vertical force component in the bow obtained from a ramming impact scenario. In the current proposal, a paragraph is added to emphasize that the basis for the requirements is the ramming scenario. This is consistent with I2.3.1 (i) for bow design loads.

Intentional ramming is not considered to be a relevant operational scenario in design ice conditions for bows with vertical sides or bulbous bows (PC6 and PC7). Hence, the longitudinal strength requirement, as well as the design accelerations based on the ramming, and the requirements will hence not be relevant for these vessels. In the rules, it is stated that this should be specified in the Class certificate or equivalent.

Application of design load formulation for dimensioning of bow structure

For the glancing impact scenario, on which the derivation of the design load for dimensioning of the bow structure is based, the ship is assumed to strike an ice edge of infinite mass with the bow shoulder as shown in Figure 1. During the collision, the ship will penetrate the ice until the normal velocity is zero, and the ship rebounds away. The footprint for a given penetration depth δ will take form of a triangle and is limited by the width W and height H.

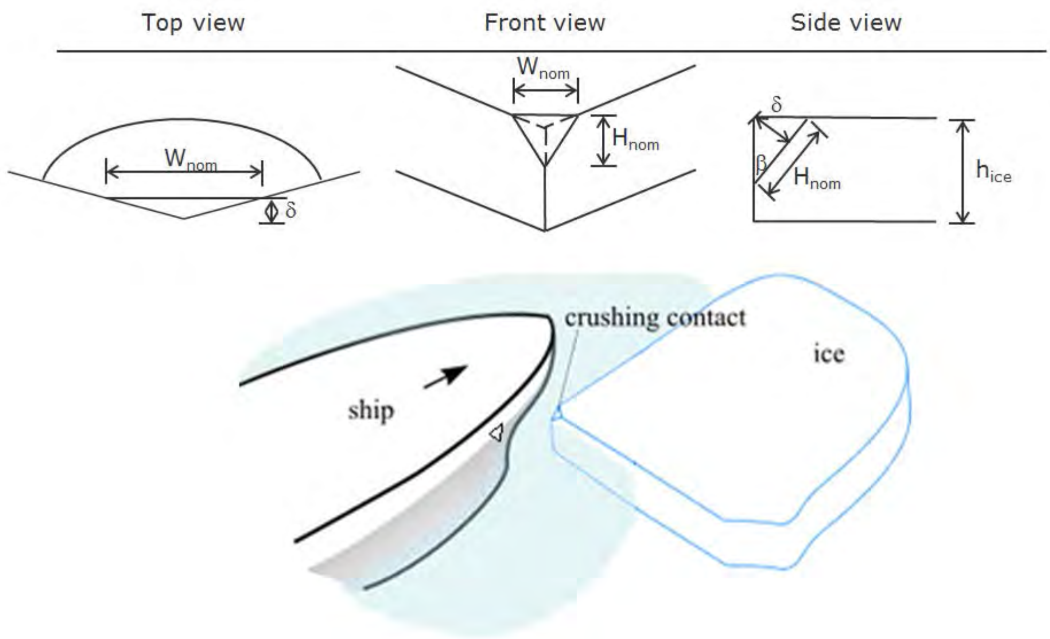

Figure 1 Design scenario for the general glancing impact collision, indicating the nominal contact geometry

The design force is found by assuming that all the initial normal kinetic energy is transformed into crushing energy of the ice. Given the initial geometry of the ice, the resulting triangular footprint is determined from the shape of the bow based on the final penetration depth. Hence, the derivation of the design load and the corresponding footprint area is a result of a simple geometry consideration as long as the vertical extent of the footprint does not exceed the assumed thickness of the ice floe.

As discussed above, the following aspects may impose limitations on the rule formulation:

- Relevancy of the glancing impact scenario for a given hull form

- Accuracy of derived load formulation

Based on available background documentation and evaluations carried out during the revision work, it has not been possible to justify the use of other scenarios than the glancing impact as governing design scenario for any specific bow form. Hence it is proposed to continue using the glancing impact scenario as basis for the dimensioning of the bow.

Regarding the derivation of the load formulation itself, aspects which potentially could justify limitations on the applicability of the load formulation are discussed below.

In the present bow design load formulation, the bow form dependency is represented by the shape coefficient *fa*, where the smaller of the crushing or flexural strength shape coefficient is used. For most conventional icebreaking bow forms, the crushing strength is normally governing, and is hence focused on below. Due to a complex equation for the crushing strength, a simplified expression has been used in the Rules. In Figure 2 (extracted from the background document for ice impact loads) the exact vs. the rule fa-factor is compared for four bow forms, and it is seen that the simplified expression may generate conservative high forces compared with the exact expression for certain bow forms (e.g. landing craft bows), and a cut-off value of 0.6 is introduced to avoid extreme values. Consequently, the upper limit of the fa-factor is for these cases considered more related to the introduction of the simplified rule expression than to represent a limitation on the general load scenario or formulation itself.

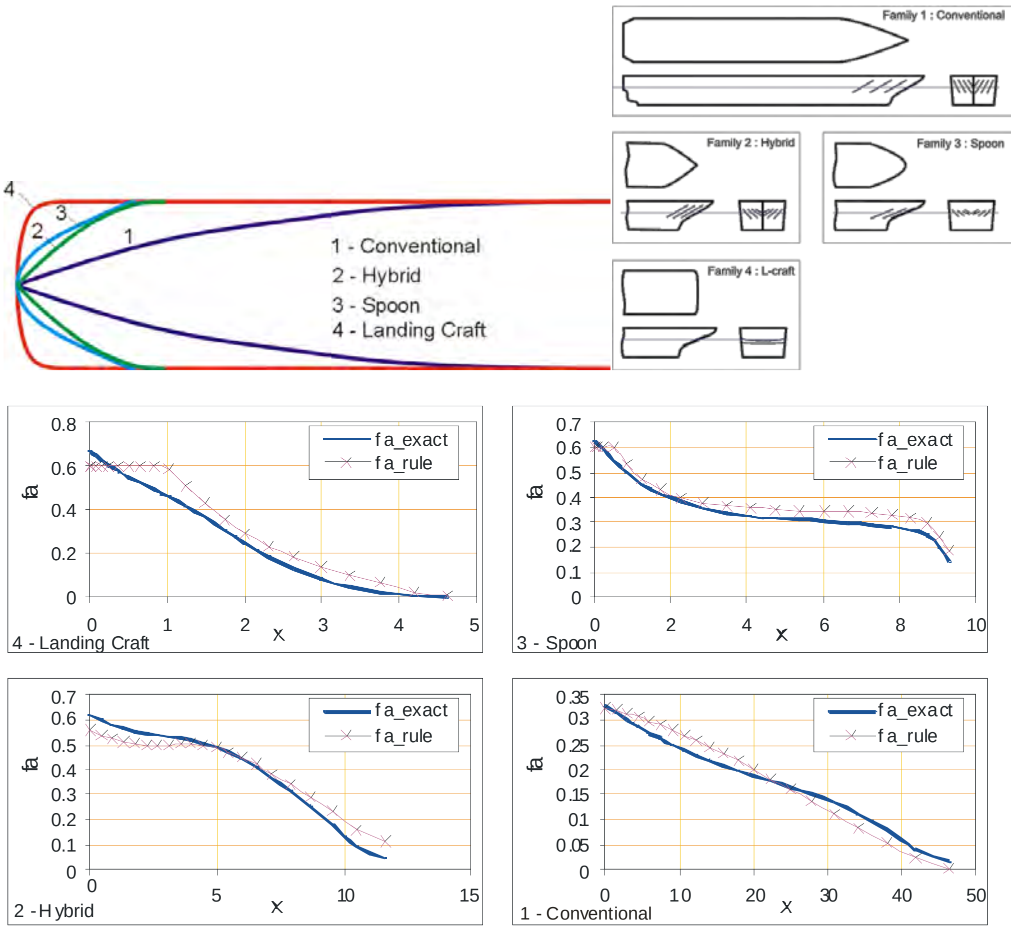

Figure 2 Comparison of exact and rule fa-coefficient for considered hull forms (I2 Background Notes)

The bow forms shown in Figure 2 have different waterplane shapes ranging from conventional to landing craft bows. When introducing the upper limit of the fa-coefficient, it is reasonable to conclude that all these bow forms lie within the application range of the load formulation. Hence, it is difficult to see that this will cause any limitations with regard to waterline angles alone.

A second aspect is related to the limitations introduced in connection with the evaluation of the corresponding contact patch area. The size of the contact area is determined based on the ratio between the calculated width and height of the triangular footprint area obtained from the collision impact scenario. To avoid that the aspect ratio approaches zero, a lower limit of 1.3 has been introduced, which corresponds to a normal frame angle of 10^0. The existence of such a lower limit may indicate that frame angles at least down to 10^0 can lie within the validity range of the formulation.

The third aspect is related to the validity of the assumption that the crushed volume of the ice is shaped like a triangular pyramid. This is in general valid as long as the vertical projection of the contact area is less than the assumed thickness of the ice floe. This assumption may be expressed by the following form:

$$H_{vert} = 0.366 \cdot F_n^{0.556} \cdot P_0^{-0.556} \cdot sin(\beta')^{-0.5} \cdot cos(\beta') \leq h_{ice}$$

Although somewhat complicated, it is possible to evaluate the combination of waterline angles α and normal frame angles β' which violates the assumption, depending on the ice class and displacement of the vessel. Some initial evaluations indicate that this may be relevant for frame angles up to 10-15^0 for larger vessels with the lowest ice classes PC6 and PC7.

It is worth mentioning that the possible limitation discussed above is only relevant as long as the defined ice thickness h_{ice} is assumed to have a physical meaning for the crushing impact scenario, and not only a “scale” parameter defining the flexural strength of the ice.

Considering the aspects above, it is very difficult to define hull angles where it is obvious that the existing load formulation is not valid. It is however reasonable to consider the formulation less applicable for vessels with small normal frame angles β', particularly in combination with larger water plate angles α (i.e. blunt or “shoe-box” shaped bow forms).

In the rule proposal, it is suggested to consider the existing load formulation valid for bow forms where the buttock angle, γ, at the stem is positive and less than 80^0, and where the normal frame angle β' at the centre of the foremost sub-region of the bow is equal to or larger than 10 degrees. A limit of 10^0 is, beyond what have been discussed above, considered to be a practical compromise, which ensures that most traditional designs are covered by the formulation. Such a limit will at the same time exclude most of the unconventional designs. However, bearing in mind the original “icebreaking bow” statement, the proposal will now cover bow forms which easily can be classified as “non-icebreaking”.

For bows with vertical sides not fulfilling the bow angle criteria proposed for the existing load formulation above, an alternative formulation has been developed based on the same glancing impact scenario. When the normal frame angle approaches zero, the vertical projection of the nominal contact area becomes equal to the assumed thickness of the ice, and may be defined as shown in Figure 3. The derivation of the impact forces generated from such a scenario is seen to be somewhat complicated and not well suited for rule application unless a simplified expression is introduced. However, a formulation for the special case where the normal frame angle is 0^0 (vertical sides), as shown in Figure 4, may be a feasible alternative for such designs. The load formulation is presented in Appendix B.

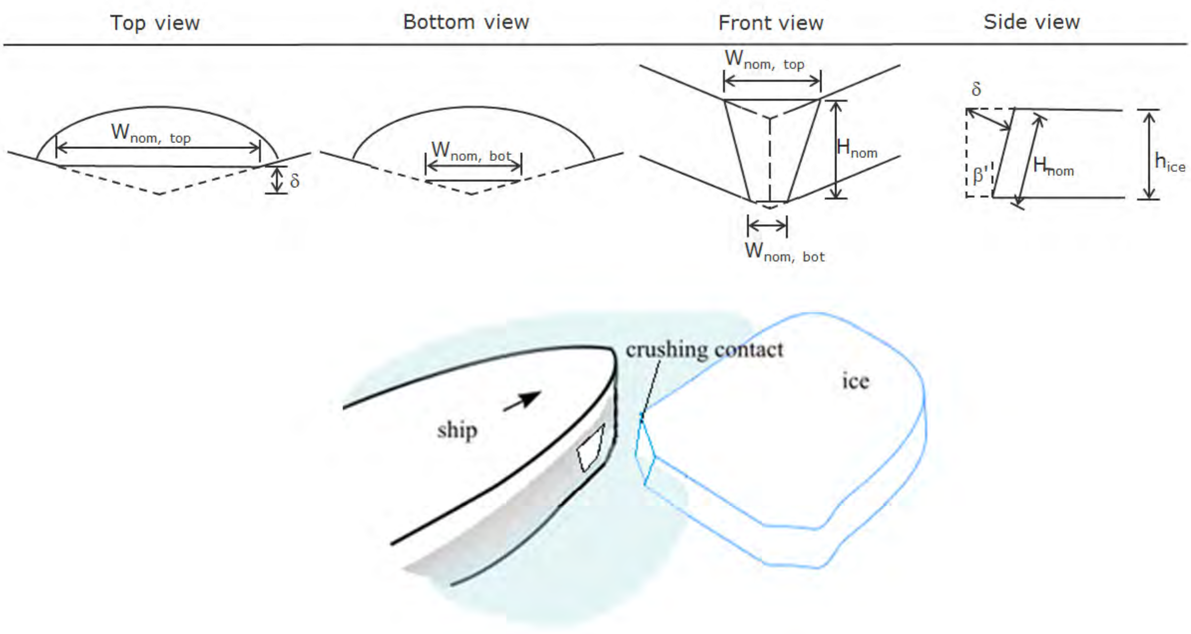

Figure 3 Glancing impact collision where the vertical projection of the contact area equals the ice thickness

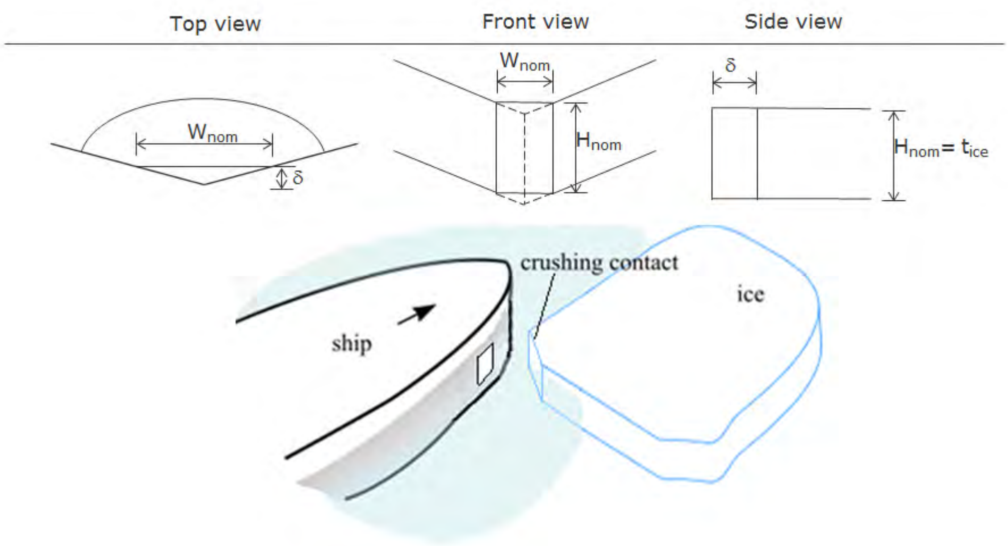

Figure 4 Glancing impact collision for a bow with vertical sides (β= 0^0)

For the case where the normal frame angle is 0^0 (vertical sides), the design force F, line load Q, and pressure P become:

$$F_n = f_a \cdot P_0^{0.526} \cdot V_{ship}{}^{0.947} \cdot h_{ice}{}^{0.474} \cdot \Delta_{ship}{}^{0.474}$$

$$Q = F_n^{0.222} \cdot P_o^{0.778} \cdot h_{ice}^{0.7}$$

$$P = F_n^{0.555} \cdot P_o^{0445} \cdot h_{ice}^{-0.6}$$

As for the existing load formulation, the terms P_0, V_{ship}, and h_{ice}, may be represented by class factors. Assuming that:

$$CF_{CV} = P_0^{0.526} \cdot V_{ship}{}^{0.947} \cdot h_{ice}{}^{0.474}$$

$$CF_{DV} = P_0^{0.778} \cdot h_{ice}{}^{0.7}$$

$$CF_{PV} = P_0^{0.445} \cdot h_{ice}{}^{-0.6}$$

the parameters read:

$$F_n = f_a \cdot CF_{CV} \cdot \Delta_{ship}{}^{0.474}$$

$$Q = F_n^{0.222} \cdot CF_{QV}$$

$$P = F_n^{0.555} \cdot CF_{PV}$$

The class factor $CF_{C,vert}$ may be given as follows for the different ice classes:

Ice class	CF_{CV}	CF_{QV}	CF_{PV}
PC 6	3.43	2.82	0.65
PC 7	2.60	2.33	0.65

The fa-factor is proposed to be:

$$f_a = \frac{\alpha}{30}$$

The alternative load formulation presented above is suggested to be used for bows with vertical-like sides, where the normal frame angle β' is between 0-10^0 at the centre of the foremost sub-region of the bow. In Table 1 to Table 4, a comparison between the new vertical bow formulation and the existing formulation (with frame angle β'= 10^0) is presented for a range of ship sizes and waterplane angles.

Table 1 Comparison of design force – existing formulation vs. proposed blunt/vertical bow formulation – PC7

	Design force - PC7							
	Δ= 10 kt		Δ= 25 kt		Δ= 50 kt		Δ= 100 kt

45	2.2	3.0	2.5	3.8	2.8	4.6	3.1	5.5

The comparison shows that the two formulations produce similar design forces and pressures (in average depending on ship size) for smaller to moderate waterplane angles. The consequences for the scantlings may be relatively stronger transverse frames due to increased height of the design load patch. The new formulation for blunt/vertical bows will however give higher forces and pressures for larger waterplane angles, which is considered reasonable. For larger waterplane angles, the simplified fa-coefficient is seen to be conservative compared with the “exact” solution, and is considered as an acceptable consequence of the proposed formulation.

When it comes to the loads on the bulb, it should first be mentioned that the bulb should be considered as an appendage, i.e. that their own structural requirements should not drive those of the overall bow structure. However, while the the blunt/vertical bow side formulation is based on a direct derivation of the glancing impact scenario, the development of a formulation for a similar relevant scenario for bulbs has proven to be difficult. For convenience, it has been proposed to use the existing and new proposed load formulation as reference. Although further revisions should continue to look into the possibility of deriving explicit formulations for all types of hull forms, including bulbs, the current proposal is considered sufficient at this stage.

Bow forms which are not covered by the above should be specially considered by each member society.

Performance/hull shape criteria for Polar Class ships

The introduction of performance hull shape criteria was not part of the original scope for this revision work. The powering requirements have been discussed in length during the development of the rules, and the exclusion of such criteria was based on a decision taken in 1997 during the 8th semi-annual harmonisation meeting of the IMO Outside Working Group which developed the Draft Code of Polar Navigation. Nevertheless, the debate has continued whether the IACS requirements should include performance requirements for reasons of safety. During the work with the load formulations and the icebreaker requirements, it was found that there is a need for a general performance requirement for all Polar Class vessels to ensure that the vessel can operate safely in the anticipated ice conditions as described by the ice class. The requirements are deliberately formulated somewhat generic, and the intention is to raise the flag and to ensure agreement between designer and owner with regard to the capabilities of the ship. Detailed guidance describing applicable procedures and detailed criteria should be developed separately. Please note that the term “representative ice conditions” does not necessary refer to the most severe ice condition as described by the ice class, but may be linked to a typical ice condition and operational mode which is representative for the intended voyage profile.

Please note that this requirement should not exclude vessels or unit types which are explicitly not designed to operate independently in ice (e.g. drill ship escorted by icebreakers, barges, etc), but such assumptions or limitations should be explicitly stated in the Class certificate or equivalent for transparency.

Task 2 – Develop criteria for icebreakers

Introduction

In the current IACS UR I it is explicitly stated that the requirements are not applicable for *Icebreakers*. By introducing *Icebreakers* in the new revision of the Rules, there is a need for providing clear directions on how ships that are to receive the additional *Icebreaker* notation should be handled. The intention with this work is to clarify the applicability of the *Icebreaker* notation (I1), include relevant structural requirements in I2, and coordinate relevant requirements in I3.

Background for rule proposal

Although not covering *Icebreakers*, the rules state that vessels which are assigned an *Icebreaker* notation may have additional requirements and are to receive special consideration. In the rules, an *Icebreaker* is referred to as a "ship having an operational profile that includes escort or ice management functions, having powering and dimensions that allow it to undertake aggressive operations in ice-covered waters, and having a class certificate endorsed with this notation."

Before discussing the detailed requirements which should be associated with the specific notation, it might be worth discussing the applicability of the notation, and the features which typically differentiate these vessels from other vessels without the additional notation. Noting the definition of *Icebreakers* above, there are clearly expectations and assumptions associated with the notation which are related to type of operations and performance including manoeuvrability and powering.

Higher polar class ships are expected to spend more of their lives in ice-infested waters, and consequently experience more and higher ice impact loads. The actual distributions of loads will therefore have a probabilistic character, which implicitly are reflected in the choice of ice class. An *icebreaker* will similarly, due to the operational profile, expect to experience more frequent and severe ice impacts relative to a commercial vessel of same parent ice class, and this may be reflected in the determination of design loads.

From a structural strength and performance point of view, the following aspects may be considered as (potential) differentiators compared to a general icebreaking vessel covered by the current Rules:

- Sufficient performance to undertake more aggressive operations in design ice conditions
    - Hull form and maneuverability
    - Propulsion power
- Sufficient strength to withstand additional loads due to more aggressive operations in design ice conditions:
    - Higher frequency of impacts during lifetime - increased probability of extreme loads
    - More available power/higher impact speeds – potentially increased extreme loads
    - Increased local loading on other parts of hull and appendages, e.g. outside defined icebelt, shoulders, bottom and stern, as well as rudders, due to increased maneuverability and aggressive operation
    - Higher global loads and accelerations due to more aggressive ramming operations

To address the expectations associated with the rule definition of an *Icebreaker*, it is reasonable to introduce additional requirements to the hull form and the propulsion power. However, in the current proposal, the general performance requirement proposed in I1 (and discussed above) is considered to sufficiently cover *Icebreakers* as well. Relevant ice conditions and acceptance criteria applicable for the type of operation should however be considered.

For the design loads which are used for dimensioning of the bow structure, one may argue that the general loading should be increased due to a more aggressive operational profile. The same applies to the horizontal and vertical extensions of the defined hull areas. However, in the current proposal, the dimensioning level in the bow is retained, but some general minimum level of strengthening in the non-bow areas have been proposed as well as increased strengthening of the stern.

During the development of the original rule proposal, a separate longitudinal strength criterion for *Icebreakers* was included. Since Icebreakers were excluded from the original rule proposal, this specific requirement was removed. In the current rule proposal, it is suggested to re-introduce this requirement.

Applicability of Icebreaker notation

The additional *Icebreaker* notation is considered applicable for all Polar Class notations.

Hull area factors and regions

As mentioned above, it might be reasonable to keep the existing design loads for dimensioning of the bow structure, based on among others the assumption that the calibration of the design loads to a large extent has been made based on experience with icebreakers. However, increased manoeuvrability, power, and more aggressive operation might increase the loading on the other parts of the vessel, particularly for the lower ice class vessels. In general, the area factor for the stern ice belt and the stern lower has been increased by approximately 25%, and all non-bow area factors should not less than the area factor determined for PC3.

The proposal is a simple percentage-increase compared to the standard area factors and is based on a review of existing ice class rules (e.g. DNV Rules for vessels intended for Arctic and icebreaking service, ABS ice class rules, etc). In the DNV Rules, the design loads in the stern icebelt is for icebreakers 80% of the bow load (same as proposed for PC3-PC7 Icebreaker), an increase of 33% compared with a ship without icebreaker notation. Similar relations may be found for the other hull areas.

The proposal was originally introduced in the DNV Rules for Polar Class ships in 2008. The intention with the requirement is to keep a minimum level of strengthening in the non-bow areas, particularly for the lower ice classes.

For Icebreakers it is suggested that the fore boundary of the stern region should at least be 0.04 L fore of WL angle = 0 degrees at UIWL, i.e. stern shoulder to be included in stern region. This is in accordance with common requirements given for icebreakers in existing ice class rules.

Loading on rudders, nozzles, azimuthing propulsion units etc

For appendages, it is stated that the design loads should be representative for the location of their attachment to the hull structure or their position within a hull area. Hence, it is reasonable to link this to the hull area factor (AF). Assuming that the hull area factor is increased for *Icebreakers*, the design loads for the appendages should be increased accordingly. However, as there are no explicit requirements for the appendages in the rules, the rule text has not been changed.

Requirements to longitudinal strength

It is suggested to re-introduce the original utilization factor to determine allowable stresses for icebreakers. A utilization factor of n=0.6 was originally introduced for icebreakers (n=0.8 for other ship types) to take into account more aggressive operations assumed to be associated with icebreakers. The requirement was later removed, as it was agreed that the Rules should not cover icebreakers.

Requirements related to machinery section I3

In the current draft revision proposal for I3, additional requirements associated with the *Icebreaker* notation are to be determined by each member society.

The only reference to *Icebreaker* is a requirement to a fast torque relief arrangement are to be fitted in order to provide effective protection of the rudder actuator in case of the rudder being pushed hard over against the stops.

Task 5 – Procedures for web frames and stringers

Introduction

The current requirements for web frames and stringers given in IACS URI2 provide little guidance for design. There is hence a need for consistency in the treatment of conventional web frames and stringers, as well as general grillage systems, in order to avoid different interpretations and design criteria among the IACS member societies.

Background for rule proposal

The Polar Class requirements are generally derived using plastic design philosophy. This is based on the consideration that some minor deformations (e.g. local denting) could be an acceptable consequence of ice operation, provided that this does not compromise the overall strength or watertight integrity of the ship.

The design criteria for plastic design are normally evaluated against loss of stiffness (stiffness change), permanent deformations or plastic strains. As opposed to elastic design, where the limit state could be a stress criterion related to first yield, plastic design has in general many possible limit states ranging from yield to final rupture.

For the plating and local frame requirements, the limit states defined in the PC rules are based on a plastic collapse mechanism. As the collapse model ignores the effect of membrane stresses, strain hardening and in principle the possible redistribution of loads to adjacent members, the structure has substantial reserve resistance beyond the design condition. This is particularly true for the local plating members, which can carry significantly higher loads while undergoing deformations several times the plate thickness before rupture. For individual ice frames, the reserve resistance is however less significant, and there are uncertainties both with regard to (the combinations of) failure modes as well as the ability to mobilize the assumed plastic resistance of the cross section and any membrane action in the member. For higher level components like web frames and stringers, the ability to mobilize additional reserve resistance may be even less apparent. Stability of web plates and flanges will have to be checked separately.

Limit states used as basis for design should reflect the potential consequences of structural failure. Assuming that the ice patch is limited in height and width, a rupture of a single plate member may not be considered very critical for the survivability of the vessel, while a structural failure of a primary member may ultimately compromise the vessel's structural integrity.

Hence, a higher utilization of the plating compared to primary members may be rationalised from a risk evaluation point of view. This type of hierarchy strength principle is also described in the background documents of the current rules, where a system of relaxed plate and stricter ice frame requirements is adopted.

In addition to the potential reserve resistance or consequences of structural failure discussed above, the selection of appropriate limit states should reflect the probability level of the design load applied on the different members. The design loads which have been derived for the Polar Classes may be considered as extreme loads, and may be considered conservative, both with regard to the derivation of the load scenario, as well as the ice class factors used as basis for the assessment. However, there are no explicit references to a formal probability level or return period for an actual trading vessel. The governing design load for all structural members, ranging from the local plating to the grillage system including bulkheads and decks, is based on a glancing impact scenario, where the impact force is represented by an average pressure over a patch area with defined height and length. For small areas, a peak pressure factor (PPF) is introduced to take into account the possible existence of higher pressure zones within the defined patch area. In addition, the PPF is used to increase the general pressure level for certain structural elements. However, both the PPF formulation and its application on the various members have been questioned, and compared to other rule formulations, the PC loads appear to be more conservative for individual members carrying larger fractions of the defined patch load. It too must be understood that the structural response in the Rules allows for limited plasticity and is thus a higher level than other Rules sets that use elastic response principles. Hence, the use of the relatively extreme Polar Class design loads may imply that an implicit (relative) safely factor could be embedded into the load formulation, at least for web frames and stringers with larger spans, depending upon the response criteria selected.

When the limit state is defined, the corresponding acceptance criteria must reflect the analysis method used and the response parameters considered in the assessment. For the assessment of individual primary members and grillage systems, several methods may be applicable:

- Analytical elastic or plastic methods
- Beam analysis
- Linear or non-linear finite element analysis

Analytical methods are generally simple in format and may be a preferred tool for simple strength checks of individual members, e.g. for establishing initial dimensions. The advantage is obviously that the necessary scantlings can be determined by well-defined formulas without the use of advanced computational tools. The drawback is however the difficulty in representing the actual response pattern, the possible complex geometry and support conditions, as well as the difficulties in properly taking into account the effect of the members being part of a grillage system, particularly in the plastic regime.

Evaluation of the structural response by use of finite element methods allows for a much more accurate representation of the actual (variations in) geometry, as well as the interaction between the different members considered. Finite element analysis requires however generally much more resources than analytical methods, and require also special competence which may not be easily accessible for all parties. Using non-linear finite element methods as basis for documenting structures to meet the reliability level of a specific code will require an in-depth understanding of the inherent safety requirements of the governing code as well, and there is definitely a need for a detailed guidance to ensure reliable and consistent results.

During the development of the original Rules, an analytical procedure for evaluating grillage systems was proposed based on the Russian rules. The formulas for web frames and stringers were based on a plastic approach and incorporated the presence of lower level strength members, taking into account their supporting and load distributing effects. Due to lack of agreement, the proposal was however excluded from the first official rules.

As part of the work related to the current rule revision, a basis for evaluating stringers and web frames both with analytical and direct calculations has been developed. Both the analytical formulations and the procedures for direct calculations were based on earlier work done by DNV-GL. During the development of the analytical formulations, it was however acknowledged that it is difficult to develop generic analytical formulations for grillage systems which can represent the actual response with sufficient degree of accuracy, taking into account the actual (variations in) geometry, boundary conditions, interactions between the different strength members. Based on the outcome from the verification of the formulations, as well as response from the first hull panel hearing phase, the accuracy of the proposed formulations were not found to meet the desired level of accuracy, and it was decided not to include the proposal formulation in the current revision proposal. In addition, concern was raised with respect to scantling outcomes for PC7 and PC6 ships in comparison to Baltic IA and IA Super scantlings, suggesting that further validation and development is needed. The derived formulations are however documented in Appendix A and may be used as reference in later revisions.

It is unfortunate that this revision work have not lead to the introduction of analytical formulations for web frames and stringers, and there is obviously a need for such formulations, particularly for determination of initial dimensions. However, as a result of the above, each member society should preferably come up with guidance for initial design.

However, for web frames and stringers being part of grillage systems, the new rule proposal assumes in any case the use of direct calculations. Direct calculations tend to become a natural and basic part of the strength documentation in ship design, and will now be expected for final documentation of grillage systems.

The rule proposal for direct calculation is intentionally left quite generic, and the specific procedure has to be developed by each member society. However, the assumptions and requirements to the execution of the analysis and evaluation of results should reflect the acceptance criteria and considerations below in order to ensure that the proposed design points are treated consistently. This includes modelling issues, mesh density, etc. as well as treatment of lower level members, connection area, stability requirements etc. In general the following criteria and considerations are included in the proposal:

Linear elastic stress analysis (beam or FE analysis):

- Web plates and flange elements in compression and shear to fulfil relevant buckling criteria
- Effective shear stress in member web plates to be less than σ_y/sqrt(3)
- von Mises stresses in member flanges to be less than 1.15 x σ_y. (assuming party fixed boundary conditions)

Non-linear stress analysis:

- The analysis shall reliably capture buckling and plastic deformation of the structure
- Detailed acceptance criteria to be decided by each member society. The acceptance criteria shall ensure a suitable margin against fracture and major buckling and yielding causing significant loss of stiffness.
- Permanent lateral and out-of plane deformation of considered member should be minor relative to the relevant structural dimensions.

The von Mises acceptance criteria for linear analysis have been discussed back and forth within the group, and it is acknowledged that throughout validation of different grillage configurations has not been carried out. Based on the discussion above, it was however from the beginning the clear opinion of the group that the acceptance criteria should incorporate a moderate degree of plasticity in the members, which means that nominal elastic normal stresses may exceed yield.

The structural capacity of the grillage depends largely on the actual structural configuration and dimensions. From the validation work carried out as part of this revision, a series of relevant grillage configurations were considered. However, the typical governing failure modes for these structures are related to shear yield and buckling stability, which means that the bending failure mode becomes less relevant.

In Figure 5, examples of relative load-deflection curves for two typical continuous girders being part of a grillage system are shown. The girder denoted T-profile consists of a plate flange and a stiffener flange, while the I-profile represents a double hull member consisting of two (inner and outer shell) plate flanges. Both the load and deflections are normalized with regard to first yield in the member flange(s). From the analyses, it is evident that the members can carry significantly larger loads than the level initiating first yield in the member without experiencing large permanent deformations, and based on an overall evaluation, a factor of 1.15 is proposed and found to be reasonable taking into account the combined ability to develop plastic moment and redistribution of stresses, in combination with a moderate fixation against rotations at the member supports. The alignment of acceptance criteria for different analysis methods should preferably be part of a detailed procedure which should be developed for direct calculations.

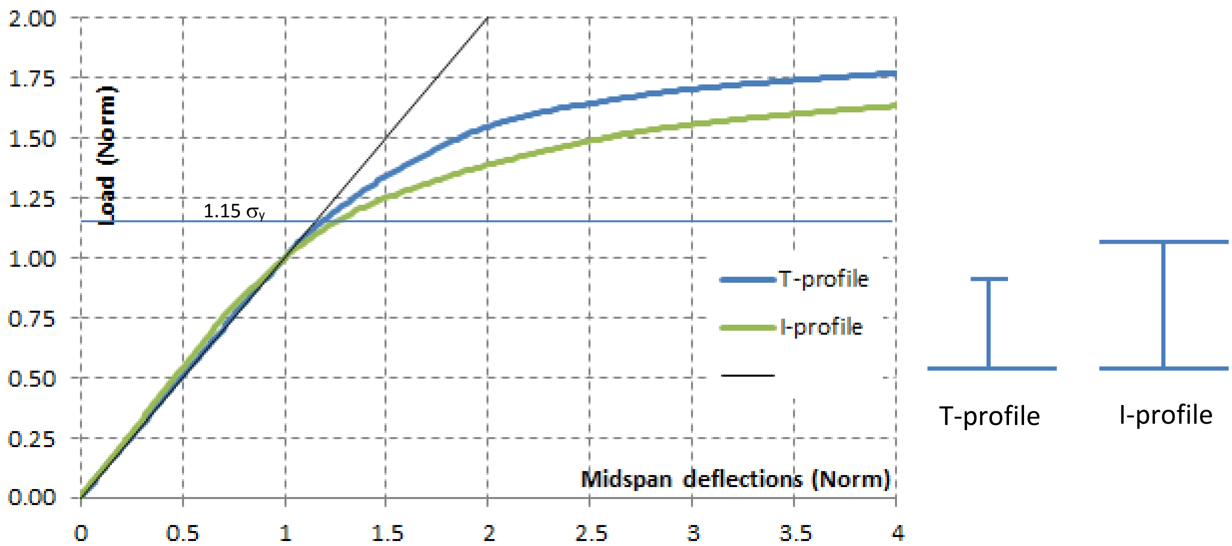

Figure 5 Typical load deflection curves for typical girder members being part of a grillage system

Editorial amendments of rule text

General editorial amendments have been proposed and the rule text has been updated accordingly. The rationale for the amendments is mainly to ease readability and to avoid misunderstandings.

Some items are found to be inconsistent or superfluous, and have consequently been removed from the proposal. This applies among others to Paragraph I2.12.5, including the table for steel grades for inboard members attached to weather exposed plating, which is found to be inconsistent with the material classes described in I2.12.2.

From the hull panel hearing process, it was observed that there was some confusion regarding the existing framing requirements for bottom structures. Hence, the text is updated to clarify the intention of the rules. When calculating the minimum shear and section modulus requirements for the bottom structure, the requirements in I2.6 should be applied irrespective of the actual framing direction. In the bottom is it considered reasonable to assume that the ice patch orientation relative to the frame direction is random, and hence it is not relevant to distinguish between the transverse and longitudinal frame configurations. In lack of a specific scenario-based formulation for the bottom structure, an ice load patch applied in a direction normal to the frame direction is considered reasonable.

The patch load application on transversely and longitudinally framed bottom structures are given in Figure 6 and Figure 7, respectively. Please note that the same philosophy applies for the plate thickness requirements

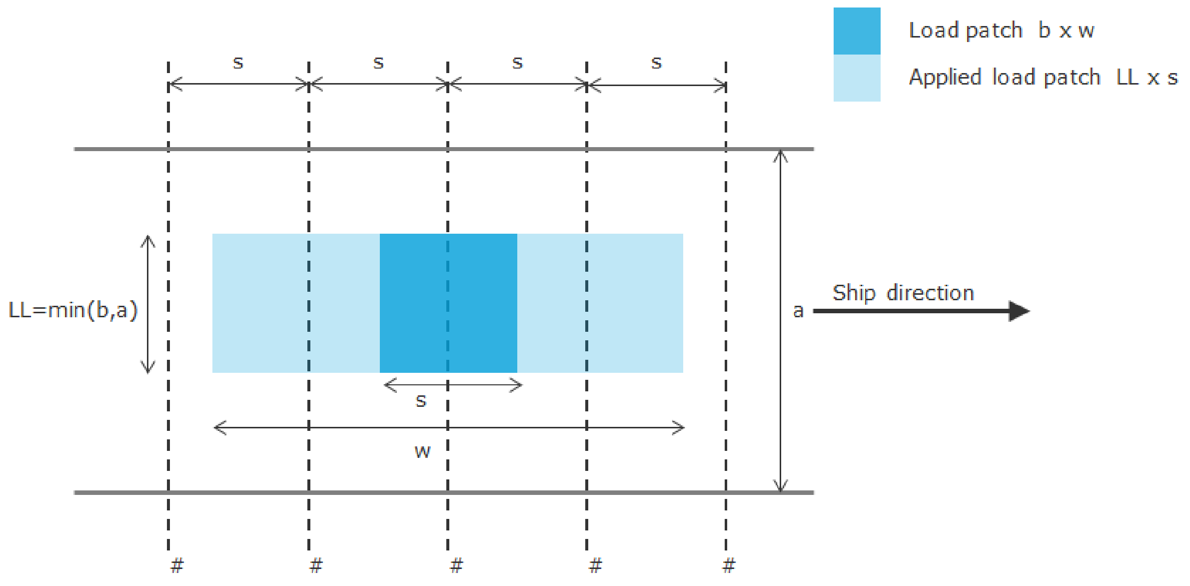

Figure 6 Application of ice load patch on transversely framed bottom structure according to paragraph I2.6

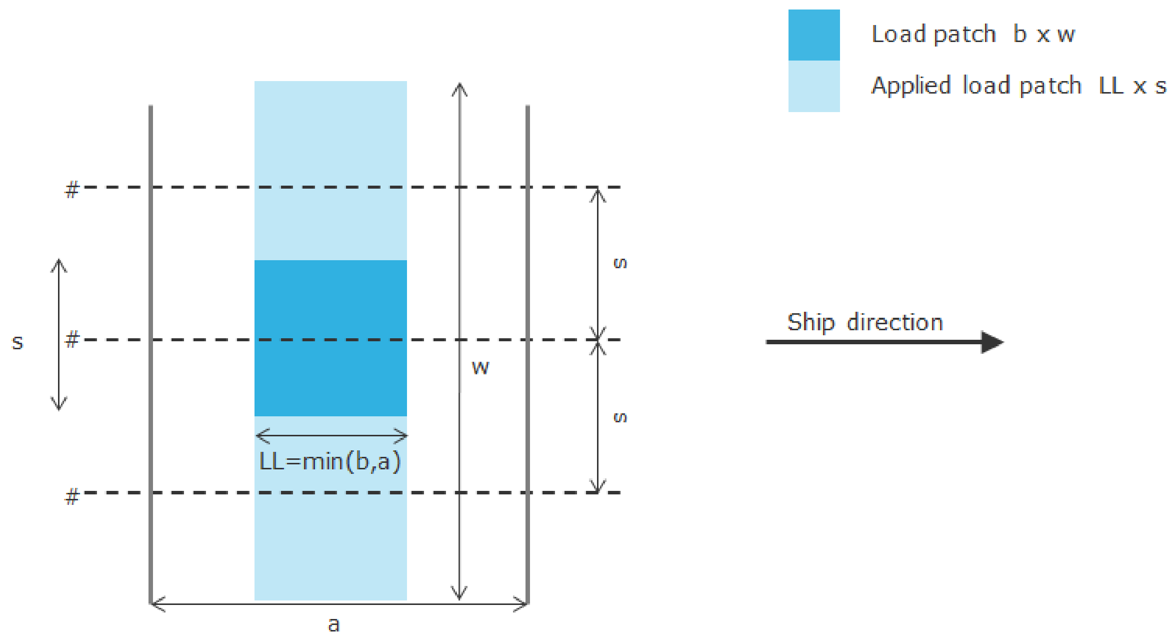

Figure 7 Application of ice load patch on longitudinally framed bottom structure according to paragraph I2.6

Other amendments include:

- The PPF for bottom framing should not be independent of patch area or structural dimensions. Consequently the peak pressure factor has been set to 1.0.
- The equation numbers have been removed as it is found that only a few are referred to in the text. Reference to paragraph numbers has been included as relevant.

Appendix A

Analytical formulations for web frames and stringers

Shear area requirements for simple web frames supporting longitudinal local frames

The general design load case for evaluating the shear strength of a simple web frame supporting longitudinal local frames is suggested to be as shown in Figure 1.

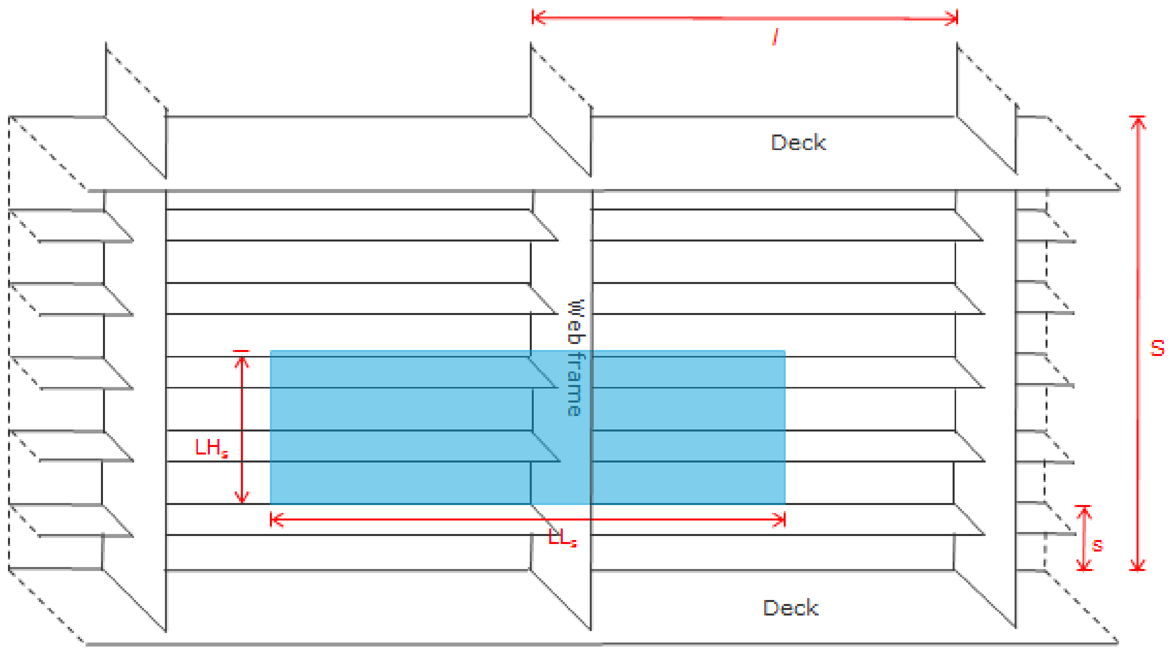

Figure 1 – Proposed design condition for the shear area requirement for simple web frames supporting longitudinal local frames

The effective shear area requirement for this condition is suggested to be as follows:

$$A_{wf} = \frac{100^2 \left(AF\ PPF_s\ P_{avg}\right) LH_s\ LL_s\ K_s}{0.577\ \sigma_F\ \eta \sin\varphi_w}$$

A_{wf} = Effective net web area of web frame supporting longitudinal local frames [cm^2]

AF = Hull Area factor from Table 3

PPF_s = Peak Pressure Factor from Table 2

P_{avg} = Average pressure within load patch according to Equation 15 [MPa]

LH_s = effective load height with respect to shear response of web frame [m]

$= min\left(b, (S - s)\right)$

b = Height of design ice load patch from Equation 12 or 14 [m]

S = Design span of considered web frame with regard to shear response [m]

s = Spacing of longitudinal frames [m]

LL_s = effective load length with respect to shear response of web frame [m]

$= w\frac{\left(l-\frac{w}{4}\right)}{l}$

w = Width of design load patch from Equation 11 or 13 [m], but is not to be taken larger than 2 *l*

l = Spacing of web frames [m], measured along the shell plate

K_s = shear force factor [-]

$= \frac{S-h}{S}$, minimum 0.55

h $= \frac{LH_s+s}{2}$ [m], if one of the web frame supports lies within considered hull area

$= \frac{LH_s}{2} + h_1$ [m], if both of the web frame supports lies outside considered hull area

h_1 = Smallest distance from web frame support to hull area boundary

η = usage factor = 1.0

φ_w = smallest angle between shell plate and the web of the web frame, measured at middle of span [deg]. The angle φ_w may be taken as 90 degrees provided the smallest angle is not less than 75 degrees.

In the proposal presented above, it is assumed that a portion of the design patch, as defined in the Rules by the height b and length w, is transferred directly to the structure supporting the web frame (e.g. a deck) and/or carried by the longitudinal local frames to the adjacent web frames. The magnitude of the force transferred to adjacent structure depends on the size of the patch load relative to the distance to the adjacent members. The effective patch area of the load carried by the considered web frame is defined by the height LH_s and length LL_s.

The effective patch load height LH_s is generally taken as the general height b, as defined in the Rules, but limited by the span of the web frame.

The load length LLs is based on the assumption that part of the loading is carried by the longitudinals directly to the adjacent web frames. If the patch length w is equal to the web frame spacing S, it is assumed that 75% is taken by the considered frame, and the remaining 25% is taken by the adjacent frames. If the patch length w is more than twice the web frame spacing S, the effective patch length is limited by the web frame spacing.

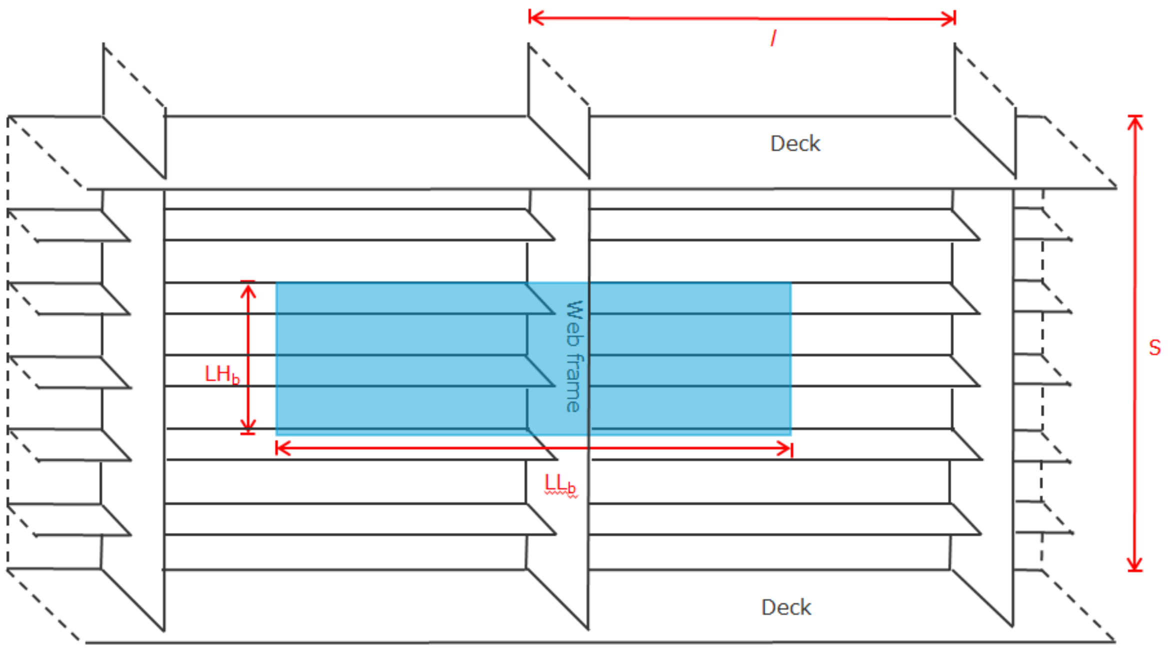
For the shear factor Ks, it is assumed that the edge of the patch load is placed a distance equal to the frame spacing from one of the supports. The shear factor represents the portion of the load taken as shear in the most loaded support assuming that both supports have the same boundary conditions. A correction is included to cover the case where the web frame spans over the whole considered hull area, i.e. it is assumed that the patch load is placed at the boundary of the hull area.

The formula assumes shear yield over the whole effective height of the web plate.

It is suggested that the general usage factor is taken as 1.0.

Section modulus requirements for simple web frames supporting longitudinal local frames

The general design load case for evaluating the bending strength of a simple web frame supporting longitudinal local frames is suggested to be as shown in Figure 2.



,

Figure 2 – Proposed design condition for the section modulus requirement for simple web frames supporting longitudinal local frames

The net elastic section modulus of the web frame is suggested to be as follows:

$$Z_{wf} = \frac{100^3 (AF\ PPF_s\ P_{avg})\ LH_b\ LL_b\ \left(S - \frac{LH_b}{2}\right)}{4\ \sigma_F\ \sin\varphi_w\ k_f}$$

A_{wf} = Net elastic section modulus of web frame supporting longitudinal local frames [cm^3]

LH_b = effective load height with respect to bending response of web frame [m]

$= min(b, S)$

LL_b = effective load length with respect to bending response of web frame [m]

$= w \frac{\left(l - \frac{w}{4}\right)}{l}$

k_f = end fixity parameter for the web frame [-]

= 2.0 when both end supports are fixed

= 1.5 when one end support is fixed

= 1.0 when both end supports are simply supported

The section modulus requirement is derived based on a semi-plastic approach, where the plastic moment obtained from a simple plastic 3-hinge mechanism (in case of restrained ends) is used as basis for determining the capacity of the member. The capacity is however evaluated against the elastic section modulus of the profile. Using the plastic bending moment as basis for the capacity assessment will for the clamped end case increase the defined capacity by 33% compared with a pure elastic approach based on first yield.

Shear area requirement for simple web frames supporting load carrying stringers

The general design load case for evaluating the shear strength of a simple web frame supporting load carrying stringers is suggested to be as shown in Figure 3.

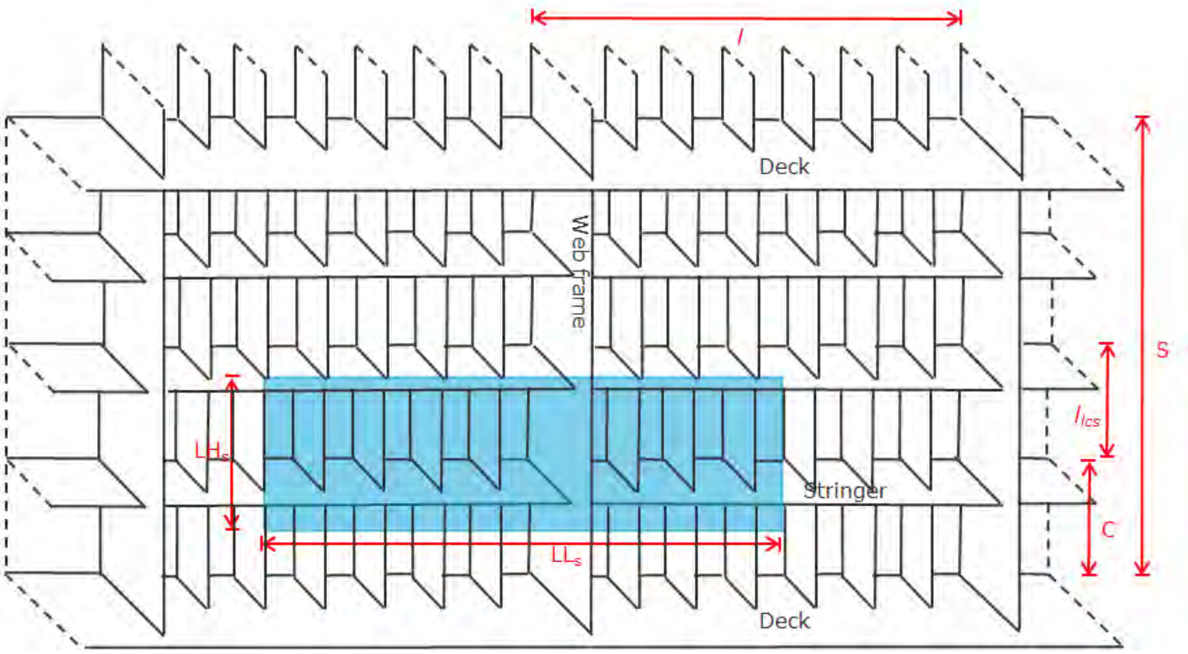


Figure 3 – Proposed design condition for the shear area requirement for simple web frames supporting load carrying stringers

The effective shear area requirement for this condition is suggested to be as follows:

$$A_{wf} = \frac{100^2 \left(AF\ PPF_s\ P_{avg}\right)\ LL_s\ LH_s\ K_s}{0.577\ \sigma_F\ \ \eta\ \sin\varphi_w}$$

A_{wf} = Effective net web area of web frame supporting load carrying stringers [cm^2]

LH_s = load height with respect to shear response of web frame [m]

$$= b\left(\frac{l - \frac{b}{4}}{l}\right)$$

LL_s = load length with respect to shear response of web frame [m]

$$= w\,\frac{\left(l_{LCS} - \frac{w}{4}\right)}{l_{LCS}}$$

l = Spacing of web frames [m], measured along the shell plate

l_{LCS} = Distance to adjacent load carrying stringer or longitudinal support member, as applicable, [m], measured along the shell plate

K_s = shear force factor [-]

$$= \frac{S - C}{S}$$

η = usage factor

φ_w = smallest angle between shell plate and the web of the web frame

In the proposal presented above, it is assumed that the design patch is located at a stringer level, and is acting as a point load on the web frame. As for the requirement for web frames supporting longitudinal local frames, a portion of the design load is assumed carried by the adjacent members, and hence the design patch on the web frame is defined by the effective height LH_s and length LL_s.

Similarly is the shear factor Ks taking into account the position of the considered load carrying stringer relative to the web frame supports.

Depending on the framing arrangement, several load carrying stringers along the web frame span should be considered.

It is suggested that the general usage factor is taken as 1.0

Section modulus requirement for simple web frames supporting load carrying stringers

The general design load case for evaluating the bending strength of a simple web frame supporting load carrying stringers is considered to be the same as for the shear strength requirement, see Figure 3.

The net elastic section modulus of the web frame is suggested to be as follows:

$$Z_{wf} = \frac{100^3\left(AF\ PPF_s\ P_{avg}\right) LL_s\ LH_s\ C\ (S - C)}{2\ \sigma_F\ \sin\varphi_w\ k_f\ S}$$

LH_b = load height with respect to bending response of web frame [m]

$$= b\left(\frac{l-\frac{b}{4}}{l}\right)$$

LL_b = load length with respect to bending response of web frame [m]

$$= w\frac{\left(l_{LCS}-\frac{w}{4}\right)}{l_{LCS}}$$

C = Smallest distance from considered load carrying stringer to web frame support [m]

kf = end fixity parameter for the web frame [-]

= 2.0 when both end supports are fixed

= 1.5 when one end support is fixed

= 1.0 when both end supports are simply supported

As for the shear area requirement, the section modulus requirement assumes that the patch load is represented as a point load at the stringer location. The same effective patch load is considered as well. The formulation is based on the plastic capacity of the member, but evaluated against the elastic section modulus.

Shear area requirement for load carrying stringers

The general design load case for evaluating the shear strength of a simple load carrying stringer is suggested to be as shown in Figure 4.

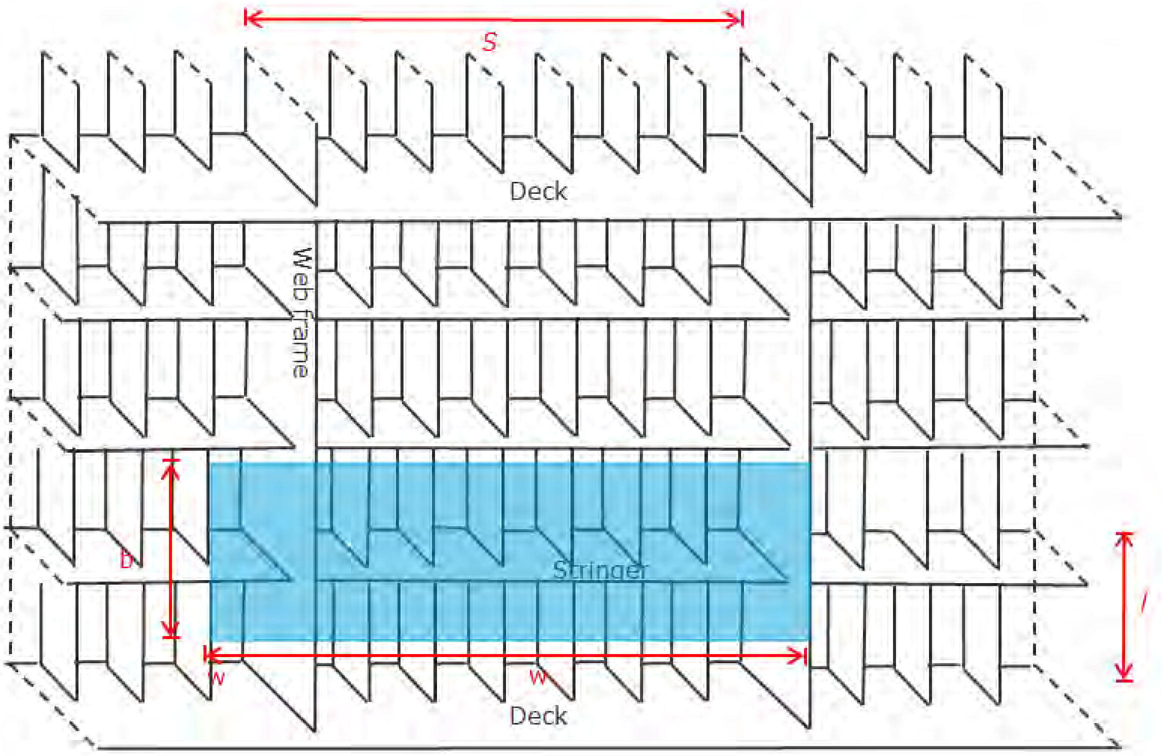

Figure 4 – Proposed design condition for the shear area requirement for load carrying stringers

The effective shear area requirement for this condition is suggested to be as follows:

$$A_{lcs} = \frac{100^2 \left(AF\ PPF_s\ P_{avg}\right) LH_s\ LL_s\ K_s}{0.577\ \sigma_F\ \eta\ \sin\varphi_w}$$

LH_s = effective load height with respect to shear response of stringer [m]

$= b\frac{\left(l-\frac{b}{4}\right)}{l}$

LL_s = effective load length with respect to shear response of stringer [m]

$= min\left(w, (S-s)\right)$

K_s = shear force factor [-]

= 0.5 if w ≥ S

$= \frac{S-\frac{LL_s+s}{2}}{S}$

η = usage factor = 1.0

φ_w = smallest angle between shell plate and the web of the web frame

Section modulus requirement for simple load carrying stringers

The general design load case for evaluating the bending strength of a load carrying stringer is considered to be the same as for the shear strength requirement, see Figure 4.

The net elastic section modulus of the load carrying stringer is suggested to be as follows:

$$Z_{lcs} = \frac{100^3 (AF\ PPF_s\ P_{avg})\ LH_b\ LL_b\ \left(S - \frac{w}{2}\right)}{4\ \sigma_F\ \ \sin\varphi_w\ \ k_f}$$

LH_b = effective load height with respect to bending response of stringer [m]

$$= b\,\frac{\left(l - \frac{b}{4}\right)}{l}$$

LL_b = effective load length with respect to bending response of web frame [m]

$$= min(w, S)$$

k_f = end fixity parameter for load carrying stringer

= 2.0 when both end supports are fixed

= 1.5 when one end support is fixed

= 1.0 when both en d supports are simply supported

φ_w = smallest angle between shell plate and the web of the web frame

Appendix B

Derivation of the oblique collision force with a vertical bows

The force is found by equating the normal kinetic energy with the ice crushing energy,

$$KE_n = E_{crush} \quad \text{(a1)}$$

The crushing energy is found by integrating the normal force over the penetration depth

$$E_{crush} = \int_0^{\delta} F_n\,(\delta)d\delta \quad \text{(a2)}$$

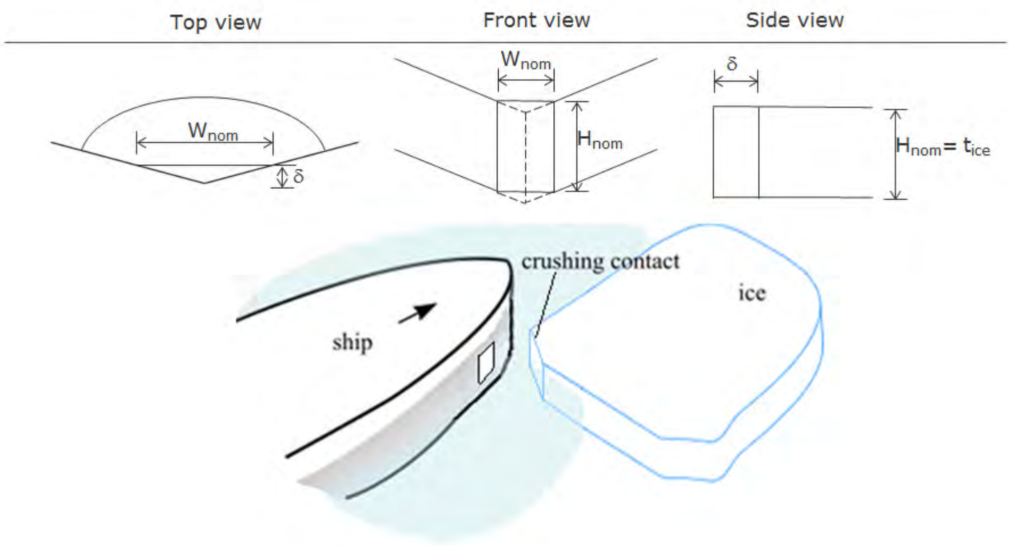
The normal kinetic energy combines the normal velocity with the effective mass at the collision point

$$KE_n = \frac{1}{2} M_e \cdot V_n^2 \quad \text{(a3)}$$

Combining the two terms gives

$$\frac{1}{2} M_e \cdot V_n^2 = \int_0^{\delta_m} F_n\,(\delta)d\delta \quad \text{(a4)}$$

The ice penetration geometry together with the pressure-area relationship is the basis of finding the force. The nominal area is found for a penetration δ



The nominal contact area is

$$A = W_{nom} \cdot H_{nom} \quad \text{(a5)}$$

The width of the W_{nom} of the nominal contact area can be determined by the nominal penetration depth δ and the ice edge angle ϕ.

$$tan\frac{\varphi}{2} = \frac{W_{nom}}{2\delta}$$

$$W_{nom} = 2\delta \cdot tan\frac{\varphi}{2} \quad \text{(a6)}$$

The height H_{nom} of the nominal contact area is fixed by the design ice thickness for each polar class

$$H_{nom} = h_{ice} \quad \text{(a7)}$$

Hence the area is

$$A = W_{nom} \cdot H_{nom} = 2h_{ice}\delta \cdot tan\frac{\varphi}{2} \quad \text{(a8)}$$

The average pressure is found from the pressure area relationship

$$P = P_0 \cdot A^{ex} \quad \text{(a9)}$$

The nominal force is

$$F_n(\delta) = P \cdot A = P_0 \cdot A^{1+ex} \quad \text{(a10)}$$

Substituting the expression for area (4) gives

$$F_n(\delta) = P_0\left(2h_{ice}\delta \cdot tan\left(\frac{\varphi}{2}\right)\right)^{1+ex} \quad \text{(a11)}$$

$$F_n(\delta) = C \cdot P_0 \cdot \delta^{1+ex} \cdot h^{1+ex} \quad \text{(a12)}$$

where we collect known quantities into the factor C

$$C = \left(2 \cdot tan\left(\frac{\varphi}{2}\right)\right)^{1+ex} \quad \text{(a13)}$$

We can now solve the energy balance equation ((a12) into (a4)) to find the maximum penetration

$$\frac{1}{2}M_e \cdot V_n^2 = C \cdot P_0 \cdot h^{1+ex} \cdot \int_0^{\delta_m} \delta^{1+ex}\, d\delta \quad \text{(a14)}$$

Accordingly we can extract the maximum penetration

$$\frac{1}{2}M_e \cdot V_n^2 = C \cdot P_0 \cdot h^{1+ex} \cdot \Big|_0^{\delta_m} \frac{\delta^{2+ex}}{2+ex}$$

$$\frac{1}{2}M_e \cdot V_n^2 = C \cdot P_0 \cdot h^{1+ex} \cdot \frac{\delta_m^{2+ex}}{2+ex}$$

$$\delta_m = \left(\frac{(2+ex)\cdot\frac{1}{2}M_e\cdot V_n^2}{C\cdot P_0\cdot h^{1+ex}}\right)^{\frac{1}{2+ex}} \quad \text{(a15)}$$

This is substituted into the expression for force (a12), to give

$$F_n = C \cdot P_0 \cdot h^{1+ex} \cdot \left(\frac{(2+ex)\cdot\frac{1}{2}M_e \cdot V_n^2}{C \cdot P_0 \cdot h^{1+ex}} \right)^{\frac{1+ex}{2+ex}} \quad \text{(a16)}$$

This can be substituted to give

$$F_n = C^{\frac{1}{2+ex}} \cdot P_0^{\frac{1}{2+ex}} \cdot \left((2+ex) \cdot \frac{1}{2} M_e \cdot V_n^2 \cdot h_{ice} \right)^{\frac{1+ex}{2+ex}} \quad \text{(a17)}$$

Substituting for M_e and V_n, we get

$$F_n = C^{\frac{1}{2+ex}} \cdot P_0^{\frac{1}{2+ex}} \cdot \left(\frac{l^2}{2C_0} \right)^{\frac{1+ex}{2+ex}} \cdot \left((2+ex) \cdot M_{ship} \cdot V_{ship}^2 \cdot h_{ice} \right)^{\frac{1+ex}{2+ex}} \quad \text{(a18)}$$

We can collect all shape related terms (comprising C and the terms with C_0 and *l*) into a simple terms fa,

$$f_a = (2+ex)^{\frac{1+ex}{2+ex}} \cdot \left(2 \tan \frac{\varphi}{2} \right)^{\frac{1+ex}{2+ex}} \cdot \left(\frac{l^2}{2C_0} \right)^{\frac{1+ex}{2+ex}} \quad \text{(a19)}$$

With fa, we can write the force equation as

$$F_n = f_a \cdot P_0^{\frac{1}{2+ex}} \cdot V_{ship}{}^{\frac{2+2\cdot ex}{2+ex}} \cdot M_{ship}{}^{\frac{1+ex}{2+ex}} \cdot h_{ice}{}^{\frac{1+ex}{2+ex}} \quad \text{(a20)}$$

Which for ex=-0.1 gives

$$F_n = f_a \cdot P_0^{0.526} \cdot V_{ship}{}^{0.947} \cdot M_{ship}{}^{0.474} \cdot h_{ice}{}^{0.474} \quad \text{(a21)}$$

This value of fa collects all form related terms (and constants) into a single fator for crushing. Equation (a21) represents only the crushing force. However the flexural design force need not be included in the design force of a blunt bow.

The ice load patch is found from Fn. Using (a20) and (a10), we can solve for the nominal contact area,

$$A = \left(\frac{F_n}{P_o} \right)^{\frac{1}{1+ex}} \quad \text{(a22)}$$

Unlike the case for an icebreaking bow form, there is no need to introduce a change in load patch shape (it is already rectangular). Accordingly, the aspect ratio is

$$AR = \frac{W_{nom}}{H_{nom}} = \frac{W_{nom}}{h_{ice}} \quad \text{(a23)}$$

$$A = h_{ice}^2 \cdot AR \quad \text{(a24)}$$

Therefore, we can write

$$H_{nom} = h_{ice} \quad \text{(a25)}$$

And from (a8) and (a22)

$$W_{nom} = \frac{\left(\frac{F_n}{P_o}\right)^{\frac{1}{1+ex}}}{h_{ice}} \quad \text{(a26)}$$

At this point we introduce a reduction in the size of the load patch (force is unchanged, so design pressure rises, correspondingly). This reduction is conservative and is done to account for the typical concentration of force that takes place as ice edges spall off. The rule (or design) patch length is

$$w = W_{nom}^{wex} = \left(\frac{F_n}{P_o}\right)^{\frac{wex}{1+ex}} \cdot h_{ice}^{-wex} \quad \text{(a27)}$$

Where with wex = 0.7, we have

$$w = F_n^{0.778} \cdot P_o^{-0.778} \cdot h_{ice}^{-0.7} \quad \text{(a28)}$$

The design load height is

$$b = \frac{w}{AR} \quad \text{(a29)}$$

Using (a23) and (a26)

$$b = F_n^{-0.333} \cdot P_o^{0.333} \cdot h_{ice}^{1.3} \quad \text{(a30)}$$

The nominal and design load patches have the same aspect ratio. The load quantities used in the scantling calculations include the line load,

$$Q = \frac{F_n}{w} \quad \text{(a31)}$$

And the pressure

$$P = \frac{Q}{b} \quad \text{(a32)}$$

Solving for Q and P

$$Q = \frac{F_n}{w} = \frac{F_n}{F_n^{0.778} \cdot P_o^{-0.778} \cdot h_{ice}^{-0.7}} \quad \text{(a33)}$$

$$P = \frac{Q}{b} = \frac{F_n^{0.222} \cdot P_o^{0778} \cdot h_{ice}^{0.7}}{F_n^{-0.333} \cdot P_o^{0.333} \cdot h_{ice}^{1.3}} \quad \text{(a34)}$$

For the rule formula

$$Q = F_n^{0.222} \cdot P_o^{0.778} \cdot h_{ice}^{0.7} \quad \text{(a35)}$$

$$P = F_n^{0.555} \cdot P_o^{0.445} \cdot h_{ice}^{-0.6} \quad \text{(a36)}$$

The design force given in (a21) may be expressed as follows in terms of class-dependent ship and ice class factors

$$F_n = f_a \cdot CF_{CV} \cdot \Delta_{ship}{}^{0.474}$$

Where

$$CF_{CV} = P_0^{0.526} \cdot V_{ship}{}^{0.947} \cdot h_{ice}{}^{0.474}$$

The class factor CF_{CV} may be given as follows for the different ice classes:

Ice class	CF_{CV}
PC6	3.43
PC7	2.60

Shape factor

From (a19) the shape factor can be written as

$$f_a = \left(1.90 \cdot \frac{l^2}{C_0} \cdot \tan\frac{\varphi}{2}\right)^{0.474}$$

Due to the complexity of Co, the following simplified equation is suggested

$$f_a = \frac{\alpha}{30}$$

UR I2 “Structural Requirements for Polar Class Ships”

Summary

This revision introduces the definitions for the ship length (L_{UI}), moulded breadth (B_{UI}) and the displacement (D_{UI}) measured at the upper ice waterline (UIWL). Additionally the table 8 has been updated in accordance with UR W11.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev.4 (Dec 2019)	17 December 2019	1 January 2021
Rev.3 (Apr 2016)	22 April 2016	1 July 2017
Rev.2 (Nov 2010)	07 November 2010	1 Jan 2012
Corr.1 (Oct 2007)	-	-
Rev.1 (Jan 2007)	-	-
New (August 2006)	-	1 March 2008

- **Rev.4 (Dec 2019)**

1 Origin of Change:

☑ Suggestion by IACS member

2 Main Reasons for Change:

2.1 - Ship length L
In Rev.3, the parameter L was defined in I2.3.2.1(e) and I2.13.4.1, as follows: *ship length as defined in UR S2.1, but measured on the upper ice waterline (UIWL)*.

In UR S2.1, the definition of ship length is the following one: *The length of L is the distance, in metres, on the summer load waterline from the fore side of the stem to the after side of the rudder post, or the centre of the rudder stock if there is no rudder post. L is not to be less than 96%, and need not be greater than 97%, of the extreme length on the summer load waterline. In ships with unusual stern and bow arrangement the length L will be specially considered*.

Therefore the length L to be used in I2 is as follows: *Distance, in metres, on the upper ice waterline (UIWL) from the fore side of the stem to the after side of the rudder post, or the centre of the rudder stock if there is no rudder post. L is not to be less than 96%, and need not be greater than 97%, of the extreme length on the upper ice waterline (UIWL). In ships with unusual stern and bow arrangement the length L will be specially considered*.

This correct definition is inserted in I2 and, as this parameter is different to the rule length "L" (as defined in UR S2.1), it is named "L_{UI}". In addition, the relevant references to "L" in I2 are updated to make reference to "L_{UI}".

2.2 - Design vertical ice force/moment
In Rev.3, the force F_{IB} defined in I2.13.2.1 is maximised by considering the ship displacement D at the upper ice waterline (UIWL), which is the maximum value of the displacement.
Therefore a definition of the displacement is added specifying that it is the displacement at the upper ice waterline (UIWL) and, as this parameter is different to the usual displacement "D", it is named "D_{UI}". In addition, the relevant references to "D" in I2 are updated to make reference to "D_{UI}".

In the same way, the force F_{IB} is maximised by considering the ship waterplane area A_{WP} at the upper ice waterline (UIWL). Therefore it is specified that the ship waterplane area to be used is the one corresponding to the upper ice waterline (UIWL).

In addition, the paragraph "*Where applicable, draught dependent quantities are to be determined at the waterline corresponding to the loading condition under consideration*" is deleted both in I2.13.2.1 and I2.13.4.1 because the said "draught dependant quantities" (i.e. displacement and waterplane area) are now determined at the upper ice waterline (UIWL).
And for transparency, it is specified in I2.13.4.1 that the still water bending moment to be used for strength calculations is the permissible still water bending moment and not the bending moment for a specific loading condition.

2.3 - Ship moulded breadth B
In Rev.3, the ship moulded breadth B is defined on Figure 7 in I2.13.2.1. As the ice waterline indicated on this figure is the upper ice waterline, B is the moulded breadth corresponding to the upper ice waterline.
As this parameter is different to the usual "B", it is named it "B_{UI}", and the definition specifies that it is to be measured at the upper ice waterline (UIWL). In addition, the relevant references to "B" in I2 are updated to make reference to "B_{UI}".

2.4 – Steel grades for weather exposed plating
In Rev.3, I2.12.4 Table 8, a symbol "F" is indicated as steel grade of mild steel for Material class III. However, steel grade "F" for mild steel is not appeared in UR W11. Therefore the symbol "F" in Table 8 is deleted and replaced by "not applicable", in line with Table 9 "Material Grade Requirements for Classes I, II and III at Low Temperatures" in UR S6.

3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

4 History of Decisions Made:

Member original proposal was submitted in December 2016. Hull Panel agrees with the proposals from the member in January 2017, with some additional comments. Following comments, a revised text was submitted in February 2017. The final Hull Panel approval has been given in October 2019.

5 Other Resolutions Changes

None

6 Any hindrance to MASS, including any other new technologies:

None

7 Dates:

Original Proposal: December 2016 Made by: Hull Panel
Panel Approval: 13 November 2019 (Ref: 19233_PHa)
GPG Approval: 17 December 2019 (Ref: 19233_IGc)

- **Rev.3 (Apr 2016)**

.1 Origin of Change:

☑ Suggestion by IACS member

.2 Main Reason for Change:

Following the approval of the 2010 revision of I2, the previous Hull Panel PT49 instructed to identify a smaller number of items which should be prioritized in the next revision phase. As basis for the new Hull Panel PT49, the following five priority items were selected:

- Design loads for non-icebreaking bow forms
- Criteria for icebreakers
- Compression design loads (not covered by this work)
- Rudder design loads (not covered by this work)
- Web frames and stringers

For details, see TB document in Part B.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

The Hull Panel PT49 submitted the first proposal to Hull Panel in March 2015. Following comments from the first hearing, a revised proposal was submitted in Sept.2015. A final proposal was submitted to Hull panel in January 2016.

.5 Other Resolutions Changes

None

.6 Dates:

Panel Approval: 15 March 2016 (Ref: 6023a)
GPG Approval: 22 April 2016 (Ref: 12187_IGh)

- **Rev.2 (Jan 2011)**

.1 Origin of Change:

☑ Request by Hull panel (PT49)

.2 Main Reason for Change:

To correct the known errors and ambiguities as well as to correct minor format issues in UR I2.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

The Hull Panel PT49 created the proposed modifications to correct the known errors and ambiguities as well as to correct minor format issues in UR I2. The Hull Panel approved these changes during the Hull Panel meeting in October 2010. GPG decided to treat the modifications as a revision rather than a correction and the effective date of implementation of the revised UR as 1 January 2012.

.5 Other Resolutions Changes

None

.6 Dates:

Original Proposal: 13 *October 2010 Made by Hull Panel*
Panel Approval: *October 2010*
GPG Approval: *07 November 2010 (Ref: 7592_IGd)*

- **Corr.1 (Oct 2007)**

No TB document available.

- **Rev.1 (Jan 2007)**

Council agreed to revise the application date of the UR for the purpose of uniform application by IACS Societies.

- **New (August 2006)**

See TB in Part B.

Part B. Technical Background

IACS AHG/PSR

IACS UR I2 – Structural Requirements for Polar Class Ships

- Technical Background -

1.0 Historical Development

An international effort has been made in the development of a uniquely integrated package of measures aimed at protecting life, property and the environment in polar waters. This so-called "harmonisation" process began when several nations recognised the benefits of aligning existing safety and pollution control standards for marine operations in polar waters, and of giving these more general applicability. Germany and Russia made proposals to IMO in the early 1990's, and these resulted in discussions amongst various interested governments who formed a working group to develop an appropriate approach. This Outside Working Group (OWG) reported its formation and aims to IMO in 1993, and was subsequently expanded to include members from industry, academic and research communities and representatives from classification societies. The efforts of the OWG culminated in the development of the IMO *Guidelines for Ships Operating in Arctic Ice-Covered Waters*, which was promulgated in December 2002 as a joint MSC/MEPC circular (MSC/Circ.1056, MEPC/Circ.399).

The structure and format of the IMO *Guidelines* are divided into construction, equipment, operational and environmental protection sections, although the *Guidelines* themselves include only a minimal set of direct technical requirements for construction. Instead, they outline performance standards and reference compliance with IACS Unified Requirements for Polar Ships as demonstrating adequate performance. Accordingly, in May of 1996, IACS GPG established a "non-permanent" Ad-Hoc Group to establish Unified Requirements for Polar Ships (AHG/PSR), with one working group for structural requirements and one for machinery requirements. Notably, the AHG/PSR also includes non-IACS working members who have expertise and knowledge to assist in the development of requirements for this specialised subject. The efforts of AHG/PSR have resulted in three sets of unified requirements for Polar Ships; UR I1 (Polar Class Descriptions and Application); UR I2 (Structural Requirements for Polar Class Ships); UR I3 (Machinery Requirements for Polar Class Ships).

2.0 Scope and Objectives

The scope of UR I2 includes ice load definition as well as specific strength requirements for plating, framing (including web frames and load-carrying stringers), plated structures (such as decks and bulkheads), and the hull girder. The scope of UR I2 also includes material requirements, as well as corrosion/abrasion allowances. General strength requirements for hull appendages, stem and stern frames, as well as some provisions for local details, direct calculations and welding, are also included. The objective of UR I2 is to provide a unified set of structural requirements to enable polar class ships to withstand the effects of global and local ice loads, as well as temperatures, characteristic of their polar class.

3.0 Points of Discussions or Possible Discussions

3.1 Application

The unified requirements for polar ships are to be applied to any ships constructed of steel and navigating in ice-infested polar waters, except for icebreakers, as specified in UR I1.1.

3.2 Hull Areas

In all existing polar class rule systems, hull area factors are used to relate the calculated bow area loads to the anticipated loads on other parts of the ship. Although it is envisioned that future rule formulations will be based on an envelope of loads derived from various interaction scenarios, the first edition of the IACS unified requirements for polar ships will only provide explicit calculations of bow glancing and ramming loads. Loads are applied to other areas of the ship by means of a hull area factor system. Because the net effect of bow form on loads elsewhere is unclear and controversial, the hull area factors used in the unified requirement are independent of hull angles and based on a nominal load for a ship of given size and class.

3.3 Design Ice Loads

The design ice load has been developed to enable each member of the hull structure to resist a single ship/ice interaction event that, although rare, has a nominal expectation of occurring once per year in polar water operations. Although any polar class ship will experience a complex mix of ship-ice interactions during its operational life, the glancing impact scenario has been selected as the basis for the scantling requirements, due to the availability of a relatively mature model describing this type of interaction. Accordingly, the maximum expected bow load associated with a glancing impact is calculated within the accuracy required to yield a sufficiently safe and robust vessel. Loads on areas of the hull other than the bow are estimated by assuming them to be a percentage of the bow load, corrected to remove bow form dependencies (see 3.2 above). Having established the magnitude of the loads for the different hull areas, the average pressure is obtained by transforming the apparent contact area into a reduced rectangular load patch.

3.4 Shell Plating and Framing Requirements

The requirements proposed for the scantlings of plating and framing are based on a loading event that begins with ship/ice edge contact over a small area, and continues with growing contact area until the entire structural grillage is loaded to its design condition. Under the design load condition, and with the selected structural response criteria, a certain level of permanent set in the plating and framing should be expected. The scantlings of all framing members are, in general, based on plastic collapse limit state formulae. To calculate the dimensions of the plating and framing, it is first necessary to determine the pressure to be used in the scantling formulae. Since it is generally acknowledged that ice loads are not uniformly distributed over the instantaneous contact area, a load concentration factor (linked to the horizontal dimension of the load patch) is applied to the average pressure. Having calculated the design pressures for the plating and main frames, it is possible to directly calculate, in conjunction with stability checks, the required scantlings of each. The design of load-carrying stringers and web frames are to be based on an analysis of the entire grillage and are to be dimensioned such that the combined effects of shear and bending do not exceed the limit state(s) defined by each member society.

3.5 Corrosion/Abrasion Additions and Steel Renewal

The proposed structural design criteria for polar class ships result in the minimum scantlings, t_{net}, required to resist the design ice loads according to various response criteria. Accordingly, abrasion/corrosion allowances, t_s, are needed to ensure that the structure can deliver the expected performance at all times between surveys. These margins are linked to anticipated wastage rates, which in turn are related to three factors; hull area, polar class, and the presence/absence of an effective coating system.

3.6 Material Requirements

In the proposed requirements for longitudinal strength, plating and framing, there is an implicit assumption that brittle fracture of structural members will not occur. To ensure that this is the case, minimum grades of steel to be used for various structural members are specified. The basic criteria for steel grade selection includes four factors; polar class, material class, thickness of the structural member, and location above or below the waterline.

3.7 Longitudinal Strength Requirements

The longitudinal strength requirements assume that ice loads resulting from head-on ramming are not occurring simultaneously with substantial wave loads. The equation to determine the ice force due to ramming is based on an analytical solution, which has been modified on the basis of energy methods and numerical results, and validated against available full-scale data. Substituting ship and class-based design values into this equation yields the maximum ice force. The maximum ice bending moment is subsequently calculated. Distributions of the shear forces and bending moments along the ship have been produced from the analytical model. Bending and shear strength requirements are then evaluated using existing longitudinal strength requirements S5, S7 and S11, with slightly revised permissible stresses because of the relative infrequency of ice loads compared with those arising from waves. Since these permissible stresses are independent of longitudinal position, buckling strength is to be verified over the entire length of the ship.

4.0 Source/Derivation of Proposed Requirements

As noted in the foregoing, UR I2 is a consequence of the international effort to harmonise standards for marine operations in polar waters, and is directly connected with the IMO *Guidelines for Ships Operating in Arctic Ice-Covered Waters* (MSC/Circ.1056, MEPC/Circ.399).

Technical Background for UR I2 Rev.2, Nov 2010

1. Scope and objectives

To correct the known typographical errors and ambiguities as well as to correct minor format issues in UR I2.

2. Engineering background for technical basis and rationale

See the attachment "Summary of proposed corrections to UR I2"

3. Source / derivation of the proposed IACS Resolution

Proposal by Hull Panel PT49. See the attachment "Summary of proposed corrections to UR I2"

4. Summary of Changes intended for the revised Resolution:

See the attachment "Summary of proposed corrections to UR I2"

5. Points of discussions or possible discussions

The Hull Panel PT49 created the proposed modifications to correct the known typographical errors and ambiguities as well as to correct minor format issues in UR I2. The Hull Panel approved these changes during the Hull Panel meeting in October 2010. GPG decided to treat the modifications as a revision rather than a correction and the effective date of implementation of the revised UR as 1 January 2012.

"Summary of proposed corrections to UR I2"

Summary of Proposed Corrections to UR I2 (Corr. 1, Oct 2007)

Correction 1 - Body plan nomenclature (I2.3.2.1 (i))

The Hull Panel agreed to replace the phrase “body plan A-A” in Figure 2 with “transverse section A-A”.

Correction 2 - Definition of ship length L (I2.3.2.1 (iii) (a))

To clarify the measurement of *L*, the Hull Panel agreed to replace the definition “L = ship length measured at the upper ice waterline (UIWL) [m]” with “L = ship length as defined in UR S2.1, but measured on the upper ice waterline (UIWL) [m]”.

Correction 3 – Equation 19 (I2.5.8)

In Equation 19, the existing definition of A_{pn} specifies that the cross-sectional area of the attached plate flange is not to be taken greater than the cross-sectional area of the local frame. However, I2.5.8 only applies to cases where the cross-sectional area of the attached plate flange exceeds the cross-sectional area of the local frame. Therefore, the definition of A_{pn} should be replaced by “A_{pn} = net cross-sectional area of the local frame [cm^2]”.

Correction 4 – Equation 21 (I2.5.8)

Since the plastic neutral axis is located at the edge of the attached shell plate and not its neutral axis, the first term in Equation 21, “$t_{pn}\ s\ z_{na} \sin\varphi_w$”, should be replaced by “$t_{pn} \cdot s \cdot (z_{na} + t_{pn}/2) \cdot \sin\varphi_w$”.

Correction 5 – Equation 26 (I2.9.2)

Equation 26 is missing a square root sign.

$$t_{wn} = 2.63\times10^{-3} \cdot c_1\sqrt{\sigma_y /(5.34 + 4 \cdot (c_1 / c_2)^2)} \quad [mm]$$

See derivation at the end of this document.

Correction 6 - Web crippling requirement (I2.9.3)

The existing definition of the yield stress “σ_y = minimum upper yield stress of the material [N/mm²]” should be replaced by “σ_y = minimum upper yield stress of the shell plate in way of the framing member [N/mm²]”. Furthermore, the definition of t_{pn} should read “in way of”.

Correction 7 – Other Areas (I2.11.2)

Since all hull areas are covered by the first 3 rows of Table 4, the last row “Other Areas” can be removed.

Correction 8 – Steel grades for Material Class III (I2.12.1)

Steel grades for Material Class III are defined in Table 6, however no Material Class III structural member is defined in Table 5. Since the only Class III materials are those defined in UR S6.1, the Hull Panel agreed to replace "the Polar ice class notation assigned to the ship and the Material Class of structural members given in Table 5" with "the Polar ice class notation assigned to the ship and the Material Class of structural members according to I2.12.2."

Technical Background (TB) document for UR I2 (Rev.3 Apr 2016)

1. Scope and objectives

Following the approval of the 2010 revision of I2, the previous Hull Panel PT49 instructed to identify a smaller number of items which should be prioritized in the next revision phase. As basis for the new Hull Panel PT49, the following five priority items were selected:

- Design loads for non-icebreaking bow forms
- Criteria for icebreakers
- Compression design loads (not covered by this work)
- Rudder design loads (not covered by this work)
- Web frames and stringers

2. Engineering background for technical basis and rationale

See attachment.

3. Source/derivation of the proposed IACS Resolution

None.

4. Summary of Changes intended for the revised Resolution:

See attachment.

5. Points of discussions or possible discussions

See attachment.

6. Attachments if any

Attachment: *PT 49 – Technical background to UR I1 and UR I2 revision proposals.*

PT 49 – Technical background to UR I1 and UR I2 revision proposals

IACS Hull Panel Project team 49

03 March 2016

Introduction

This document describes the rationale and background for the Rule proposal developed by PT 49 on the revision of IACS Unified Requirements for Polar Class Ships, UR I2.

The proposal covers the following aspects:

- Design loads for non-icebreaking bows
- Requirements for icebreaker notation
- Strength evaluation of web frames and stringers

The proposal includes changes in I1 which are related to the introduction of the specific icebreaker requirements. As a consequence of specifying the application of blunt and bulbous bows, some requirements or assumptions to the hull form, performance, and operational limitations are included as well. This is discussed in more detail below.

A proposal originating from the I3 working group related to propeller submergence has been included in I1.

In the original scope of work, design requirements for rudders as well as evaluation of ice compression loads were included. Due to time and budgetary constraints, these tasks have not been prioritized at this stage. These items should be reassessed in the next revision phase.

Some proposals developed as part of this revision work did not reach agreement within the group, and are hence been left out from the final UR I revision proposal. Some references to these proposals are however included and discussed for possible use in later revisions.

General acceptance criteria for direct calculations for web frames and girders have been included in the rule proposal, and it is opened up for both linear and non-linear calculation methods. However, detailed procedures for how these structures are to be evaluated is not included, and it is considered crucial that a common approach is developed to ensure consistent practice and interpretation among the classification societies. Hence, it is advised that that a separate group is tasked to develop a detailed guidance describing suitable evaluation procedures for web frames and stringers.

A general clean-up of the rule text has been carried out to correct typos, inconsistencies etc.

Task 1 – Design loads for non-icebreaking bows

Introduction

The rule design load formulation for dimensioning of the bow structure is according to IACS URI2 only valid for vessels with icebreaking forms. The definition of *icebreaking form* is however non-existent, but it is reasonable to assume that the term excludes vessels with bulbous bows, or vessels with extreme blunt or vertical bow forms. The aim of the current revision has been to clarify the applicability of the existing load formulation, and specify alternative methods, or limitations, for other bow forms not covered by the existing formulation. In addition, other relevant requirements which depend on the bow form are addressed, including longitudinal strength requirements and design accelerations as given in I3.

Background and summary of the new rule proposal

The Polar Class requirements do not give any explicit limitations with regard to hull form for any ice class. It is however evident that the rule requirements are developed with traditional icebreaking designs in mind, on which also most of the operational experience and validations have been based. The rules are seen to be less applicable for unconventional designs, with one of the most apparent deficiencies being the definitions of the design loads.

In the new revision proposal, the text in I1 is amended to emphasize that the Polar Class notations are developed for ships intended for independent operation in ice-infested polar waters. This has clearly been the basis for the development, and should be stated explicitly stated in the Rules.

Although intended for independent operation and customized for traditional icebreaking forms, the Polar Class notations have been applied on vessels with alternative designs. These include traditional commercial vessels with hull shapes optimized for open water, for which the (two) lower Polar Classes are considered to be a possible alternative to the (two) highest Baltic classes. In addition, ship-shaped offshore units have been assigned higher Polar Class notations without being designed for independent operation in ice. Increased focus on energy efficiency and multi-functional vessels calls for innovative solutions which will not necessary be covered by the hull families considered during the initial development of the rules. Hence, in the new revision proposal, design procedures for alternative designs have been addressed.

The load formulation which is basis for the Polar Class strength requirements is based on a set of ship/ice interaction scenarios, which are considered to be the most demanding design cases for "standard" polar class vessels. During the development of the Rules, dozens of different ship/ice interaction scenarios were identified and considered potentially relevant for structural design. Preferably the governing design scenario for any part of the hull should be chosen from a "library" of relevant scenarios, depending on ship size, type, shape, class etc. However, in the current rules, two selected scenarios are considered to be governing, namely:

- Ramming scenario
- Glancing impact scenario

The ramming scenario is considered to be governing for the longitudinal strength, while the glancing impact scenario is considered to be dimensioning for the structural design of the bow (and used as basis for the remaining part of the hull structure). During the development of the rules, the ice compression scenario was also considered as potentially governing for the transverse strength of the midship structure, but have until now not been addressed explicitly in the Rules.

The reasons for imposing limitations with regard to bow form to the original design load formulation are not explicitly explained in the available background documentation. One reason may be the fact that alternative designs were not considered during the development of the rules, and that the limitation is a simple consequence of insufficient validation and verification. In any case it is reasonable to assume that possible limitations are related to the validity of the assumption that the glancing impact actually is the governing scenario, and/or the validity of the derivation of the load formulation itself. These will be discussed in more detail below.

When it comes to the derivation of the load formulation, several assumptions which potentially could limit the applicability of the formulation are discussed below. Extremities lie typically within this category, and are often not covered by any validation or calibration against available full scale and model test data. As mentioned above, the main focus during the development was on traditional icebreaking bows, and other bow shapes including bulbous bows were not part of the evaluation. Consequently, no validations or calibrations of such hull shapes are found. However, if the applicability of the load formulation should be limited to the bow forms considered during the development of the Rules, many bow forms which easily can be classified as “icebreaking” will be excluded. Other aspects limiting the applicability are discussed below, including approximations introduced by the simplified hull shape coefficient fa, the limitations introduced with regard to the patch aspect ratio, and the relevancy of the assumed shape of the ice footprint area.

In the current Rule proposal, the term *icebreaking form* has been removed. Instead, the validity of the existing load formulation has been defined by introducing limitations on bow angles.

Certain limitations to the hull form have been introduced for ice classes PC1-PC5. These vessels are normally purpose-built for operation in difficult ice conditions, and bow forms which are not considered effective for ice operation should generally be avoided. For the higher ice classes, bows with vertical sides and bulbous bows are examples which are not considered effective.

A paragraph addressing the expectation that Polar Class vessels should be able to operate independently in ice conditions representative for the ice class have been added in I1. However, requirements to hull form and performance should not restrict the application of new, innovative or other purpose-built designs which do not fit directly into the formulations, but these should be subject to special consideration by each Society.

For PC6 and PC7, open water bows including bows with vertical sides and bulbous bows may be accepted, and alternative load formulations have been developed for these cases. In general, bulbs should be treated as a structural appendage, i.e. the own structural requirements should not drive those of the overall structure.

The longitudinal strength requirements and the design accelerations given in URI3.6 are derived based on the vertical force component in the bow obtained from a ramming impact scenario. In the current proposal, a paragraph is added to emphasize that the basis for the requirements is the ramming scenario. This is consistent with I2.3.1 (i) for bow design loads.

Intentional ramming is not considered to be a relevant operational scenario in design ice conditions for bows with vertical sides or bulbous bows (PC6 and PC7). Hence, the longitudinal strength requirement, as well as the design accelerations based on the ramming, and the requirements will hence not be relevant for these vessels. In the rules, it is stated that this should be specified in the Class certificate or equivalent.

Application of design load formulation for dimensioning of bow structure

For the glancing impact scenario, on which the derivation of the design load for dimensioning of the bow structure is based, the ship is assumed to strike an ice edge of infinite mass with the bow shoulder as shown in Figure 1. During the collision, the ship will penetrate the ice until the normal velocity is zero, and the ship rebounds away. The footprint for a given penetration depth δ will take form of a triangle and is limited by the width W and height H.

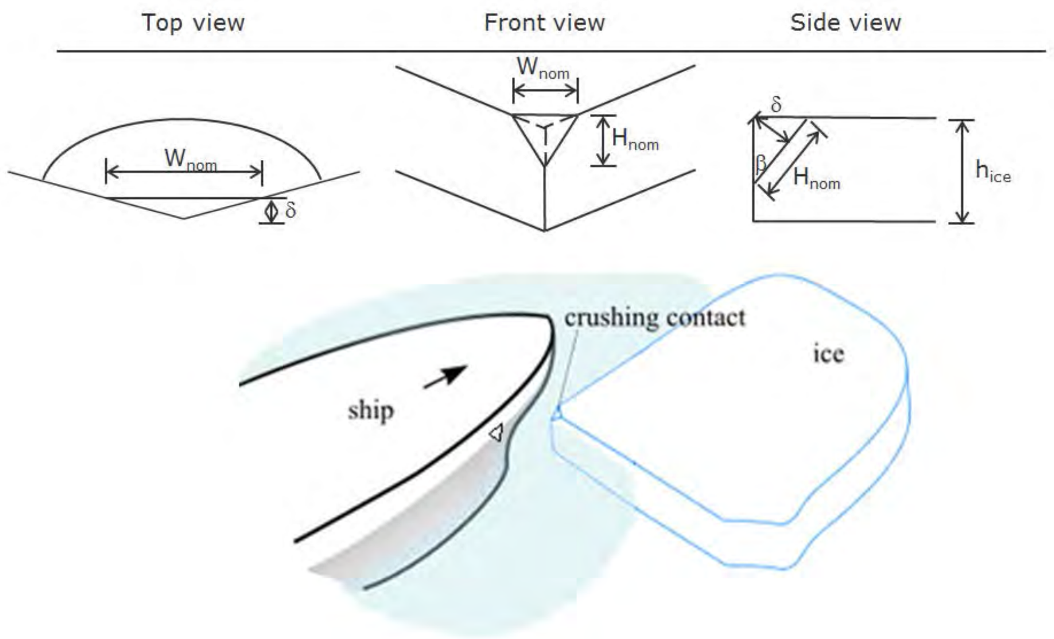

Figure 1 Design scenario for the general glancing impact collision, indicating the nominal contact geometry

The design force is found by assuming that all the initial normal kinetic energy is transformed into crushing energy of the ice. Given the initial geometry of the ice, the resulting triangular footprint is determined from the shape of the bow based on the final penetration depth. Hence, the derivation of the design load and the corresponding footprint area is a result of a simple geometry consideration as long as the vertical extent of the footprint does not exceed the assumed thickness of the ice floe.

As discussed above, the following aspects may impose limitations on the rule formulation:

- Relevancy of the glancing impact scenario for a given hull form

- Accuracy of derived load formulation

Based on available background documentation and evaluations carried out during the revision work, it has not been possible to justify the use of other scenarios than the glancing impact as governing design scenario for any specific bow form. Hence it is proposed to continue using the glancing impact scenario as basis for the dimensioning of the bow.

Regarding the derivation of the load formulation itself, aspects which potentially could justify limitations on the applicability of the load formulation are discussed below.

In the present bow design load formulation, the bow form dependency is represented by the shape coefficient *fa*, where the smaller of the crushing or flexural strength shape coefficient is used. For most conventional icebreaking bow forms, the crushing strength is normally governing, and is hence focused on below. Due to a complex equation for the crushing strength, a simplified expression has been used in the Rules. In Figure 2 (extracted from the background document for ice impact loads) the exact vs. the rule fa-factor is compared for four bow forms, and it is seen that the simplified expression may generate conservative high forces compared with the exact expression for certain bow forms (e.g. landing craft bows), and a cut-off value of 0.6 is introduced to avoid extreme values. Consequently, the upper limit of the fa-factor is for these cases considered more related to the introduction of the simplified rule expression than to represent a limitation on the general load scenario or formulation itself.

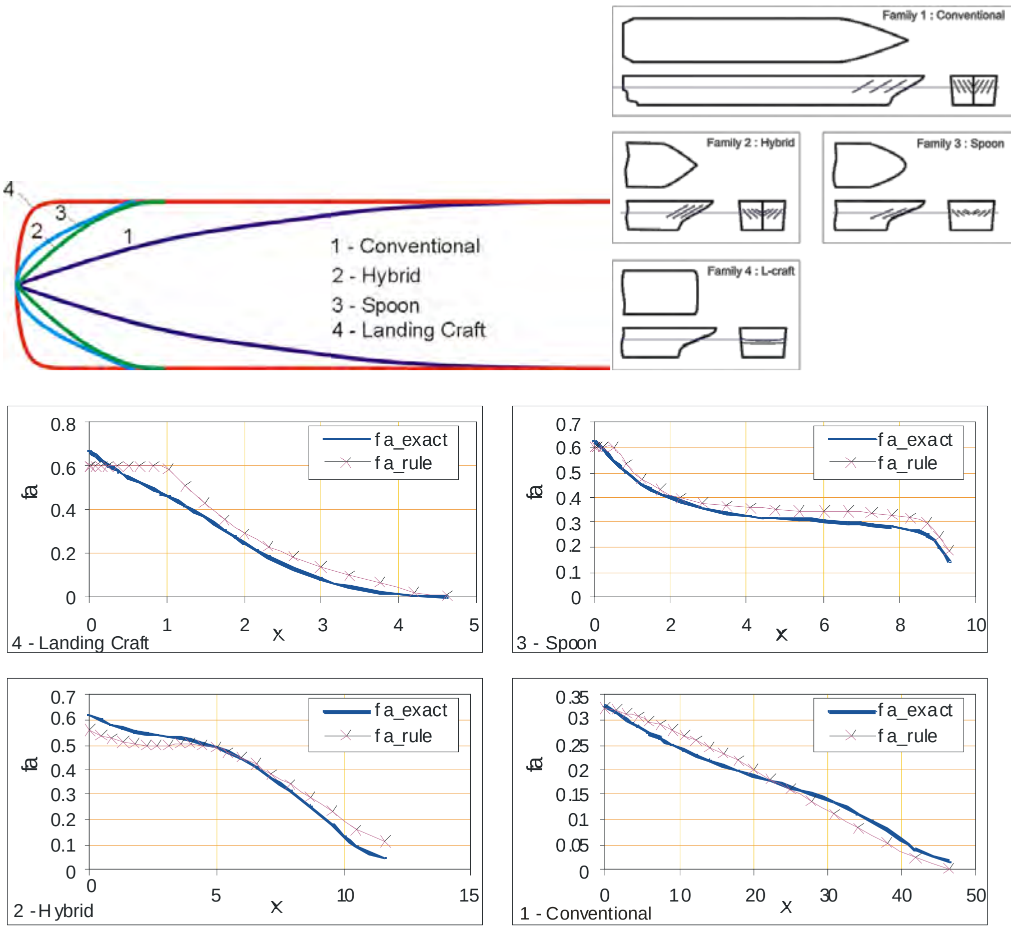

Figure 2 Comparison of exact and rule fa-coefficient for considered hull forms (I2 Background Notes)

The bow forms shown in Figure 2 have different waterplane shapes ranging from conventional to landing craft bows. When introducing the upper limit of the fa-coefficient, it is reasonable to conclude that all these bow forms lie within the application range of the load formulation. Hence, it is difficult to see that this will cause any limitations with regard to waterline angles alone.

A second aspect is related to the limitations introduced in connection with the evaluation of the corresponding contact patch area. The size of the contact area is determined based on the ratio between the calculated width and height of the triangular footprint area obtained from the collision impact scenario. To avoid that the aspect ratio approaches zero, a lower limit of 1.3 has been introduced, which corresponds to a normal frame angle of 10^0. The existence of such a lower limit may indicate that frame angles at least down to 10^0 can lie within the validity range of the formulation.

The third aspect is related to the validity of the assumption that the crushed volume of the ice is shaped like a triangular pyramid. This is in general valid as long as the vertical projection of the contact area is less than the assumed thickness of the ice floe. This assumption may be expressed by the following form:

$$H_{vert} = 0.366 \cdot F_n^{0.556} \cdot P_0^{-0.556} \cdot sin(\beta')^{-0.5} \cdot cos(\beta') \leq h_{ice}$$

Although somewhat complicated, it is possible to evaluate the combination of waterline angles α and normal frame angles β' which violates the assumption, depending on the ice class and displacement of the vessel. Some initial evaluations indicate that this may be relevant for frame angles up to 10-15^0 for larger vessels with the lowest ice classes PC6 and PC7.

It is worth mentioning that the possible limitation discussed above is only relevant as long as the defined ice thickness h_{ice} is assumed to have a physical meaning for the crushing impact scenario, and not only a "scale" parameter defining the flexural strength of the ice.

Considering the aspects above, it is very difficult to define hull angles where it is obvious that the existing load formulation is not valid. It is however reasonable to consider the formulation less applicable for vessels with small normal frame angles β', particularly in combination with larger water plate angles α (i.e. blunt or "shoe-box" shaped bow forms).

In the rule proposal, it is suggested to consider the existing load formulation valid for bow forms where the buttock angle, γ, at the stem is positive and less than 80^0, and where the normal frame angle β' at the centre of the foremost sub-region of the bow is equal to or larger than 10 degrees. A limit of 10^0 is, beyond what have been discussed above, considered to be a practical compromise, which ensures that most traditional designs are covered by the formulation. Such a limit will at the same time exclude most of the unconventional designs. However, bearing in mind the original "icebreaking bow" statement, the proposal will now cover bow forms which easily can be classified as "non-icebreaking".

For bows with vertical sides not fulfilling the bow angle criteria proposed for the existing load formulation above, an alternative formulation has been developed based on the same glancing impact scenario. When the normal frame angle approaches zero, the vertical projection of the nominal contact area becomes equal to the assumed thickness of the ice, and may be defined as shown in Figure 3. The derivation of the impact forces generated from such a scenario is seen to be somewhat complicated and not well suited for rule application unless a simplified expression is introduced. However, a formulation for the special case where the normal frame angle is 0^0 (vertical sides), as shown in Figure 4, may be a feasible alternative for such designs. The load formulation is presented in Appendix B.

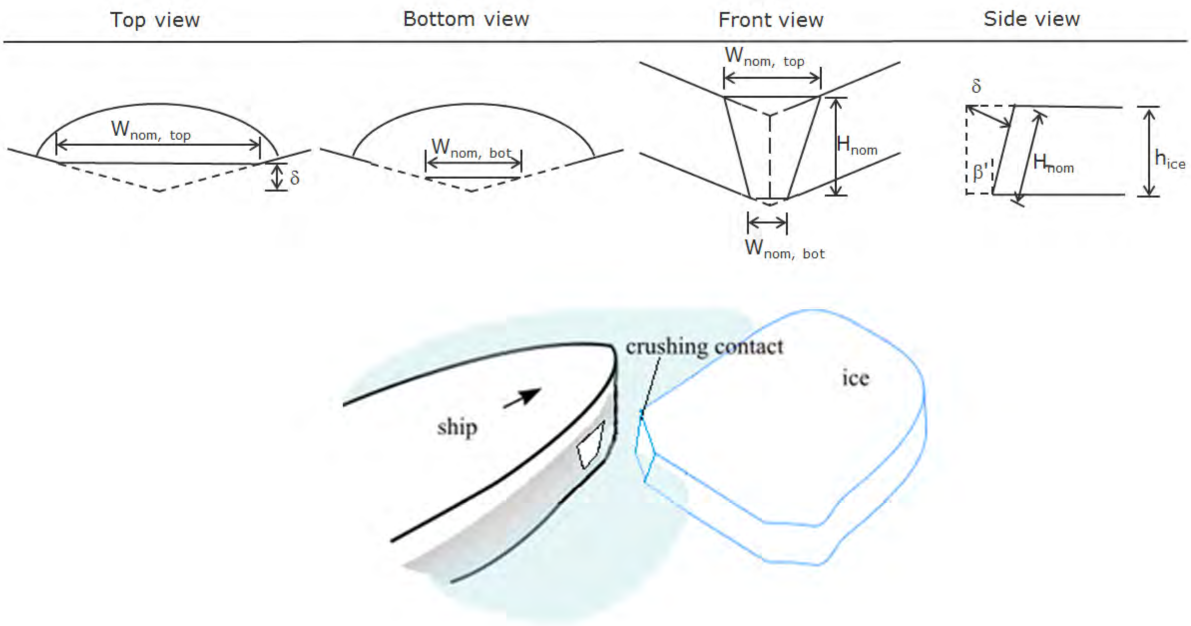

Figure 3 Glancing impact collision where the vertical projection of the contact area equals the ice thickness

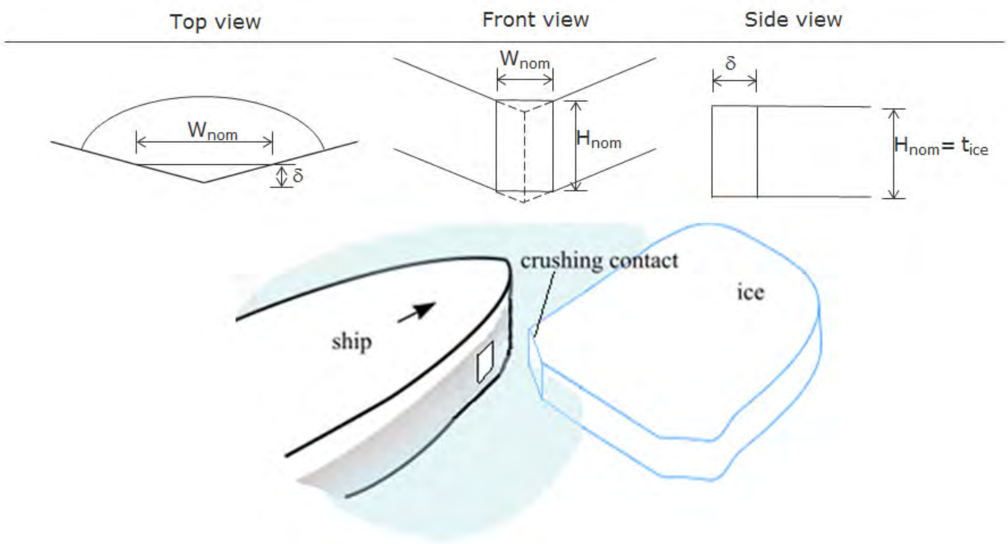

Figure 4 Glancing impact collision for a bow with vertical sides ($\beta = 0^0$)

For the case where the normal frame angle is 0^0 (vertical sides), the design force F, line load Q, and pressure P become:

$$F_n = f_a \cdot P_0^{0.526} \cdot V_{ship}{}^{0.947} \cdot h_{ice}{}^{0.474} \cdot \Delta_{ship}{}^{0.474}$$

$$Q = F_n^{0.222} \cdot P_o^{0.778} \cdot h_{ice}^{0.7}$$

$$P = F_n^{0.555} \cdot P_o^{0445} \cdot h_{ice}^{-0.6}$$

As for the existing load formulation, the terms P_0, V_{ship}, and h_{ice}, may be represented by class factors. Assuming that:

$$CF_{CV} = P_0^{0.526} \cdot V_{ship}{}^{0.947} \cdot h_{ice}{}^{0.474}$$

$$CF_{DV} = P_0^{0.778} \cdot h_{ice}{}^{0.7}$$

$$CF_{PV} = P_0^{0.445} \cdot h_{ice}{}^{-0.6}$$

the parameters read:

$$F_n = f_a \cdot CF_{CV} \cdot \Delta_{ship}{}^{0.474}$$

$$Q = F_n^{0.222} \cdot CF_{QV}$$

$$P = F_n^{0.555} \cdot CF_{PV}$$

The class factor $CF_{C,vert}$ may be given as follows for the different ice classes:

Ice class	CF_{CV}	CF_{QV}	CF_{PV}
PC 6	3.43	2.82	0.65
PC 7	2.60	2.33	0.65

The fa-factor is proposed to be:

$$f_a = \frac{\alpha}{30}$$

The alternative load formulation presented above is suggested to be used for bows with vertical-like sides, where the normal frame angle β' is between 0-10^0 at the centre of the foremost sub-region of the bow. In Table 1 to Table 4, a comparison between the new vertical bow formulation and the existing formulation (with frame angle β'= 10^0) is presented for a range of ship sizes and waterplane angles.

20	2.1	1.9	2.4	2.4	2.7	2.9	3.0	3.5
25	2.2	2.1	2.5	2.7	2.8	3.3	3.1	3.9
30	2.2	2.4	2.5	3.0	2.8	3.6	3.1	4.4
35	2.2	2.6	2.5	3.3	2.8	4.0	3.1	4.7
40	2.2	2.8	2.5	3.6	2.8	4.3	3.1	5.1
45	2.2	3.0	2.5	3.8	2.8	4.6	3.1	5.5

The comparison shows that the two formulations produce similar design forces and pressures (in average depending on ship size) for smaller to moderate waterplane angles. The consequences for the scantlings may be relatively stronger transverse frames due to increased height of the design load patch. The new formulation for blunt/vertical bows will however give higher forces and pressures for larger waterplane angles, which is considered reasonable. For larger waterplane angles, the simplified fa-coefficient is seen to be conservative compared with the "exact" solution, and is considered as an acceptable consequence of the proposed formulation.

When it comes to the loads on the bulb, it should first be mentioned that the bulb should be considered as an appendage, i.e. that their own structural requirements should not drive those of the overall bow structure. However, while the the blunt/vertical bow side formulation is based on a direct derivation of the glancing impact scenario, the development of a formulation for a similar relevant scenario for bulbs has proven to be difficult. For convenience, it has been proposed to use the existing and new proposed load formulation as reference. Although further revisions should continue to look into the possibility of deriving explicit formulations for all types of hull forms, including bulbs, the current proposal is considered sufficient at this stage.

Bow forms which are not covered by the above should be specially considered by each member society.

Performance/hull shape criteria for Polar Class ships

The introduction of performance hull shape criteria was not part of the original scope for this revision work. The powering requirements have been discussed in length during the development of the rules, and the exclusion of such criteria was based on a decision taken in 1997 during the 8^{th} semi-annual harmonisation meeting of the IMO Outside Working Group which developed the Draft Code of Polar Navigation. Nevertheless, the debate has continued whether the IACS requirements should include performance requirements for reasons of safety. During the work with the load formulations and the icebreaker requirements, it was found that there is a need for a general performance requirement for all Polar Class vessels to ensure that the vessel can operate safely in the anticipated ice conditions as described by the ice class. The requirements are deliberately formulated somewhat generic, and the intention is to raise the flag and to ensure agreement between designer and owner with regard to the capabilities of the ship. Detailed guidance describing applicable procedures and detailed criteria should be developed separately. Please note that the term “representative ice conditions” does not necessary refer to the most severe ice condition as described by the ice class, but may be linked to a typical ice condition and operational mode which is representative for the intended voyage profile.

Please note that this requirement should not exclude vessels or unit types which are explicitly not designed to operate independently in ice (e.g. drill ship escorted by icebreakers, barges, etc), but such assumptions or limitations should be explicitly stated in the Class certificate or equivalent for transparency.

Task 2 – Develop criteria for icebreakers

Introduction

In the current IACS UR I it is explicitly stated that the requirements are not applicable for *Icebreakers*. By introducing *Icebreakers* in the new revision of the Rules, there is a need for providing clear directions on how ships that are to receive the additional *Icebreaker* notation should be handled. The intention with this work is to clarify the applicability of the *Icebreaker* notation (I1), include relevant structural requirements in I2, and coordinate relevant requirements in I3.

Background for rule proposal

Although not covering *Icebreakers*, the rules state that vessels which are assigned an *Icebreaker* notation may have additional requirements and are to receive special consideration. In the rules, an *Icebreaker* is referred to as a "ship having an operational profile that includes escort or ice management functions, having powering and dimensions that allow it to undertake aggressive operations in ice-covered waters, and having a class certificate endorsed with this notation."

Before discussing the detailed requirements which should be associated with the specific notation, it might be worth discussing the applicability of the notation, and the features which typically differentiate these vessels from other vessels without the additional notation. Noting the definition of *Icebreakers* above, there are clearly expectations and assumptions associated with the notation which are related to type of operations and performance including manoeuvrability and powering.

Higher polar class ships are expected to spend more of their lives in ice-infested waters, and consequently experience more and higher ice impact loads. The actual distributions of loads will therefore have a probabilistic character, which implicitly are reflected in the choice of ice class. An *icebreaker* will similarly, due to the operational profile, expect to experience more frequent and severe ice impacts relative to a commercial vessel of same parent ice class, and this may be reflected in the determination of design loads.

From a structural strength and performance point of view, the following aspects may be considered as (potential) differentiators compared to a general icebreaking vessel covered by the current Rules:

- Sufficient performance to undertake more aggressive operations in design ice conditions
  - Hull form and maneuverability
  - Propulsion power
- Sufficient strength to withstand additional loads due to more aggressive operations in design ice conditions:
  - Higher frequency of impacts during lifetime - increased probability of extreme loads
  - More available power/higher impact speeds – potentially increased extreme loads
  - Increased local loading on other parts of hull and appendages, e.g. outside defined icebelt, shoulders, bottom and stern, as well as rudders, due to increased maneuverability and aggressive operation
  - Higher global loads and accelerations due to more aggressive ramming operations

To address the expectations associated with the rule definition of an *Icebreaker*, it is reasonable to introduce additional requirements to the hull form and the propulsion power. However, in the current proposal, the general performance requirement proposed in I1 (and discussed above) is considered to sufficiently cover *Icebreakers* as well. Relevant ice conditions and acceptance criteria applicable for the type of operation should however be considered.

For the design loads which are used for dimensioning of the bow structure, one may argue that the general loading should be increased due to a more aggressive operational profile. The same applies to the horizontal and vertical extensions of the defined hull areas. However, in the current proposal, the dimensioning level in the bow is retained, but some general minimum level of strengthening in the non-bow areas have been proposed as well as increased strengthening of the stern.

During the development of the original rule proposal, a separate longitudinal strength criterion for *Icebreakers* was included. Since Icebreakers were excluded from the original rule proposal, this specific requirement was removed. In the current rule proposal, it is suggested to re-introduce this requirement.

Applicability of Icebreaker notation

The additional *Icebreaker* notation is considered applicable for all Polar Class notations.

Hull area factors and regions

As mentioned above, it might be reasonable to keep the existing design loads for dimensioning of the bow structure, based on among others the assumption that the calibration of the design loads to a large extent has been made based on experience with icebreakers. However, increased manoeuvrability, power, and more aggressive operation might increase the loading on the other parts of the vessel, particularly for the lower ice class vessels. In general, the area factor for the stern ice belt and the stern lower has been increased by approximately 25%, and all non-bow area factors should not less than the area factor determined for PC3.

The proposal is a simple percentage-increase compared to the standard area factors and is based on a review of existing ice class rules (e.g. DNV Rules for vessels intended for Arctic and icebreaking service, ABS ice class rules, etc). In the DNV Rules, the design loads in the stern icebelt is for icebreakers 80% of the bow load (same as proposed for PC3-PC7 Icebreaker), an increase of 33% compared with a ship without icebreaker notation. Similar relations may be found for the other hull areas.

The proposal was originally introduced in the DNV Rules for Polar Class ships in 2008. The intention with the requirement is to keep a minimum level of strengthening in the non-bow areas, particularly for the lower ice classes.

For Icebreakers it is suggested that the fore boundary of the stern region should at least be 0.04 L fore of WL angle = 0 degrees at UIWL, i.e. stern shoulder to be included in stern region. This is in accordance with common requirements given for icebreakers in existing ice class rules.

Loading on rudders, nozzles, azimuthing propulsion units etc

For appendages, it is stated that the design loads should be representative for the location of their attachment to the hull structure or their position within a hull area. Hence, it is reasonable to link this to the hull area factor (AF). Assuming that the hull area factor is increased for *Icebreakers*, the design loads for the appendages should be increased accordingly. However, as there are no explicit requirements for the appendages in the rules, the rule text has not been changed.

Requirements to longitudinal strength

It is suggested to re-introduce the original utilization factor to determine allowable stresses for icebreakers. A utilization factor of n=0.6 was originally introduced for icebreakers (n=0.8 for other ship types) to take into account more aggressive operations assumed to be associated with icebreakers. The requirement was later removed, as it was agreed that the Rules should not cover icebreakers.

Requirements related to machinery section I3

In the current draft revision proposal for I3, additional requirements associated with the *Icebreaker* notation are to be determined by each member society.

The only reference to *Icebreaker* is a requirement to a fast torque relief arrangement are to be fitted in order to provide effective protection of the rudder actuator in case of the rudder being pushed hard over against the stops.

Task 5 – Procedures for web frames and stringers

Introduction

The current requirements for web frames and stringers given in IACS URI2 provide little guidance for design. There is hence a need for consistency in the treatment of conventional web frames and stringers, as well as general grillage systems, in order to avoid different interpretations and design criteria among the IACS member societies.

Background for rule proposal

The Polar Class requirements are generally derived using plastic design philosophy. This is based on the consideration that some minor deformations (e.g. local denting) could be an acceptable consequence of ice operation, provided that this does not compromise the overall strength or watertight integrity of the ship.

The design criteria for plastic design are normally evaluated against loss of stiffness (stiffness change), permanent deformations or plastic strains. As opposed to elastic design, where the limit state could be a stress criterion related to first yield, plastic design has in general many possible limit states ranging from yield to final rupture.

For the plating and local frame requirements, the limit states defined in the PC rules are based on a plastic collapse mechanism. As the collapse model ignores the effect of membrane stresses, strain hardening and in principle the possible redistribution of loads to adjacent members, the structure has substantial reserve resistance beyond the design condition. This is particularly true for the local plating members, which can carry significantly higher loads while undergoing deformations several times the plate thickness before rupture. For individual ice frames, the reserve resistance is however less significant, and there are uncertainties both with regard to (the combinations of) failure modes as well as the ability to mobilize the assumed plastic resistance of the cross section and any membrane action in the member. For higher level components like web frames and stringers, the ability to mobilize additional reserve resistance may be even less apparent. Stability of web plates and flanges will have to be checked separately.

Limit states used as basis for design should reflect the potential consequences of structural failure. Assuming that the ice patch is limited in height and width, a rupture of a single plate member may not be considered very critical for the survivability of the vessel, while a structural failure of a primary member may ultimately compromise the vessel's structural integrity.

Hence, a higher utilization of the plating compared to primary members may be rationalised from a risk evaluation point of view. This type of hierarchy strength principle is also described in the background documents of the current rules, where a system of relaxed plate and stricter ice frame requirements is adopted.

In addition to the potential reserve resistance or consequences of structural failure discussed above, the selection of appropriate limit states should reflect the probability level of the design load applied on the different members. The design loads which have been derived for the Polar Classes may be considered as extreme loads, and may be considered conservative, both with regard to the derivation of the load scenario, as well as the ice class factors used as basis for the assessment. However, there are no explicit references to a formal probability level or return period for an actual trading vessel. The governing design load for all structural members, ranging from the local plating to the grillage system including bulkheads and decks, is based on a glancing impact scenario, where the impact force is represented by an average pressure over a patch area with defined height and length. For small areas, a peak pressure factor (PPF) is introduced to take into account the possible existence of higher pressure zones within the defined patch area. In addition, the PPF is used to increase the general pressure level for certain structural elements. However, both the PPF formulation and its application on the various members have been questioned, and compared to other rule formulations, the PC loads appear to be more conservative for individual members carrying larger fractions of the defined patch load. It too must be understood that the structural response in the Rules allows for limited plasticity and is thus a higher level than other Rules sets that use elastic response principles. Hence, the use of the relatively extreme Polar Class design loads may imply that an implicit (relative) safely factor could be embedded into the load formulation, at least for web frames and stringers with larger spans, depending upon the response criteria selected.

When the limit state is defined, the corresponding acceptance criteria must reflect the analysis method used and the response parameters considered in the assessment. For the assessment of individual primary members and grillage systems, several methods may be applicable:

- Analytical elastic or plastic methods
- Beam analysis
- Linear or non-linear finite element analysis

Analytical methods are generally simple in format and may be a preferred tool for simple strength checks of individual members, e.g. for establishing initial dimensions. The advantage is obviously that the necessary scantlings can be determined by well-defined formulas without the use of advanced computational tools. The drawback is however the difficulty in representing the actual response pattern, the possible complex geometry and support conditions, as well as the difficulties in properly taking into account the effect of the members being part of a grillage system, particularly in the plastic regime.

Evaluation of the structural response by use of finite element methods allows for a much more accurate representation of the actual (variations in) geometry, as well as the interaction between the different members considered. Finite element analysis requires however generally much more resources than analytical methods, and require also special competence which may not be easily accessible for all parties. Using non-linear finite element methods as basis for documenting structures to meet the reliability level of a specific code will require an in-depth understanding of the inherent safety requirements of the governing code as well, and there is definitely a need for a detailed guidance to ensure reliable and consistent results.

During the development of the original Rules, an analytical procedure for evaluating grillage systems was proposed based on the Russian rules. The formulas for web frames and stringers were based on a plastic approach and incorporated the presence of lower level strength members, taking into account their supporting and load distributing effects. Due to lack of agreement, the proposal was however excluded from the first official rules.

As part of the work related to the current rule revision, a basis for evaluating stringers and web frames both with analytical and direct calculations has been developed. Both the analytical formulations and the procedures for direct calculations were based on earlier work done by DNV-GL. During the development of the analytical formulations, it was however acknowledged that it is difficult to develop generic analytical formulations for grillage systems which can represent the actual response with sufficient degree of accuracy, taking into account the actual (variations in) geometry, boundary conditions, interactions between the different strength members. Based on the outcome from the verification of the formulations, as well as response from the first hull panel hearing phase, the accuracy of the proposed formulations were not found to meet the desired level of accuracy, and it was decided not to include the proposal formulation in the current revision proposal. In addition, concern was raised with respect to scantling outcomes for PC7 and PC6 ships in comparison to Baltic IA and IA Super scantlings, suggesting that further validation and development is needed. The derived formulations are however documented in Appendix A and may be used as reference in later revisions.

It is unfortunate that this revision work have not lead to the introduction of analytical formulations for web frames and stringers, and there is obviously a need for such formulations, particularly for determination of initial dimensions. However, as a result of the above, each member society should preferably come up with guidance for initial design.

However, for web frames and stringers being part of grillage systems, the new rule proposal assumes in any case the use of direct calculations. Direct calculations tend to become a natural and basic part of the strength documentation in ship design, and will now be expected for final documentation of grillage systems.

The rule proposal for direct calculation is intentionally left quite generic, and the specific procedure has to be developed by each member society. However, the assumptions and requirements to the execution of the analysis and evaluation of results should reflect the acceptance criteria and considerations below in order to ensure that the proposed design points are treated consistently. This includes modelling issues, mesh density, etc. as well as treatment of lower level members, connection area, stability requirements etc. In general the following criteria and considerations are included in the proposal:

Linear elastic stress analysis (beam or FE analysis):

- Web plates and flange elements in compression and shear to fulfil relevant buckling criteria
- Effective shear stress in member web plates to be less than σ_y/sqrt(3)
- von Mises stresses in member flanges to be less than 1.15 x σ_y. (assuming party fixed boundary conditions)

Non-linear stress analysis:

- The analysis shall reliably capture buckling and plastic deformation of the structure
- Detailed acceptance criteria to be decided by each member society. The acceptance criteria shall ensure a suitable margin against fracture and major buckling and yielding causing significant loss of stiffness.
- Permanent lateral and out-of plane deformation of considered member should be minor relative to the relevant structural dimensions.

The von Mises acceptance criteria for linear analysis have been discussed back and forth within the group, and it is acknowledged that throughout validation of different grillage configurations has not been carried out. Based on the discussion above, it was however from the beginning the clear opinion of the group that the acceptance criteria should incorporate a moderate degree of plasticity in the members, which means that nominal elastic normal stresses may exceed yield.

The structural capacity of the grillage depends largely on the actual structural configuration and dimensions. From the validation work carried out as part of this revision, a series of relevant grillage configurations were considered. However, the typical governing failure modes for these structures are related to shear yield and buckling stability, which means that the bending failure mode becomes less relevant.

In Figure 5, examples of relative load-deflection curves for two typical continuous girders being part of a grillage system are shown. The girder denoted T-profile consists of a plate flange and a stiffener flange, while the I-profile represents a double hull member consisting of two (inner and outer shell) plate flanges. Both the load and deflections are normalized with regard to first yield in the member flange(s). From the analyses, it is evident that the members can carry significantly larger loads than the level initiating first yield in the member without experiencing large permanent deformations, and based on an overall evaluation, a factor of 1.15 is proposed and found to be reasonable taking into account the combined ability to develop plastic moment and redistribution of stresses, in combination with a moderate fixation against rotations at the member supports. The alignment of acceptance criteria for different analysis methods should preferably be part of a detailed procedure which should be developed for direct calculations.

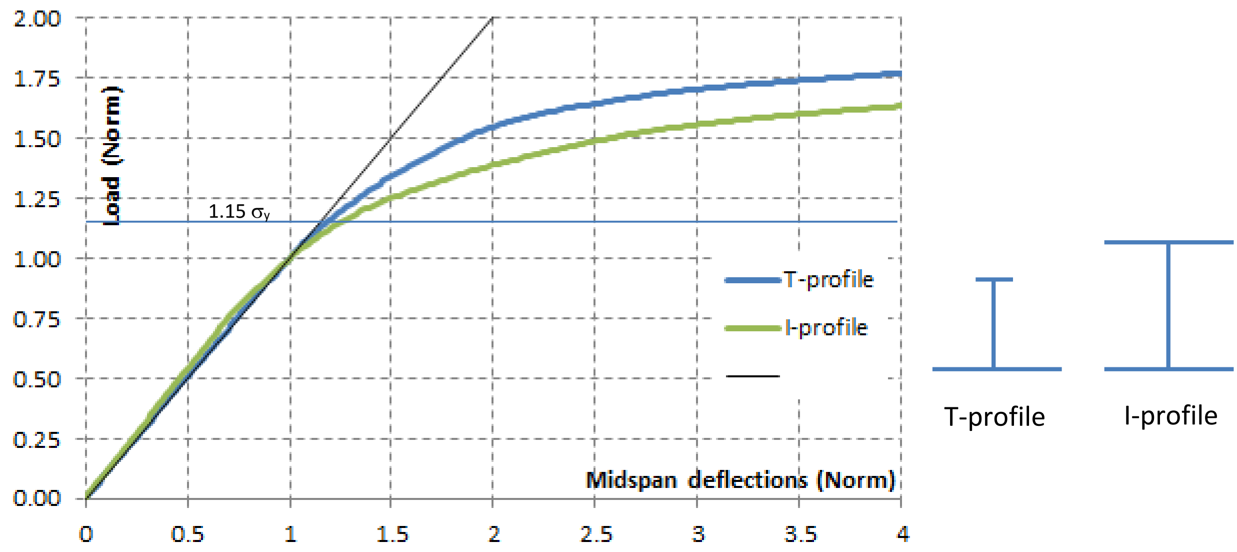

Figure 5 Typical load deflection curves for typical girder members being part of a grillage system

Editorial amendments of rule text

General editorial amendments have been proposed and the rule text has been updated accordingly. The rationale for the amendments is mainly to ease readability and to avoid misunderstandings.

Some items are found to be inconsistent or superfluous, and have consequently been removed from the proposal. This applies among others to Paragraph I2.12.5, including the table for steel grades for inboard members attached to weather exposed plating, which is found to be inconsistent with the material classes described in I2.12.2.

From the hull panel hearing process, it was observed that there was some confusion regarding the existing framing requirements for bottom structures. Hence, the text is updated to clarify the intention of the rules. When calculating the minimum shear and section modulus requirements for the bottom structure, the requirements in I2.6 should be applied irrespective of the actual framing direction. In the bottom is it considered reasonable to assume that the ice patch orientation relative to the frame direction is random, and hence it is not relevant to distinguish between the transverse and longitudinal frame configurations. In lack of a specific scenario-based formulation for the bottom structure, an ice load patch applied in a direction normal to the frame direction is considered reasonable.

The patch load application on transversely and longitudinally framed bottom structures are given in Figure 6 and Figure 7, respectively. Please note that the same philosophy applies for the plate thickness requirements

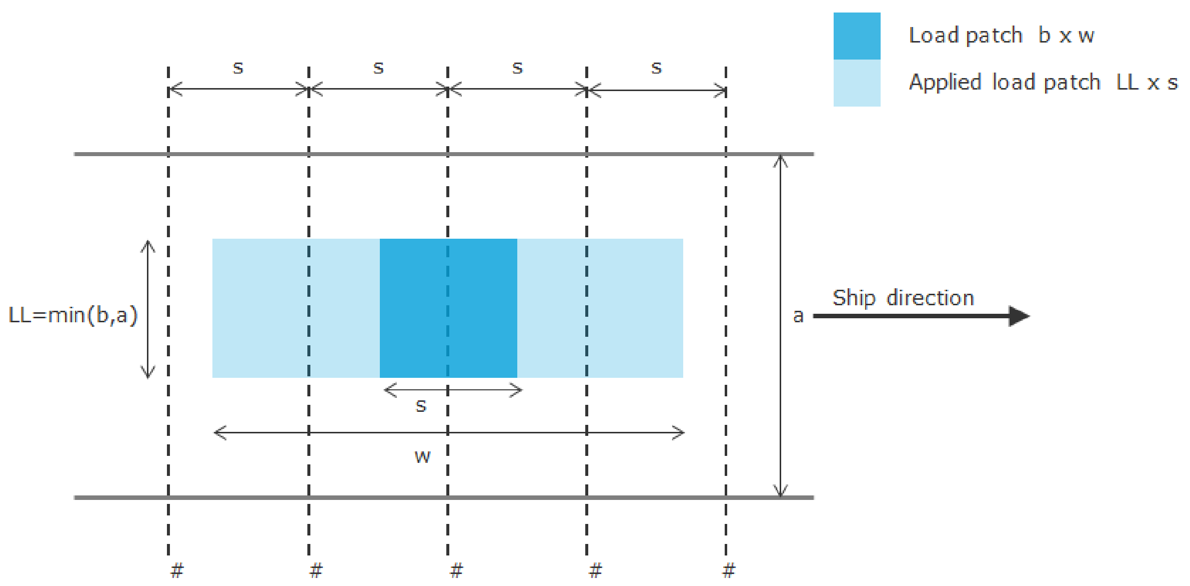

Figure 6 Application of ice load patch on transversely framed bottom structure according to paragraph I2.6

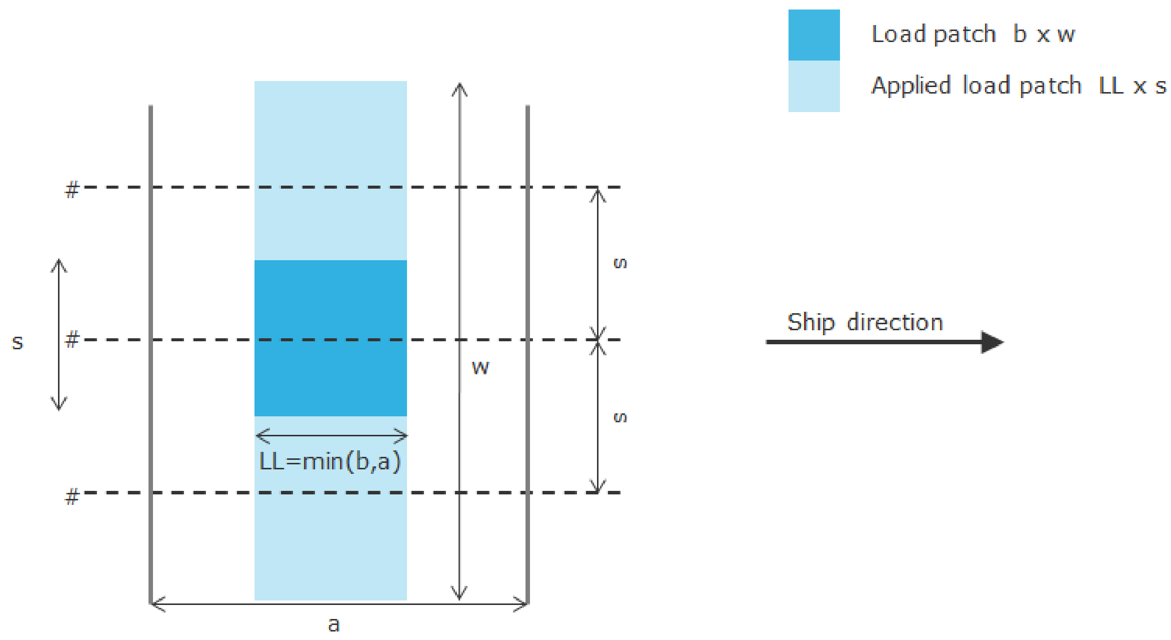

Figure 7 Application of ice load patch on longitudinally framed bottom structure according to paragraph I2.6

Other amendments include:

- The PPF for bottom framing should not be independent of patch area or structural dimensions. Consequently the peak pressure factor has been set to 1.0.
- The equation numbers have been removed as it is found that only a few are referred to in the text. Reference to paragraph numbers has been included as relevant.

Appendix A

Analytical formulations for web frames and stringers

Shear area requirements for simple web frames supporting longitudinal local frames

The general design load case for evaluating the shear strength of a simple web frame supporting longitudinal local frames is suggested to be as shown in Figure 1.

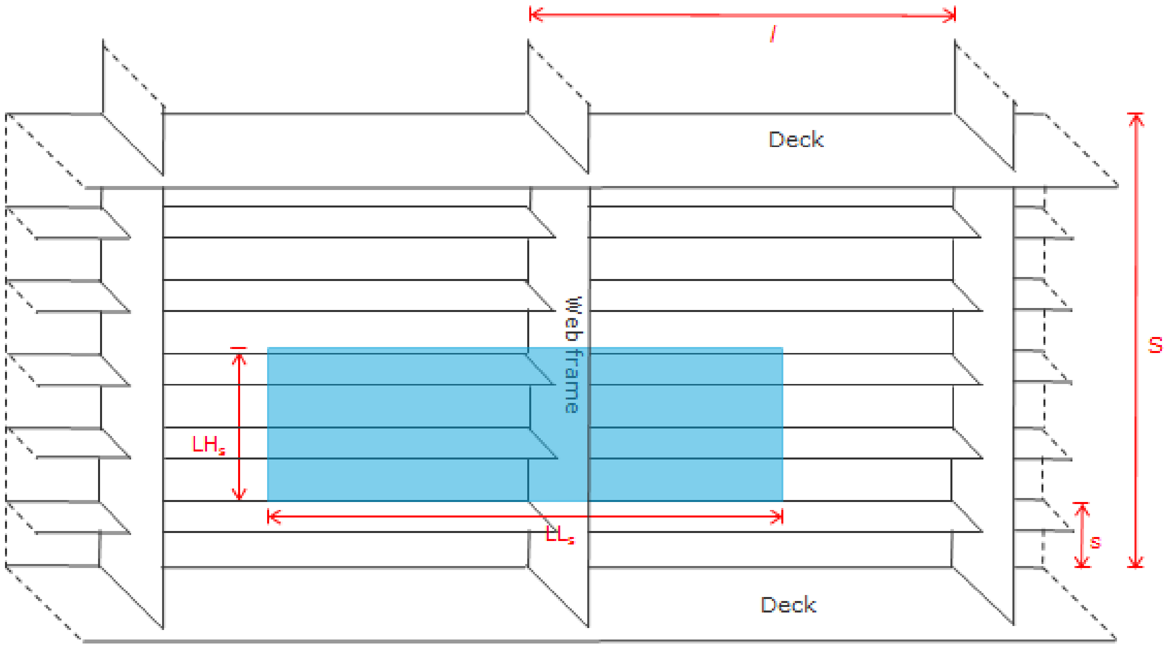

Figure 1 – Proposed design condition for the shear area requirement for simple web frames supporting longitudinal local frames

The effective shear area requirement for this condition is suggested to be as follows:

$$A_{wf} = \frac{100^2 (AF\ PPF_s\ P_{avg})\ LH_s\ LL_s\ K_s}{0.577\ \sigma_F\ \eta \sin \varphi_w}$$

A_{wf} = Effective net web area of web frame supporting longitudinal local frames [cm^2]

AF = Hull Area factor from Table 3

PPF_s = Peak Pressure Factor from Table 2

P_{avg} = Average pressure within load patch according to Equation 15 [MPa]

LH_s = effective load height with respect to shear response of web frame [m]

$= min(b, (S - s))$

b = Height of design ice load patch from Equation 12 or 14 [m]

S = Design span of considered web frame with regard to shear response [m]

s = Spacing of longitudinal frames [m]

LL_s = effective load length with respect to shear response of web frame [m]

$$= w\frac{\left(l-\frac{w}{4}\right)}{l}$$

w = Width of design load patch from Equation 11 or 13 [m], but is not to be taken larger than 2 *l*

l = Spacing of web frames [m], measured along the shell plate

K_s = shear force factor [-]

$=\frac{S-h}{S}$, minimum 0.55

h $=\frac{LH_s+s}{2}$ [m], if one of the web frame supports lies within considered hull area

$=\frac{LH_s}{2}+h_1$ [m], if both of the web frame supports lies outside considered hull area

h_1 = Smallest distance from web frame support to hull area boundary

η = usage factor = 1.0

φ_w = smallest angle between shell plate and the web of the web frame, measured at middle of span [deg]. The angle φ_w may be taken as 90 degrees provided the smallest angle is not less than 75 degrees.

In the proposal presented above, it is assumed that a portion of the design patch, as defined in the Rules by the height b and length w, is transferred directly to the structure supporting the web frame (e.g. a deck) and/or carried by the longitudinal local frames to the adjacent web frames. The magnitude of the force transferred to adjacent structure depends on the size of the patch load relative to the distance to the adjacent members. The effective patch area of the load carried by the considered web frame is defined by the height LH_s and length LL_s.

The effective patch load height LH_s is generally taken as the general height b, as defined in the Rules, but limited by the span of the web frame.

The load length LLs is based on the assumption that part of the loading is carried by the longitudinals directly to the adjacent web frames. If the patch length w is equal to the web frame spacing S, it is assumed that 75% is taken by the considered frame, and the remaining 25% is taken by the adjacent frames. If the patch length w is more than twice the web frame spacing S, the effective patch length is limited by the web frame spacing.

For the shear factor Ks, it is assumed that the edge of the patch load is placed a distance equal to the frame spacing from one of the supports. The shear factor represents the portion of the load taken as shear in the most loaded support assuming that both supports have the same boundary conditions. A correction is included to cover the case where the web frame spans over the whole considered hull area, i.e. it is assumed that the patch load is placed at the boundary of the hull area.

The formula assumes shear yield over the whole effective height of the web plate.

It is suggested that the general usage factor is taken as 1.0.

Section modulus requirements for simple web frames supporting longitudinal local frames

The general design load case for evaluating the bending strength of a simple web frame supporting longitudinal local frames is suggested to be as shown in Figure 2.

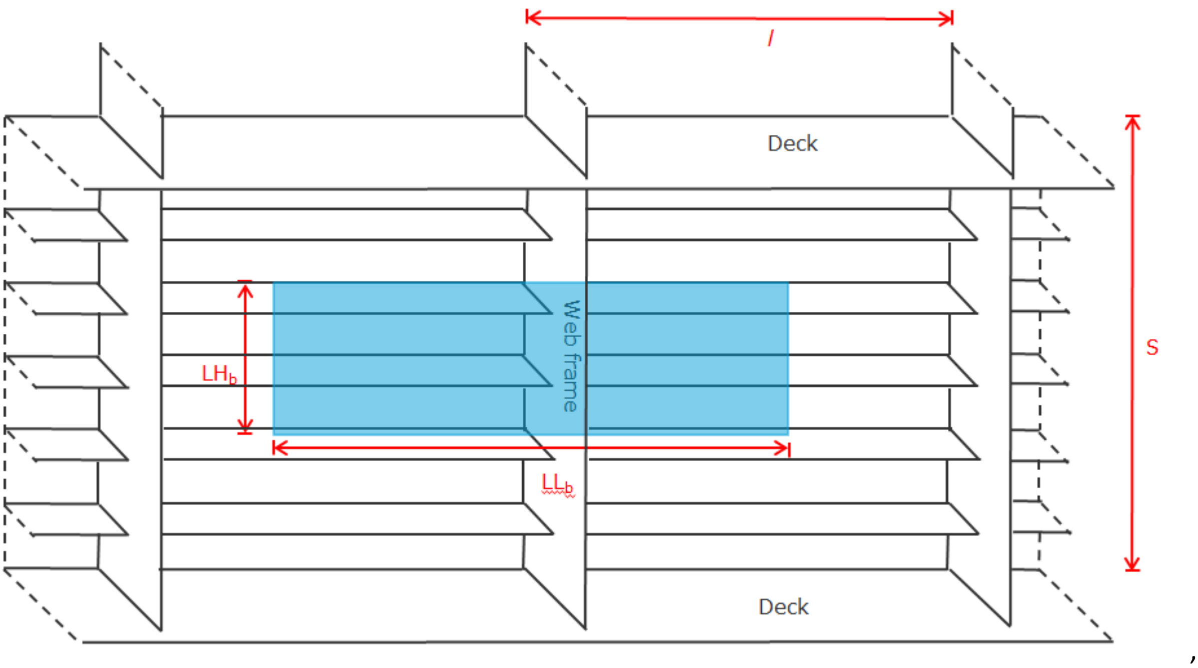

Figure 2 – Proposed design condition for the section modulus requirement for simple web frames supporting longitudinal local frames

The net elastic section modulus of the web frame is suggested to be as follows:

$$Z_{wf} = \frac{100^3 (AF\ PPF_s\ P_{avg})\ LH_b\ LL_b\ \left(S - \frac{LH_b}{2}\right)}{4\ \sigma_F\ \ \sin\varphi_w\ \ k_f}$$

A_{wf} = Net elastic section modulus of web frame supporting longitudinal local frames [cm^3]

LH_b = effective load height with respect to bending response of web frame [m]

$= min(b, S)$

LL_b = effective load length with respect to bending response of web frame [m]

$= w \frac{\left(l - \frac{w}{4}\right)}{l}$

k_f = end fixity parameter for the web frame [-]

= 2.0 when both end supports are fixed

= 1.5 when one end support is fixed

= 1.0 when both end supports are simply supported

The section modulus requirement is derived based on a semi-plastic approach, where the plastic moment obtained from a simple plastic 3-hinge mechanism (in case of restrained ends) is used as basis for determining the capacity of the member. The capacity is however evaluated against the elastic section modulus of the profile. Using the plastic bending moment as basis for the capacity assessment will for the clamped end case increase the defined capacity by 33% compared with a pure elastic approach based on first yield.

Shear area requirement for simple web frames supporting load carrying stringers

The general design load case for evaluating the shear strength of a simple web frame supporting load carrying stringers is suggested to be as shown in Figure 3.

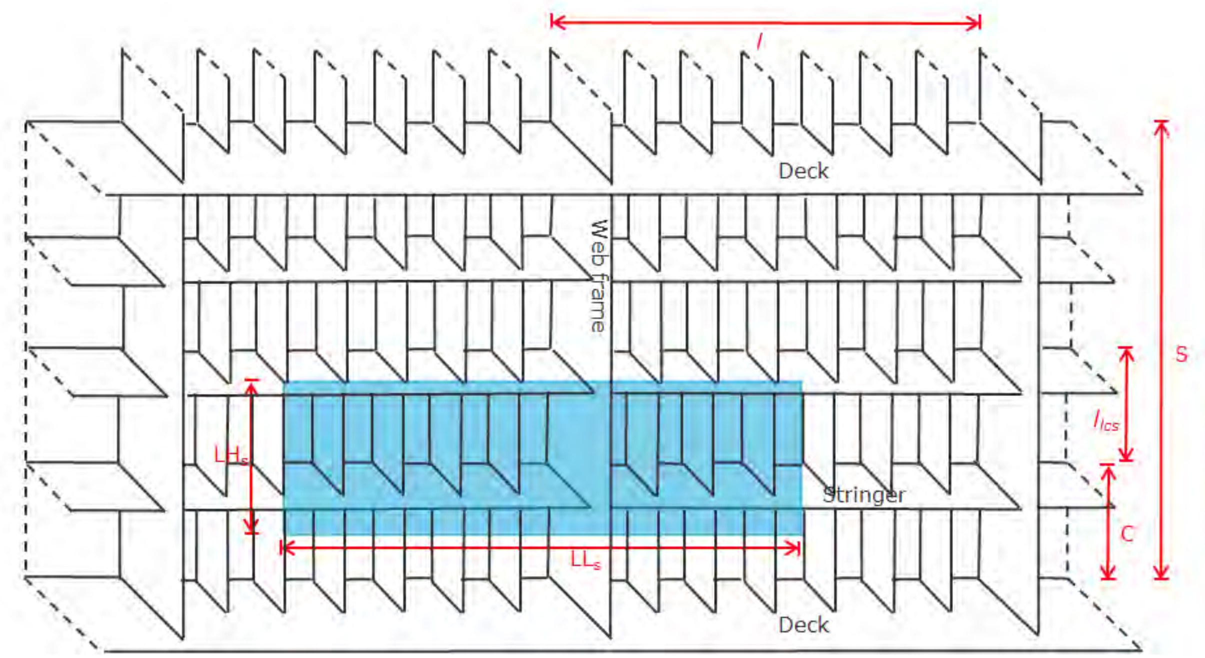

Figure 3 – Proposed design condition for the shear area requirement for simple web frames supporting load carrying stringers

The effective shear area requirement for this condition is suggested to be as follows:

$$A_{wf} = \frac{100^2 \left(AF\ PPF_s\ P_{avg}\right)\ LL_s\ LH_s\ K_s}{0.577\ \sigma_F\ \ \eta \sin \varphi_w}$$

A_{wf} = Effective net web area of web frame supporting load carrying stringers [cm^2]

LH_s = load height with respect to shear response of web frame [m]

$$= b\left(\frac{l - \frac{b}{4}}{l}\right)$$

LL_s = load length with respect to shear response of web frame [m]

$$= w\,\frac{\left(l_{LCS} - \frac{w}{4}\right)}{l_{LCS}}$$

l = Spacing of web frames [m], measured along the shell plate

l_{LCS} = Distance to adjacent load carrying stringer or longitudinal support member, as applicable, [m], measured along the shell plate

K_s = shear force factor [-]

$$= \frac{S - C}{S}$$

η = usage factor

φ_w = smallest angle between shell plate and the web of the web frame

In the proposal presented above, it is assumed that the design patch is located at a stringer level, and is acting as a point load on the web frame. As for the requirement for web frames supporting longitudinal local frames, a portion of the design load is assumed carried by the adjacent members, and hence the design patch on the web frame is defined by the effective height LH_s and length LL_s.

Similarly is the shear factor Ks taking into account the position of the considered load carrying stringer relative to the web frame supports.

Depending on the framing arrangement, several load carrying stringers along the web frame span should be considered.

It is suggested that the general usage factor is taken as 1.0

Section modulus requirement for simple web frames supporting load carrying stringers

The general design load case for evaluating the bending strength of a simple web frame supporting load carrying stringers is considered to be the same as for the shear strength requirement, see Figure 3.

The net elastic section modulus of the web frame is suggested to be as follows:

$$Z_{wf} = \frac{100^3\left(AF\ PPF_s\ P_{avg}\right) LL_s\ LH_s\ C\ (S - C)}{2\ \sigma_F\ \sin\varphi_w\ k_f\ S}$$

LH_b = load height with respect to bending response of web frame [m]

$$= b\left(\frac{l - \frac{b}{4}}{l}\right)$$

LL_b = load length with respect to bending response of web frame [m]

$$= w\frac{\left(l_{LCS} - \frac{w}{4}\right)}{l_{LCS}}$$

C = Smallest distance from considered load carrying stringer to web frame support [m]

kf = end fixity parameter for the web frame [-]

= 2.0 when both end supports are fixed

= 1.5 when one end support is fixed

= 1.0 when both end supports are simply supported

As for the shear area requirement, the section modulus requirement assumes that the patch load is represented as a point load at the stringer location. The same effective patch load is considered as well. The formulation is based on the plastic capacity of the member, but evaluated against the elastic section modulus.

Shear area requirement for load carrying stringers

The general design load case for evaluating the shear strength of a simple load carrying stringer is suggested to be as shown in Figure 4.

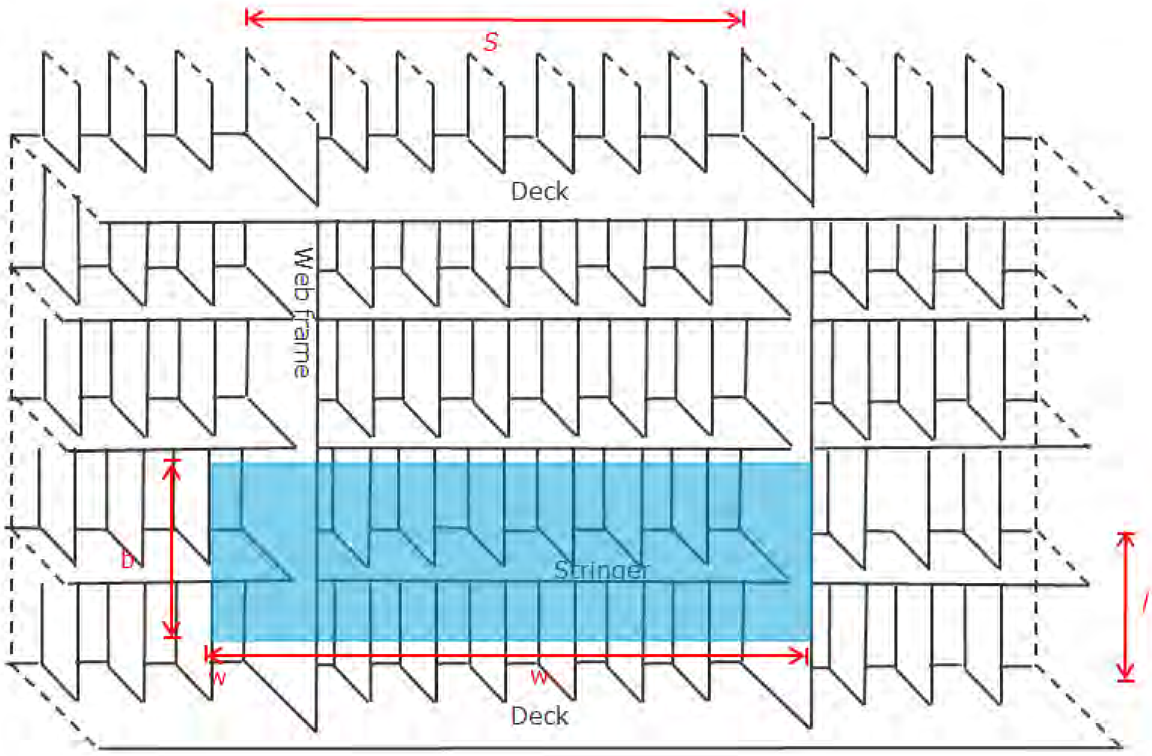

Figure 4 – Proposed design condition for the shear area requirement for load carrying stringers

The effective shear area requirement for this condition is suggested to be as follows:

$$A_{lcs} = \frac{100^2 (AF\ PPF_s\ P_{avg})\ LH_s\ LL_s\ K_s}{0.577\ \sigma_F\ \eta\ \sin\varphi_w}$$

LH_s = effective load height with respect to shear response of stringer [m]

$$= b\frac{\left(l-\frac{b}{4}\right)}{l}$$

LL_s = effective load length with respect to shear response of stringer [m]

$$= min(w, (S-s))$$

K_s = shear force factor [-]

= 0.5 if w ≥ S

$$= \frac{S-\frac{LL_s+s}{2}}{S}$$

η = usage factor = 1.0

φ_w = smallest angle between shell plate and the web of the web frame

Section modulus requirement for simple load carrying stringers

The general design load case for evaluating the bending strength of a load carrying stringer is considered to be the same as for the shear strength requirement, see Figure 4.

The net elastic section modulus of the load carrying stringer is suggested to be as follows:

$$Z_{lcs} = \frac{100^3 (AF\ PPF_s\ P_{avg})\ LH_b\ LL_b\ \left(S - \frac{w}{2}\right)}{4\ \sigma_F\ \ \sin\varphi_w\ \ k_f}$$

LH_b = effective load height with respect to bending response of stringer [m]

$= b\frac{\left(l-\frac{b}{4}\right)}{l}$

LL_b = effective load length with respect to bending response of web frame [m]

$= min(w, S)$

k_f = end fixity parameter for load carrying stringer

= 2.0 when both end supports are fixed

= 1.5 when one end support is fixed

= 1.0 when both en d supports are simply supported

φ_w = smallest angle between shell plate and the web of the web frame

Appendix B

Derivation of the oblique collision force with a vertical bows

The force is found by equating the normal kinetic energy with the ice crushing energy,

$$KE_n = E_{crush} \quad \text{(a1)}$$

The crushing energy is found by integrating the normal force over the penetration depth

$$E_{crush} = \int_0^{\delta} F_n\,(\delta) d\delta \quad \text{(a2)}$$

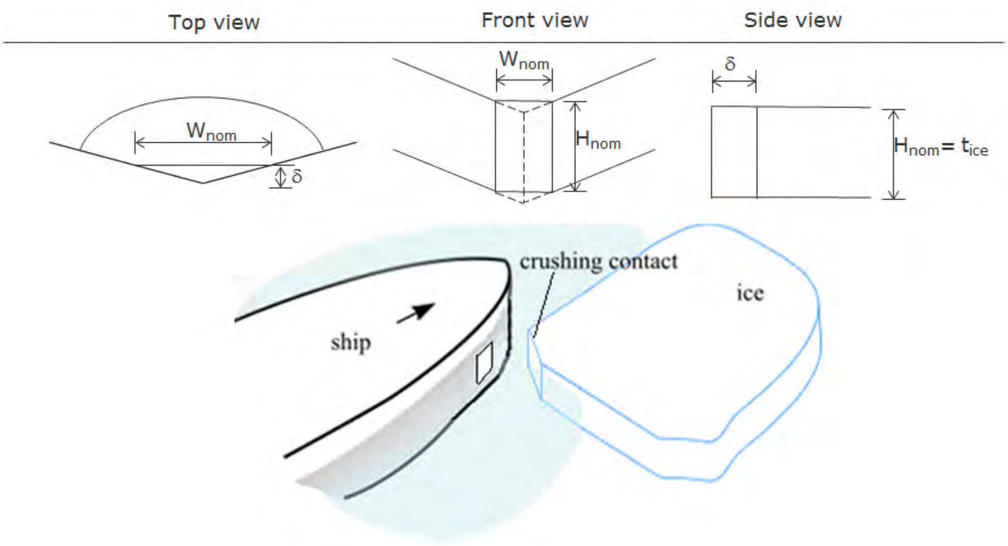
The normal kinetic energy combines the normal velocity with the effective mass at the collision point

$$KE_n = \frac{1}{2} M_e \cdot V_n^2 \quad \text{(a3)}$$

Combining the two terms gives

$$\frac{1}{2} M_e \cdot V_n^2 = \int_0^{\delta_m} F_n\,(\delta) d\delta \quad \text{(a4)}$$

The ice penetration geometry together with the pressure-area relationship is the basis of finding the force. The nominal area is found for a penetration δ



The nominal contact area is

$$A = W_{nom} \cdot H_{nom} \quad \text{(a5)}$$

The width of the W_{nom} of the nominal contact area can be determined by the nominal penetration depth δ and the ice edge angle ϕ.

$$tan\frac{\varphi}{2} = \frac{W_{nom}}{2\delta}$$

$$W_{nom} = 2\delta \cdot tan\tfrac{\varphi}{2} \quad \text{(a6)}$$

The height H_{nom} of the nominal contact area is fixed by the design ice thickness for each polar class

$$H_{nom} = h_{ice} \quad \text{(a7)}$$

Hence the area is

$$A = W_{nom} \cdot H_{nom} = 2h_{ice}\delta \cdot tan\tfrac{\varphi}{2} \quad \text{(a8)}$$

The average pressure is found from the pressure area relationship

$$P = P_0 \cdot A^{ex} \quad \text{(a9)}$$

The nominal force is

$$F_n(\delta) = P \cdot A = P_0 \cdot A^{1+ex} \quad \text{(a10)}$$

Substituting the expression for area (4) gives

$$F_n(\delta) = P_0\left(2h_{ice}\delta \cdot tan\left(\tfrac{\varphi}{2}\right)\right)^{1+ex} \quad \text{(a11)}$$

$$F_n(\delta) = C \cdot P_0 \cdot \delta^{1+ex} \cdot h^{1+ex} \quad \text{(a12)}$$

where we collect known quantities into the factor C

$$C = \left(2 \cdot tan\left(\tfrac{\varphi}{2}\right)\right)^{1+ex} \quad \text{(a13)}$$

We can now solve the energy balance equation ((a12) into (a4)) to find the maximum penetration

$$\tfrac{1}{2}M_e \cdot V_n^2 = C \cdot P_0 \cdot h^{1+ex} \cdot \int_0^{\delta_m} \delta^{1+ex}\, d\delta \quad \text{(a14)}$$

Accordingly we can extract the maximum penetration

$$\tfrac{1}{2}M_e \cdot V_n^2 = C \cdot P_0 \cdot h^{1+ex} \cdot \Big|_0^{\delta_m} \tfrac{\delta^{2+ex}}{2+ex}$$

$$\tfrac{1}{2}M_e \cdot V_n^2 = C \cdot P_0 \cdot h^{1+ex} \cdot \tfrac{\delta_m^{2+ex}}{2+ex}$$

$$\delta_m = \left(\frac{(2+ex)\cdot\frac{1}{2}M_e\cdot V_n^2}{C\cdot P_0\cdot h^{1+ex}}\right)^{\frac{1}{2+ex}} \quad \text{(a15)}$$

This is substituted into the expression for force (a12), to give

$$F_n = C \cdot P_0 \cdot h^{1+ex} \cdot \left(\frac{(2+ex) \cdot \frac{1}{2} M_e \cdot V_n^2}{C \cdot P_0 \cdot h^{1+ex}} \right)^{\frac{1+ex}{2+ex}} \quad \text{(a16)}$$

This can be substituted to give

$$F_n = C^{\frac{1}{2+ex}} \cdot P_0^{\frac{1}{2+ex}} \cdot \left((2+ex) \cdot \frac{1}{2} M_e \cdot V_n^2 \cdot h_{ice} \right)^{\frac{1+ex}{2+ex}} \quad \text{(a17)}$$

Substituting for M_e and V_n, we get

$$F_n = C^{\frac{1}{2+ex}} \cdot P_0^{\frac{1}{2+ex}} \cdot \left(\frac{l^2}{2C_0} \right)^{\frac{1+ex}{2+ex}} \cdot \left((2+ex) \cdot M_{ship} \cdot V_{ship}^2 \cdot h_{ice} \right)^{\frac{1+ex}{2+ex}} \quad \text{(a18)}$$

We can collect all shape related terms (comprising C and the terms with C_0 and *l*) into a simple terms fa,

$$f_a = (2+ex)^{\frac{1+ex}{2+ex}} \cdot \left(2 \tan \frac{\varphi}{2} \right)^{\frac{1+ex}{2+ex}} \cdot \left(\frac{l^2}{2C_0} \right)^{\frac{1+ex}{2+ex}} \quad \text{(a19)}$$

With fa, we can write the force equation as

$$F_n = f_a \cdot P_0^{\frac{1}{2+ex}} \cdot V_{ship}{}^{\frac{2+2\cdot ex}{2+ex}} \cdot M_{ship}{}^{\frac{1+ex}{2+ex}} \cdot h_{ice}{}^{\frac{1+ex}{2+ex}} \quad \text{(a20)}$$

Which for ex=-0.1 gives

$$F_n = f_a \cdot P_0^{0.526} \cdot V_{ship}{}^{0.947} \cdot M_{ship}{}^{0.474} \cdot h_{ice}{}^{0.474} \quad \text{(a21)}$$

This value of fa collects all form related terms (and constants) into a single fator for crushing. Equation (a21) represents only the crushing force. However the flexural design force need not be included in the design force of a blunt bow.

The ice load patch is found from Fn. Using (a20) and (a10), we can solve for the nominal contact area,

$$A = \left(\frac{F_n}{P_o} \right)^{\frac{1}{1+ex}} \quad \text{(a22)}$$

Unlike the case for an icebreaking bow form, there is no need to introduce a change in load patch shape (it is already rectangular). Accordingly, the aspect ratio is

$$AR = \frac{W_{nom}}{H_{nom}} = \frac{W_{nom}}{h_{ice}} \quad \text{(a23)}$$

$$A = h_{ice}^2 \cdot AR \quad \text{(a24)}$$

Therefore, we can write

$$H_{nom} = h_{ice} \quad \text{(a25)}$$

And from (a8) and (a22)

$$W_{nom} = \frac{\left(\frac{F_n}{P_o}\right)^{\frac{1}{1+ex}}}{h_{ice}} \quad \text{(a26)}$$

At this point we introduce a reduction in the size of the load patch (force is unchanged, so design pressure rises, correspondingly). This reduction is conservative and is done to account for the typical concentration of force that takes place as ice edges spall off. The rule (or design) patch length is

$$w = W_{nom}^{wex} = \left(\frac{F_n}{P_o}\right)^{\frac{wex}{1+ex}} \cdot h_{ice}^{-wex} \quad \text{(a27)}$$

Where with wex = 0.7, we have

$$w = F_n^{0.778} \cdot P_o^{-0.778} \cdot h_{ice}^{-0.7} \quad \text{(a28)}$$

The design load height is

$$b = \frac{w}{AR} \quad \text{(a29)}$$

Using (a23) and (a26)

$$b = F_n^{-0.333} \cdot P_o^{0.333} \cdot h_{ice}^{1.3} \quad \text{(a30)}$$

The nominal and design load patches have the same aspect ratio. The load quantities used in the scantling calculations include the line load,

$$Q = \frac{F_n}{w} \quad \text{(a31)}$$

And the pressure

$$P = \frac{Q}{b} \quad \text{(a32)}$$

Solving for Q and P

$$Q = \frac{F_n}{w} = \frac{F_n}{F_n^{0.778} \cdot P_o^{-0.778} \cdot h_{ice}^{-0.7}} \quad \text{(a33)}$$

$$P = \frac{Q}{b} = \frac{F_n^{0.222} \cdot P_o^{0778} \cdot h_{ice}^{0.7}}{F_n^{-0.333} \cdot P_o^{0.333} \cdot h_{ice}^{1.3}} \quad \text{(a34)}$$

For the rule formula

$$Q = F_n^{0.222} \cdot P_o^{0.778} \cdot h_{ice}^{0.7} \quad \text{(a35)}$$

$$P = F_n^{0.555} \cdot P_o^{0.445} \cdot h_{ice}^{-0.6} \quad \text{(a36)}$$

The design force given in (a21) may be expressed as follows in terms of class-dependent ship and ice class factors

$$F_n = f_a \cdot CF_{CV} \cdot \Delta_{ship}{}^{0.474}$$

Where

$$CF_{CV} = P_0^{0.526} \cdot V_{ship}{}^{0.947} \cdot h_{ice}{}^{0.474}$$

The class factor CF_{CV} may be given as follows for the different ice classes:

Ice class	CF_{CV}
PC6	3.43
PC7	2.60

Shape factor

From (a19) the shape factor can be written as

$$f_a = \left(1.90 \cdot \frac{l^2}{C_0} \cdot \tan\frac{\varphi}{2}\right)^{0.474}$$

Due to the complexity of Co, the following simplified equation is suggested

$$f_a = \frac{\alpha}{30}$$

UR I3 "Machinery Requirements for Polar Class Ships"

Summary

In Corr.1, Identification of typographical errors with formulae, parameters and paragraph numbering where clarifications were needed.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Corr.1 (Dec 2024)	14 December 2024	-
Rev.2 (Jan 2023)	20 January 2023	1 July 2024
Corr.1 (Oct 2007)	Oct 2007	-
Rev.1 (Jan 2007)	Jan 2007	1 March 2008
New (Aug 2006)	Aug 2006	1 July 2007

- **Corr.1 (Dec 2024)**

1 Origin of Change:

☑ Suggestion by IACS member

2 Main Reason for Change:

Identification of typographical errors with formulae, parameters and paragraph numbering where clarifications were needed.

Update of UR I3 (Rev. 2) was noted to have typographical errors with formulae, parameters and paragraph numbering, therefore a review was undertaken to address this as well as taking an opportunity to correct any further observed amendments from panel members.

3 Surveyability review of UR and Auditability review of PR

Not applicable.

4 Human Element issues assessment

Not applicable.

5 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None.

6 History of Decisions Made:

Members review of UR I3 (Rev. 2) had identified locations for attention as follows;

- Paragraph 4.1 (Table 1)
- Paragraph 5.3.9 (Equation 17)
- Paragraph 5.3.9 (Equation 18)
- Paragraph 5.6.3.2 (Equation 34)
- Paragraph 6.3.3.2 (Equation 47)
- Paragraph 6.3.3.2 (Table 14)
- Paragraph 6.4.1
- Paragraph 6.4.3 (Equation 56)
- Paragraph 6.5.4.5
- Paragraph 6.5.4.7

7 Other Resolutions Changes:

None.

8 Any hinderance to MASS, including any other new technologies:

None.

9 Dates:

Original Proposal	: 15 February 2024	(Ref: PM24004_IMa)
Panel Approval	: 28 November 2024	(Ref:PM24004_IMg)
GPG Approval	: 14 December 2024	(Ref: 11166_IGo)

- **Rev.2 (Jan 2023)**

1 Origin of Change:

☑ Suggestion by IACS member

2 Main Reason for Change:

− General Update of this UR

Rev.1 of UR I3 (including Corr.1) contained a number of reserved paragraphs and two different versions of blade fatigue assessment methods. This prevents a clear and unambiguous interpretation of I3, yielding different results for the same case. This was resolved in a first step.

The main technical reason for the additional review and amendment was an insufficient validation of rule requirements/calculations and reserved paragraphs, which contradict a smooth application of I3. Additionally, a need for simple formula and some amendments resulting from an Industry Hearing in 2007 was noticed.

- Introduction of Requirements for Icebreaker Vessels

  It was found that UR I1 and I2 contained requirements for icebreaker vessels, whereas UR I3 did not. In order to obtain a complete rule set for icebreaker vessels it was decided that the UR I3 draft would be extended to also include icebreaker requirements.

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

- General Update of this

  UR None.

- Introduction of Requirements for Icebreaker

  Vessels None.

4 History of Decisions Made:

- General Update of this UR
  Members' practices and experiences on Polar/Ice Class ships have been reflected, taking into account inputs from two experts from VTT as representative of TRAFI and the result of Industry Hearing (held in 2007 and 2014).

  a) Introduction of Requirements for Icebreaker Vessels The following sub-

     tasks have been addressed.

  b) Re-analyse existing full-scale measurements (as far as

     available/accessible) and derive/adapt load formulae for Icebreakers,

     duly covering off-design load cases as well.

     It was quickly discovered that measurement results from icebreakers are no longer available for analysis. As a consequence of this, estimation of load levels has been based on information given in earlier TB documents,

  c) Review icebreaker requirements of IACS members and other sources, TB notes and early I3 proposals in order to find ice breaker equivalent load formulae.

     Earlier TB notes and individual Societies' class rules have been looked into and used in the PT's work. Earlier TB notes formed the basis for load increase for icebreakers, as measurements used to obtain blade loads for merchant vessels originally were done on icebreakers, and then scaled down to match merchant vessel load levels.

  d) Further develop UR I3 to include paragraphs for Icebreaker load

calculation, additional load cases and further requirements, specific for Icebreakers.
Based on earlier TB notes, blade loads for icebreakers have been included. Further, the amount of load cycles for fatigue evaluation has been increased, and the wording on steering systems has been revised. Details can be found in TB notes in Annex 1 to this document.

5 Other Resolutions Changes:

- General Update of this

  UR None.

- Introduction of Requirements for Icebreaker

  Vessels None.

6 Any hinderance to MASS, including any other new technologies:

None.

IACS Unified Requirements for Polar Ships

Background Notes to

"Propeller Ice Interaction Loads"

by Robin Browne and Lasse Norhamo

PROPELLER ICE INTERACTION LOADS

1 SCOPE AND OBJECTIVES

The propeller design ice loads given in I3(Section I3.4 of the Machinery Requirements for Polar Ship), are the result of extensive research and development by circumpolar nations over the past 25 years. The R&D has included analysis of service history of propeller damages, propeller and shaft load measurements on full scale trials, laboratory investigations and numerical simulation of propeller and ice interaction.

The decision was taken at the start of the project that the most modern ice interaction models and information would be used in the process of developing new regulations and to be consistent with the FMA requirements

The manner, in which the Requirements have been developed from this material, and their detailed explanation, is given below in Section 3.

2. BACKGROUND

The mid 1970's to late 1980's was a time of great activity in the Arctic Marine field in North America, Russia and Scandinavia, with a large number of new buildings of icebreakers and ice class cargo vessels and supply vessels. These supported the offshore oil drilling activity and mineral transport in the Canadian Arctic, transportation on the Russian Northern Sea Route and in the Baltic, and U.S. scientific and strategic interests in Antarctica and Alaska. Arctic Marine R&D, including studies of ice loading on propellers and machinery systems, grew in step with this commercial activity.

In North America, machinery ice loading studies generally took the form of data acquisition, and subsequent analysis, on full scale trials of the many new builds. Information recorded was generally shaft thrust and torque relative to ship and propeller operating conditions and the encountered ice conditions.

In Scandinavia, principally Finland, the objective was a more fundamental understanding of propeller ice loading, based on detailed trials of a few, generally small vessels. Blade ice loads were measured directly, underwater video was added to the recordings, and some long term trials were conducted. The blade load measurement technology was also transferred to Canada and Russia for two trials on the Canadian Arctic Supply Vessel "Robert Lemeur" and Russian Arctic Icebreaker "Arctika".

Russia carried out some shaft and blade load measurements. Moreover, with by far the largest Arctic fleet, Russia benefited from the statistical analysis of machinery performance and damages.

During this period, it became increasingly evident that existing machinery protection regulations were not adequate to the task, and had in many areas become irrelevant. For example, blade scantlings in the Baltic and Canadian rules were dependent upon a design ice torque, rather than a direct expression of the out-of-plane blade bending moment, which can cause major blade deformation and breakage.

Experienced designers and manufacturers were using their own improved understanding and practices, especially with regard to propeller design.

In Russia, the detailed analysis of blade failures on high ice class icebreakers led to greatly improved designs in stainless steel, with emphasis on material properties and quality of the castings.

At the end of the 1980's, both the Canadian and Baltic marine authorities had decided to update their respective machinery protection regulations. In order to share expertise and resources, a joint research project arrangement (JRPA#6) on the important matter of blade design ice loads, was entered into between Canada and Finland.

Finland would develop a numerical simulation model of propeller and ice interaction during the ice milling operation, which would incorporate a Finnish model for contact load components and a Canadian model for non-contact load components. A number of associated research programmes provided additional information, such as ice properties at interaction velocities, and analysis of available full scale data.

The ice block impact condition on the back of a blade, such as occurs when a propeller is dragged through ice, can generate extreme loads. This condition is avoided by masters as imprudent operation, and is not a design condition.

The lack of directly measured blade loads on a large propeller in Arctic conditions also gave impetus to a joint Canadian-American project for propeller ice load trials on USCGC “Polar Star” in the early 1990’s.

The JRPA#6 three-dimensional numerical simulation model was developed by the mid-1990’s, and was used to determine parametric influences upon propeller and ice interaction loads. These loads applied to open propellers and included backward blade bending moment, blade spindle torque, propeller torque and shaft thrust.

Included in the load formulae was the parameter of blade attack angle. The exact value of this parameter is not known at the time of maximum load and it was therefore necessary to make a final calibration of the formulae using all available full scale data. A design interaction blade attack angle of + 4 degrees was adopted.

The dependencies in the load formulae, with some modifications based on Russian R&D results, find their way into the load formulae in the IACS unified design requirements.

The numerical simulation model did not address the ducted propeller directly, nor maximum forward blade loads. However, it was possible to determine working formulations based on available full scale data.

3. Points of Discussion

I3.4.3 Design Ice Loads for Open Propeller

I3.4.3.1 Maximum Backward Blade Force

The formula for the maximum backward blade ice force on a propeller blade, derived from the JRPA#6 numerical simulation model, is given in Reference 8 as:

$$F_{bl} = -93.0 \times [\, \sigma \times EAR/Z \,]^{0.287} \times [\, H_i/D \,]^{1.36} \times e^{(-0.183\alpha)} \times (nD)^{0.712} \times D^{2.02} \quad \text{kN}$$

where:

D	=	propeller diameter in metres
Z	=	number of blades
EAR	=	expanded blade area ratio

n	=	propeller rotational speed rps
H_i	=	ice thickness in metres
α	=	apparent angle of attack
	=	ϕ- arctan ($V/(0.7\pi nD)$)
ϕ	=	pitch angle at 0.7R
σ	=	uniaxial unconfined compressive strength of ice in MPa

The blade force does not increase indefinitely, with increase in the ratio of ice thickness/propeller diameter. This is due to two factors:

- As ice thickness and block size and inertia increase, the interaction moves towards the infinite ice block case, and the loads move asymptotically to a limiting value.
- As ice thickness increases to be greater than blade length, the interaction geometry becomes more asymmetric, and the ice block tends to rotate on contact away from the blade, thereby releasing or limiting the load.

It was found that this limiting effect is as follows:

when $H_i/D > 0.65$, the value of $H_i/D = 0.65$

This blade force is known from full scale observations and measurements [10, 12,13, 16] and laboratory tests [4], to be distributed radially in a strip close to the blade leading edge, with an equivalent point location for blade root stress calculation at 0.8R and approximately 0.2 of chord back from the leading edge.

This load formula was modified for use as a Regulatory model by the substitution of:

- H_{ice} for H_i. Each PC ice class has a design ice thickness, as given in the Regulation Table 3.1. These values are used for the appropriate class in the formula calculations.
- A coefficient S_{ice} to account for the ice strength influence. The ice strength influence is an increase of approximately 20% in ice load for a doubling of ice strength, as would be the case in going from first year to multi-year ice. Full scale data in [15] support this. In Table 3.2, S_{ice} is given as 1.2 for ice classes which may interact with multi-year ice. For ice classes PC5 to PC2 S_{ice} has been selected as an intermediate value of 1.1 in order to adjust backward ice force F_{bl} to full scale validation data.
- The use of a single decimal place in the exponent values for simplicity. Higher accuracy cannot be justified.
- The adoption of an angle of attack of + 4 degrees. The angle of attack at the time of maximum backward blade load is known to be small, but the exact value is not known. Its practical measurement is beyond current possibility. The value of + 4 degrees was selected as the value which brings the formula and full scale data into agreement. For fixed pitch propellers, maximum backward ice load does not occur at "heavy ice condition ship speeds", because propeller speeds will be low, but in a condition of lower ice concentration/thickness where ship speed and propeller speed are higher. In this situation the propeller can hit a large ice block at a low attack angle and experience a large load. Therefore 0,85 of nominal speed has been selected for practical use.

As a result of the above measures, the formulae for maximum backward blade force in the regulation section I3.4.3.1 become:

$$D_{limit} = 0.85 \times (H_{ice})^{1.4}$$

When $D < D_{limit}$

$$F_b = -27 \times S_{ice} \times (nD)^{0.7} \times [EAR/Z]^{0.3} \times D^2 \quad \text{kN}$$

When $D > D_{limit}$

$$F_b = -23 \times S_{ice} \times (nD)^{0.7} \times [EAR/Z]^{0.3} \times (H_{ice})^{1.4} \times D \quad \text{kN}$$

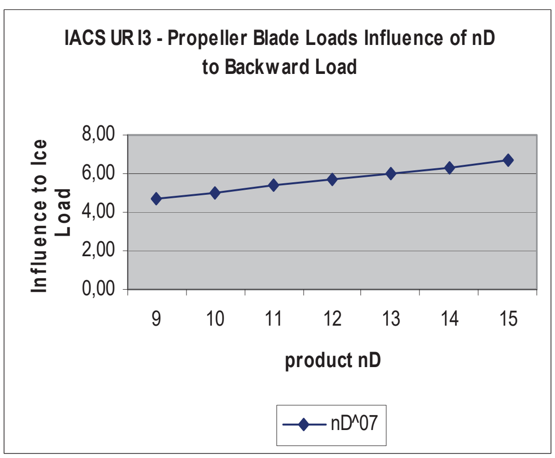
Ice Class	H_{ice} [m]	S_{ice} [-]	S_{qice} [-]
PC1	4.0	1.2	1.15
PC2	3.5	1.1	1.15
PC3	3.0	1.1	1.15
PC4	2.5	1.1	1.15
PC5	2.0	1.1	1.15
PC6	1.75	1	1
PC7	1.5	1	1

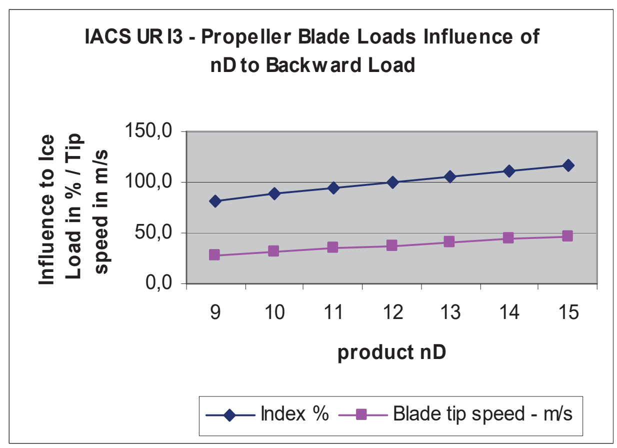
H_{ice} Ice thickness for machinery strength design

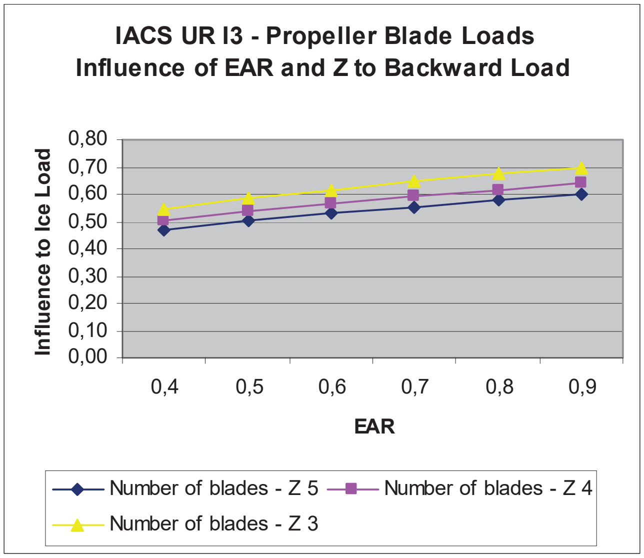
S_{ice} Ice strength index for blade ice force

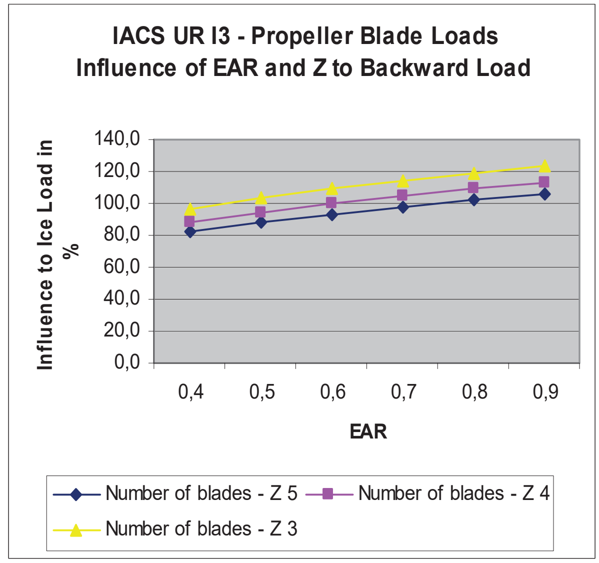
S_{qice} Ice strength index for blade ice torque

The most significant parameters are generally Ice Class, giving rise to H_{ice} and S_{ice}, and propeller diameter. The product nD normally varies little in practical designs (an upper limit normally exists for the avoidance of blade tip cavitation), and EAR/Z does not normally vary very much.



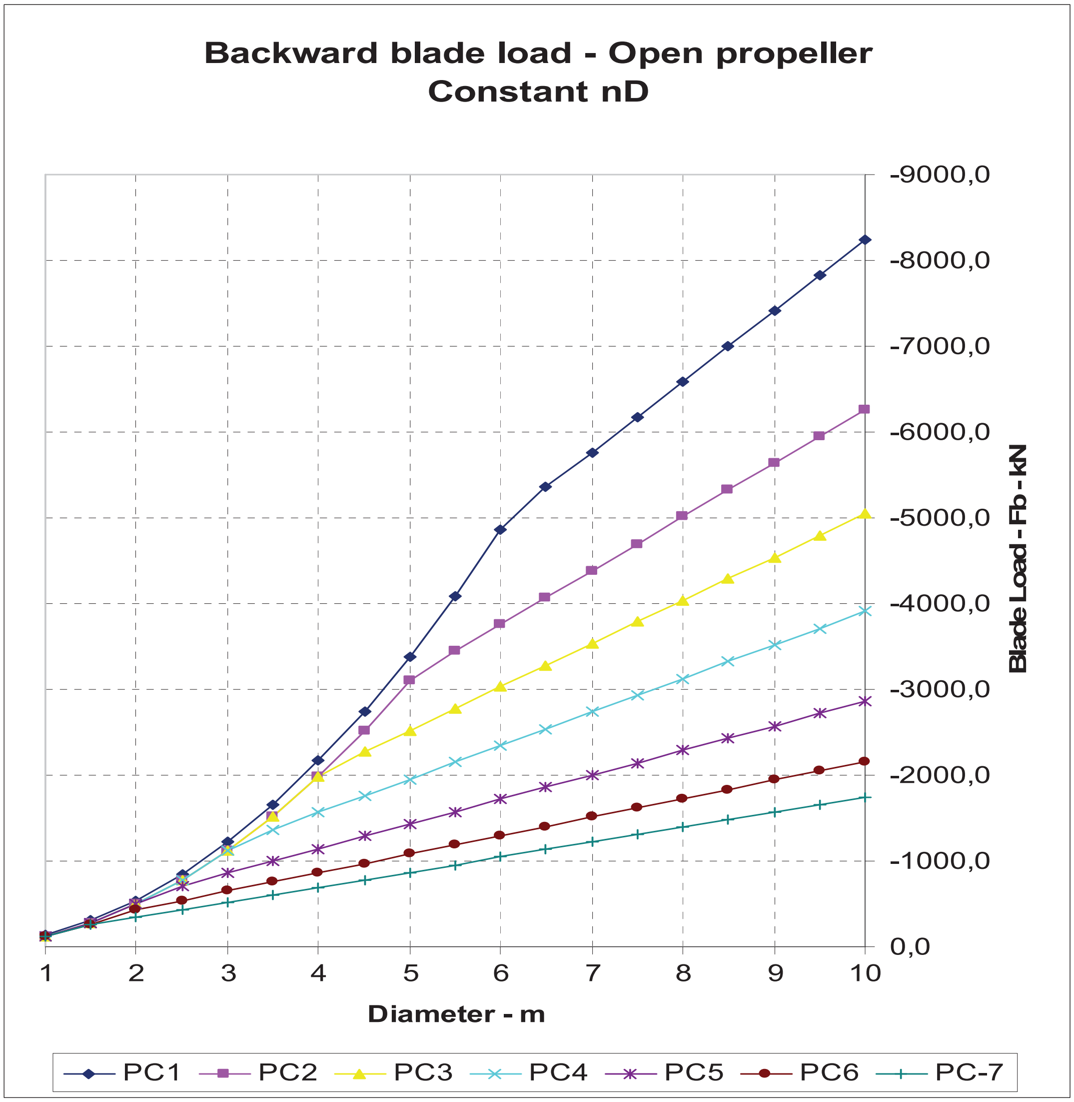






The above formulae show that for any given ice class, and accompanying design ice thickness, the design ice load for small propellers increases with the square of diameter, until D_{limit} is reached. Above D_{limit}, design ice load increases linearly with increase in diameter. Both statements are valid provided that nD is kept constant and EAR/Z is same.

The graphical presentation of the loads for PC1 to PC7, D = 1 to 8m, nD = 12, EAR = 0.7 and Z=4 is given below [16].

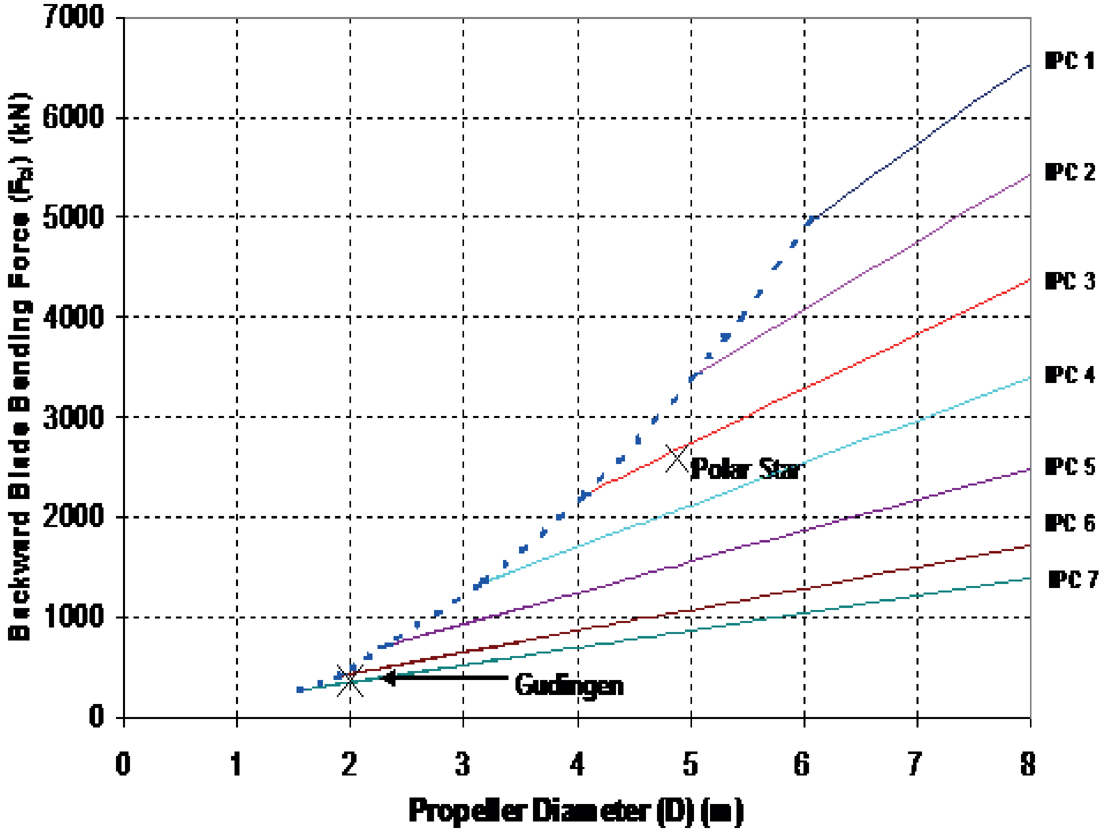


The maximum directly measured blade loads for the vessels "**Gudingen**" - PC7 equivalent (PC6 questioned) – and "**Polar Star**" – PC3 equivalent demonstrate the overall validity of the load model in the proper manner. These ships are plotted in the next diagram, which was drawn before final adjustment of constants (10% reduction) and new S_{ice} values (1.1 instead of 1.2) for PC2 to PC5 and is therefore presented in purpose of entirety. These adjustments were considered reasonable based on validations carried out and acknowledging that the PC1 ice class is the only one intended "year round operation in all Polar areas".

Shaft measured thrust loads on some icebreakers have also been corrected to propeller loads by taking shaft dynamics into account [15]. The resulting propeller loads, relative to propeller diameter and ice thickness are of the same order of magnitude as given in the above Regulatory Load Figure.

For blade scantlings design, the maximum backward blade load is to be applied as shown in the regulations Table 1, load case 1 for the full milling condition and Load case 2, the tip milling condition for skewed CP-propellers in particular. Although the blade load is not in practice of uniform intensity [4], this simplification over the specified area, has an equivalent effect.
Load case 5 in the same table is intended for blade trailing edge loading for reversible (rotational direction) propellers. This is developed based on observed ice damages (bent blade tips at trailing

edge side) and shall take care of skewed blade form. Thus there is no need for any limitation of skew angle.



I3.43.2 Maximum Forward Blade Force

The forward blade load on the open propeller is a non-contact load occurring due to the very close proximity of an ice block and propeller blade. These loads have been measured directly [9], but the exact mechanism of their generation and the shape of the load distribution on the blade are not fully understood. The formulae in regulation section I3.4.3.2, model the available full scale information.

D_{limit} = $2/[1-d/D] \times H_{ice}$ m

When $D<D_{limit}$

F_f = $250 \times [EAR/Z] \times D^2$ kN

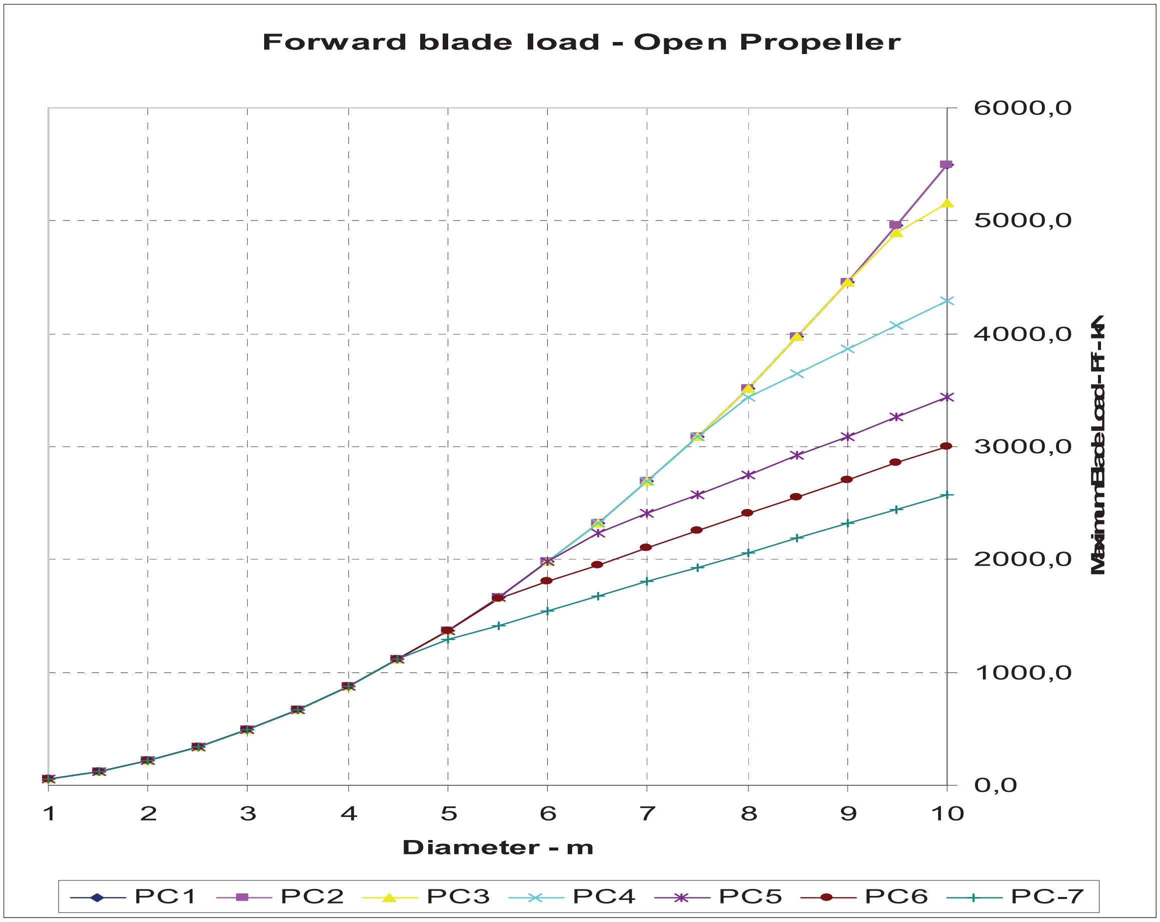
When D>Dlimit

F_f = $500 \times (1/[1-d/D]) \times H_{ice} \times [EAR/Z] \times D$ kN

At any given propeller diameter, the forward blade load increases with ice thickness, until ice thickness equals blade length and one whole blade at any time can be shielded by the ice block.

These loads are to be applied following the same scheme as for the full milling backward blade loads, except that the loads are applied to the face (pressure) side of the blade.

The graphical presentation of the loads for PC1 to PC7, D = 1 to 10m, d/D = 0.36, nD = 12, EAR = 0.7 and Z=4 is given below.



I3.4.3.4 Maximum Propeller Ice Torque

The formula for maximum propeller ice torque (ice torque or polar moment applied to the shaft by the propeller at the propeller location), derived from the JRPA#6 numerical simulation model, is given in Reference 8 as:

$$Q_{max} = 234 \times (1\text{-}d/D) \times \sigma^{0.195} \times (H_i/D)^{1.07} \times (-0.902 \times J^2 + J + 0.438)$$

$$\times (P/D)^{0.162} \times (t/D)^{0.605} \times (nD)^{0.173} \times D^{3.04} \quad \text{kNm}$$

Where:

J	=	V/nD
t/D	=	blade thickness/diameter ratio

When $H_i/D > 0.55$, H_i/D should be taken as 0.55

It is noted that for geometrically and dynamically similar interaction conditions, propeller ice torque varies with the cube of propeller diameter, as opposed to the square of propeller diameter for ice force in I3.4.3.1 and I3.4.3.2.

This load formula was modified for use as a Regulatory model by the substitution of:

- H_{ice} for H_i.
- A coefficient S_{qice} to account for the ice strength influence. The ice strength influence is an increase of approximately 15% in ice load for a doubling of ice strength, as would be the case in going from first year to multi-year ice. In Table 3.2, S_{qice} is given as 1.15 for ice classes which may interact with multi-year ice.
- The use of two decimal places in the exponent values for simplicity. Higher accuracy cannot be justified.
- The adoption of a J value of 0.5, which provides the maximum value for the J term expression in brackets.
- Pitch and blade thickness are taken at 0.7 radius in m. Pitch shall correspond to MCR at zero speed of ship. For CP propeller this can be taken as 70% of the design pitch at maximum ship speed in open water at maximum continuous rating of the engine.
- Rotational speed - n – shall be corresponding zero speed of ship

As a result of the above measures, the formulae for maximum propeller ice torque in the regulation section I3.4.3.4 become:

$$D_{limit} = 1.81 \times H_{ice}$$

When $D < D_{limit}$

$$Q_{max} = 105 \times (1-d/D) \times S_{qice} \times (P_{0,7}/D)^{0.16} \times (t_{0.7}/D)^{0.6} \times (nD)^{0.17} \times D^3 \quad \text{kNm}$$

When $D > D_{limit}$

$$Q_{max} = 202 \times (1-d/D) \times \underline{S_{qice}} \times H_{ice}^{1.1} \times (P_{0,7}/D)^{0.16} \times (t_{0.7}/D)^{0.6} \times (nD)^{0.17} \times D^{1.9} \text{ kNm}$$

Shaft measured ice torque loads on some icebreakers have also been corrected to propeller torques by taking shaft dynamics into account [15]. The resulting propeller torques, relative to propeller diameter and ice thickness are of the same order of magnitude as given in the above formulae.

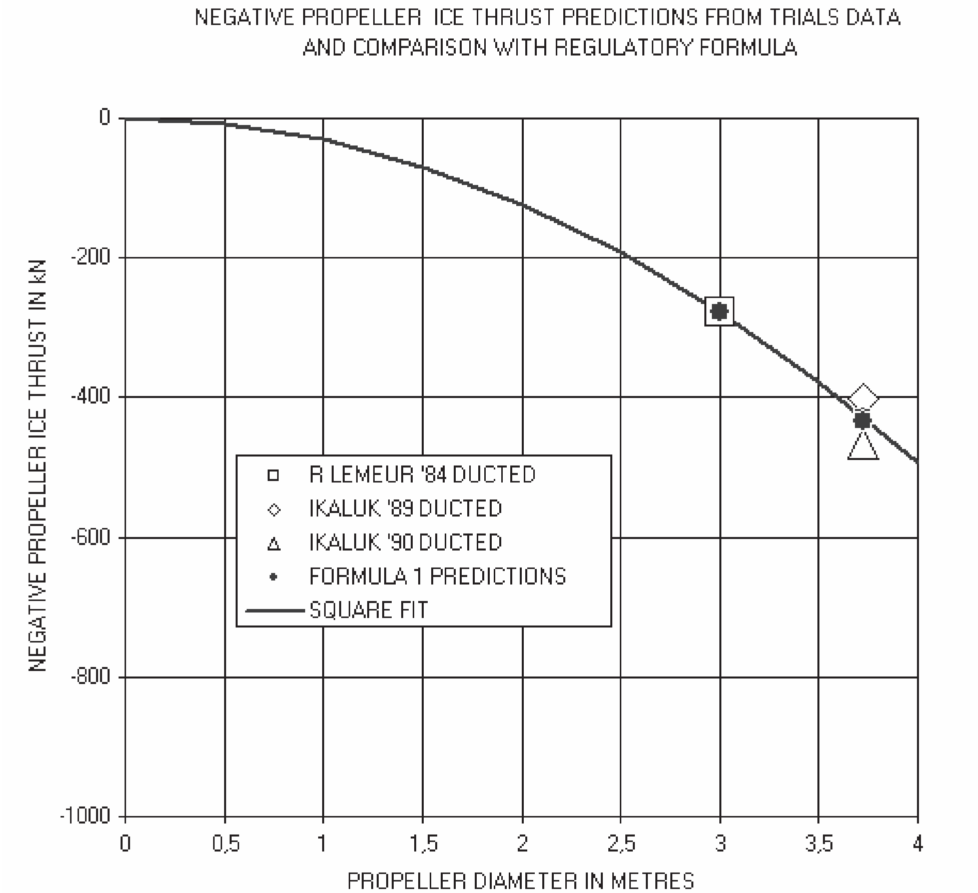
I3.4.3.5 Maximum Propeller Ice Thrust

When the propeller blade in-plane and out-of-plane ice loads were resolved in the shaft axial direction, the maximum ice thrust was found to be approximately 1.1 times the out-of-plane blade load, F_b or F_f.

In the figure below, long term negative propeller ice thrust predictions from trials data [15] for “Ikaluk” and “Robert Lemeur” are compared with the above formulae. The propeller thrust predictions are derived from shaft measured data using shaft dynamic response characteristics. The expected value in 500 hours of operation is used, and the regulatory formula values for blade load are multiplied by 1.1 in order to represent shaft thrust.

It is noted that the full scale data match the regulatory formulae very well. This also provides additional validation for the diameter squared influence upon backward propeller blade ice forces.

Load pattern location on the blades are given in the Table 2 , load cases 1 and 5.



I3.4.4 Design Ice Loads for Ducted Propeller

I3.4.4.1 Maximum Backward Blade Force

For ducted propellers, the backward blade ice force increases with increase in ice thickness until ice thickness equals about 25% of propeller diameter or about 70% of blade length. This is shown very clearly by shaft thrust data for “Nathanial Palmer” [14] in level ice of increasing thickness.

Ice of thickness 70% blade length can include the largest ice blocks which can enter a ducted propeller without impacting the duct. Therefore, the open propeller model should model the ducted propeller for backward blade force, within this ice thickness range.

Following this reasoning, the formulae for maximum backward blade ice force become:

$D_{limit} = 4 \times H_{ice}$

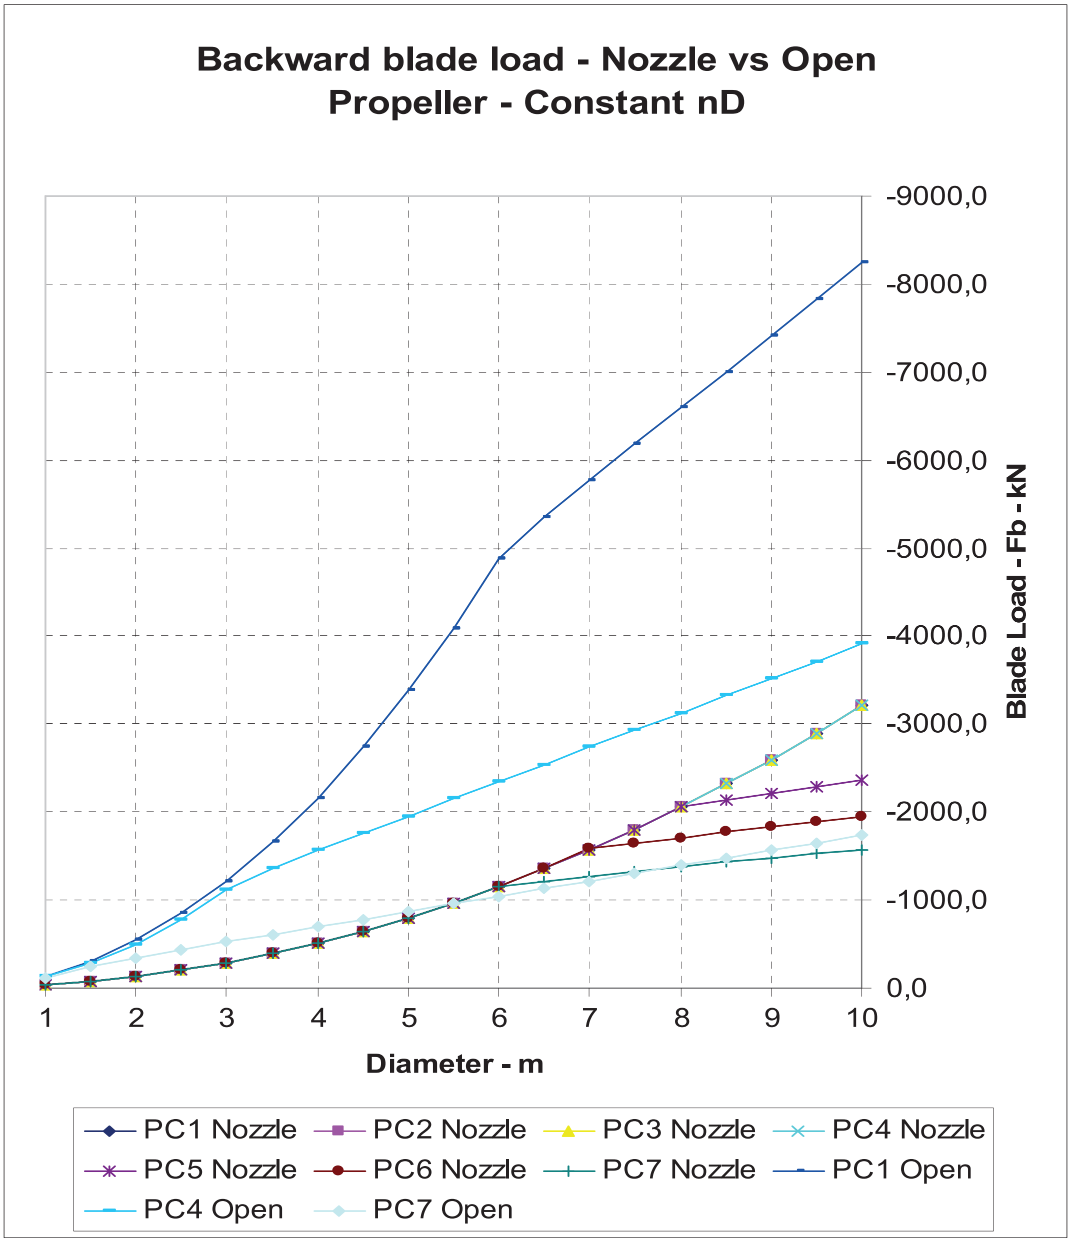
When $D < D_{limit}$

$F_b = -9.5 \times S_{ice} \times (nD)^{0.7} \times [EAR/Z]^{0.3} \times D^2$ kN

When $D > D_{limit}$

$F_b = -66 \times S_{ice} \times (nD)^{0.7} \times [EAR/Z]^{0.3} \times (H_{ice})^{1.4} \times D^{0.6}$ kN

Following diagram show backward bending load for ducted propeller with same constants as for open propeller. PC1, PC4 and PC7 open propellers are presented in the same diagram for comparison purpose.



I3.4.4.2 Maximum Forward Blade Force

The maximum forward blade force is close to the maximum forward blade force on an open propeller of the same diameter.

This is indicated from full scale Baltic data [9]. Additionally, the maximum directly measured forward blade force on the "Robert Lemeur" agrees with this formulation.

Load patterns location on the blades are given in the Table 2, load cases 2 and 5. Note that forward bending load covers half of the blade width on leading edge side.

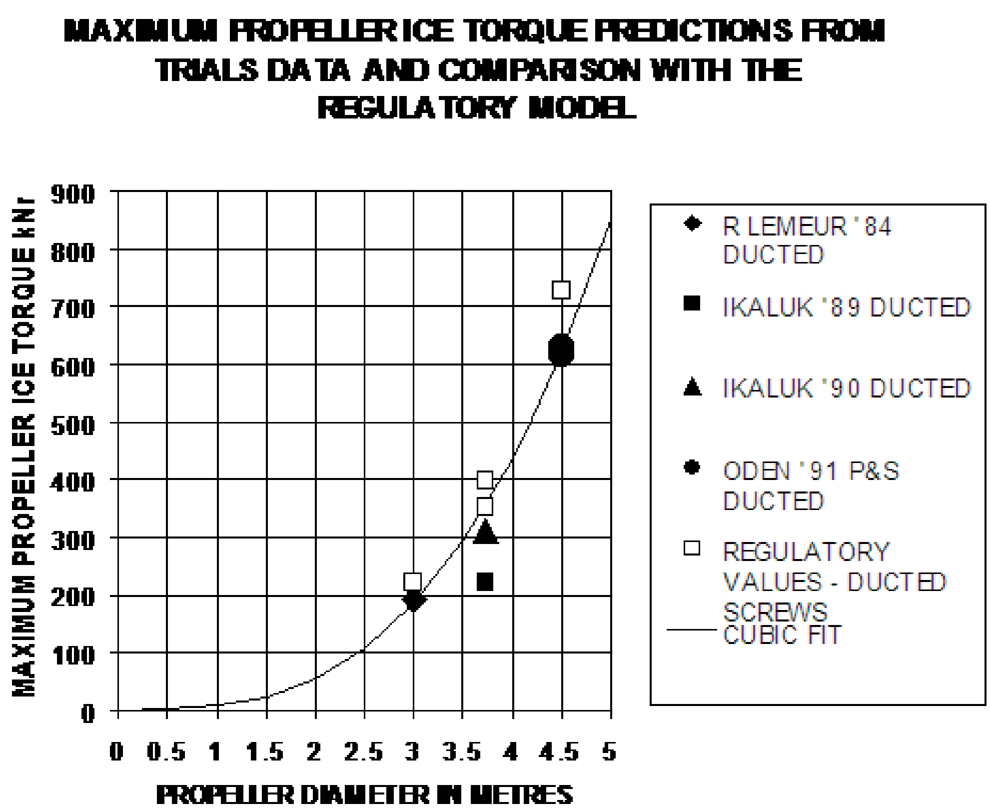
I3.4.4.3 Maximum Propeller Ice Torque

The maximum propeller ice torque is to be taken as 70% of the torque on an open propeller of the same diameter.

In the figure below, long term maximum propeller ice torque predictions from trials data [15] for "Ikaluk", "Robert Lemeur" and "Oden" are compared with the regulatory requirement. The propeller ice torque predictions are derived from shaft measured data using shaft dynamic response characteristics. The expected value in 500 hours of operation is used. The expected value in 500 hours of operation is used.

A cubic fit is put through the full scale data, which provides support for the propeller diameter parametric relationship developed from the numerical simulation model.

It is noted that the regulatory requirement is set just slightly higher than the full scale data long term predictions.



I3.4.4.5 Maximum Propeller Ice Thrust

When the propeller blade in-plane and out-of-plane ice loads were resolved in the shaft axial direction, the maximum ice thrust was found to be approximately 1.1 times the out-of-plane blade load, F_b or F_f.

Background Notes and Verification

for

"Machinery Fastening Loading Accelerations"

by Robin Browne

1. SCOPE AND OBJECTIVES

Accelerations imposed upon machinery due to ice impact/ramming are required in order that the integrity of holding down arrangements of essential machinery is maintained.

Machinery Fastening Loading Accelerations are specified in the Machinery Requirements URI3.6. The formulae in URI3.6 defining these accelerations, require in turn, additional information on bow vertical ice force and bow side ice force magnitudes from the Structural Requirements URI2 (latest version December 2004).

Using the latest versions of URI2 and URI3, an Excel spreadsheet program has been written to calculate the machinery fastening global accelerations corresponding to ship conditions where full scale trials data of global ship accelerations have been measured.

2. POINTS OF DISCUSSION

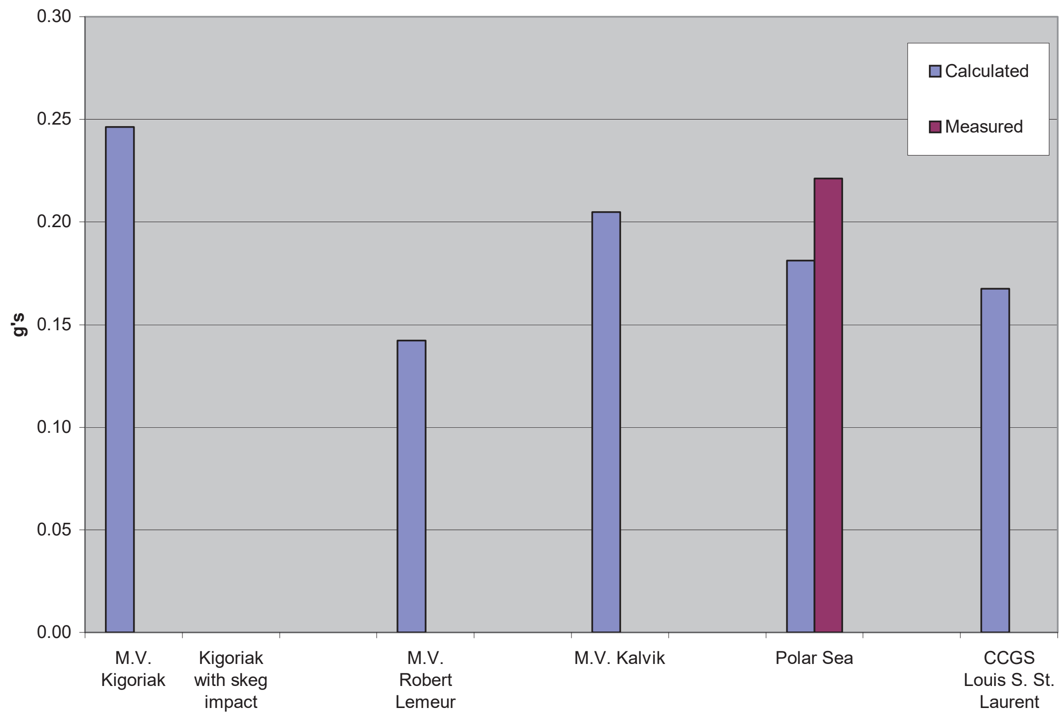
There is a paucity of data for global ship accelerations. However, the data that exist have been extracted from reports of full scale icebreaker tests and trials, and reported in Ref 1, from which the acceleration formulae in UR I3.6 are taken.

COMPARISON OF FULL SCALE DATA WITH UR REQUIREMENTS

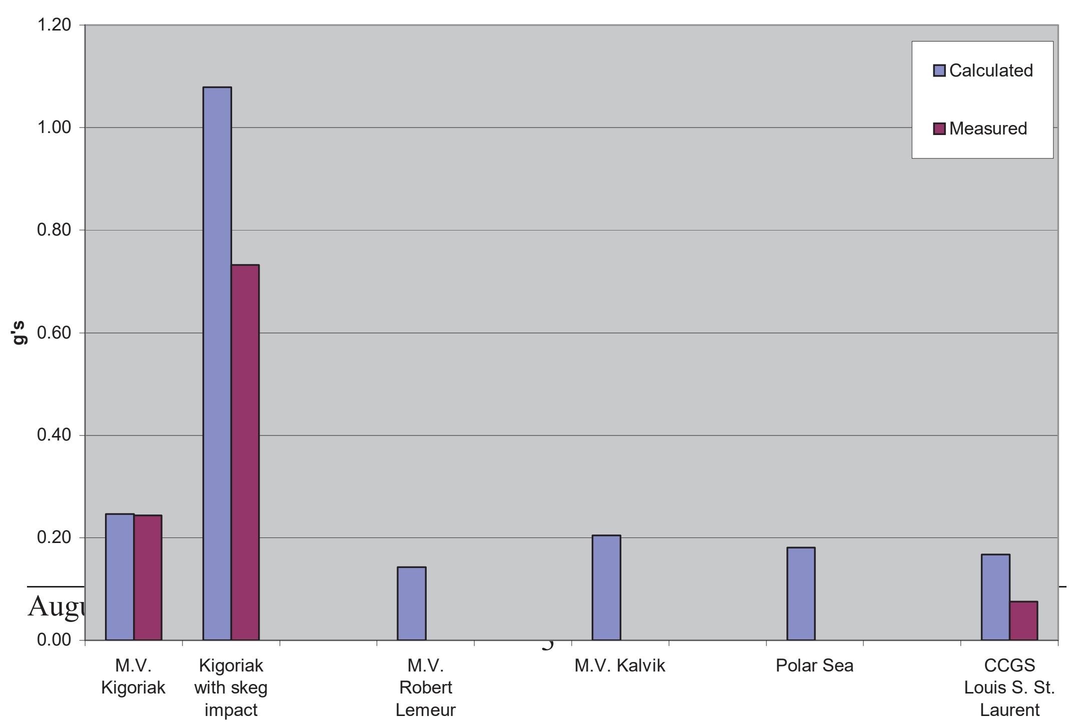
The calculated UR requirements are based on assumptions/standards for the ramming or ice interaction speeds of vessels of any given Polar Class. The full scale data were not necessarily recorded at these ramming speeds, and, for the purposes of comparison, have therefore been adjusted linearly to the standard values.

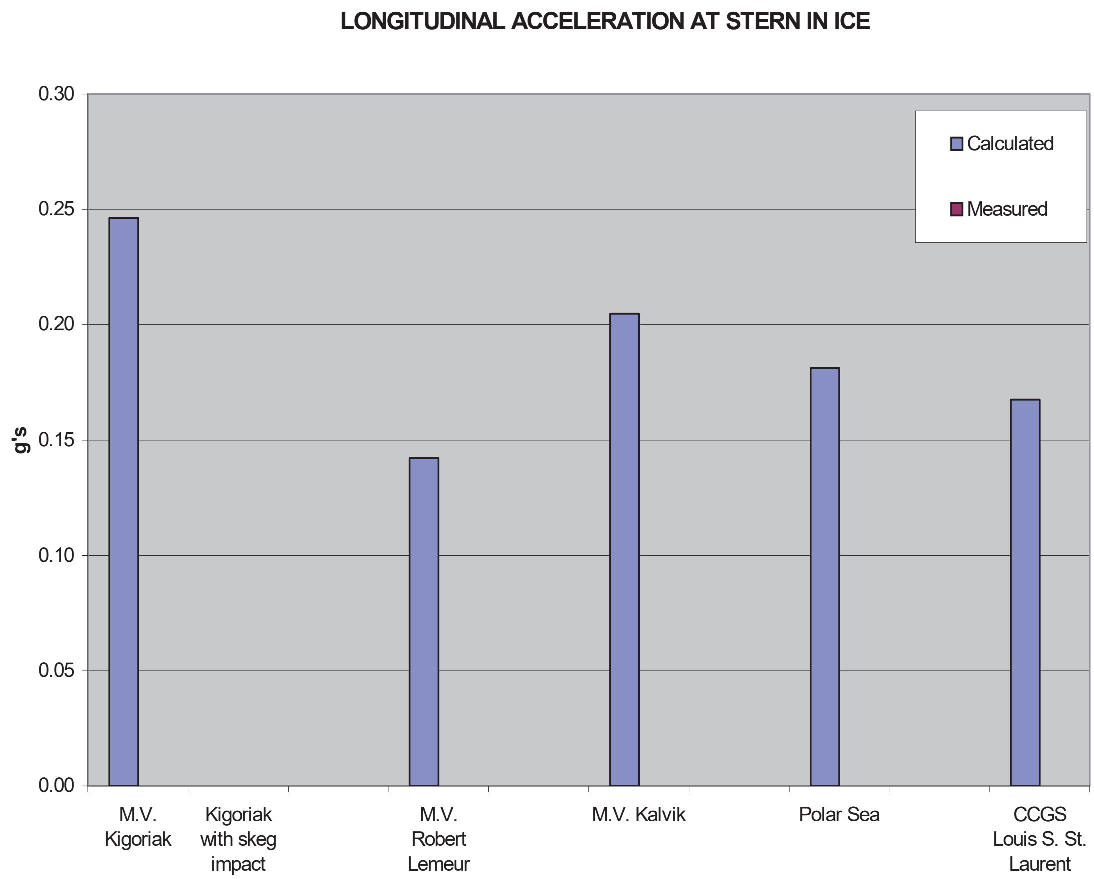
I3 6.2 LONGITUDINAL ACCELERATION COMPARISONS

LONGITUDINAL ACCELERATION AT BOW IN ICE



LONGITUDINAL ACCELERATION AT MIDSHIPS IN ICE





The UR required vertical accelerations show a generally good agreement with actual measured values from icebreakers in operating conditions. There are, however, many fewer data. There is just one comparison for the bow (Polar Sea), three for midships (Kigoriak with and without skeg contact and Louis St Laurent), and none for the stern. It is of course clear that there should be negligible difference in accelerations measured simultaneously at these three locations on a vessel. The four records should therefore be seen as agreement for four cases at all locations. These were all directly measured accelerations at the noted locations.

Polar Sea
CCGS Louis S. St. Laurent

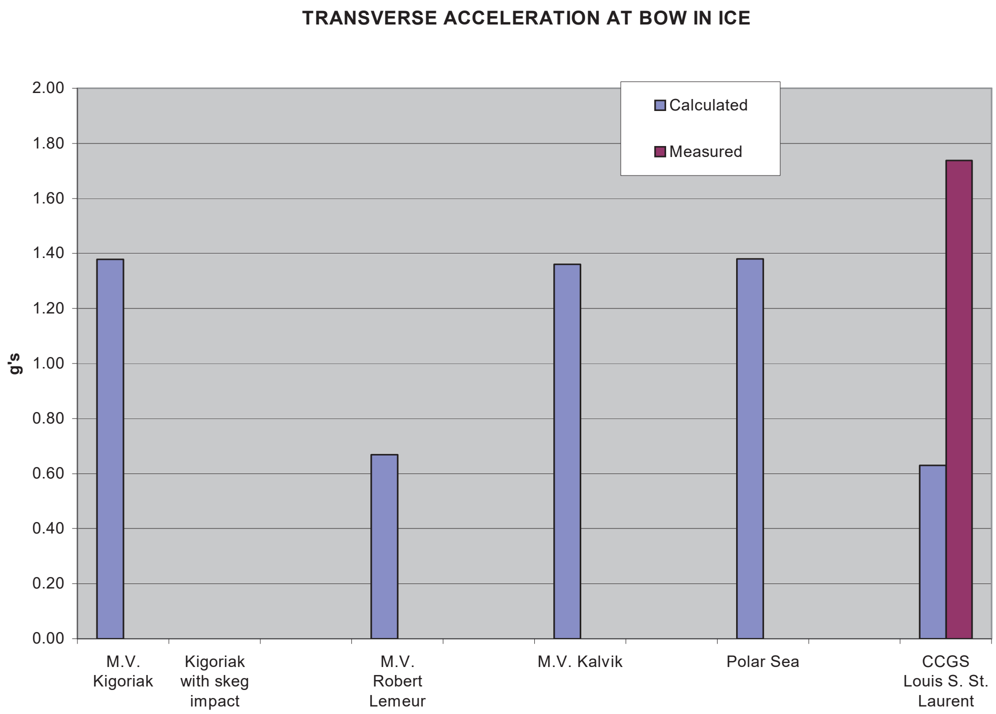
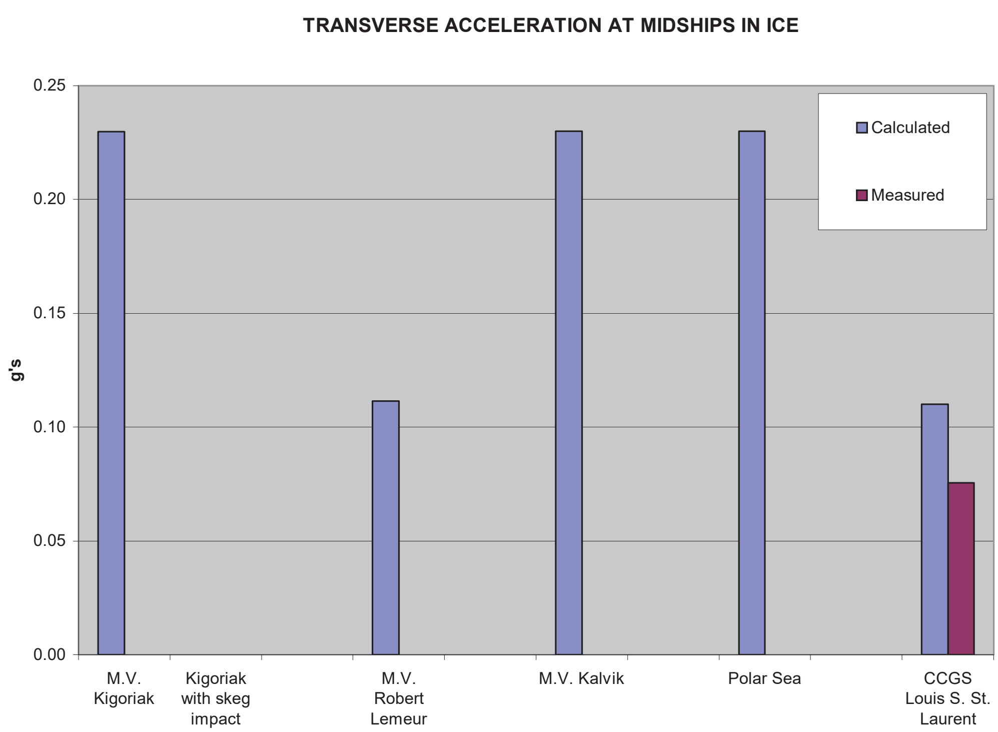
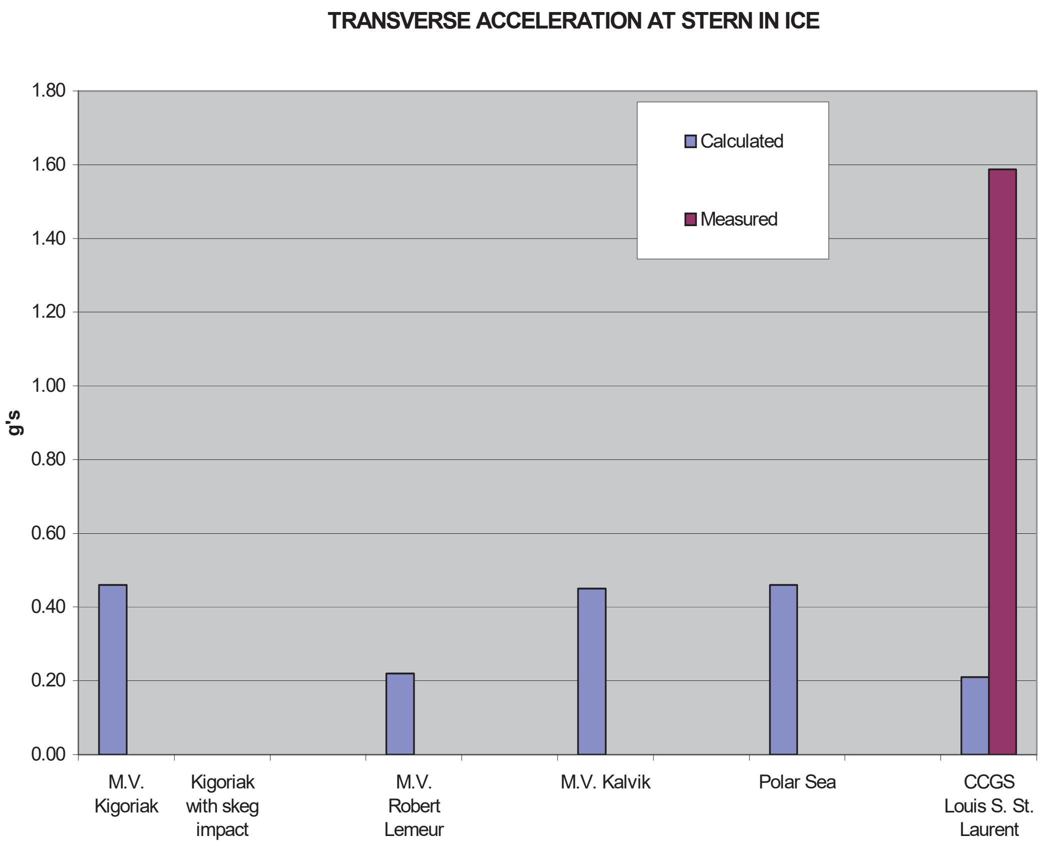
The UR required vertical accelerations show a generally good agreement with actual measured values from icebreakers in operating conditions. There are four comparisons for the bow (Kigoriak, Robert Lemeur, Kalvik, and Polar Sea), and one each for midships (Louis St Laurent) and the stern (Kalvik). These were all directly measured accelerations at the noted locations.

I3 6.4 TRANSVERSE ACCELERATION COMPARISONS







Transverse accelerations are only available for one vessel, Louis St Laurent. The measurements were made at midships, using a gyro-stabilised linear and angular acceleration array. The direct measurement of transverse acceleration at midships shows reasonable agreement with the UR requirements. However, those at bow and stern are very high relative to the UR requirements.

It is suspected that resolution of the bow and stern accelerations from the recorded linear and angular accelerations has been faulty. However, these trials were conducted in the late '70s and there is no means of verifying this statement. It is, however, technically reasonable to expect the transverse accelerations at any location to be reasonably similar to the vertical accelerations. The calculated values are such. The published transverse accelerations at bow and stern for Louis St Laurent are therefore rejected as incorrect.

SUMMARY

All available, and considered reliable, measured full scale global accelerations of icebreakers, show generally good agreement with the Machinery URI3 requirements. These requirements are considered sufficiently accurate as they stand.

IACS Unified Requirements for Polar Ships

Background Notes to

“Blade design" version 2.0

by Pekka Koskinen, Robin Browne and Lasse Norhamo

IACS UR I3
Technical Background
Propeller Blade design

1 SCOPE AND OBJECTIVES

It was a requirement that the use of modern analytical tools be considered to replace the current blade strength requirements. The design of blades and their skews have altered considerably in the recent years, noting that some failures could not have been predicted by the rules and requirements currently in place.

This document gives information on how the requirements for propeller design given in IACS UR I3 (Section 5 of the Machinery Requirements forPolar Ship) have been developed. Direct citations from the Unified Requirements are written in Italics, and comments on the paragraph in question are written in normal text.

2 POINTS OF DISCUSSION

I3.5.1 Design Principle

The propeller design has to fulfil the maximum load design criteria. The maximum load design criterion is based on estimation of the maximum load expected once during the ship's service life. This load should not cause any significant damage to the blade that could put the ship's safety at risk. However, local yielding on the blade may occur.

This maximum load is based on normal prudent vessel operation in ice, relative to the vessel design, ice class and the ice conditions. Even higher ice loads can be generated by "off-design" operating conditions, such as might occur if a propeller blade were to strike an ice feature, when the propeller was stopped and the vessel was moving.

A requirement therefore exists, to protect the machinery system from such "off-design" loads – called "Blade failure load – F_{ex}" and is used as one design criteria for blade attachment, hub strength, CP-mechanishm and propeller shaft, as well as for thrust bearing..

The strength of the propulsion line components are, subsequently, to be designed according to the "selective strength principle". This means that the first damage should be to a component that is relatively easy to repair, and whose damage does not cause any remarkable risk to the ship's safety. Damages to other shaft line components are then avoided. For most designs, the propeller blade is likely to be the selected "sacrificial" component.

The selective strength principle is quite similar to the "pyramid of strength" principle. However, a true pyramid of strength, where the strength requirement increases stepwise from the propeller along the shaft line, is impractical, and would cause overly high strength requirements for some shaftline components. This is why the "selective strength criteria" can be applied in the new requirements and "pyramid strength principal" is limited to propeller and propeller shaft.

I3.5.3 Blade Design

I3.5.3.1 Maximum Blade Stresses

Blade stresses are determined on the basis of estimated maximum loads, which act on realistic areas of the blade, and bend the blade in both the forward and backward directions. Blade stress data are required in both bending directions for fatigue loading calculations.

For an open propeller, the main load case is generally where the propeller is milling an ice block, and the ice pressure load acts on the leading edge of the forward side (suction side of blade with vessel going forwards) of the blade (Figure 1a). This load bends the blade backwards.

Full-scale experience indicates that loads acting over the tip area (Figure 1b), also occur (Koskinen & Jussila 1991, and DNV damage investigations 1983-1990). Again, these loads bend the blade backwards when the vessel is going ahead. These loads may occur for example when a ship is turning, and an ice block enters the propeller in the radial direction. This tip load case is often the most critical one for highly skewed propellers.

Forward blade bending loads also occur. Whereas their magnitude is reasonably well defined, their nature and exact location are not as well understood as for the backward bending loads. The same load distribution as for the ice block milling condition (Figure 1a) is used, as a worst case scenario.

The same load case distributions are used for ducted propellers. However, the relative magnitudes of the loads are different, with the forward bending case generally being the most important.

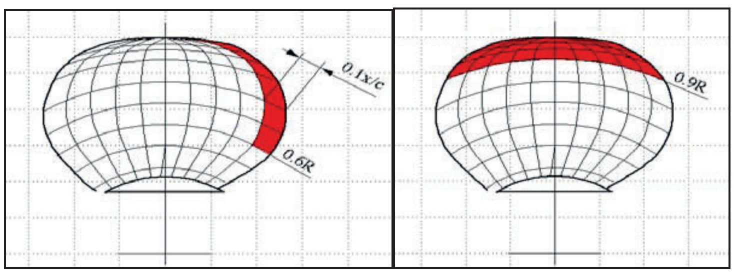

Figure 1. Location of the load on the blade with original load pattern 10% of section length

In order to determine the methodology to be used for calculating blade stresses, three alternate procedures have been studied.

The traditional procedure, on which the present ice class rules are based, gives bending stresses that are caused by a point load on the blade. It is assumed that the blade is a cantilever beam, and the stresses due to spindle torque are neglected.

Another methodology, proposed by the Russian register (Katsman & Andryushin 1997), takes into account the additional stresses (constraint torsion) due to the spindle torque.

The third methodology is based on FE-analysis, in which loads are applied on the blade as shown in Figure 1.

These methods have been compared by the Machinery Working Group. FE-analysis for propeller blades were carried out by each classification society, and the results were compared with those obtained by the other methods. The comparison was carried out by Lloyds Register in the form of an Excel Workbook. The comparison showed that the simplified methods could not predict the blade stresses with reasonable accuracy. In general it is not accepteble that an advanced method, in this case FE-analysis ended up in considerably higher stresses in a blade. In addition, the measured stresses from the icebreaker Polar Star, showed good agreement with the stresses obtained with FE-analysis (Browne 1998). On other hand, calculated stresses for “Gudingen” propeller indicate that blades should have been destroyed, if the estimated loads had been acting in true case. Gudingen propeller has been made to comply 1A Super, when as the ship it self has 1A ice class. This ship has been operated 20 years in occasionally difficult ice conditions without visible damage on the propeller blades.

Based on these studies it was decided to use FE-analysis in the rules for stress calculation. However, there was a significant scatter in the stresses calculated by different classification societies using FE-analysis. This emphasises a need of guidelines for FE-analysis in the new UR.

Ice load contact patterns for F_b and F_f were increased from 10% to 20% of the chord length. See Fig. 2

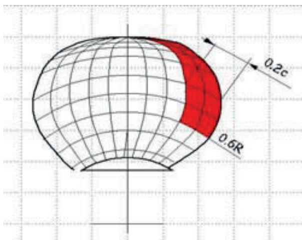

Fig. 2 Ice load contact area for F_b and F_f

During winter 2003 DNV experienced several propeller damages caused by propeller – ice interaction during reversed operation in ice condition. The blade tips on the trailing edge side have most likely been bent by ice during reversing of propellers.
Even if these damages may be considered as minor, engine load may be seriously affected requiring immediate temporary repair (cutting off the bent blade tip and opposite one for balancing).

1. Bent blade tip on the trailing edge side 2. Detail of the same

Propeller facts:

- Fixed pitch;
- Skew angle 24^o;
- Diameter 5.8 m;
- Engine power about 9500 kW.
- Ice Class ICE-1B.

In the In the areas where damages have been experienced the ice conditions were severe for ice class ICE-1B ships, in fact ice thickness in excess of 60-70 cm.

Considering that the damaged propellers did satisfy the current ICE-1B rules (in fact the tip thickness is 50% above the requirement) DNV has carried out several FEM analyses both in order to estimate blade stresses caused by ice loads and effect of possible modifications of blade shape and thickness profiles
Several propellers having skew angles close to 25° would fulfil the I3 criteria as drafted and nevertheless be vulnerable to above type damages.

DNV carried out number of FE-calculations in order to determine proper criteria for skewed fixed pith propellers. See examples of stress plots below.

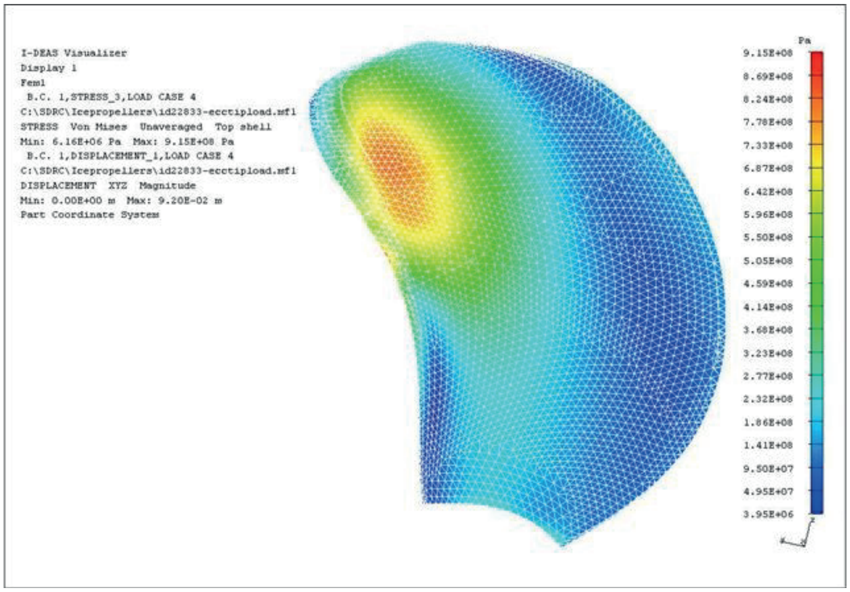

Fig . 3 Von-Mises stresses – load from 0.6R to 1.0R on trailing edge - Suction side

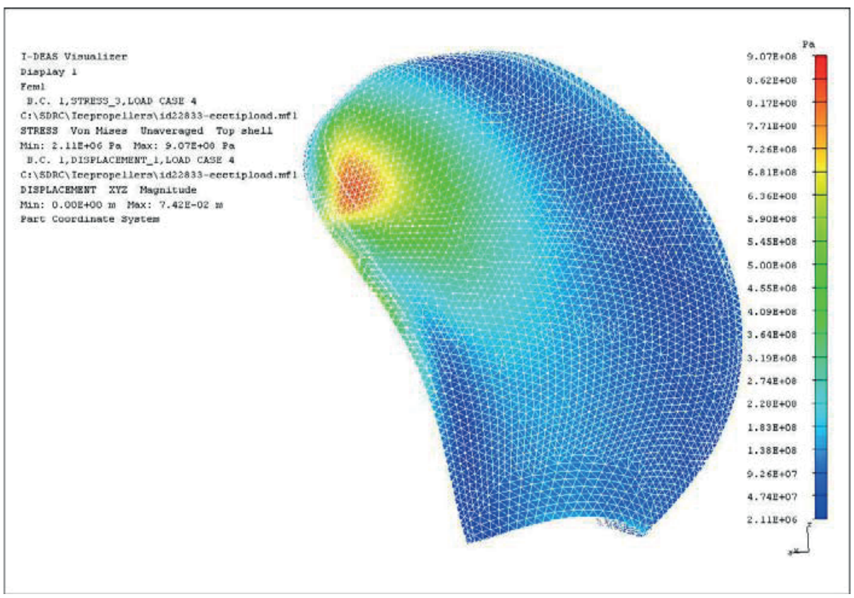

Fig . 4 Von-Mises stresses – load from 0.8R to 1.0R on trailing edge - Suction side

This resulted in an additional ice load case – trailing edge load – that provides proper trailing edge strength for reversible rotation propellers, and eliminates need for any skew angle limitation for which the I3 is valid.

Trailing edge load case – (load case 5 for open and ducted propellers):

- *60 % of F_f or F_b which one is greater*
- *Uniform pressure applied on propeller face (pressure side) to an area from 0.6R to the tip and from the trailing edge to 0.2 times the chord length*

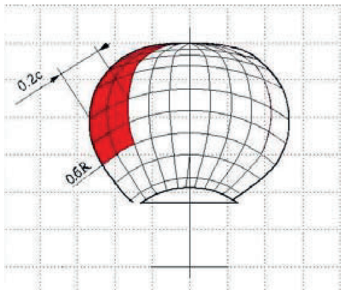

Fig. 5 Trailing edge load case for reversible propellers

Forward bending load - F_f - for ducted propellers did not have same type load pattern as open propellers. Based on validation of 4 ducted propellers and re-assesment of measurement results, following load pattern was selected – Load case 3:

- *Uniform pressure applied on the blade face (pressure side) to an area from 0.6R to the tip and from the leading edge to 0.5 times the chord length.*

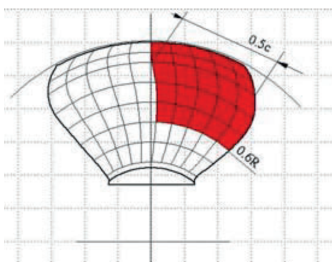

Fig . 6 Ducted propeller – Forward load

I3.53.1 Maximum blade stresses

Calculated blade stress for maximum ice loads shall have sufficient safety margin (1,5) to the material reference stress in order to avoid harmfull distortion of the blade considering consequences for maintenance of propulsion capacity.

Permissible static stress can thus be defined as :

σ_{ref}: / S

σ_{ref} *is reference stress, defined as:*

$$\sigma_{ref} = 0.7 \cdot \sigma_u \ \textit{or}$$
$$\sigma_{ref} = 0.6 \cdot \sigma_{0.2} + 0.4 \cdot \sigma_u \ \textit{which ever is lesser}$$

Where σ_u and $\sigma_{0.2}$ are representative values for the blade material at considered section.

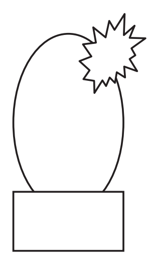
A reference stress has originally been developed to reflect the real capability of the blade to carry loads aimed to in particular for extreme loads, i.e. plastic bending of the blade. This has been used in definition of the Blade failure load – F_{ex}. The formula for σ_{ref} takes into account, for example, the increase in strength of the blade due to work hardening of the material. The reference stress is a combination of the 0.2-proof stress and ultimate tensile strength ($\sigma_{ref} = 0.6 \cdot \sigma_{0.2} + 0.4 \cdot \sigma_u$). The development of the formulae is based on a test series carried out by VTT where cantilever beams made of blade materials were bent. The cross-section of the beam was 6*20 mm and three bronze and two stainless steel materials were tested. The development of the reference strength formula was carried out in close co-operation with Det Norske Veritas.

During the work of the MWG, a concern arose that the reference strength equation might overestimate the strength of high tensile strength steels. Therefore, the reference strength was limited to 0.7 times the ultimate strength of the blade material.

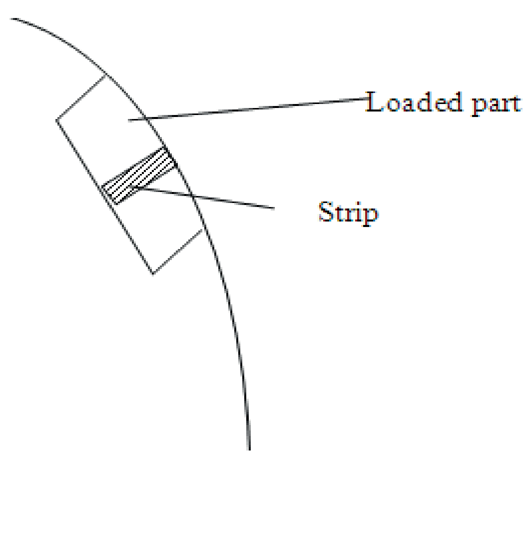
I3. 5.3.2 Blade Edge Thicknes

Analytic method to derive formula for required tip / edge thickness is explained below.

Basic principle:
Propeller tip or edges shall not be subject to permanent deflections when exposed to an extreme, local ice pressure of 16 N/mm^2.



Assumption:
The local loading will cause high stresses just inside the loaded area. It is assumed that for a narrow strip within the loaded area, the stresses may be calculated by cantilever beam theory.



Load prediction
If the breadth, B of the strip is set to unity, the resulting load will be:

$$F_{edge} = pA = 16 \cdot 1 \cdot X$$

Where X equals the length of the strip, i.e. the distance from the contour to the ending of the loaded area.

Assuming constant pressure, bending moment arm may be taken as half the length of the strip.

I.e.:

$$M_{edge} = F_{edge} \cdot arm = 16X \cdot 0.5X = 8X^2$$

Stress calculation:
Further, the section modulus for calculation of stresses at the innermost part of the strip is:

$$w_{strip} = \frac{B \cdot t^2}{6} = \frac{1 \cdot t^2}{6}$$

Stresses at the innermost part of the strip is found as:

$$\sigma_{edge} = \frac{M_{edge}}{w_{strip}} = \frac{8X^2}{\frac{t^2}{6}} = \frac{48X^2}{t^2}$$

Stresses up to yield strength are allowed. This prevents permanent deflections and takes into account current experience that steel blades are less exposed to edge damages than bronze blades (existing edge criterion refers to tensile strength). Hence, edge thickness must not be less than:

$$t \approx \frac{7X}{\sqrt{\sigma_y}}$$

Where σ_y is yield strength of material

In this respect, no safety factor is included. In case safety factor is taken as 1.5, 2.0 or 3.0, the figure in front of X would be 8.5, 10 or 12, respectively (instead of 7).

2.5% of the chord length (0.025C) is a relevant reference for calculating maximum stresses due to extreme local ice pressures at the propeller blade edges - figures for this location is normally given in the section table. However, for large chord lengths (in particular towards the tip), the reference to 0.025C will read to unreasonably large edge dimensions. Hence, the considered distance from the contour to the considered location of the blade should be limited. 50 mm seems to be a reasonable limitation. In the same way a minimum limitation should be applied. 20 mm is suggested.

Including a safety factor of 2.0 with respect to yielding, the following is found:

$$t_{contour} = \frac{10X}{\sqrt{\sigma_y}} \text{ [mm]}$$

For the tip thickness requirement (maximum profile thickness towards tip), chord length is not relevant as reference, and should instead include the propeller diameter, as today (take into account that a minimum value should apply). For instance:

$$t_{tip} = \frac{50(D+10)}{\sqrt{\sigma_y}}$$

Where D is propeller diameter [m]

This ensures that the length of the ”calculation strip”, X is never taken less than 50mm, even for a small propeller.

For simplicity, this thickness should refer to a fixed radial point, but because the propeller tip is normally rounded, and to avoid conflict with the edge requirement, it should not apply directly to the 1.0R. A better reference is 0.95R. I.e.:

$$t_{0.95R} = \frac{50(D+10)}{\sqrt{\sigma_y}} \text{ [mm]}$$

Including Ice class dependency:
In case a dependency of ice class is wanted, this could easily be done introducing a ice class dependency for the extreme ice pressure. This could be tabulated changing the factors used in the formulae above. Assuming that 16 N/mm^2 represents the extreme ice pressure relevant for PC1 (and PC2), the following is suggested:

$$t_{contour} = 2.5X\sqrt{\frac{p_{ext}}{\sigma_y}} \text{ [mm]}$$

X is location for measuring contour thickness [mm], to be taken as 0.025C, but not larger than 50 mm nor less than 20 mm.

and

$$t_{0.95R} = 12.5(D+10)\sqrt{\frac{p_{ext}}{\sigma_y}}$$

Where p_{ext} is the maximum local ice pressure. and selected based on the measured maximum local ice pressure.

Based on validation exercise and consequent use of permissible stress following has been selected:

$$t_{edge} = x\ S\ S_{ice}\sqrt{\frac{p_{ice}}{\sigma_{ref}}}$$

x = is distance from the blade edge measured perpendicularly to the edge and shall
= be 2,5% of chord length, minimum 2,5% of 0.975R section length, however need not be taken greater than 45 mm
S = safety factor

= 2,5 for trailing edges
= 3,5 for leading edges
= 5 for tip
S_{ice} = according to Section I3.4.4.2
p_{ice} = ice pressure
= 16 Mpa

σ_{ref} as defined in 5.3.1

Edge thickness is for leading edge and trailing edge for reversible rotation open propellers. Tip thickness refers to the max thickness of the cylindrical section at 0,975R.

Technical Background (TB) document for UR I3 Rev.2 (Jan 2023)

1. Scope and objectives

- General Update of this UR
  Existing requirements have been comprehensively reviewed.

- Introduction of Requirements for Icebreaker Vessels
  The extension of Rev.2 was initiated to incorporate requirements for Icebreakers into UR I3. The main reason for this was that URs I1 and I2 contains such requirements, and in order to obtain a more complete rule set UR I3 should be amended with such requirements.

2. Engineering background for technical basis and rationale

- General Update of this UR
  Members' practices and experiences on Polar/Ice Class ships.

- Introduction of Requirements for Icebreaker Vessels
  See *4. Summary of Changes intended for the revised Resolution*.

3. Source/derivation of the proposed IACS Resolution

- General Update of this UR
  None

- Introduction of Requirements for Icebreaker Vessels
  None

4. Summary of Changes intended for the revised Resolution:

- General Update of this UR

4.1 Comprehensive revision of existing Sections I3.4 to I3.6 was carried out based upon the following:

a) The two blade fatigue methods have been compared. The intention with the IACS method was to have a more transparent method compared to the Finnish-Swedish method. The reason for this was to facilitate easier control by the user on the calculations when the results are not as expected. Both methods are based on the Miner summarize method for variable amplitude loading, and both methods are using the Weibull load distribution. The IACS method divides the load into load blocks and direct summing up the damage caused by each load block. The accuracy increases with increasing number of load blocks. Within the validity range and given accuracy of the Finnish-Swedish method gives corresponding results.

According to the VTT R-00717-08 the formula for r (eq. 9 and 11) gives an error less than 10% over the specified interval 5 million to 100 million cycles for N_{ice}. Within this range the IACS method Miner sum varies from approximately 0.4 to 1.0.

The formulae validity is limited to N_{ice} < 100 million which means ice class with N_{ice} > 100 million are outside the validity rang.

b) Reserved paragraphs have been discussed and PT members agreed on the wording. Simple formulae for different components have been introduced, as it was requested by industry, and used during the validation.

c) The problem of determination of spindle torque based on blade failure load has been raised by Industry as being too conservative. In order to base a new approach on measurements, a JIP was introduced to accommodate full scale measurements and incorporating CPP makers in the development and validation process. As a result, a new simple formula was developed as well as application of advanced calculation methods enabled. Measured blade geometries and deformation results have been provided for the adaptation of individual advanced calculation methods.

d) Blade tip requirement was deleted, because there was no connection to the blade tip load cases (to be dealt with by FEA) and requirements are not adjusted. Additionally, it was found that all example cases fulfil the requirement by far.

e) Torsional loads: Based on findings from validation (a big CP propeller case, calculation and full-scale measurements) an excitation case with a shorter excitation phase (45°) was introduced as excitation case 4. This case improves the situation of differences between simulation and full-scale measurement; however, the gap could not be closed, especially for the speed drop. In order to reduce the scope of torsional simulation investigations, it was agreed to require a simulation only at bollard pull condition with maximum attainable rpm and torque.

It was noted that the torsional simulation in time domain reveals reasonable results with respect to calculated torque (to be used further for dimensional check) but showed also a speed drop, which exceeds measurements by far. This speed drop moves the excited high torsional peak downwards to lower speeds and partly into open water resonances or even barred speed ranges. This causes problems for plants having such behaviour. Especially vulnerable are direct drives with FPP and low cylinder number two stroke engines. Although such plants with PC (or equivalent) ice classes are not in service, the PT did consider this problem due to the comparable calculation methods for the Baltic Ice Classes and the probable chance to get a criterion for powering. As a result, the PT included the alternative determination of the peak torque by a frequency domain analysis, if a first blade order exists. The alternative needs to consider the static torque, vibratory part of open water excitation and vibratory part of ice excitation.

f) Flexible couplings: Based on the discussion with flexible coupling makers and their providers for torsional simulations (mainly engine makers), we have agreed that a fatigue curve for flexible couplings cannot provided and therefore a fatigue strength check has to be performed at certain load numbers, where the makers provide guaranteed minimum torque capacities. Nomenclature of makers has been introduced for an easier reference.

g) Some material issues have been discussed and decided:

- Equivalency of Charpy V value according investigation report of VTT for nodular cast iron

- keeping Charpy V values (steel) for the sake of equivalency to Baltic Ice Rules and Canadian ASPPR (Arctic Shipping Pollution Prevention Regulations), but referring to UR W7 and W27, if they require higher values for the considered component

h) Industry Hearing result contains a number of small but helpful hints for more detailed and clear wording. The main part concentrates on the spindle torque load due to blade failure load and the dynamic torque analysis. The spindle torque problem was dealt with in the BlaFex JIP. The discussion about torsional loads was very extended and a separate meeting was held with the engine maker WinGD – formerly Wärtsilä Switzerland and MAN Copenhagen. The presented proposal for an alternative calculation based on frequency domain analysis was discussed. A number of influencing parameters for the time domain analysis have been investigated and the high chance to get different results based on the same rule was demonstrated. As a result of the Industry Hearing a number of amendments for better wording have been introduced, clarifications but also alternative calculation methods introduced, e.g., a table with Fourier coefficients for a range of different blade numbers to enable a simple determination of the ice excitation in a Frequency domain calculation.

i) In an extension of PM11914_, the simplified calculation procedure proposed by industry was investigated and documented in Part B of validation report (see e above). It turned out that the method is not always conservative and loads can be highly over estimated. The PT proposed not to introduce this procedure.

j) It turned out that there is a complete lack of full-scale measurements for directly coupled two stroke propulsion plants. Those plants are in service with Baltic Ice Class Notations but may be expected in the two lowest Polar Classes in the future. IACS could go ahead, e.g., with CIMAC and organize a JIP to gain sufficient full-scale data. This could be aligned with the outstanding power requirement.

k) It turned out that blade material fatigue data, especially for steel grades, are rarely available. It is recommended to solve this problem with the relevant industry.

l) The Panel considered the PT's recommendation to approve the Rev.2 of this UR prepared by the PT under PM11914a in order to gain experience on a wide community based upon the understanding that, after a necessary time period, e.g., five years, IACS may revisit critical points as described above and in a separate document.

4.2 Change in text regarding ventilation requirements

The requirements to ventilation given in I3.12 has been opened up for alternative arrangements. The industry reported difficulties with fulfilling the absolute requirement of having ventilation openings on both sides of the ship, particularly for passenger vessels. An alternative text was proposed and circulated in the Machinery Panel. The decision was to open up for manual de-icing and anti-icing arrangements as alternatives to having openings on both sides of the ship. Further, the absolute requirement to heating of the inlet air has been replaced with a requirement that temperature of inlet air shall be suitable for safe operation of machinery and accommodation.

4.3 Figures with new plots including excitation case 4

New Figures made by the PT under PM11914a were added. The new plots are taken from the one Member's implementation of the Finnish Swedish Ice Class Rules (FSICR) for *Ice(1A)* which corresponds to PC7.

- Introduction of Requirements for Icebreaker Vessels

4.5 Increase in blade loads

Backward blade force Fb has been increased by 10% for Icebreakers in line with earlier TB note for blade loads, wherein it is described that original blade loads measured on actual Icebreakers (which formed the basis for blade loads in UR I3) were decreased by approx. 10% to fit merchant vessels. The backward bending load is a direct contact load between ice and blade. The forward blade bending force Ff is assumed not be affected by the increase as this load originates from vacuum between blade and ice pulling the blade forward.

4.6 Increase in load cycles for fatigue evaluation

The assumed operational profile of Icebreakers means they will operate more often, and more vigorously in heavy ice conditions compared to merchant vessels. Following this rationale, the number of ice impacts on the propellers during the ship's service life would be higher, and a factor of 3 has been chosen as it aligns with the increase in blade loads from a statistical point of view. See reasoning for this in Attachment 1.

4.7 Change in text for clarification of steering gear requirements

The text in I3.13.4 contains a new requirement for additional torque relief arrangements for Icebreakers, which was modified by the PT to clarify when said arrangements should be triggered. In addition, a piece of text has been added to accommodate alternative steering systems, e.g., electric steering gear. This is because the original text was clearly written with hydraulic steering systems in mind, but the market showed an increasing trend of electric steering gear, particularly on azimuth units.

5. Points of discussions or possible discussions

- General Update of this UR

    a) Wording in paragraph I3.12 has been changed in line with discussions among Machinery Panel members and comments from some Members. It is no longer an absolute requirement to have ventilation openings on both sides of the ship.

    b) Figures initially prepared by the PT were replaced by new figures covering all 4 load cases.

    c) Some minor editorial changes have been implemented, mainly wrt. wording.

    d) With regard to a query on the application of this UR to transverse thrusters, it has been explained by the PT that the scope of UR I3 is main propulsion machinery, and the requirement I3.5.1 quoted by a Machinery Panel member is not aimed at tunnel thrusters (or any other auxiliary thrusters for that matter), but rather on main propulsion propellers mounted in the bow region, such as forward facing shaft lines or bow mounted main propulsion thrusters. Therefore, it has been confirmed that a failed tunnel thruster is normally not a safety concern, and it is not within the scope of UR I3.

    e) For the gap between UR I3 and FSICR pointed out by a Member, the following course of action has been agreed by this Panel: *Rev.2 of this UR would be finalised without further developing requirements on rudder equipment (which has traditionally been regarded as hull appendages), but this Panel should inform GPG of the need for Hull Panel and Machinery Panel to simultaneously review IACS URs I2 and I3 (according to the following responsibilities (Hull Panel for UR I2 and Machinery Panel for UR I3), at a later stage, to solve the gap between I series URs and FSICR.*

    As given in item 4.2 above, a discussion was held within the Machinery Panel wrt the requirements to ventilation in I3.12. The conclusion from this discussion was implemented in the UR.

- Introduction of Requirements for Icebreaker Vessels

    A philosophy document was drafted by the PT after brainstorming in the first PT workshop. This was to identify focus areas where Icebreakers should receive special attention wrt. merchant vessels. This philosophy document was circulated within the PT for comments, and the PT concluded on the way forward based on comment replies.

    The document together with comments and conclusions is included in Attachment 2.

6. Attachments if any

- General Update of this UR

  None.

- Introduction of Requirements for Icebreaker Vessels

  Attachment 1: Supplementary notes to selection of ice loads and No. of cycles for ice going vessels with class notation “Icebreaker”
  Attachment 2: IACS UR I3 Icebreaker extension – Suggested approach

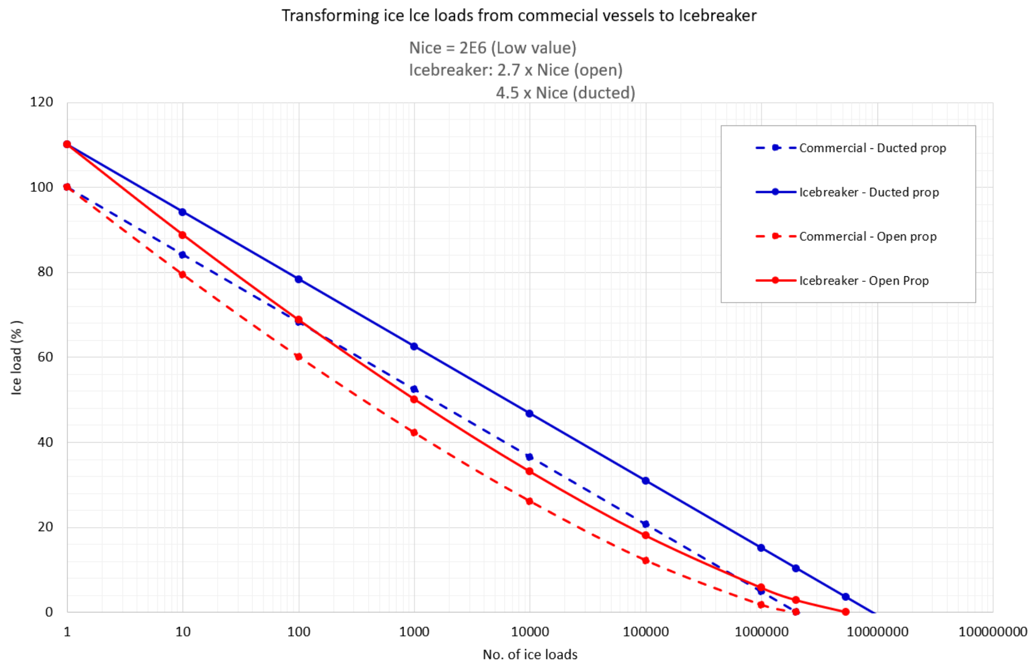
In the following, a brief background is presented aiming to substantiate what is a reasonable increase in ice loads as well as number of ice impacts for a propulsion system in an icebreaker vs. those of a commercial vessel. Quite much of the background material, such as ice loads measurement reports etc. is not available anymore, and hence the reasoning is based on a limited amount of references as well as fractions of remaining historical documents. Technical background documents available for the IACS UR I3 do not fully explain the transformation process from measurements and simulations to the selected ice loads and their associated No. of cycles. Further, the rationale for and details related to subsequent modifications and adjustments are not fully given.

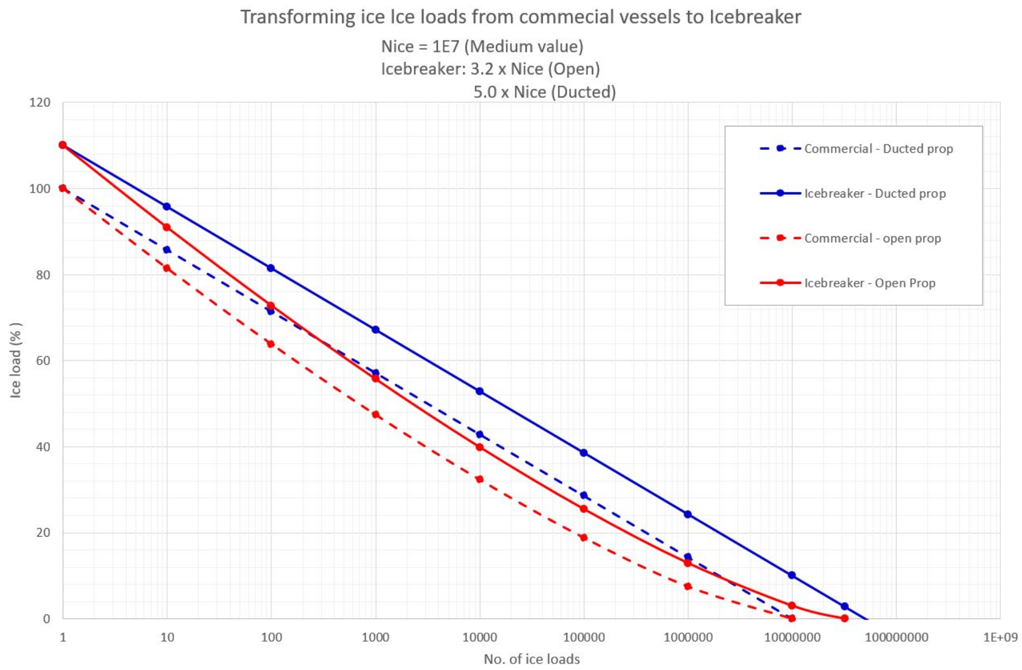
Some basic assumptions and considerations

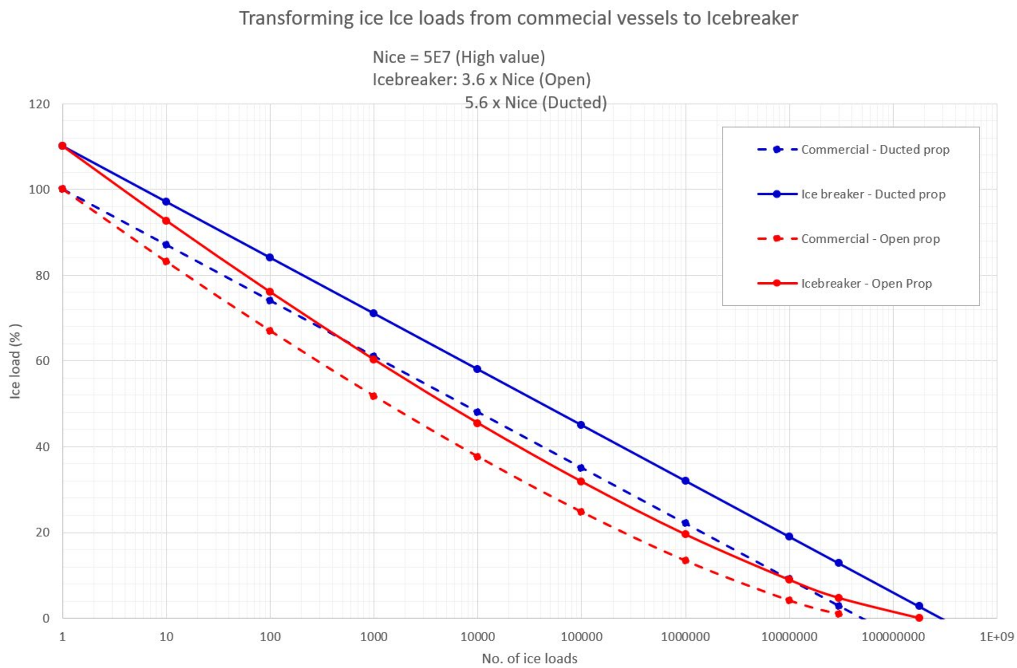
- The ice load levels and their associated No. of cycles described in IACS UR I3 are relevant for cargo vessels operating in ice
- In the technical background for propeller ice interaction loads, it is mentioned that prior to final publication of ice loads, the general level for backward bending ice load was reduced with 10%. Further, we interpret statements in this document so that this reduction originates from validation studies related load levels on icebreakers vs. cargo vessels, i.e. for icebreakers a 10% higher load level must be expected than formulated in existing rules.
- In the proposal for new icebreaker rules, it has been assumed that the main reason for the difference in backward blade bending loads between cargo vessels and ice breaker is the higher ice exposure for the latter – since ice breakers operate more in ice, there will be more ice impacts at all ice load levels. Due to the statistical distribution of ice loads, this means implicitly that also the maximum load level (which is described in the rules) will increase as a consequence.
- No. of load cycles for forward blade bending ice loads is stated to be higher than the backwards bending loads. However, taking all uncertainties into account this difference is not included in the rules. Hence, No. of ice loads for forward load is the taken same as for backward load.
- The forward blade bending ice load is mainly caused by a suction force occurring when a blade passes near an ice block. Even if also this load in the rules is specified to have a statistical distribution, a similar reduction in load level was not made in the calibration process presenting the final ice loads for cargo vessels. Although this may appear inconsistent, it may be explained by limitations related to low pressure (will not be less than vacuum), and that the current statistical distribution therefore represents a simplification. Hence, an upscaling of forward blade bending loads from cargo vessels to ice breakers is not seen relevant.

Relevant statistical correction of No. of cycles when maximum load level is increased with 10%

In the following, we have considered the necessary increase in number of ice loads, N_{ice} that will follow in case the maximum load level is increased with 10% due to higher degree of ice exposure. Hence, number of ice impacts are increased with the same factor at all load levels in the statistical distribution. This is done for three example cases, assumed to represent a realistic range of load cycles (N_{ice}), given the possible variation in ice classes and design parameters.







From the above, it is seen that when number of ice impacts are increased at all load levels in order to increase the maximum forward bending ice load with 10%, the number of ice loads for cargo vessels must be multiplied with a factor in the range of 2.7 to 5.6 within a relevant range of ice loads, considering both open and ducted propellers.

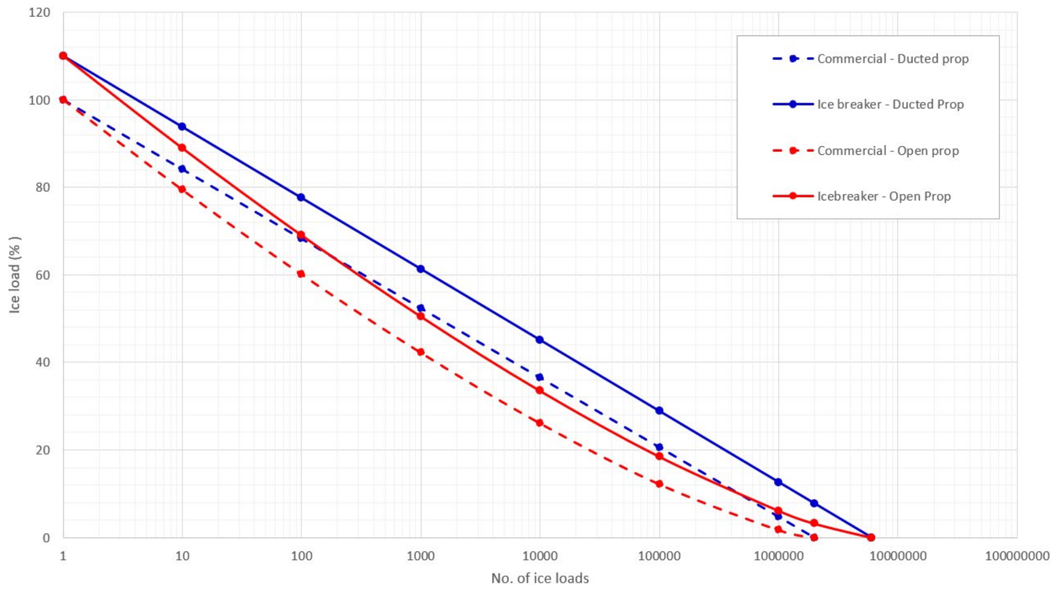
It is seen as reasonable that an ice breaker experiences substantially more ice impact loads on the propulsion system than a commercial (cargo) vessel. It should however, be kept in mind that apparently the No. of ice impacts used for cargo vessels in current ice rules, have not been reduced when calibrating / validating the results. Therefore a limited increase in No. of ice loads may be used when updating the ice rules to be valid for ice breakers – as the base value (for commercial / cargo ships) may have been conservatively chosen. A common multiplication factor of 3.0 on number of ice loads for all ice breakers is a simple approach and seems sufficient, taking the above into account. Further, this is perceived also as a reasonable value describing the increase of ice exposure for icebreakers vs. cargo vessels, given the limited documentation available on this topic.

Simplified statistical correction of No. of cycles when maximum load level is increased with 10%

In the following, we have evaluated the consequences if increasing number of ice loads, Nice with a factor of 3.0 for icebreakers vs. commercial / cargo vessels. Maximum load level is at the same time increased with 10%. This is done for three example cases – same as previously described.

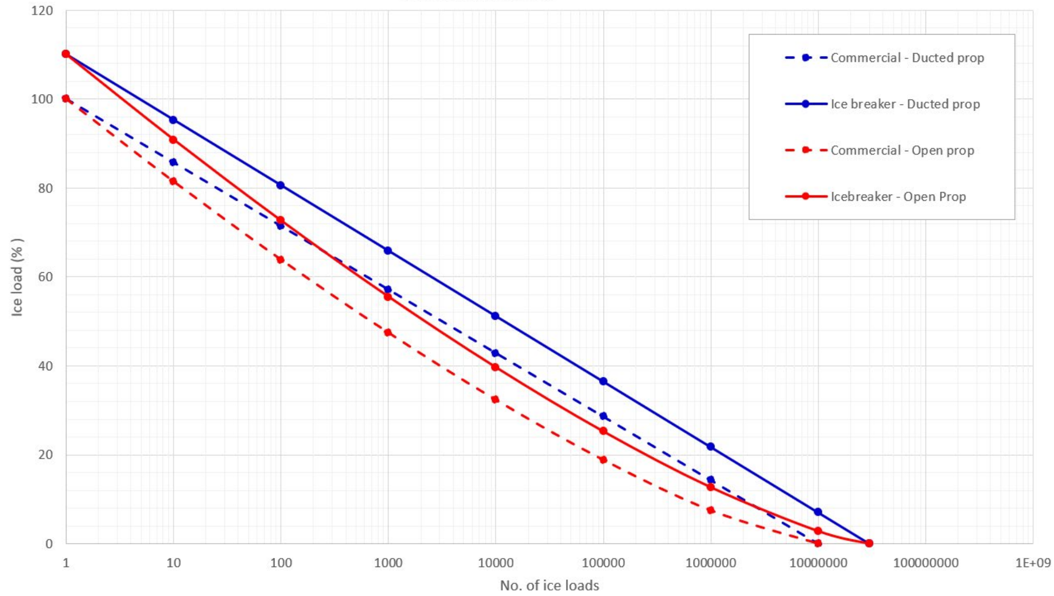
Transforming ice Ice loads from commecial vessels to Icebreaker

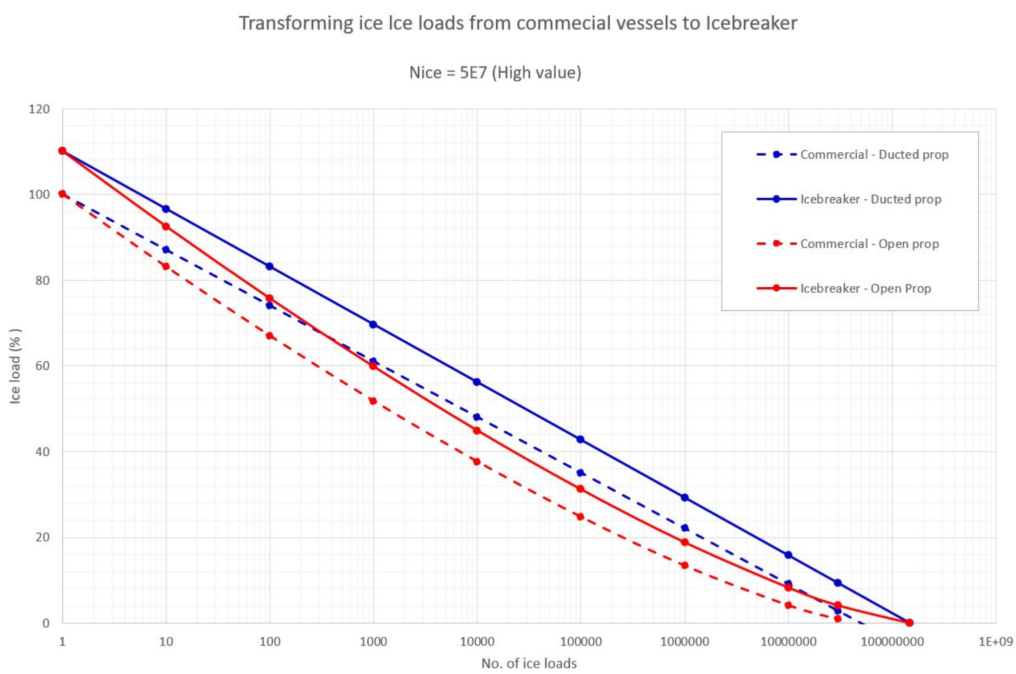
Nice = 2E6 (Low value)
Icebreaker: 3 x Nice



Transforming ice Ice loads from commecial vessels to Icebreaker

Nice = 1E7 (Medium value)
Icebreaker: 3 x Nice





The above figures show that with this simplified approach a reasonably consistent increase in number of loads is seen on all load levels.

Conclusive remark

Based on the documentation available a 10% increase in forward blade bending ice load can be justified for icebreakers. As a simplified approach, it seems reasonable to increase number of corresponding ice loads with a factor of 3.

1 Background

The Project Team has been tasked with extending the current draft of IACS UR I3 to incorporate requirements also for Icebreakers. An effort has been made to identify which parts of propulsion plants that need addressing.

2 Suggested changes and considerations to rule requirements

2.1 Blade loads

2.1.1

Blade loads are assumed to be higher for icebreakers, and the original loads forming basis for the F_f and F_b loads in UR I3 were taken from full scale measurements on Icebreakers. These loads were then scaled down to fit merchant vessels. Unfortunately, the original measurement data from the icebreakers are no longer available, meaning another way to scale the loads back up may be needed. There is however information in the Technical Background Document 'Propeller ice loads' indicating that the reduction in ice loads is around 10% from the original icebreaker loads. It is suggested to increase the loads for icebreakers by 20%. Half of this is justified by the above mentioned original reduction. The rest is to account for statistical variations in that an increase in load cycles (see 2.2 below) also increases the statistical probability that the peak load experienced during the vessel's lifetime will be higher.

Feedback from the PT members: two members have agreed to 20%, and one member has agreed to the initial 10% subject to further increase if detailed justification can me made.

Conclusion of the PT: It is concluded that a preliminary increase of 10% is agreed. Further effort will be put into justifying additional increase.

2.1.2

The two blade loads F_f and F_b are assumed to originate from two different phenomena; F_b from ice bending the blade backwards and F_f from a vacuum forming between blade and ice, bending/pulling the blade forward. As the load originating from vacuum is assumed to not be affected by the change of the vessel's service, F_f will not be increased for icebreakers. F_b is however assumed to be affected, as this is a direct contact load between ice and blade.

Feedback from the PT members: all members have agreed.

Conclusion of the PT: It is agreed that only backward blade load is increased for icebreakers.

2.1.3

The next question would be to determine if this increase in blade loads should apply to both open and ducted propellers. According to the technical background document for propeller ice loads, the backward blade loads for ducted propellers increase as for open propellers up to an ice thickness corresponding to about 25% of propeller diameter. For this reason, the limit diameter for ducted propellers is set to $4*H_{ice}$ (giving $H_{ice} = D/4$). Considering this, it would make sense to increase the icebreaker backward blade load for ducted propellers as for open propellers for $D < D_{limit}$. Considering that H_{ice} for PC vessels ranges from 1.5 to 4 m, D_{limit} for a PC(7) vessel is already at 6 m and D_{limit} for a PC(4) vessel is 10 m. Consequently, there are very few PC vessels for which the actual propeller diameter will exceed D_{limit}. For this reason, one could conclude that there is no reason to distinguish between blade loads for propellers above or below D_{limit}, and thus increase the load by the same factor regardless of diameter.

Feedback from the PT members: no objections have been raised to the understanding that blade loads for both ducted and open propellers shall be affected, but one PT member has disagreed to disregarding ducted propellers exceeding D_{limit}.

Conclusion of the PT: The PT seems to agree that blade loads for both open and ducted propellers shall be increased for icebreakers. Disregarding the (assumingly very small number of) vessels with ducted propellers above D_{limit} was only intended as an effort to simplify the rule text, and as there is not a consensus within the PT, this will not be done. Increase in blade load will also affect propellers above D_{limit}.

2.1.4

It should be considered if the ice strength index should be increased for ice classes PC(2) and PC(3) to a level corresponding to PC(1). The reasoning being that all ice classes PC(1) - PC(3) are intended for operation in multi-year ice, and hence the strength index should possibly be the same (S_{ice} = 1.2). On the other hand, it may be difficult to argue that this would be different for icebreakers compared to merchant vessels.

Feedback from the PT members: two members have disagreed to changing S_{ice} for icebreakers, while one member has agreed. The latter member has also suggested that the procedure of alternative design may be applied if project specific ice strength shall be used.

Conclusion of the PT: It is concluded that ice strength index is not to be affected by vessel service, and consequently S_{ice} will remain unchanged for icebreakers. Perhaps a future update of UR I3 could consider the plausibility of this factor with respect to intended operational areas for vessels vs. typical ice strength.

2.2 Loads and no. of cycles

2.2.1 Load cycles

It is assumed that icebreakers will operate more often, and more vigorously in ice compared to merchant vessels. Following this assumption, they will accumulate a higher number of load cycles on the propulsion machinery during their lifetime than merchant vessels with the same ice class. Consequently, the parameter N_{ice} may need to be increased for icebreakers, and a factor of 2 or 3 is suggested.

Feedback from the PT members: two members have agreed in principle while another member has, agreeing to the increase, tried to include a detailed approach.

Discussion by the PT: It is established that a higher number of load cycles is very relevant but that finding a proper technical justification is challenging. In this situation, a possible way forward is to increase the number of cycles by a moderate factor. Another way is to find alternative justification the suggested approach (See below).

The difference in N_{ice} for neighboring PC classes of merchant vessels is about 25-30%, and for icebreaker's classes the same difference may be kept, I suppose.

If we will be able to appreciate even one correspondence between operational conditions of any PC class of merchant vessel and any PC class of icebreaker it will be easy to complete the full table for N_{ice}, like table below which is prepared in assumption that number of cycles of icebreaker of PC7 category will be close to merchant vessel of PC3 class one.

	merchant	approximate difference	icebreaker	
PC1	21×10^6	123%PC2	55×10^6	previous value is increased for coefficient from 3-rd column
PC2	17×10^6	115%*PC3	45×10^6	
PC3	15×10^6	115%*PC4	39×10^6	
PC4	13×10^6	120%*PC5	34×10^6	
PC5	11×10^6	125%*PC6	28×10^6	
PC6	9×10^6	150%*PC7	22×10^6	
PC7	6×10^6		15×10^6	same as merchant PC3

Conclusion of the PT: A consensus was not obtained on how to link a PC class to the corresponding icebreaker PC class, although this would be a possible way forward. Instead an approach of linking increase in load cycles to increase in blade load using statistical methods was investigated. The approach is explained in document "Ice load F_b - increase in no of cycles for icebreakers".

2.2.2 Weibull factor for ice load spectrum

Another consideration is that the magnitude of the less frequent load cycles experienced by icebreakers may in general be higher, arguing that perhaps the Weibull shape parameter should be different for this type of vessels (currently, shape factor is k=0.75 for open propellers and k=1.0 for ducted propellers). There is however currently no concrete suggestion for what this new parameter should be.

Feedback from the PT members: two members have acknowledged relevance of k-factor but have expressed their view that it is challenging.

Conclusion of the PT: Technical background for selection of k-factors seems not to be available, and unless any of the PT members have experience with this type of studies it is deemed a too complicated matter to solve with the limited resources available to the PT. If both the maximum load and the number of cycles are increased this will lift the S-N curve and thereby account for some additional higher loads with low occurrence. Changing the Weibull k-factor will therefore not be considered further.

2.3 Shafting

2.3.1 Torsional loads

Ice induced torsional loads for shaft lines follows a formula which is independent of blade loads (F_b, F_f), e.g.:

$$10.9 \cdot \left(1 - \frac{d}{D}\right) \cdot \left(\frac{P_{0.7}}{D}\right)^{0.16} \cdot (n \cdot D)^{0.17} \cdot D^3 \text{ [kNm]}$$

The rule torsional loads will hence not be affected by icebreaker duty, unless the formulas for Q_{max} are changed. One could also consider to increase the ice milling duration ($N_Q = 2 * H_{ice}$) to reflect the assumed operational conditions for icebreakers.

Feedback from the PT members: one PT member has disagreed to differentiating between icebreaker and merchant ships, and another member has, while agreeing in principle to the logic of increasing duration of ice milling, expressed its view that the technical justification may be a challenging process.

Conclusion of the PT: Most of the measurement data used in the development of UR I3 has been done on icebreakers, and there is no evidence in the TB documents that a downscaling of the shaft loads has been done to better fit merchant vessels. It is therefore thought that the formulas may be applicable also to icebreakers in their current form.

2.3.2 Thrust loads

In the current rules, and similarly in the FSICR, design ice thrust loads are derived directly from the blade loads. As the blade loads are likely to be increased for icebreakers, the thrust loads will follow. Suggested approach is to let the thrust loads remain unchanged for icebreakers.

Feedback from the PT members: all members have agreed.

Conclusion of the PT: It is concluded that thrust loads will remain unchanged for icebreakers

2.4 Steering gear

Requirements for steering gear turning speeds for icebreakers are already included in UR I3.13.4. These requirements seem to have been made having conventional rudders in mind. Would the same requirements be applicable to azimuthing propulsors?

Feedback from the PT members: reference to UI SC242 has been suggested by two members.

Discussion by the PT: The turning speeds in question refer to when the rudder is forced to the side by a large external force (in this context; primarily by going astern into an ice ridge), and the torque relief arrangements needed to protect the steering gear and rudder stock. The current draft UR I3 already specifies additional requirements for icebreakers, wherein a secondary, high capacity relief arrangement is required. The requirement seems to be written for conventional rudders with hydraulic steering gears, and the question remains if this should also be addressed for azimuthing propulsors, which these days are frequently delivered with electric steering gears? The rule text can also remain as it is, leaving the interpretation for electric steering gears to each Society.

I3.13.4 Additionally, for ice breakers fast acting torque relief arrangements (acting at 15% higher pressure than set pressure of safety valves) are to be fitted in order to provide effective protection of the rudder actuator in case of the rudder being pushed rapidly hard over against the stops. The turning speeds to be assumed for each ice class are shown in Table 18 below.

The arrangement is to be designed such that steering capacity can be speedily regained.

Ice Class	PC1–2	PC3-5	PC6 – 7
Turning speeds [deg/s]	40	20	15

Table 18: Steering gear turning speeds for ice breakers

Conclusion of the PT: The text in I1.13.4 will be updated to clarify the intention behind the additional torque relief arrangement. Additionally, text will be added to address non-hydraulic steering gear. Azimuth units will not receive special attention, as it is assumed they will be turned by the ice in the same manner as rudders.

Technical Background (TB) document for UR I3 Corr.1 (Dec 2024)

1. Scope and objectives

- Correction to formulae, parameters, parameters and paragraph numbering where clarifications were needed

2. Engineering background for technical basis and rationale

- Identification of typographical errors with formulae, parameters and paragraph numbering where clarifications were needed

3. Source/derivation of the proposed IACS Resolution

- Finnish Transport and Communications Agency, Regulation TRAFICOM/68863/03.04.01.00/2021

4. Summary of Changes intended for the revised Resolution:

- Correction to formulae, parameters and paragraph numbering where correction or clarifications were needed

Update of UR I3 (Rev. 2) was noted to have typographical errors with formulae, parameters and paragraph numbering, therefore a review was undertaken to address this as well as taking an opportunity to correct any further observed amendments from panel members.

5. Points of discussions or possible discussions

5.1 Identified formulae, and proposed corrections

- Table 1: Definition of symbols
  Symbol presented within the table for number of propeller blades, *z*, has been corrected to uppercase to reflect entries within the UR where number of propeller blades is utilised

- Equation 17
  A Member raised a question with regard to a missing parameter, k_3, for fixed or azimuthing installations and this parameter being missing, as compared to FSIC requirements as mentioned in section 2 above. The PT manager for Rev. 2 of this UR was consulted and had indicated the missing parameter was not part of the discussion under Rev.2 therefore this is concluded as an omission and has been reinstated

- Equation 18
  Immersion function, *f*, identified as missing '*-1*' at the end of the formula. Equation corrected to include this and presented as

$$f = \frac{h_0 - H_{ice}}{D/2} - 1$$

- Equation 34
  Formula presented in equation 34 displays multiple parameters to ice torque excitation for frequency domain calculations. However, definition parameter E_0 was missing within the text below the equation. Parameter E_0 is understood to by number of ice blocks in contact and has been entered

- Equation 47
  Maximum ice loads according to regression formula has been identified incorrect index for s_{fl}, presented as C_2 when this should be C_3. Equation corrected for correct index

  $$\rho = C_1 \cdot (\sigma_{ice})_{max}{}^{C_2} \cdot \sigma_{fl}{}^{C_3} \cdot log(N_{ice})^{C_4}$$

- Table 14: Values for parameter *G* for different *m/k* ratios
  The table presented is missing *m/k* ratios above *10*, and these have been entered into table 14

m/k	G	m/k	G	m/k	G
3	6	6.5	1871	10	3.629×10^6
3.5	11.6	7	5040	10.5	11.899×10^6
4	24	7.5	14034	11	39.917×10^6
4.5	52.3	8	40320	11.5	136.843×10^6
5	120	8.5	119292	12	479.002×10^6
5.5	287.9	9	362880		
6	720	9.5	1.133×10^6		

- Equation 56
  Definition of parameter Q_s, determining spindle torque for application in Equation 55, shows definitions of Safety Factor, *S*, with two values, *1.3* and *1.0* to be used in determining Qs, however they both are applied to Q_{sex}. The *S* value of *1.3* is identified to be applied to Q_{smax} and has been corrected

- A Member raised a question with regard to the origin of Paragraph 6.5.4.7 (now updated to 6.5.5.2 in Corr.1) and previous PT Manager was consulted for this, whereby the origin of this paragraph has been within the requirement since 2007, however the origin has been difficult to source. However, the text is considered to be recognised from international standards and existing Class Rules and provides a mechanism for assessment of such arrangements

  A Member raised a point for clarification for formulae with logarithmic context (equations 15, 43, 47, 48, 51 60, 70 and 71) whereby a common or a natural logarithm are presented. Review of background documentation (such as, 'VTT-R-00717-08 Fatigue design methodology propellers in ice') for these, confirmed equations as presented are in line with the context within Rev. 2 of the UR.

5.2 Paragraph numbering

- It has been identified that paragraph 6.5.4.5 Gear transmissions does not have any subsections and is considered to be reflected under existing paragraph 6.5.4.7 providing acceptance criterion for geared propulsion systems. Therefore, renumbering of paragraph entries has been undertaken collating geared systems under new paragraph 6.5.5, with subsequent adjustment of numbering through to next section, 6.6 Azimuthing main propulsors.

6. Attachments if any

UR L2 "Intact stability – matter of class"

Summary

UR L2 requires that class will only be assigned to ships with a length of 24 m and above after demonstrating adequate intact stability. This revision considers the amendments to Resolution MSC.267(85), Intact Stability Code, since revision 2.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev.3 (Nov 2023)	24 November 2023	1 January 2025
Rev.2 (Apr 2013)	18 April 2013	1 July 2014
Rev.1 (June 2000)	15 June 2000	-
NEW (1988)	*No records*	-

- **Rev.3 (Nov 2023)**

1 Origin:

☑ Based on IACS Requirement (Periodic review of IACS Resolutions)

2 Main Reason for Change:

Since 2013 IMO approved several amendments to the 2008 Intact Stability Code (MSC 267(85)).

3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

4 History of Decisions Made:

The Unified Requirements L2 of 2013 was updated with respect to the amendments made to 2008 INTACT Stability Code. Safety Panel agreed that it would be premature to consider Interim Guidelines on the 2nd Generation Intact Stability Criteria.

Discussed by correspondence in the Safety Panel.

5 Other Resolutions Changes

IACS Recommendation 24 Intact Stability was updated with respect to the amendments to the 2008 Intact Stability Code (MSC 267(85)) approved in the last decade.

6 Any hinderance to MASS, including any other new technologies:

None

7 Dates:

Panel Approval:	09 November 2023	(Ref: PS23036cISf)
GPG Approval:	24 November 2023	(Ref: 22183hIGb)

- **Rev.2 (Apr 2013)**

.1 Origin for Change:

☑ Suggestion by IACS member

.2 Main Reason for Change:

Entry into force of the INTERNATIONAL CODE ON INTACT STABILITY, 2008 (2008 IS CODE), IMO RES. Msc.267(85).

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

The Form A was approved by the GPG on 9 November 2011.

.5 Other Resolutions Changes

IACS Recommendation 99 (Recommendations for the Safety of Cargo Vessels of less than Convention Size)

.6 Dates:

Original proposal: *10 October 2011 Made by: Statutory panel*
Panel Approval: *14 March 2013 (Statutory panel)*
GPG Approval: *18 April 2013 (Ref. 11160_IGf)*

- **Rev.1 (June 2000)**

WP/SSLL submitted a draft Rev.1 UR L 2 to GPG 48 for approval with its progress report on 14/1/2000. The revision was approved by GPG 48.
See TB document in Part B.

- **NEW (1988)**

No TB document available.

Part B. Technical Background

List of Technical Background (TB) documents for UR L2:

◄▼►

Technical Background for Rev.1 UR L2

1. **Objective and Scope**

   The objective for this revision of UR L2 had been to update the reference to the IMO resolution pertaining to intact stability standards which is revised and amended since the last update of this UR.

2. **Source of Proposed Requirements**

   The requirements pertaining to intact stability for types of ships covered by IMO instruments are contained in IMO Resolution A. 749(18) amended by Resolution MSC.75(69).

3. **Points of Discussion**

   During the 35th meeting the question was raised within WP/SSLL whether in the context of UR L2 the existing reference to superseded IMO Res. A.167 should be updated to refer to IMO Res. A.749 instead. Members agreed not to increase the class requirements on intact stability and consequently decided to make reference to only those chapters of Res. A.749 which had already been part of Res. A.167.

* * * * *

Technical Background UR L2.doc/10/5/00 by WP/SSLL Chairman

Technical Background for UR L2 Rev.2, Apr 2013

1. Scope and objectives

IACS Unified Requirement L2 requires all new ships with a length of 24 m and above to be assigned class only after it has been demonstrated that their intact stability is adequate for the service intended.

2. Engineering background for technical basis and rationale

The discussion among PT members dealt with the possible applicability to ships having a length of less than 24 m, and all members have the same opinion that this UR should apply to vessel having a length of 24 m or greater. In case of classified vessel having a length of less than 24 m, flag requirements should be applied. Where there are no flag requirement IACS may apply class requirement where specified, 2008 IS Code or other recognized industry standard.

3. Source / derivation of the proposed IACS Resolution

The requirements for Intact Stability are covered in depth by the INTERNATIONAL CODE ON INTACT STABILITY, 2008 (2008 IS CODE), IMO RES. Msc.267(85) entered into force on 1 July 2010.

The mandatory requirements included in Unified Requirement L2 are those pertaining PART A of the IMO RES. Msc.267(85).

4. Summary of Changes intended for the revised Resolution:

Removals
1. Reference to IMO Resolution A.749(18), chapters 3.1, 3.2 and 4.1 as amended by MSC Resolution 75(69) has been removed.

Additions
1. Reference to Part A of IMO Resolution MSC.267(85)has been included

2 The sentence "**Where other criteria are accepted by the Administration concerned, these criteria may be used for the purpose of classification."** has been added in order to allow IACS to use criteria included in Part B of the 2008 IS Code or other standards as an alternative to the requirements of Part A if accepted by the Flag Administration.

5. Points of discussions or possible discussions

See Para 2.

L 3 Intact stability of tankers during liquid transfer Operations

(Deletion in May 2001)

Technical Background

a) Objective/Scope

The objective was to deal with different level of implementation of L 3 by Members.

b) Points of Discussion

Experience has shown that tankers with wide tanks can have severe intact stability problems during loading and unloading procedures (lolling effects). To prevent pollution from such effects, MARPOL I/Reg.25A requests oil tankers of 5000 DWT and above to meet minimum intact stability requirements in port.
Noting this as a hazard to all kinds of tankers but not only oil tankers, WP/SSLL was tasked to develop a corresponding UR. To ensure sufficient intact stability during loading and unloading L 3 requires a minimum GM of 0.15 m in harbour conditions, to be ensured by design only or by detailed instructions for planning of loading and unloading. L 3 Rev.1 was applicable to all tankers not subject to MARPOL I/Reg.25A.

However, LR did not accept L 3 as there was no mechanism within their Society to make a UR concerning stability part of LR Rules until IMO makes it a statutory requirement.

c) GPG discussion

1) GPG Chairman instructed WP/SSLL to review L 3 implementation status on 7 October 1998.

WP/SSLL reported back to GPG 45 (October 1998) that :
(i) Group 1: either implemented L 3 to a large extent or completely;
(ii) Group 2: not implemented or not intending to implement L 3 to a larger extent than was covered by MARPOL I/25A.
(iii) Group 3: fully implemented L 3 or intending to implement L 3.

2) Though GPG agreed to downgrade L 3 to REC 60, it has been put aside to discuss how to apply para.6.2 of Internal Information No. 15 – indication of Members who were implementing L3 and those not.

3) Finally, GPG/Council agreed that L3 be downgraded to Recommendation 60 on 18 May 2001.

2a. Specification of the data utilised in the development/revision of the proposed IACS Resolution, if any

None

3. Source/derivation of the proposed IACS Resolution

None

4. Summary of Changes intended for the revised Resolution:

The 2008 INTACT Stability Code has been amended in the last decade and UR L2 has been amended with references to these.

5. Points of discussions or possible discussions

The consideration of the Interim Guidelines on the 2nd Generation Intact Stability Criteria was discussed (MSC.1/Circ.1627). It was agreed that it is premature to consider this IMO instrument for the time being and further experience should be gained first.

6. Attachments if any

UR L4 "Closure of Chain Lockers"

Summary

Following the 10th Anniversary review, Corr.2 has been prepared to update the standards which are referenced in the UR.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Corr.2 (Feb 2022)	17 February 2022	-
Corr.1 (Aug 2011)	23 August 2011	-
Rev.3 (Mar 2011)	22 March 2011	1 January 2012
Rev.2 (Nov 2005)	2 November 2005	-
Rev.1 (July 2003)	29 July 2003	-
NEW (Nov 2002)	14 November 2002	1 July 2003

- **Corr.2 (Feb 2022)**

1 Origin of Change:

☐ Other: 10th Anniversary Review

2 Main Reason for Change:

During the 10th Anniversary review it was noted that some of the standards referenced in the UR were out of date.

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None

4 History of Decisions Made:

The Safety Panel discussed the UR by correspondence. Some debate was made about the use of butterfly nuts for a protection cover of a quick release mechanism of an anchor, which was finally not agreed by the panel for safety reasons. It was only concluded to update the referenced outdated standards or indicate their version information in the UI.

5 Other Resolutions Changes:

None

6 Any hinderance to MASS, including any other new technologies:

None

7 Dates:

Original Proposal	: 22 October 2021	(Made by IACS member)
Panel Approval	: 31 January 2022	(Ref: PS21015bISg)
GPG Approval	: 17 February 2022	(Ref: 21197_IGd)

- ## Corr.1 (Aug 2011)

.1 Origin for Change:

☑ Suggestion by an IACS member

.2 Main Reason for Change:

To reinstate the examples of acceptable closing arrangements of spurling pipes, which was inadvertently deleted during the last revision.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

The correction was originally initiated by an IACS member and drafted by PermSec.

.5 Other Resolutions Changes

None

.6 Dates:

Original proposal: 5 August 2011 Made by: An IACS member
GPG Approval: 23 August 2011 (Ref.11137_IGb)

- ## Rev.3 (Mar 2011)

.1 Origin for Change:

☑ Other (Based on Vessel Incident: Port state inspections found some instances where access openings on chain lockers could not be demonstrated as being watertight)

.2 Main Reason for Change:

To clarify requirements for access openings below the weather deck on spurling pipes and chain lockers.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

The revision was originally initiated by an IACS member and drafted through discussions and email correspondence within the Hull Panel. Version approved by the Hull Panel was sent to the Statutory Panel for review and concurrence. Final version drafted by the Statutory Panel after discussions and further revisions by the Statutory Panel.

.5 Other Resolutions Changes

None

.6 Dates:

Original proposal: 1 July 2010 Made by: An IACS member
Panel Approval: 11 August 2010 (Hull Panel); 18 Feb 2011 (Statutory panel)
GPG Approval: 22 March 2011 (Ref. 11047_IGc)

- **Rev.2 (Nov 2005)**

Refer to TB document in Part B Annex 3

- **Rev.1 (July 2003)**

Refer to TB document in Part B Annex 2

- **New (Nov 2002)**

Refer to TB document in Part B Annex 1

Part B. Technical Background

List of Technical Background (TB) documents for UR L4:

Annex 1. **TB for New (Nov 2002)**

See separate TB document in Annex 1.

Annex 2. **TB for Rev.1 (July 2003)**

Annex 3. **TB for Rev.2 (Nov 2005)**

See separate TB document in Annex 3.

Annex 4. **TB for Rev.3 (March 2011)**

See separate TB document in Annex 4.

Annex 5. **TB for Corr.2 (Feb 2022)**

See separate TB document in Annex 5.

Note: There is no separate Technical Background (TB) document for Corr.1 (Aug 2011).

Technical Background Document
WP/SSLL
UR L4, New 2002

The Working Party on subdivision, stability and load lines has been tasked to develop a UR to ensure watertightness of chain lockers. At the same time the IMO subcommittee SLF introduced such a requirement in the revised annex for the 1988 Load Line Protocol.

The WP agreed unanimously that this requirement meets all criteria considered necessary by the WP in their previous deliberations on this issue as there are the pressure height to be assumed and the closure of access opening to the chain locker by means of a cover secured by closely spaced bolts, as also advised by GPG in the actual Work Programme of the WP/SSLL.

However, due to the situation that not all new-build ships are built under the provisions of the 1988 Protocol a UR covering the remaining ships remains necessary. The WP agreed to use the same wording used in the IMO text amended by a respective application paragraph.

Date of Submission: 25 Sept 2002
Permanent Secretariat

IACS

TECHNICAL BACKGROUND

UR L4 Rev.1 Closure of chain lockers

ABS raised the question of clarification of acceptable means of closure, having been presented with arrangements that vary from canvas hoods with tie-downs to split steel plates that cover the spurling pipe while accommodating the presence of the chain to minimize the ingress of water to the chain locker.

GPG concurred that a footnote should be added and approved the text as follows:

"(*) examples of acceptable arrangements are such as:
- i.) steel plates with cutouts to accommodate chain links or
- ii.) canvas hoods with a lashing arrangement that maintains the cover in the secured position".

Permanent Secretariat 17 July 2003

UR L4 (Rev.2, Nov 2005)

Technical background

TB

The text of existing UR L4 (rev. 1) cannot be read otherwise than the separation of the cable (chain) lockers should be watertight. The approval practice that is established for supply vessels is not in accordance with this UR. Therefore, it was proposed that the text should be changed so it would be clear that only the cable (chain) locker as a whole is to be made watertight, and that common boundary between, or separating, adjacent cable (chain) lockers need not be watertight.

Submitted by Statutory Panel Chairman
14 Sept 2005

Permsec's Note (Implementation Date)

The Statutory Panel Chairman proposed that if GPG would consider it necessary to indicate an implementation date, considering the practice in place and that the modifications carried out do not modify its technical essence, the UR might be applied uniformly as soon as it is adopted by the Council.

GPG decided that an implementation date for this revision is not needed.

Council approved UR L4(Rev.2) on 1 Nov 2005 (5030dICa).

Technical Background for UR L4 Rev.3, Mar 2011

1. Scope and objectives

To clarify watertight standard applicable to access openings situated below the weather deck on spurling pipes and chain lockers.

2. Engineering background for technical basis and rationale

Access openings situated below the weather deck on spurling pipes and chain lockers are to be watertight. There have been instances of inspections of the chain locker by port state authorities where the access cover and its fittings on the chain locker could not be demonstrated as being watertight.

The text of the UR is therefore being modified to explicitly state requirements for access openings below the weather deck.

3. Source/derivation of the proposed IACS Resolution

The source of the information was obtained through input from the Hull Panel and Statutory Panel.

4. Summary of Changes intended for the revised Resolution:

New text covering requirements in 2. above have been introduced in this revision.

5. Points of discussions or possible discussions

The revisions were made through discussions and email correspondence separately within the Hull Panel and Statutory Panel, which involved incorporating individual comments and accepting the consolidated text.

6. Attachments if any

None

Technical Background (TB) document for UR L4 (Corr.2 Feb 2022)

1. Scope and objectives

UR L4 reached its 10th Anniversary and needed to be reviewed to ensure its continued applicability.

2. Engineering background for technical basis and rationale

Reference was made to ISO 24059(2021) during discussion.

3. Source/derivation of the proposed IACS Resolution

See section 5 "Points of discussions or possible discussions"

4. Summary of Changes intended for the revised Resolution:

Only the referenced standards were updated.

5. Points of discussions or possible discussions

During the review one Safety Panel members questioned whether butterfly nuts could be accepted to secure the cover to the anchor quick release in accordance with ISO 24059 (2021).

The Panel discussed the possibility and the risk mitigation measures which might be used – additional damage stability calculations and/or alarm to warn when the cover was not properly secured. Neither of these risk mitigation measures was supported.

Concerns were raised that permitting butterfly nuts on the cover of the anchor quick release would not be in accordance with the existing text of the UR.

In addition ILLC 1966 + 1988 Protocol as amended, Regulation 22-2 states that "Where means of access are provided, they shall be closed by a substantial cover and secured by closely spaced bolts." Although this could be taken to only refer to access for personnel, it would be potentially confusing to permit butterfly nuts for one opening and not for the other.

A majority of the Safety Panel decided that butterfly nuts would not be acceptable to secure the cover to the anchor quick release mechanism.

The Safety Panel concluded that no changes to the text would be made other than for the updates to the standards.

6. Attachments if any

None

UR L5 "Computer Software for Onboard Stability Calculations"

Summary

There was uncertainty about the need to model both sides of a ship in a Type 3 program. This has now been clearly included in paragraph 4.1.3 of the UR.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev.4 (June 2020)	24 June 2020	1 July 2021
Rev.3 (June 2017)	27 June 2017	1 July 2018
Corr.1 (Nov 2006)	November 2006	-
Rev.2 (Sept 2006)	September 2006	January 2007
Rev. 1 (Feb 2005)	February 2005	1 July 2005
New (May 2004)	May 2004	1 July 2005

- **Rev. 4 (June 2020)**

.1 Origin of Change:

☑ Suggestion by IACS member

.2 Main Reason for Change:

- To clarify that the pre-defined relevant damage cases of a Type 3 software shall contemplate both sides of the ship.

3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

4 History of Decisions Made:

One Panel Member asked the Panel views regarding pre-programmed damage cases of Type 3 software. The Member pointed out that for Type 3 software pre-programmed damage cases may be provided for only one side of the ship assuming that the Master can confirm compliance with damage stability requirements by carrying out the calculation twice to assess, for instance, unsymmetrical loading condition on the other side of the ship.

The Member considered that IACS UR L5 does not require damage cases to be pre-programmed for both sides of the ship and international conventions do not require mandatory application of MSC.1/Circ.1461.

The above understanding was not supported by the Panel. The qualified majority agreed that since vessels can have asymmetric compartmentation, an initial list in loaded conditions, or asymmetric loading, it is necessary that Type 3 software be pre-program with damages on both sides of the ship. Members also agreed that this understanding can be clearly read in MSC.1/Circ.1461. An additional clear reference was found in the UK MCA Marine Guidance Note (MGN) 611 (M) "Damage Stability: Alternative verification method for tankers" where previously the Panel had completed a review task upon UK MCA request.

Based on the above, the Panel decided to introduce a clarification into § 4.1.3 to avoid misinterpretations of the requirement.

5 Other Resolutions Changes:

None

6 Any hinderance to MASS, including any other new technologies:

None

7 Dates:

Original Proposal:	3 February 2020 made by Safety Panel Member
Panel Approval:	3 June 2020 (Ref: PS20007_Isi)
GPG Approval:	24 June 2020 (Ref: 20096_IGb)

• Rev.3 (June 2017)

.1 Origin of Change:

☑ Suggestion by IACS member
☑ Based on IMO Regulation

.2 Main Reason for Change:

- To eliminate the vague expressions to prevent different applications by Societies (Task 36)

- To amend the UR L5 with the definition and technical specification of a new Type 4 for SRtP software (Task 37)

.3 List of non-IACS Member Classification Societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

Task 36:

The discussion within the panel was started on the uniform applicability of UR L5; it dealt with several aspects of such UR. In particular it was agreed by the majority that the following actions were necessary:

- to achieve a common understanding on the wording "1%/50cm max"; and
- to review UR L5 in order to eliminate the vague expressions to prevent different applications by Societies.

Following to the outcome of SLF 53, as per the PA in Rec.3.1 of IACS Observer Report, the Statutory Panel has been requested to specify the output data to be provided by Type 3 software for SRtP, taking into account the suggested output as per IACS UR L5 and the proposal amendments to SOLAS Regulation II-1/8-1. This issue has been included in the task relevant to the revision of the UR L5.

Task 37:

The task comes out from the discussion within the Statutory Panel with the aim of amending the UR L5 with the definition and technical specification of a new Type 4 for SRtP software on the basis of the discussion comments carried out within SP.

.5 Other Resolutions Changes

None

.6 Dates:

TECHNICAL BACKGROUND

UR L 5 (New, 2004)

1. Objective and Scope

UR L5 is an IACS Unified Requirement addressing minimum requirements for the approval of onboard software and hardware used for stability calculations.

Basing on the analysis of the of existing IACS Resolutions and other guidelines containing requirements for onboard computers, this UR provides minimum requirements for software and hardware used for stability calculations onboard of a ship.

The UR is applicable to new installations and covers passive systems and the off-line operation mode of active systems only. Requirements related to on-line interface for active systems, for instance remote tank sounding or draught reading, are not covered by this UR. The use of automatic data input by means of e.g. automatic draft reading systems is explicitly exempted from this UR. Systems taking any kind of active control are also exempted.

2. Source of Proposed Requirements

Onboard Computer for Stability Calculation	
Paragraph	**Source**
1. General Item 2 Item 3 Item 6	 - Similar to Rec. 48 Paragraph 1.3 - Res. MSC.75(69) Amendments to Res. A.749(18) Paragraph 2.2.1 - Res. MSC.75(69) Amendments to Res. A.749(18) Paragraph 2.2.2 - UR S1 Paragraph S1.2.3
6. Approval Procedure 6.1 General Approval 6.2 Specific Approval	- UR S1 Paragraph S1.2.3 - Rec. 48 Paragraph 2.2.3 - Rec. 48 Paragraph 2.1.1 thru 2.1.6
7. Operation Manual Item 2, 3, 7,	- Res. MSC.75(69) Amendments to Res. A.749(18) Paragraph 2.2.3 - MSC/Circ.891 Paragraph 5.1.3
9. Periodical Testing	- Res. MSC.75(69) Amendments to Res. A.749(18) Paragraph 2.2.4 - UR S1 Paragraph S1.1.3
10. Other Requirements	- MSC/Circ.891 Paragraph 3.1.6 - MSC/Circ.891 Paragraph 4.3.2

3. Points of Discussion

- Experience has shown, that results of several onboard stability calculation programs are different from those documented in the stability booklet. Usually those differences are caused by simplified input data e.g. due to disregarding trim. Therefore great importance should be placed on the question of accuracy.

- The discussion about damage stability calculation concentrated on the question wether an onboard stability calculation program should calculate individual damage calculations for each loading condition or use a limit curve for the assessment of permissible stability according to requirements of damage stability. It was agreed, that in accordance with SOLAS II-1/Reg. 25-8, damage stability has to be established by using one limit curve without consideration of effects of e.g. differences in trim for a special loading condition.

- Members agreed that the information given by a computer should comprise the information requested by all applicable stability requirements.

- A further important issue covered was the definition of active vs. passive systems and, as a result, the judgement of stability software to be regarded as "safety related" or "safety critical". Members current practice in this concern seems to be differing: some members classify a system using online input data as safety critical, others assess a system safety critical that actively controls or initiates actions (i.e. loading or tank filling/ discharging operations).

- The question of performing rigorous damage stability calculation was raised. It was proposed to distinguish two software kinds: a) systems calculating directly and b) systems verifying damage stability requirements by means of a KG/GM limit curve. The latter might be treated as a variation of those covering intact stability calculating only.

- A discussion was held on *Hardware* and the question whether a system of two nominated computers and the approved software can be considered as acceptable in view of the amendments to the IS Code, requesting approved hard and software. The WP confirmed the view that both, a system meeting the requirements to have two nominated computers available or one approved computer, can be considered as an “approved system” according to the amended IS Code.

4. Decision by Voting

NK proposed to introduce a paragraph stating that;
“damage stability calculation software is not required for ships with arrangement given small possibilities for variation in the distribution of cargoes and ballast, and ships on regular and fixed trading pattern where the approved Damage Stability Booklet gives sufficient guidance.”
After a thorough discussion of pro's and con's, a majority of 8 vs 2 Members preferred not to introduce such a paragraph as there were seen different possibilities to cope with the applicable damage stability requirements of such ships within a stability software in a quite simple manner.

* * * * *

With the Work Programme 2003-2004 GPG redirected this task to the Working Group calling for clarifications of the following issues.

- WP/SSLL is to complete the work to address “hardware approval” in direct communication with WP/EL and finalize UR L[5], utilizing the latest version of UR L[5]. The responsibility of finalizing the draft UR L[5] rests with the WP/SSLL.

- The two Chairmen are to review the draft L[5] together before submission to GPG for approval.

- WP/SSLL and WP/EL are to also utilize the draft Inf. Inf. prepared by AHG/COMP in finalizing UR L[5] and incorporate directly or by reference the relevant aspects and requirements for the AHG/COMP’s draft Int. Inf.

WP/EL XXV and ADH/COMP's last meeting outcomes have been considered by the WP/SSLL.

It was unanimously agreed that WP should not take any action on correction UR L[5] from stability's point of view. As no specific proposals on hardware approval have been received from WP/EL and bearing in mind that existing IACS UR S1 and UR S1A do not contain any requirements on hardware approval WP/SSLL, taking into account the result of informal discussion on this issue between WP/SSLL and WP/EL Chairmen, unanimously agreed to remove UR L[5] chapter "Hardware approval" and advise GPG accordingly. Draft Int. Inf. elaborated by AHG/COMP should not be taken into account when preparing the latest version of UR L[5] because the Section "Scope" of Draft Int. Inf. contains the following instruction: "For guidance on testing of loading instrument/stability computer software and hardware, refer to REC.No.48".

proposed Implementation date: 1 January 2005

Technical Background
for
IACS UR L5 (Rev.1)

1. Objective

To achieve uniformity among IACS Members in implementing UR L5.

2. Background

On 18/09/2004, ABS questioned whether Members intended to apply UR L5 to “software installed after 1 July 2005” as written in L5(version: May 2004). This would effectively mean that L5 apply to software installed after 1 July 2005 on existing ships, ships in construction or future new construction.

3. Discussion

3.1 In response to the ABS enquiry, NK informed as follows (3007bNKd, 21/09/2004):

NK, however, will implement the UR L5 only for new ships the keels of which are laid on or after 1 January 2005 due to following impracticable and unreasonable reasons.

.1 Existing ships

Since stability computer is not required to be onboard up to now, it is much difficult to identify whether ships has the stability computer onboard, when the stability computer was/will be provided on ships and when the software was/will be up-dated.

.2 Ships under construction

There are many ships, which were already initiated to construct before the date of adoption of the UR L5. Many shipbuilders have already purchased/contracted the software not to comply with the new UR L5 for installation after 1 July 2005 on these ships. This implementation scheme will cause such an unreasonable situation to impose replacement of the purchased software by the new type software.

NK, therefore, decided the UR L5 does not apply to stability software on ships constructed before 1 January 2005 with a view to avoiding confusions.

3.2 In the meantime, WP/SSLL had discussed the same topic and provided the following advice to GPG on 14/10/2004.

1) WP/SSLL agreed by majority that UR L5 shall apply to existing ships as well as new builds. NK representative is of the position that it shall apply only to new builds. Although ABS was not represented at the meeting its position has already been indicated by the ABS GPG Member.

2) It was also agreed by majority that the implementation date shall be the date of shipowner's/software developer's application to the Society for software approval.

3) It was decided that the UR L5 should be applied as it is. The UR can be further reconsidered after the compilation of some practical experiences on its application.

3.3 This matter was taken up at GPG 57th meeting (Oct 2004) where BV also indicated its intention to make reservation to L5, stating that:

- BV considers that we should not have requirements which cannot be identified/verified by our surveyors.
- BV believes that it is the responsability of the owners/masters to have an up-to-date equipment.

GPG 57 decided to further consider, in prospect of the IMO Intact Stability Code becoming partly mandatory, how to achieve uniform implementation of UR L5.

3.4 GL and RS were of the view that UR L5 (May 2004) apply to new *software* only and regulate the approval of the new software, and no serious difficulties in applying L5 to existing *ships* were envisaged.

4. Decision

Having observed other Members likely to follow NK and BV, GPG finally decided that the application statement of L5 should be amended with a view to achieving uniform implementation by all IACS Societies.

The preamble of L5 was amended to the effect that L5 apply to stability software on ships contracted for construction on or after 1 July 2005.

Submitted by the Permanent Secretariat
3 Feb 2005

UR L5 rev. 2 – Technical Background

The 1st paragraph of the Preamble of Rev. 1 of UR L5 read "The use of onboard computers for stability calculations is not a requirement of class. However, a stability software installed onboard shall cover all stability requirements applicable to the ship. This UR, which requires both software approval and either hardware approval or the provision of at least two nominated computers, applies to onboard computers which are provided with software capable of performing stability calculations for the vessel."

The Statutory Panel noted that the requirements applicable to the hardware requirements, which were included in the text of this UR prepared by the former WP/SSLL, had been deleted by GPG56.

The Panel considered that other parts of the UR needed to be editorially revised to remove references to hardware approval in order to eliminate any ambiguity on this aspect.

Editorial modifications have been also introduced in Table 1.

GPG discussion

Approved GPG, without further amendment, 6077cIGb, 1 August 2006.

Technical Background

UR L5 (Rev. 2, Corr. 1, Nov 2006) – Onboard Computers for Stability Calculations

1) UR L5 (Rev. 2) was adopted by Council in September 2006, however NK in 6077cNKc (attached as Annex 1) raised some concerns that they had received from industry with respect to the implementation of UR L5 (Rev. 2).

2) In their email NK proposed amending the last paragraph under the 'Application' section to be in line with the previous version of UR L5 and including the implementation statement as a footnote.

3) Other options including posting more than one version of the UR on the website were considered by GPG but in the end 8 members agreed to the proposed corrigenda to UR L5 (Rev. 2) and Corrigenda 1 to UR L5 (Rev.2) was therefore adopted by GPG and Council on 17 November 2006.

4) Specific comments from members can be seen in the GPG Chairman's concluding email, 6077cIGd (attached as Annex 2).

5) To avoid similar confusion in the future, ABS proposed, and were supported by other members, that it would be preferable to include the application statement for a UR in its "implementation statement" rather than in the text of the UR itself. This information has been forwarded to the Panel Chairmen for their reference.

Prepared by Permanent Secretariat
23 November 2006

<u>Attached:</u>
Annex 1 – NK message (6077cNKc)
Annex 2 – GPG Chair's message (6077cIGd)

Annex 1

Date: 30 October 2006
To: Mr. Mo Jianhui, Chairman of GPG
Cc: All GPG Members
Cc: Permanent Secretary

Subject: 6077cNKc: Maintenance of IACS Resolution - UR L5 (SP6011fPCf)

Dear Chairman,

1. Reference is made to UR L5 (rev.2) adopted in September 2006 circulated with IAb of 27 September 2006.

2. I have to apologize for raising this when UR L5 (rev.2) has been adopted, however NK believes that GPG should consider our proposal to resolve misunderstanding of industries.

3. Recently NK has received questions from our clients with respect to the implementation of UR L5 (rev.2). The questions are as to whether onboard stability software in compliance with UR L5 shall be installed on ships contracted for construction on or after "1 July 2005" or "1 January 2007".

4. As far as communication with our clients is concerned, their confusion is caused by the application statement "The requirements in this UR apply to stability software on ships contracted for construction on or after 1 January 2007.", which was changed from "1 July 2005" to "1 January 2007" in the revision of UR L5.

5. They are convinced that UR L5 requires to install onboard stability software on ships contracted for construction on or after "1 July 2005" by our explanations. However, NK has still concerns that our clients who not contact us would continue to have misunderstanding of this issue unless the application statement of UR L5 (rev.2) is revised.

6. Therefore, NK would propose the corrigenda with a view to eliminating possible misunderstanding. The text is attached for your easy reference.

Best regards,

Tetsuya Kinoshita
NK IACS GPG Member

Annex 2

TO: IACS GPG Members
CC: Mr. R. Leslie, IACS Perm. Sec.
Our Ref: G061052

Subject: 6077cIGd : Maintenance of IACS Resolution - UR L5 (SP6011fPCf)

1. All members replied to my IGc, with their Council Members¡¯ concurrence.

2. 8 members agreed to the UR L5(Corr. 1, xx 2006) as proposed in NKc, while

2.1 GL, in GLb, had no objection to the NK¡¯s proposal, and proposed to keep former versions of revisions on the website to provide easy access to URs applicable to ships built/ or contracted
at various dates.

2.2 CCS, in CCc, proposed to post both version of L5 or new version with underline version on the website to avoid the confusion.

2.3 ABS, in ABc, further commented that there is no need to maintain multiple revisions of URs available on the IACS website. However, it would be preferable to include the application statement for a UR in its "implementation statement" rather than in the text of the UR itself and we should keep this in mind going forward. NK and other members have similar position.

3. Having reviewed members¡¯ comment on the issue, this is a typical example on how we include the ¡°implementation statement¡± to avoid the mis-interpreted by industry of installation requirement and technical requirement. I do agree ABS comment that we can only post our updated resolution on the Website. However, we should bear in mind that the revision of resolution should not amend the installation requirement if the resolution is only an improvement on technical requirement.

4. I, therefore, conclude that

4.1 the UR L5(Corr. 1, xx 2006), as attached which I incorporated NK proposal into approved Rev.2 of UR L5, is adopted

4.2 Permsec is requested to

4.2.1 typeset the resolution and post it on the Website and circulate to member for implementation and record

4.2.2 prepare the Technical Background document reflecting the discussion at GPG

4.2.3 inform this example to all Panel chairmen for their reference.

Regards,

Mo Jianhui
IACS GPG Chairman

Technical Background (TB) document for UR L5 (Rev.3 June 2017)

1. Scope and objectives

The use of onboard computers for stability calculations is not a requirement of class.

In passenger ships constructed on or after 1st January 2014, Type 4 stability software is to be provided onboard, in case of not providing shore-based support for safe return to port (SRtP).

However, a stability software installed onboard shall cover all stability requirements applicable to the ship. This UR, which requires only software approval, applies to onboard computers which are provided with software capable of performing stability calculations for the vessel.

2. Engineering background for technical basis and rationale

None.

3. Source / derivation of the proposed IACS Resolution

The Rev.3 of URL5 was deemed necessary within Statutory Panel in order to solve questions raised on the uniform application within IACS Societies. Furthermore, amendments to SOLAS included in MSC Res.325(90), Ch II-1 Reg 8-1 3) require:

“For the purpose of providing operational information to the Master for safe return to port after a flooding casualty, passenger ships constructed on or
after 1 January 2014 shall have:
.1 onboard stability computer; or
.2 shore-based support,
based on guidelines developed by the Organization”

Therefore, Statutory Panel established PT 30 in order to fulfill the following Tasks:

Task 36:

The discussion within the panel was started on the uniform applicability of UR L5; it dealt with several aspects of such UR. In particular it was agreed by the majority that the following actions were necessary:

- to achieve a common understanding on the wording “1%/50cm max”; and
- to review UR L5 in order to eliminate the vague expressions to prevent different applications by Societies.

Following to the outcome of SLF 53, as per the PA in Rec.3.1 of IACS Observer Report, the Statutory Panel has been requested to specify the output data to be provided by Type 3 software for SRtP, taking into account the suggested output as per IACS UR L5 and the proposal amendments to SOLAS Regulation II-1/8-1. This issue has been included in the task relevant to the revision of the UR L5.

Task 37:

The task comes out from the discussion within the Statutory Panel with the aim of amending the UR L5 with the definition and technical specification of a new Type 4 for SRtP software on the basis of the discussion comments carried out within SP.

4. Summary of Changes intended for the revised Resolution

- **Application**

  The references to the 1966 Load Line Convention or the 1988 Protocol to the Load Line Convention, as amended, the IMO MODU Code and/or the 2008 IS Code, has been added as well as the requirement of a Type 4 stability software for safe return to port (SRtP) of passenger ships in case of not providing shore-based support for safe return to port (SRtP), has been included.

- **Types of stability software**

  The Type 2 definition has been modified to allow for two different approaches with respect to the use of the limit curve; furthermore the definition of the new Type 4 dedicated for SRtP has been included.

- A new paragraph clearly requiring that Type 3 and Type 4 stability software should be based on hull form models has been included

- **Functional requirements**

  This section has been split into two sub-sections:

  4.1 General requirements for any type of stability software which includes the minimum requirements common for all the types of stability software and

  4.2 Further requirements for Type 4 stability software which includes the minimum requirements dedicated for SRtP purposes.

  The Panel agreed that the UR need not specify what the software is "not" required to calculate and, therefore, the following two proposed items were deleted:

  - The system is not intended to compute transient asymmetrical flooding whereby the ship could capsize under the immediate inrush of floodwater before there is time for equalization measures to take effect.

  - The system is not intended to make any allowance for the motion of the ship in a seaway, including the effects of tide, current or wave action.

  The Panel, agreeing that UR L5 should be limited to stability software, and not address the number of PCs required to run that software, concluded that the proposal for at least two independent stability computers should be removed from this revision.

- **Acceptable tolerances**

  Table 1 has been revised with the addition of "+/-" before the tolerace values in order to explicitly show that the tolerances should be applied in both directions.

  The word "max" after tolerance values in Table 1 has been deleted and footnote 2 has been added to clarify the application when two values are given.

  The explication "(both solid and corrected for free surfaces)" has been added to GMt with the aim to clearly indicate thee application of this tolerance.

  The tolerance for FS correction has been deleted as it is considered as a redundancy for the alrady present tolerances (having the same value of 2%) for Free surface effect and Displacement.

  The definition of the distance of unprotected openings from WL has been clarified.

  Three additional notes to Table 1 on the application of tolerances have been introduced in order to achive a uniform application by IACS Societies

- **Approval Procedure**

  Verification of functional requirements under paragraph 4.1.2 has ben included.

- **Specific Approval**

  The sentence "For Type 4 stability software for SRtP, the Society shall examine at least three damage cases, each of them associated with at least three loading conditions taken from the ship's approved stability information. Output of the software is to be compared with results of corresponding load / damage case in the approved damage stability booklet or an alternative independant software source." has been added.

5. Points of discussions or possible discussions

Task 36:

1 Identify to achieve a common understanding on the wording "1% / 50cm max"

1. 1 A common position has been achieved on all the tolerances in Table 1 having double values with the addition of the following note:

> When applying the tolerances in Table 1 having two values, the allowable tolerance is the greater of the two values.

1.2 Furthermore the Panel agreed with the PT's recommendation to delete the requirement of the tolerance relevant to FS correction with the following technical justification:

a) Being the FS correction the ratio free surface moment / displacement, and being the tolerance requested the same value (2%) for displacement, free surface moment, free surface correction, we can conclude that this requirement is redundant, because we already have got the requirement of free surface moment and the requirement of displacement.

b) While both FS correction and Displacement show, in general, wide values, and therefore the requirement of 2% as tolerance is easily fulfilled, the FS correction show in general a very small value (some centimetres) for which the fulfillment of 2% as tolerance may be very hard.

Due to the above deletion, it was considered necessary to add the clarification *"(both solid and corrected for free surface)"* after GMt.

1.3 After it has been noted that "margin line" has no reference in SOLAS 2009, but URL5 may be applied also to vessel approved under deterministic SOLAS in which margin line is defined, it has been unanimously agreed to amend the existing text in Table 1

"Distance to unprotected openings or margin line from WL, if applicable" with the revised text

Distance from WL to unprotected and weathertight openings, margin line or other relevant point if applicable.

2 Review UR L5 in order to eliminate the vague expressions to prevent different applications by Societies.

At paragraph 5 the second sentence states:

> *Deviation from these tolerances shall not be accepted unless the Society considers that there is a satisfactory explanation for the difference and that there will be no adverse effect on the safety of the ship.*

The following questions relevant to the uniform application have been raised:

1) What is the technical criteria on the basis of which members shall evaluate when *" ..omissis ....there will be no adverse effect on the safety of the ship."* ?

2) On the basis of what technical considerations an explanation is "satisfactory"?
At paragraph 5.1 the second sentence states:

Output data tolerances are to be close to zero, however, small differences associated with calculation rounding or abridged input data are acceptable.

3) What is the limit for considering differences as *small differences*?
At paragraph 5.1 the third sentence states:

Additionally differences associated with the use of hydrostatic and stability data for trims that differ from those in the approved stability information, are acceptable subject to review by the individual Society.

4) what is the limit for considering acceptable differences associated with the use of hydrostatic and stability data for trims that differ from those in the approved stability information?

5) in what does the review by the individual Society consist?

After a lengthy discussion the outcome of the majority of the PT members is what has been included as Notes in Table 1, and forwarded to the Panel. The Panel discussed there additional notes and amended the same and the final version as agreed by the Panel is reflected in Rev.3 of the UR.

Furthermore, it has been unanimously noted by PT members that the definition of Type 2 stability software is vague when referring to previously approved loading condition, therefore such wording has been deleted. This was agreed by the Safety Panel which replaced the deleted text with “checking all the stability requirements (intact and damage stability) on the basis of a limit curve.”

3. Discussion on the conclusion in item 3.2 of PCf (how to apply for ships with major conversion and offshore units) ;

As far as item 3. is concerned, the conclusions stated in paragraph 3.2 of SP10006cPCf are:

1) UR L 5 shall be applied to existing ships contracted for construction prior to 1 July 2005, but which undergo a major conversion (refer to example in UI SC 226.1)! after that date;

2) The qualifying majority is of the view that UR L 5 should be in general applied to offshore units. The mandatory installation of stability software on such units should be left to discretion of each member.

These conclusions have been agreed by the majority of the PT members with a concern pertaining the application date.

Task 37:

The terms of references established by SP for the PT work relevant to task 37 is included in the work specification in the approved Form A:

1. to develop the draft revised UR L5 based on the conclusion/comments in 1.3) of SP11016cPCx dated 5th June 2012

2. to review Section 6 of the existing UR L5 and to revise it, if needed, with view to reflecting any unique aspects of Type 4 software to be tested initially and periodically

3. to review the following Panel Member's position/comments included in SP11016c PCz 1) noting comments made by Panel Chairman included in SP11016c PCz 2) and advise the Panel accordingly:

4. to review the following Panel Member's comments in SP11016c PCz 1) noting comments made by Panel members included in SP11016c PCz 3) and advise the Panel accordingly.

As far as 1. is concerned all the conclusion/comments have been considered and included in URL5draft11.doc.; the wording 3D geometric (hull forms) has been modified because one half of PT members deems that "3D" confuses and it is sufficient to provide the sentence only "Both Type 3 and Type 4 stability software should be based on hull form model." The other half of PT members prefers the alternative sentence "Both Type 3 and Type 4 stability software should be based on hull form models that is directly calculates from a full three-dimensional geometric mode".

Similarly the sentences in 4.1.3 and 4.1.4 included between square brackets are those for which a majority has not been reached within the PT so the final decision whether maintain the text of not, is left to SP members

As far as the stability criteria to be fulfilled by Type 4 software, as IMO did not establish any criterion on the matter, they are left to the discretion of the Administration.

As far as 2. is concerned, the last sentence in 6. has been added within square brackets because the majority whether to maintain or delete such a sentence was not reached within PT 30.

PT 30 unanimously agreed that only the inclusion in 6.2 of the request of a minimum number of [three] loading condition and [three] damage cases is necessary; the number of at least three loading conditions and three damage cases was unanimously agreed within PT 30 but was left to square brackets for final acceptance by Safety Panel.

PT 30 also unanimously agreed that no modification is necessary to the remaining paragraph 6. 7. 8. 9. 10, as the requirements included in such paragraphs may be applied also to the Type Four software without any need of further changes.

As far as 3. and 4.are concerned, the opinion unanimous shared within PT 30 on the matter is that, as the necessity of the creation of the Type 4 has been unanimously recognized, and that the Type 4 has been included in URL5-draft11.doc, the pre-programmed damage cases are not the huge number of probabilistic damage cases developed in order to fulfill SOLAS Ch. II-1, but they are only some cases which are necessary for the periodical checking of the software only. These damage cases may be not necessarily fetched from those of SOLAS, but they shall be "frozen" (not editable) exactly as the test conditions referred in the present URL5 item 6.2; their use is for the software approval and periodical checking only.

On the other hand in case of a passenger ship the keel of which is laid on or after 1 January 2009 not subject to SRtP requirements, if she is provided with a software capable of carrying out stability calculation, this software is required to be as Type 2, in which any loading case is compared with one or more GM/KG limiting curves according to SOLAS.

A passenger ship the keel of which is laid after 1 January 2009 and subject to SRtP requirements should be provided with Type 2 software and, if not assisted by a shore based emergency team, with a Type 4 software, which, as defined in the URL5-draft11.doc at item 3, is a software calculating damage stability associated with an actual loading condition and an actual flooding case, using direct application of user defined damage, for the purpose of providing operational information for safe return to port.

Therefore a PT Member’s idea of the switch between "pre-programmed damage cases" and "actual damage cases" can be completed by a simple choice of input model, then the "unchangeable" becomes "changeable" is supportable by PT 30 and included in 4.2 of URL5-draft11.doc.

Furthermore during the PT discussion, one PT Member raised the following point:

One other additional issue. Noting that URL5 states ' The requirements of this UR apply to stability software on ships contracted for construction on or after 1 January 2007 PT Member, in the past, raised a query regarding the application of this UR to:

- ship's which undergo conversions on are after said date
- offshore units

It appears that some Class Societies apply this UR to all of the above. It would be sensible to have a unified approach in this matter and we request that this be considered within this review.

The PT Member is concerned that application date of 1st January 2007 may require retrospective application to offshore units and therefore request that the panel considers our request for application date to be moved to December 2013.

The majority of PT Members shares that for the application date as requested by one PT Member, there are no specific comments. For the application of this UR L5 to offshore unit, PT 30 majority deems that "offshore unit" include the mobile offshore drilling unit which apply the quite different both intact and damage stability requirements. Therefore the wording "offshore unit" should be changed with "ships covered by the IMO resolution MSC.235(82) as amended and 2008 SPS Code as amended, or any other offshore support vessels which is undergoing review at IMO."

The output of the PT was considered within the Panel and the conclusions drawn from the same are included in Rev.3 of the UR.

6. Attachments

None.

Technical Background (TB) document for UR L5 (Rev.4 June 2020)

1. Scope and objectives

UR L5 is an IACS Unified Requirement addressing minimum requirements for the approval of onboard software and hardware used for stability calculations.

This revision was made to clearly indicate that the pre-defined relevant damage cases of both sides of the ship are to be included in Type 3 software.

2. Engineering background for technical basis and rationale

None

3. Source/derivation of the proposed IACS Resolution

Internal query raised by a member, in conjunction with the comment it received from UK PSC.

4. Summary of Changes intended for the revised Resolution:

Paragraph 4.1.3 has been revised so that it specifies the pre-defined relevant damage cases of both sides of the ship are to be pre-programmed in Type 3 software.

5. Points of discussions or possible discussions

For the inquiry raised by a member that whether master can confirm the compliance with damage stability requirement by carrying out the calculation twice by transposing the loading conditions to the opposite side at unsymmetrical loading condition with the damage case for only one side pre-programmed with Type 3 software, a majority of members considered that requiring the suggested method is not meeting the requirement for the check to be automatic, although it would be theoretically possible to consider asymmetric loading in this way.

During the discussion by email correspondence, one member commented that the method is permissible only if suitable warnings are provided but this view is not included in this change.

For reference, previously the Panel has reviewed UK MCA Marine Guidance Note (MGN) 611(M) "Damage Stability: Alternative verification method for tankers - UK interpretations and procedures" under the subject PS18020j upon the request of UK MCA and it introduces consideration on one ship side damage as a shortcoming for implementation of MSC.1/Circ.1461 in its item 2.2.

TB (Deletion of UR MI)
Cylinder Overpressure Monitoring of Internal Combustion Engines

Technical Justification for
deletion and the need for revision of M35 and M36.

1. WP/MCH Task 64 was established to review the requirement in UR M1 for cylinder overpressure monitoring of internal combustion engines.

2. The objectives of the Task were to review the requirement in UR M1 for cylinder overpressure monitoring of internal combustion engines and address its application to unattended machinery spaces.

3. The work specification included:
• Review SOLAS II-1 Reg 27.2 and UR M1.
• Determine whether remote indication/alarm is feasible and consider its inclusion in UR M35 and M36 for alarms for periodically unattended internal combustion engines.

4. The background to the task was that IACS WP/MCH members reported cases of owners requesting alarms for cylinder overpressure to be included with the other UMS alarms. It is acknowledged that sentinel valves only provide audible indication when crew members are within earshot.

5. The current requirement for overpressure monitoring stems back to when the design of combustion equipment and operation of engines was not always reliable with the possibilities of excessive fuel charge, pre-ignition and “hanging up” of injection valves. Cylinder pressure relief valves were installed and generally set a pressure corresponding to 110% of the maximum cylinder pressure.

6. The improvements in design and reliability of combustion equipment associated with current designs of marine diesel engines has led the industry to agree that the need for full overpressure relief to be unnecessary and that a sentinel valve could be an acceptable means of indicating that excessive cylinder firing pressure was being affected. By nature of its function the operation of such a sentinel valve would only be recognised in an attended machinery space.

7. Acceptance of a sentinel valve has now been questioned as it does not protect an engine cylinder from excessive pressure as identified in SOLAS Chapter II-1, Regulation 27.2. It is proposed to delete M1 from the Unified Requirements concerning Machinery Installations.

8. It is however recognised that cylinder pressure monitoring is one of the parameters that provides an input to the safe and reliable operation of electronically controlled engines and requirements for monitoring cylinder pressure and provision of overpressure alarm are considered essential where a single failure in equipment or system design could be the cause of cylinder overpressure. . In this respect the WP will propose a new task to review M 35 and M36.

29/06/2004, WP/MCH Chairman

UR M3 "Speed governor and overspeed protective device"

Summary

The UR provides requirements for Speed governor and overspeed protective devices.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable

New (1971)	1971	-

- **Rev.7 (Feb 2023)**

1 Origin of Change:

☑ Based on IACS Requirement (New revision of UR M43 and deletion of UR M47)

2 Main Reason for Change:

The references made in UR M3 to requirements of UR M43 and UR M47 are obsolete due to the deletion of these requirements.

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

Text.

4 History of Decisions Made:

Members agreed to the deletion of the references to UR M43 and UR M47 in M3.1.3 following the deletion and changes made for UR M43 Rev. 1 and the deletion of UR M47 (PM20906dIMh).

5 Other Resolutions Changes:

None.

6 Any hinderance to MASS, including any other new technologies:

M3.1.3 requires local control of engines, which precludes MASS operations.

7 Dates:

Original Proposal	: 30 December 2022	(Ref: PM20906dIMd)
Panel Approval	: 10 January 2024	(Ref: 23186_PMa)
GPG Approval	: 02 February 2024	(Ref: 23186_IGc)

- **Rev.6 (Nov 2018)**

.1 Origin for Change:

☑ Other (*External Query raised through IACS member*)

.2 Main Reason for Change:

To include newer IACS requirements for testing generator sets i.e. Testing Engine and Alternator together, including the coupling.

UR M3.2 specifies requirements for speed governors of prime movers used for driving generators, whilst UR E13.4.4 specifies requirements for voltage regulation system of A.C. generators - including voltage regulation during transient conditions. As such there are IACS requirements when either one of them is separately tested but there are no specific IACS requirements when testing a generator set.

.3 List of non-IACS Member Classification Societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

- Form A approved under 16230_IGa/IAa in December 2016.
- Draft UR submitted to GPG under 16230 (Ref. 16230_PMb – 25 October 2018)

.5 Other Resolutions Changes

None

.6 Dates:

Original Proposal: February 2017 Made by: Machinery Panel
Panel Approval: 25 October 2018 (Ref: 16230_PMb)
GPG Approval: 12 November 2018 (Ref: 16230_IGb)

Annex 3. **TB for Rev.7 (Feb 2024)**

See separate TB document in Annex 3.

***Note**: There are no Technical Background (TB) documents available for New (1971), Rev.1 (1984), Rev.2 (1986), Rev.3 (1990), Rev.4 (June 2002) and Corr.1 (Aug 2003).*

Technical Background
UR M3 (Rev.5 Feb 2006)

Machinery Panel Task PM5201

In the course of revision of UR M3, giving rise to Rev.4 (June 2002), the wording of M3.2.1 was changed, and joined with the requirements which was in last sentence of M3.2.3 .

Thus, the requirement for recovery time to steady state not to exceed 5 seconds when the total consumer load is applied suddenly, was made applicable to emergency generating sets.

It resulted from industry that modern turbocharged engines cannot satisfy the above requirement, and can hardly cope with transient frequency variation, unless the engine is oversized in respect of the total consumer load.

Especially for passenger ships, where the emergency power requirement is quite high, it resulted difficult to satisfy the requirement while complying with other practical constraints.

It was therefore decided to evaluate the requirement in UR M3 Rev.4 against the SOLAS Reg. II-1/42 and Reg II-1/43

It resulted that the requirement from the UR was effectively stricter that SOLAS, in that the SOLAS Regulations II-1/42.2 and 43.2 do require the emergency source of power to be capable of supplying “simultaneously” the required services, but the scope of the regulation is the power balance, and not the transitory behaviour at start-up and during switching on, which, according to Reg. 42.3.1.2 is only subject to a limit of 45 seconds upon failure of the electrical supply from the main source of electrical power.

There was therefore some room for softer but technically sound requirements and it was considered that there is no need for much stricter load-taking capability requirements for the emergency generating sets.

The proposal put forward highlighted that supplying the electrical load in steps, similarly to what regularly accepted for the main source of electrical power, is a technically sound solution, provided the following constraints are complied with:

- the 45 seconds limits is to be satisfied;
- the emergency power distribution systems is to be made such that the loads are automatically switched on in steps;
- the load steps are not larger than the emergency source of power can accept without giving rise to excessive frequency disturbances,
- the maximum allowable load step for the generator should be established in advance, to enable a suitable power distribution system design

The UR has been modified accordingly.

Submitted by MCH Panel Chairman
30 Dec 2005

Permsec's note: **GPG discussion**

1. DNV(NVa) commented as follows:

   DNV can not accept the requirement given in M3.2.3. We require 3 equal steps since modern engine with high charging air pressure will normally not be able to take 50% sudden load. This is the reason for adding the new requirement for emergency generator. If we where to require load steps of 50%, almost every installation will have to be verified in accordance with the exception given M3.2.3. Consequently DNV can not agree to have a UR where in most the cases the exception has to be applied.

2. LR replied(LRb):

   In LR's view the Form A of this task was specific in as much emergency generator prime movers were to be addressed only. The comment in NVa seem to indicate a change of direction.

   As far as we are concerned the current requirements for the main generator prime movers do allow a relaxation of loading from two steps to three steps and therefore we do not see the argument as being strong enough to stop completion of this task. LR is not convinced that the majority of the engines will have difficulties in coping with the two step load. We would prefer to see the draft submitted to Council for adoption based on 3/4 majority.

3. DNV responded:

   DNV understand LR's comment in LRb, and have therefore reconsidered the situation and decided that we can accept UR M3 as revised in (PM5201).

Therefore, unanimous agreement was achieved at GPG level, too (6001_IGc, 25 Jan 06)

Implementation (6001_ICa, 6 Feb 2006):
UR M3(Rev.4) was adopted on 6 Feb 2006. The requirements introduced therein are to be implemented within one year of adoption by Council. END

Technical Background (TB) document for UR M3 (Rev.6 Nov 2018)

1. Scope and objectives

The objective is to revise UR M3 to include additional requirements to cover generator sets i.e. Engine and Alternator together, including the coupling.

2. Engineering background for technical basis and rationale

Following an external query associated with the transient voltage response limitation (when applying the two load steps to maximum power loading), it was recognised that there were neither specific IACS requirements for testing an Engine and an Alternator together nor which included the coupling, where installed.

It was noted that while UR M3.2 specifies requirements for speed governors of prime movers used for driving generators, UR E13.4.4 specifies requirements for voltage regulation system of A.C. generators - including voltage regulation during transient conditions. As such there are IACS requirements when either one of them is separately tested but are not aligned with each other for the case when the two items are tested together.

While UR E13 requires that all tests are to be carried out in accordance with IEC 60092-301, there are deviations between UR M3 and IEC 60092-301 when it comes to load steps used for testing. After discussions, the Panel agreed to use this opportunity to consider aligning the load tests required in UR M3 to that of IEC 60092-301.

After further discussion and based on a qualified majority, it was concluded that the tests required by UR M3 and by UR E13 are different and both tests need to be carried out.

3. Source / derivation of the proposed IACS Resolution

External query raised through IACS member.

4. Summary of Changes intended for the revised Resolution:

Fig. 1 from UR M3 has been revised to align it with the figure in ISO 8528-5:2013, which provides limiting curves for up to 5 power stages.
The reference to paragraph 3.1.1 in M3.2.1 was changed to 3.2.5

5. Points of discussions or possible discussions

In addition to the items listed under point 4 above, the following items were also discussed by the Machinery Panel:

Consideration was given to include requirements covering cyclic irregularity and frequency cyclic variation, including an associated testing procedure to verify that it is within the allowed tolerance. Based on a qualified majority subsequent to further review, the panel expressed a view that requirements for cyclic irregularity and frequency cyclic variation should not be included.

Regarding the alignment of tests as required by UR M3 and UR E13, based on a qualified majority it was concluded that the tests required by UR M3 and by UR E13 are different and both tests need to be carried out.

A new sub-section M3.3 was evaluated for inclusion, in order to specify additional requirements for generating sets covering torsional vibration, coupling selection criteria, power requirement, rating plate for generator sets and testing requirements associated with engine and alternator. After discussion, the qualified majority of panel Members decided not to include this new sub-section in UR M3 and to include it in a new dedicated UR.

6. Attachments if any

None

Technical Background (TB) document for UR M3 (Rev.7 Feb 2024)

1. Scope and objectives

To update UR M3 following revision 1 of UR M43 and the deletion of UR M47.

2. Engineering background for technical basis and rationale

None.

2a. Specification of the data utilised in the development/revision of the proposed IACS Resolution, if any

N/A.

3. Source/derivation of the proposed IACS Resolution

None.

4. Summary of Changes intended for the revised Resolution:

The reference to UR M43.8 and M43.10 requirements and to UR M47 have been deleted in M3.1.3, as some of these requirements have been deleted, or are not deemed necessary.

5. Points of discussions or possible discussions

None.

6. Attachments if any

None.

IACS WP/MCH

TECHNICAL BACKGROUND DOCUMENT

Rev.2, M9 – Safety valves for crankcases of internal combustion engines.

2.1. Scope and objectives

The item is covered by Task 41. The question put forward by RINA initiated the revision . Proposal was related to the possible use of more than two crankcase explosion relief valves, which seemed to be in conflict with text in current IACS UR M9, Note 2.

2.2 Points of discussion

The subject was discussed, and it was agreed that the use of more than two safety valves could be accepted from a technical point of view, provided they otherwise satisfied the requirements of UR M9.2 and M10.4.

In order to avoid future confusion as to this it was agreed to propose a revision of IACS UR M9, by deleting the present Note 2.

2.3 Source/derivation of proposed requirements

Initiated by question made by RINA in their fax MAC/VBC/25182 - 1999-06-16

2.4 Decision by voting.

All WP/MCH members agreed in above.

Submitted by WP/MCH Chairman on 10 May 2000

Technical Background

Revision UR M9 (Rev.3) and M10(Rev.2)
New URs (M 66 & M67) for Type Testing Crankcase Explosion Relief Valves and Oil Mist Detection Arrangements

1. WP/MCH Task 55 was established to review the requirements in URM9 “Safety valves for crankcases of internal combustion engines” and M10 “Protection of internal combustion engines against crankcase explosions” for applicability and suitability to modern diesel engines.

2. The work specification included the following:
   - Review crankcase explosion reports for the past 10 years.
   - Review SOLAS requirements applicable to diesel engine crankcase safety.
   - Establish philosophy for a holistic approach to crankcase safety.
   - Consider the applicability of the safeguards in M9 and M10 for crankcase to all types of modern diesel engines – (high speed, medium speed and large slow speed engines + “large” and “small” bore engines).
   - Propose a set Unified Requirements for crankcase safety that include:
     - Requirements for submission of plans and particulars
     - Assessment of engine arrangements
     - Design of equipment
     - Testing of equipment and safety arrangements
     - Type testing requirements
     - Monitoring arrangements
     - Protection of engine and personnel
     - Through life survey and inspection

3. The background to the task was that there have been a number of serious incidents involving crankcase explosions in large diesel engines in the past 5-6 years that have resulted in loss of life and major damage to ships and their machinery. Questions have been raised regarding the adequacy of current standards for crankcase safety with engine builders and ship-owners pressing for revision/re-assessment of the current the standards that essentially stem from the Reina del Pacifico incident in 1947.

4. UR M9 has been extended to address design requirements for explosion relief valves in terms of a required provision of a flame arrester that prevents the passage of flame following a crankcase explosion and for valve to be type tested. The possible effects of shielding on relief valve efficacy have been recognised with a requirement for testing if such shielding is fitted.

5. The revised M9 also includes requirements for a manufacturer’s installation and maintenance manual with instructions installation, maintenance and actions required to be followed after a crankcase explosion. Requirements for marking of the valves have also been included.

6. UR M10 has been revised to remove requirements for the explosion relief valve (moved to M9) and clarify the existing text. The revised M10 now includes requirements for type testing of oil mist detection/monitoring systems and compliance with the oil mist manufacturer’s instructions. Requirements for arrangements and installation onto the engine have been defined and also for system testing.

7. UR M10 also addresses alternative methods of preventing the build-up of oil mist and methods of assessment.

8. To support the extensive revisions to M9 and M10 new Unified Requirements for type testing explosion relief valves and for oil mist monitoring/detection arrangements have been developed. These URs provide a common standard against which relief valves and oil mist monitoring/detection systems cane be assessed. They define the scope, purpose, test facilities, processes, assessment and reporting.

Note by the Permanent Secretariat:

1. GPG added the following implementation statement to the URs:

> "Engines are to be fitted with components and arrangements complying with this UR when:
> 1) an application for certification of an engine is dated on/after 1 January 2006; or
> 2) installed in new ships for which the date of contract for construction is on or after 1 January 2006."

2. The URs (M 66 & 67, M9(Rev.2) and M20(Rev.3)) do not apply to existing engines on the existing ships.

Submitted by WP/MCH Chairman 24th August 2004

Technical Background Document
UR M9(Rev.3, Corr.1, November 2005)
UR M10(Rev.2, Corr.1, November 2005)
UR M66(New, Corr.1, November 2005)
UR M67(New, Corr.1, November 2005)

1. These UR Ms were adopted in Jan 2005 for implementation from 1 Jan 2006.

2. However, IACS was requested, via the Machinery Panel, by CIMAC and MAN/B&W, to postpone the 1 Jan 06 implementation date for the type testing requirements for crankcase explosion relief valves and crankcase oil mist detection/monitoring and alarm arrangements contained in IACS URs M66 and M67, respectively.

3. This discussion led to re-issuance of these UR Ms, changing the implementation statements.

These UR Ms were re-issued as 'Corr.1' on 29 Nov 2005.

4. GPG Chairman's message (4069gIGk, 14/11/2005) contains a more detailed background for this amendment.

For records, GPG/Council Chairmen's messages are attached to the TB document for the January 2005 versions.

Subject: 4069gICd: UR M66, M67 - application date

Date: 23 Nov 05

TO: IACS Council Members

TO: IACS GPG Chairman & Members

TO: IACS Permanent Secretary: Mr. R. Leslie

TO: IACS Machinery Panel Chairman: Dr. U. Petersen

FROM: R. D. Somerville
File Ref: T-12-2

Subject: 4069gICd: UR M66, M67 - application date

1. All Members have replied to ICc. Eight Members have supported the proposed course of action in IGk.

2. Lloyd's, supported by RINA, proposes that the URs need not be withdrawn, as proposed in IGk, but that only the implementation date need be changed. LR proposed posponement to 1 July 06 -- instead of 1 Jan 07, as proposed in IGk.

2.1 Regarding the implementation date of 1 July 06 vs. 1 Jan 07, this had already been debated in GPG and the strong majority supported 1 Jan 2007. I conclude 1 January 2007 is agreed.

2.2 Regarding whether to "withdraw" the URs or "postpone" their date of application, to my understanding either approach is acceptable and will result in the same outcome.

3. Therefore to accomodate the request that the URs not be withdrawn, I conclude that the agreed course of action is:

3.1 **Perm Sec** is to revise the uniform application statements for the URs, as follows, reissue them, and post them on the IACS website:

3.1.1 For URs M66 and M67:

"Note: Engines are to be fitted with components and arrangements complying with this UR when:
1) an application for certification of an engine is dated on/after 1 January 2007; or
2) installed in new ships for which the date of contract for construction is on or after 1 January 2007."

3.1.2 For UR M9, Rev.3:

"2. Engines are to be fitted with components and arrangements complying with Revision 3 of this UR, except for M9.8, when:

1) an application for certification of an engine is dated on/after 1 January 2006; or
2) installed in new ships for which the date of contract for construction is on or after 1 January 2006.
The requirements of M9.8 apply, in both cases above, from 1 January 2007."

3.1.3 For UR M10, Rev.2:

"2. Engines are to be fitted with components and arrangements complying with Revision 2 of this UR, except for M10.8, when:
1) an application for certification of an engine is dated on/after 1 January 2006; or
2) installed in new ships for which the date of contract for construction is on or after 1 January 2006.
The requirements of M10.8 apply, in both cases above, from 1 January 2007."

3.2 **Machinery Panel** is to:
a. inform CIMAC and MAN/B&W of the postponed application of URs M66 and M67, and the intention to update them;
b. update URs M66 and M67, as quickly as possible, taking account of CIMAC's, MAN/B&W and Panel Member's inputs;
c. once adopted at Panel level, send the revised URs to CIMAC for quick review/comment and notification to the equipment suppliers;
d. further update the URs as needed in light of any comments received from CIMAC;
e. submit the revised URs to GPG for approval not later than the end of the 1st Q 2006.

3.3 Upon adoption of the revised URs by IACS Council, **Machinery Panel** is to send them to CIMAC for their information and requesting that CIMAC notify the equipment suppliers of the requirements.

Regards,
Robert D. Somerville
IACS Council Chairman

CC: IACS Machinery Panel Chairman: Dr. U. Petersen

CC: IACS Permanent Secretary: Mr. R. Leslie

FROM: S.R. McIntyre

File Ref: T-12-2

Subject: 4069gIGk: UR M66, M67 - application date

1. IACS has been requested, via the Machinery Panel, by CIMAC and MAN/B&W, to postpone the 1 Jan 06 implementation date for the type testing requirements for crankcase explosion relief valves and crankcase oil mist detection/monitoring and alarm arrangements contained in IACS URs M66 and M67, respectively. Their request is to give the equipment manufacturers and the engine builders more time to adapt to the new requirements. Industry has also recommended the need for some improvements/clarifications in the two URs, which the Machinery Panel has agreed are needed/appropriate.

1.1 Since CIMAC was involved in the IACS decision, some years ago, to develop these URs, in retrospect it would have been advisable to submit the URs for external review by CIMAC before their adoption to ensure that CIMAC would be fully aware of the requirements and the timetable for their implementation--and working with IACS Societies to ensure that their suppliers were apprised of and complying with the new requirements. Unfortunately, this was not done.

1.2 The type testing requirements of URs M66 and M67 are invoked in recent revisions of M9 and M10, respectively.

2. The Machinery Panel recommended that GPG postpone implementation of URs M66 and M67 and advised GPG that both URs need to be updated/clarified.

2.1 Several Members have also advised that they needed more time for initial implementation and could not implement the two URs from 1 Jan 06 as had been originally agreed by Council.

3. Having carefully considered the input from CIMAC, MAN/B&W, the Machinery Panel and Members, GPG agrees that IACS should postpone the implementation of these URs by one year to give time for updating them, vetting the changes with CIMAC, notifying industry and for Members to process the related rule changes. Therefore, GPG requests Council's agreement to the following course of action:

3.1 URs M66 and M67, along with M9.8 of M9, Rev.3 and M10.8 of M10, Rev.2 are to be withdrawn pending the updating of M66 and M67, which needs to be accomplished as quickly as possible (ie. the target date of 1st Q 2006 for revising M66, agreed at GPG 59, needs to be accelerated);

3.2 The updated URs, once adopted at Panel level are to be sent to CIMAC by the Machinery Panel for quick review/comment by CIMAC, and then further updated by the Panel in light of any comments received, prior to submission to GPG/Council;

3.3 The updated URs M66 and M67, once adopted by GPG/Council, are to be issued as "Corr" (since the initial versions will never have been implemented)--with uniform application from 1 Jan 2007 (instead of 1 Jan 2006);

3.4 M9, Rev.3 without M9.8, and M10, Rev. 2, without M10.8, are to be reissued as "Corr" until the updated M66 and M67 are adopted by Council, at which time M9.8 and M10.8 are to be included in M9, Rev.4 and M10, Rev.3, respectively for application from 1 Jan 2007.

4. Council Chairman is kindly requested to seek Council's agreement to this course of action as soon as possible.

Regards,
S.R. McIntyre
IACS GPG Chairman

Technical Background

Revision UR M9 (Rev.3) and M10(Rev.2)
New URs (M 66 & M67) for Type Testing Crankcase Explosion Relief Valves and Oil Mist Detection Arrangements

1. WP/MCH Task 55 was established to review the requirements in URM9 “Safety valves for crankcases of internal combustion engines” and M10 “Protection of internal combustion engines against crankcase explosions” for applicability and suitability to modern diesel engines.

2. The work specification included the following:
    - Review crankcase explosion reports for the past 10 years.
    - Review SOLAS requirements applicable to diesel engine crankcase safety.
    - Establish philosophy for a holistic approach to crankcase safety.
    - Consider the applicability of the safeguards in M9 and M10 for crankcase to all types of modern diesel engines – (high speed, medium speed and large slow speed engines + “large” and “small” bore engines).
    - Propose a set Unified Requirements for crankcase safety that include:
        - Requirements for submission of plans and particulars
        - Assessment of engine arrangements
        - Design of equipment
        - Testing of equipment and safety arrangements
        - Type testing requirements
        - Monitoring arrangements
        - Protection of engine and personnel
        - Through life survey and inspection

3. The background to the task was that there have been a number of serious incidents involving crankcase explosions in large diesel engines in the past 5-6 years that have resulted in loss of life and major damage to ships and their machinery. Questions have been raised regarding the adequacy of current standards for crankcase safety with engine builders and ship-owners pressing for revision/re-assessment of the current the standards that essentially stem from the Reina del Pacifico incident in 1947.

4. UR M9 has been extended to address design requirements for explosion relief valves in terms of a required provision of a flame arrester that prevents the passage of flame following a crankcase explosion and for valve to be type tested. The possible effects of shielding on relief valve efficacy have been recognised with a requirement for testing if such shielding is fitted.

5. The revised M9 also includes requirements for a manufacturer’s installation and maintenance manual with instructions installation, maintenance and actions required to be followed after a crankcase explosion. Requirements for marking of the valves have also been included.

6. UR M10 has been revised to remove requirements for the explosion relief valve (moved to M9) and clarify the existing text. The revised M10 now includes requirements for type testing of oil mist detection/monitoring systems and compliance with the oil mist manufacturer's instructions. Requirements for arrangements and installation onto the engine have been defined and also for system testing.

7. UR M10 also addresses alternative methods of preventing the build-up of oil mist and methods of assessment.

8. To support the extensive revisions to M9 and M10 new Unified Requirements for type testing explosion relief valves and for oil mist monitoring/detection arrangements have been developed. These URs provide a common standard against which relief valves and oil mist monitoring/detection systems cane be assessed. They define the scope, purpose, test facilities, processes, assessment and reporting.

Note by the Permanent Secretariat:

1. GPG added the following implementation statement to the URs:

> "Engines are to be fitted with components and arrangements complying with this UR when:
> 1) an application for certification of an engine is dated on/after 1 January 2006; or
> 2) installed in new ships for which the date of contract for construction is on or after 1 January 2006."

2. The URs (M 66 & 67, M9(Rev.2) and M20(Rev.3)) do not apply to existing engines on the existing ships.

Submitted by WP/MCH Chairman 24th August 2004

6. UR M10 has been revised to remove requirements for the explosion relief valve (moved to M9) and clarify the existing text. The revised M10 now includes requirements for type testing of oil mist detection/monitoring systems and compliance with the oil mist manufacturer's instructions. Requirements for arrangements and installation onto the engine have been defined and also for system testing.

7. UR M10 also addresses alternative methods of preventing the build-up of oil mist and methods of assessment.

8. To support the extensive revisions to M9 and M10 new Unified Requirements for type testing explosion relief valves and for oil mist monitoring/detection arrangements have been developed. These URs provide a common standard against which relief valves and oil mist monitoring/detection systems cane be assessed. They define the scope, purpose, test facilities, processes, assessment and reporting.

Note by the Permanent Secretariat:

1. GPG added the following implementation statement to the URs:

> "Engines are to be fitted with components and arrangements complying with this UR when:
> 1) an application for certification of an engine is dated on/after 1 January 2006; or
> 2) installed in new ships for which the date of contract for construction is on or after 1 January 2006."

2. The URs (M 66 & 67, M9(Rev.2) and M20(Rev.3)) do not apply to existing engines on the existing ships.

Submitted by WP/MCH Chairman 24th August 2004

UR M10 "Protection of internal combustion engines against crankcase explosions"

Summary

UR M10 was updated to address the crankcase safety for engines fuelled with gas or low flashpoint fuels and the conditions for accepting a ventilation of the crankcase.

1 Origin of Change:

☑ Suggestion by IACS member

2 Main Reason for Change:

The changes in UR M10 were made after discussions on the following points raised by a member:

1) Should we interpret IGC 13.6.17 and 16.7.3.3 as meaning that the engine should be so designed that the gas concentration in the crankcase cannot exceed the LFL of methane whatever the operating conditions?
2) Is an external air supply intended to dilute the methane concentration in the crankcase permitted or not?

3 Surveyability review of UR and Auditability review of PR

None.

4 Human Element issues assessment

Not applicable.

5 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None.

6 History of Decisions Made:

The matter was discussed by Machinery Panel under task PM18909 starting in February 2018. Members agreed to consult CIMAC.

The following CIMAC feedback was considered by the Panel:

- CIMAC message dated June 21, 2019
- CIMAC report "Protection of internal combustion engines against crankcase explosions", 2020-03 (1st edition)
- CIMAC message dated May 30, 2024 (CIMAC WG2 Feedback).

7 Other Resolutions Changes:

None.

8 Any hinderance to MASS, including any other new technologies:

None.

9 Dates:

Original Proposal:	February 2018	Made by: Member society
Panel Approval:	08 November 2024	PM18909_IMzf
GPG Approval:	24 November 2024	24145_IGg

• Rev 4 (July 2013)

.1 Origin of Change:

- Suggestion by IACS member

.2 Main Reason for Change:

To implement definitions of Low-, Medium- and High-Speed Engines as made in UR M71.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

The matter was discussed by Machinery Panel under PM 12407 during 16th and 17th Meeting and all members agreed with the introduction of the same definitions as made in the UR M71. The implementation date agreed is 01 January 2015.

.5 Other Resolutions Changes

None

.6 Dates:

Original Proposal: September 2012 by Machinery Panel
Machinery Panel Approval: 25 June 2013
GPG Approval: 24 July 2013 (Subject No: 12189_IGb)

Part B. Technical Background

List of Technical Background (TB) documents for UR M10:

Annex 1. **TB for Rev.2 (Jan 2005)**

See separate TB document in Annex 1.

Annex 2. **TB for Rev.2 Corr.1 (Nov 2005)**

See separate TB document in Annex 2.

Annex 3. **TB for Rev.3 (Sept 2008)**

See separate TB document in Annex 3.

Annex 4. **TB for Rev.4 (July 2013)**

See separate TB document in Annex 4.

Annex 5. **TB for Rev.5 (Nov 2024)**

See separate TB document in Annex 5.

Note: There are no Technical Background (TB) documents available for New (1972), Rev.1 (1991), Corr.1 (1997) and Rev.2 Corr.2 (Oct 2007).

Technical Background

Revision UR M9 (Rev.3) and M10(Rev.2)
New URs (M 66 & M67) for Type Testing Crankcase Explosion Relief Valves and Oil Mist Detection Arrangements

1. WP/MCH Task 55 was established to review the requirements in URM9 “Safety valves for crankcases of internal combustion engines” and M10 “Protection of internal combustion engines against crankcase explosions” for applicability and suitability to modern diesel engines.

2. The work specification included the following:
   - Review crankcase explosion reports for the past 10 years.
   - Review SOLAS requirements applicable to diesel engine crankcase safety.
   - Establish philosophy for a holistic approach to crankcase safety.
   - Consider the applicability of the safeguards in M9 and M10 for crankcase to all types of modern diesel engines – (high speed, medium speed and large slow speed engines + “large” and “small” bore engines).
   - Propose a set Unified Requirements for crankcase safety that include:
     - Requirements for submission of plans and particulars
     - Assessment of engine arrangements
     - Design of equipment
     - Testing of equipment and safety arrangements
     - Type testing requirements
     - Monitoring arrangements
     - Protection of engine and personnel
     - Through life survey and inspection

3. The background to the task was that there have been a number of serious incidents involving crankcase explosions in large diesel engines in the past 5-6 years that have resulted in loss of life and major damage to ships and their machinery. Questions have been raised regarding the adequacy of current standards for crankcase safety with engine builders and ship-owners pressing for revision/re-assessment of the current the standards that essentially stem from the Reina del Pacifico incident in 1947.

4. UR M9 has been extended to address design requirements for explosion relief valves in terms of a required provision of a flame arrester that prevents the passage of flame following a crankcase explosion and for valve to be type tested. The possible effects of shielding on relief valve efficacy have been recognised with a requirement for testing if such shielding is fitted.

5. The revised M9 also includes requirements for a manufacturer’s installation and maintenance manual with instructions installation, maintenance and actions required to be followed after a crankcase explosion. Requirements for marking of the valves have also been included.

6. UR M10 has been revised to remove requirements for the explosion relief valve (moved to M9) and clarify the existing text. The revised M10 now includes requirements for type testing of oil mist detection/monitoring systems and compliance with the oil mist manufacturer's instructions. Requirements for arrangements and installation onto the engine have been defined and also for system testing.

7. UR M10 also addresses alternative methods of preventing the build-up of oil mist and methods of assessment.

8. To support the extensive revisions to M9 and M10 new Unified Requirements for type testing explosion relief valves and for oil mist monitoring/detection arrangements have been developed. These URs provide a common standard against which relief valves and oil mist monitoring/detection systems cane be assessed. They define the scope, purpose, test facilities, processes, assessment and reporting.

Note by the Permanent Secretariat:

1. GPG added the following implementation statement to the URs:

> "Engines are to be fitted with components and arrangements complying with this UR when:
> 1) an application for certification of an engine is dated on/after 1 January 2006; or
> 2) installed in new ships for which the date of contract for construction is on or after 1 January 2006."

2. The URs (M 66 & 67, M9(Rev.2) and M20(Rev.3)) do not apply to existing engines on the existing ships.

Submitted by WP/MCH Chairman 24th August 2004

Technical Background Document
UR M9(Rev.3, Corr.1, November 2005)
UR M10(Rev.2, Corr.1, November 2005)
UR M66(New, Corr.1, November 2005)
UR M67(New, Corr.1, November 2005)

1. These UR Ms were adopted in Jan 2005 for implementation from 1 Jan 2006.

2. However, IACS was requested, via the Machinery Panel, by CIMAC and MAN/B&W, to postpone the 1 Jan 06 implementation date for the type testing requirements for crankcase explosion relief valves and crankcase oil mist detection/monitoring and alarm arrangements contained in IACS URs M66 and M67, respectively.

3. This discussion led to re-issuance of these UR Ms, changing the implementation statements.

These UR Ms were re-issued as ‘Corr.1’ on 29 Nov 2005.

4. GPG Chairman’s message (4069gIGk, 14/11/2005) contains a more detailed background for this amendment.

For records, GPG/Council Chairmen’s messages are attached to the TB document for the January 2005 versions.

Subject: 4069gICd: UR M66, M67 - application date

Date: 23 Nov 05

TO: IACS Council Members

TO: IACS GPG Chairman & Members

TO: IACS Permanent Secretary: Mr. R. Leslie

TO: IACS Machinery Panel Chairman: Dr. U. Petersen

FROM: R. D. Somerville
File Ref: T-12-2

Subject: 4069gICd: UR M66, M67 - application date

1. All Members have replied to ICc. Eight Members have supported the proposed course of action in IGk.

2. Lloyd's, supported by RINA, proposes that the URs need not be withdrawn, as proposed in IGk, but that only the implementation date need be changed. LR proposed posponement to 1 July 06 -- instead of 1 Jan 07, as proposed in IGk.

2.1 Regarding the implementation date of 1 July 06 vs. 1 Jan 07, this had already been debated in GPG and the strong majority supported 1 Jan 2007. I conclude 1 January 2007 is agreed.

2.2 Regarding whether to "withdraw" the URs or "postpone" their date of application, to my understanding either approach is acceptable and will result in the same outcome.

3. Therefore to accomodate the request that the URs not be withdrawn, I conclude that the agreed course of action is:

3.1 **Perm Sec** is to revise the uniform application statements for the URs, as follows, reissue them, and post them on the IACS website:

3.1.1 For URs M66 and M67:

"Note: Engines are to be fitted with components and arrangements complying with this UR when:
1) an application for certification of an engine is dated on/after 1 January 2007; or
2) installed in new ships for which the date of contract for construction is on or after 1 January 2007."

3.1.2 For UR M9, Rev.3:

"2. Engines are to be fitted with components and arrangements complying with Revision 3 of this UR, except for M9.8, when:

1) an application for certification of an engine is dated on/after 1 January 2006; or
2) installed in new ships for which the date of contract for construction is on or after 1 January 2006.
The requirements of M9.8 apply, in both cases above, from 1 January 2007."

3.1.3 For UR M10, Rev.2:

"2. Engines are to be fitted with components and arrangements complying with Revision 2 of this UR, except for M10.8, when:
1) an application for certification of an engine is dated on/after 1 January 2006; or
2) installed in new ships for which the date of contract for construction is on or after 1 January 2006.
The requirements of M10.8 apply, in both cases above, from 1 January 2007."

3.2 **Machinery Panel** is to:
a. inform CIMAC and MAN/B&W of the postponed application of URs M66 and M67, and the intention to update them;
b. update URs M66 and M67, as quickly as possible, taking account of CIMAC's, MAN/B&W and Panel Member's inputs;
c. once adopted at Panel level, send the revised URs to CIMAC for quick review/comment and notification to the equipment suppliers;
d. further update the URs as needed in light of any comments received from CIMAC;
e. submit the revised URs to GPG for approval not later than the end of the 1st Q 2006.

3.3 Upon adoption of the revised URs by IACS Council, **Machinery Panel** is to send them to CIMAC for their information and requesting that CIMAC notify the equipment suppliers of the requirements.

Regards,
Robert D. Somerville
IACS Council Chairman

CC: IACS Council Members
CC: IACS GPG Members

CC: IACS Machinery Panel Chairman: Dr. U. Petersen

CC: IACS Permanent Secretary: Mr. R. Leslie

FROM: S.R. McIntyre

File Ref: T-12-2

Subject: 4069gIGk: UR M66, M67 - application date

1. IACS has been requested, via the Machinery Panel, by CIMAC and MAN/B&W, to postpone the 1 Jan 06 implementation date for the type testing requirements for crankcase explosion relief valves and crankcase oil mist detection/monitoring and alarm arrangements contained in IACS URs M66 and M67, respectively. Their request is to give the equipment manufacturers and the engine builders more time to adapt to the new requirements. Industry has also recommended the need for some improvements/clarifications in the two URs, which the Machinery Panel has agreed are needed/appropriate.

1.1 Since CIMAC was involved in the IACS decision, some years ago, to develop these URs, in retrospect it would have been advisable to submit the URs for external review by CIMAC before their adoption to ensure that CIMAC would be fully aware of the requirements and the timetable for their implementation--and working with IACS Societies to ensure that their suppliers were apprised of and complying with the new requirements. Unfortunately, this was not done.

1.2 The type testing requirements of URs M66 and M67 are invoked in recent revisions of M9 and M10, respectively.

2. The Machinery Panel recommended that GPG postpone implementation of URs M66 and M67 and advised GPG that both URs need to be updated/clarified.

2.1 Several Members have also advised that they needed more time for initial implementation and could not implement the two URs from 1 Jan 06 as had been originally agreed by Council.

3. Having carefully considered the input from CIMAC, MAN/B&W, the Machinery Panel and Members, GPG agrees that IACS should postpone the implementation of these URs by one year to give time for updating them, vetting the changes with CIMAC, notifying industry and for Members to process the related rule changes. Therefore, GPG requests Council's agreement to the following course of action:

3.1 URs M66 and M67, along with M9.8 of M9, Rev.3 and M10.8 of M10, Rev.2 are to be withdrawn pending the updating of M66 and M67, which needs to be accomplished as quickly as possible (ie. the target date of 1st Q 2006 for revising M66, agreed at GPG 59, needs to be accelerated);

3.2 The updated URs, once adopted at Panel level are to be sent to CIMAC by the Machinery Panel for quick review/comment by CIMAC, and then further updated by the Panel in light of any comments received, prior to submission to GPG/Council;

3.3 The updated URs M66 and M67, once adopted by GPG/Council, are to be issued as "Corr" (since the initial versions will never have been implemented)--with uniform application from 1 Jan 2007 (instead of 1 Jan 2006);

3.4 M9, Rev.3 without M9.8, and M10, Rev. 2, without M10.8, are to be reissued as "Corr" until the updated M66 and M67 are adopted by Council, at which time M9.8 and M10.8 are to be included in M9, Rev.4 and M10, Rev.3, respectively for application from 1 Jan 2007.

4. Council Chairman is kindly requested to seek Council's agreement to this course of action as soon as possible.

Regards,
S.R. McIntyre
IACS GPG Chairman

Technical Background

UR M10 (Rev. 3, Sept 2008) and UI SC 228 (New, Dec 2008)

Existing SOLAS Regulation Analysis

SOLAS Reg. II-1/27.5 requires:

Main turbine propulsion machinery and, where applicable, main internal combustion propulsion machinery and auxiliary machinery shall be provided with automatic shutoff arrangements in the case of failures ....which could lead rapidly to .... serious damage or explosion. The administration may permit overriding automatic shutoff devices.

SOLAS Reg. II-1/31.2.10 requires:

Automation systems shall be designed in a manner which ensures that threshold warning of impending or imminent slowdown or shutdown of the propulsion machinery is given to the officer in charge of the navigational watch in time to assess the navigational circumstances in an emergency. In particular, the system shall control, monitor, alert and take safety action to slow down or stop propulsion while providing the officer in charge of the navigational watch an opportunity to manually intervene, except for those case where manual intervention will result in total failure of the engine and/or propulsion equipment within a short time, for example in the case of overspeed.

SOLAS Reg. II-1/31.3 requires:

Where the main propulsion and associated machinery, including sources of main electrical supply, are provided with various degrees of automatic or remote control and are under continuous manual supervision from a control room the arrangements and controls shall be so designed, equipped and installed that the machinery operation will be as safe and effective as if it were under direct supervision; for this purpose regulations 46 to 50 shall apply as appropriate. Particular consideration shall be given to protect such spaces against fire and flooding.

SOLAS Reg. II-1/47.2 requires:

Internal combustion engines of 2,250 kW and above or having cylinders of more than 300 mm bore shall be provided with crankcase oil mist detectors or engine bearing temperature monitors or equivalent devices.

Summarising SOLAS:

Engines are to be fitted with safety system shutting off the engines to prevent serious damage or explosion and overrides may be permitted.

The safety system, either in attended or unattended machinery spaces, is to alert and take action (alarm + slow down or stop) but, when action is taken on the propulsion system, the watch officer is to be given an opportunity to intervene (alarm + override), except for those case where manual intervention will result in total failure of the engine and/or propulsion equipment within a short time.

For periodically unattended machinery, engines larger than a given size are to be equipped with oil mist detectors or bearing temperature monitors or equivalent devices (SOLAS does not specify which action they are to initiate); the same applies to machinery systems under automatic or remote control or under remote manual supervision.

Existing IACS UR Analysis

- IACS UR M10 in item 10.8 gives a requirement applicable to oil mist detectors (including type testing to UR M67), but does not require an oil mist detector (OMD) to be fitted.

- IACS UR M35 Table 1 (slow speed main engines in unattended machinery spaces) requires an OMD to be installed and give alarm and **slow** down.

- IACS UR M35 Table 2 (medium speed main engines in unattended machinery spaces) requires an OMD to be installed and give alarm and **shut** down.

- (IACS UR M36 Table 1 (auxiliary engines in unattended machinery spaces) requires an OMD to be installed and give alarm and shut down).

- IACS UR M67 gives standard type testing conditions for OMD.

Summarising IACS URs:
OMD (or equivalent arrangements) is to be fitted only to engines when installed in an unattended machinery space.
The actions to be taken are described in M35, M36.
The alarm system is to be in accordance with M29.
The safety system is to be in accordance with M30.
The OMD is to be type tested in accordance with M.67

Assessment of ISO TC8/SC1 WD 7240-26 "Fire detection and alarm systems - Point type oil mist detectors"
This document has been considered.
Summary of review:
It addresses requirements applicable to oil mist detectors to be used in open spaces for fire detection systems in buildings and vessels. (It is not deemed applicable to oil mist detectors to be used in engine crankcases, even if some part could be used as guidance).

Summarising findings – changes to M10 and new SC228
It is recognized that:

1. An OMD is a safety device and this also applies to bearing temperature devices and equivalent devices where fitted instead of an OMD.
2. Where OMD arrangements or alternative arrangements are used to initiate slow down, an alarm is to be given before intervention of the safety system.
3. Where OMD arrangements or alternative arrangements are used to initiate shut down, the alarm may be given upon intervention of safety system.
4. Where arrangements are provided for overriding a safety system, they are to be such that inadvertent operation is prevented.
5. Visual indication is to be given at the relevant control station(s) when a safety override is operated.
6. The consequences of overriding a safety system are to be established and documented.

The Rev.3 of UR M10 and a new UI SC228 has been prepared to address the above.

Submitted by Machinery Panel Chairman
30 July 2008

Permanent Secretariat note (January 2009):

- UR M10 Rev.3 was approved, with the following implementation statement, by GPG on 11 September 2008 (ref. 6098_IGj):

  "Note:
  1) The requirements of M10 Rev. 3 are to be uniformly implemented by IACS Societies for engines:
  i) when an application for certification of an engine is dated on or after 1 January 2010; or
  ii) which are installed in new ships for which the date of contract for construction is on or after 1 January 2010.
  2) The "contract for construction" date means the date on which the contract to build the vessel is signed between the prospective owner and the shipbuilder. For further details regarding the date of "contract for construction", refer to IACS Procedural requirement (PR) No.29."

- After initial review by GPG new UI SC228 was returned to Machinery Panel to clarify a possible discrepancy between the UI text and revised UR M10.8, before being approved by GPG on 22 December 2008 (ref. 6098_IGl).

Technical Background (TB) document for UR M10 (Rev.4 July 2013)

1 Scope and objectives

Introducing definitions for Low-, Medium- and High-Speed Engines in the new UR M71 made it necessary to investigate the effect on other documents using these terms.

The changes introduced are not expected have any effect on the technical content of the UR, the sole purpose is to align the documents.

2 Engineering background for technical basis and rationale

Requirements in the URs applicable to I.C. engines do depend upon engine speed and engine design. It was therefore necessary to introduce definitions of engine speed in the newly developed UR M71.

3 Source / derivation of the proposed IACS Resolution

UR M71

4 Summary of Changes intended for the revised Resolution

It was considered in the panel that the applicability of different requirement is better defined by making reference to engine speed. Hence the same definitions have been introduced.

5 Points of discussions or possible discussions

This task was triggered by IACS Machinery Panel as a result of discussion of a Member's proposal during 15th, 16th and 17th Panel Meetings. Definitions for Low-, Medium- and High-Speed Engines were introduced in the new UR M71 "Type Testing of I.C. Engines".

Technical Background (TB) document for UR M10 (Rev.5 Nov 2024)

1. Scope and objectives

The amendments to the UR M10 refer mainly to the following points:

- A detailed evaluation regarding the safety of the crankcase is required for dual fuel or gas engines.
- Ventilation of the crankcase is permitted for engines fuelled with gas or low-flashpoint fuel, where necessary to maintain the gas concentration in the crankcase below LEL
- Where a forced extraction of crankcase atmosphere is provided, the crankcase pressure level is not to affect the reliable function of measurement and safety devices (such as oil mist detection) in the crankcase.
- The selection of the OMD sample points locations and the sample extraction rate (if applicable) from the crankcase may be justified by tests on a running engine.
- "Engine bearing temperature monitors and equivalent devices" have been defined.

2. Engineering background for technical basis and rationale

The engineering background was derived from the members' expertise and from information and comments from CIMAC. In particular, the following background has been used as a basis for Rev.5 of UR M10:

- CIMAC reply to the Panel dated June 21, 2019
- CIMAC report "Protection of internal combustion engines against crankcase explosions", 2020-03 (1st edition)
- CIMAC WG2 Feedback dated May 30, 2024
- The definitions related to the *engine bearing temperature monitors and equivalent devices* have been introduced based on the newly proposed revised UI SC76 (task PM18908c).

3. Source/derivation of the proposed IACS Resolution

Proposal by an IACS Member Society, following request by an engine manufacturer.

4. Summary of Changes intended for the revised Resolution:

- Paragraph M10.5 has been modified and completed as follows:
  UR M10.5 Ventilation of crankcase, and any arrangement which could produce a flow of external air into the crankcase, is in principle not permitted except for gas engines or dual fuel engines fuelled with gas or low-flashpoint fuel, where this might be necessary to maintain the gas concentration in the crankcase below LEL provided that:

  1) *It is demonstrated that the risk connected with a crankcase explosion is not increased by the ventilation system.*
  2) *The operation of the ventilation system is monitored.*
  3) *The automatic safety actions to be activated and / or the risk mitigation measures to be implemented in case of detection of a ventilation failure are specified by the engine manufacturer and justified in the safety concept of the engine.*

- In paragraph M10.5.2:

  The vacuum value (2.5 10^{-4} Pa) not to be exceeded has been deleted.
  The text of M10.5.2 has been replaced with the following one:
  When forced extraction of crankcase atmosphere is provided, the crankcase pressure level is not to influence the reliable function of measurement and safety devices (such as oil mist detection) in the crankcase.

- New paragraph M10.6 requiring a detailed evaluation of the crankcase safety for DF or gas engines has been added:

  M10.6 For dual fuel or gas engines a detailed evaluation regarding the safety of the crankcase is to be carried out justifying that:

  1) *either the gas concentration in the crankcase remains below the LEL without specific measures, or*
  2) *the risk of a crankcase explosion is reduced through specific measures (see, for example, M10.5 or M10.23).*

- Definitions of *engine bearing temperature monitors or equivalent devices* have been added, in line with new proposed revised UI SC76.

- In paragraph M10.19, which requires plans showing details and the arrangement of oil mist detection to be submitted for approval, a new subparagraph (i) has been added.

  This addition emphasizes that documentation should align with the agreement between the engine designer and the oil mist detection system manufacturer, to be retained as supporting documentation for reference purposes. This is followed by a complementary new clause (ii), specifying an acceptable alternative to evidence of studies justifying the location of the sample points and the extraction rate for OMD (if applicable):

  (i) Documentation containing evidence of studies justifying the selected location of Sample points and the sample extraction rate (if applicable), supported by a confirmation from the oil mist detection system manufacturer, from the crankcase and the spaces mentioned in M10.2, is to be provided to the Classification Society for reference purposes only.

  (ii) As an alternative to the evidence of studies, an oil mist inlet test may be performed on a running engine. Test conditions such as setup, records or engine loads are to be agreed upon between engine designer, oil mist detector (OMD) manufacturer and respective class society. The test engine is to be chosen to demonstrate OMD arrangement suitability to cover a specified range of engine types and configurations. To allow a repeatable and comparable test, an oil mist generator as described under UR M67 is to be used.

5. Points of discussions or possible discussions

One member's view was that the severity of the crankcase explosion had to be considered in the revised UR. This was not supported by the Panel based on CIMAC statement that, as compared to liquid fuel diesel engines, fuel gas in the crankcase does not increase explosion severity as well as probability even under stoichiometric conditions. Furthermore, additional flow of air into the crankcase does not increase severity of oil mist explosions.

One member suggested that the gases extracted from the crankcase should be re-circulated for combustion, e.g. to the compressor inlet. This was not supported by the Panel.

One member suggested that the design of the crankcase and / or arrangement of the explosion relief valves could be considered in the evaluation of the crankcase safety for dual fuel or gas engines. This was not supported by the Panel.

Discussions were held on the maximum gas concentration in the crankcase (80% or 100% LEL) to be considered as acceptable without specific measures (see M10.6.1). Noting that:

- CIMAC did not support the 80% LEL value but suggested replacing it with e.g. "...remains below hazardous concentrations",
- IGC 13.6.17 requires that *"the crankcases of internal combustion engines that can run on gas shall be arranged to alarm before 100% LFL",*

it was finally decided to remove "80%", using the following wording:

M10.6 For dual fuel or gas engines a detailed evaluation regarding the safety of the crankcase is to be carried out justifying that:

1) either the gas concentration in the crankcase remains below ~~80% of~~ the LEL, or
2) the risk of a crankcase explosion is reduced through specific measures (see, for example, M10.5 or M10.23).

Based on a proposal from CIMAC, the following new clause, requiring limiting the air flow introduced into the crankcase by the OMD operation, was proposed to be added:

M10.22 If air is introduced into the crankcase by the operation of the OMD system, the flow of air is to be limited to a minimum and the amount is to be negligible.

However, some members believed that a clarification was necessary for the expressions "flow of air is to be limited" and "the amount is to be negligible" to allow verification of compliance. It was then decided not to include the proposed clause in the UR but mention it in the TB.

None

Technical Background
Revision of M16 (Rev.1)

M16 dates back to 1974 and has not been revised since then. A revision is necessary of following reasons:

1. The wording “safety device” implies that it should be function tested. All safety functions are normally required to be verified by testing, except these devices for emergency operation. In order to justify this practice the heading should be altered to just “devices for emergency......”.

2. M16 mentions no verification of the devices. Full verification by testing various combinations during sea trial is considered too much (see 1), but a trial mounting before the sea trial should be required.

3. M16 does not require any minimum power in these emergency operating conditions. Without a certain minimum the objective of these devices is unclear.

4. M16 does not require specification of available/permissible power in the various combinations. This should be available onboard.

5. A high permissible power in these emergency operating conditions may jeopardise the last stage reduction gearing due to the influence of shaft alignment on gear faceload distribution. This potential problem should be addressed.

Submitted by WP/MCH Chairman
02 December 2004

Rev.4, M18 – Parts of internal combustion engines for which material tests are required.

2.1 Scope and objectives

The item is covered by Task 41. Question was put forward by DNV. Ref. fax DNV J-450 dated 1999-07-02.

2.2 Points of discussion

A discussion was initiated based on DNV's earlier input.

It was agreed that the term "Supercharger" used in UR M18.2 and M23 is to be understood as turbochargers and engine driven compressors (incl. "Root blowers"), but not auxiliary blowers.

The question "mass produced" or "non-mass produced" is considered quite important as to UR M18.2/M23. It appears that Manufacturer Survey Arrangements (MSAs) are currently issued based on conditions actually not covered by IACS UR, and IACS members' normal procedures are to some extent differing from the procedure laid out in the URs.
It was agreed to take this matter up later as a separate task in order to clarify/rectify the requirements given in M18.5.

As to M 18.1 and M18.2, it was agreed to propose this revised as follows:

- *Amend M18.1:* *The list given below applies to engines and superchargers not covered by M5 and M23*

- *Amend M18.2 (xiv):* *Supercharger shaft and rotor, including blades (Supercharger is understood as turbochargers and engine driven compressors (incl. "Root blowers"), but not auxiliary blowers).*

2.3 Source/derivation of proposed requirements

Initiated by question forwarded by DNV in their fax DNV J-450 dated 1999-07-02.

2.4 Decision by voting.

All WP/MCH members agreed in above.

Technical Background for Rev.5, M 20

1. Scope of objectives

This revision is to introduce a requirement for machinery verification run during dry docking to verify safe operation of main and auxiliary machinery. This is one of the outcomes of the ESP Tripartite (IACS, OCIMF, INTERTANKO) technical Working Group which was held on 15 October 1999 in London.

2. Points of discussions or possible discussions

- BV (GPG) did not agree to the first sentence of the proposed requirement in that it is the owners' responsibility to check the machinery installations are in good operational condition after a ship is re-floated. However, all Council unanimously agreed to the amendment.
- NEW MVR Requirement has been positioned in new section M 20.5. Originally it was proposed to place it under UR Z7 with change to its title "Hull Classification Surveys and Machinery Verification Runs". Subsequent GPG discussion yielded that it should be placed in UR Z 18, however, the Permsec suggested to put it in M 20 since the Z 18 had not been formally adopted.

3. Source/derivation of proposed requirements

The final minute of the Tripartite meeting reads (C 40/6/WP.1):

- IACS has given further consideration to this item and proposed the following wording for inclusion in IUR Z7:
  "At the time of dry docking a dock trial is to be carried out to attending surveyors' satisfaction to confirm satisfactory operation of main and auxiliary machinery. If significant repairs are carried out to main or auxiliary machinery or steering gear, consideration should be given to a sea trial to attending surveyors' satisfaction.
- The Working Group agreed to the above wording.
- This measure would be applicable to any type of ship but would not be recorded in the CER for Tankers.

Prepared by the IACS Permanent Secretariat

Technical Background Document
WP/SRC Task 1
New UR Z 18, Z21 and deletion of M20
(+ Rev.8 of Z7)

Objective and Scope:

To review existing UR M 20 and relocate it as a UR under UR Z.

Source of Proposed Requirements:

WP/SRC Chairman reported by e-mail 6 May 1999 that WP/SRC Members had discussed and reviewed the requirements contained in UR M20 through correspondence and at their last meeting and had relocated the text of M20 to a new UR Z18. A proposal for resolving ABS' existing reservations against M20 is included in the proposed UR Z18.

Points of Discussion:

WP/SRC unanimously agreed to the proposed draft UR Z 18.

Note by the Permanent Secretariat

GPG did not accept WP/SRC's proposal for resolving ABS' reservations since the proposal would not, in fact, lead to any greater uniformity in practice than by simply retaining ABS' existing reservations, and therefore did not approve the proposed UR Z18, pending receipt and consideration of an acceptable means of resolving ABS' reservations from the ABS GPG representative. The ABS GPG representative reported to GPG, at its 51st meeting on 2-4 October 2001 that ABS was not prepared to change its practice and that he could not identify any means of resolving ABS' reservations without significant change to other Members practices, which other Members were not prepared to accept.

Therefore, GPG expressed its preparedness to live with ABS reservation to the tail shaft survey requirements of ex M20 (now Z21), agreed to isolate it from Z18.

Outcome:

- Delete M 20;
- Create new Z18 excluding tail shaft survey requirements;
- Create new Z21 for the tail shaft survey requirements.
- Revision 8 of Z7 to have the same descriptions of special survey as those in Z10s and Z18.

  (GPG considered it prudent to keep Revision 8 of Z7 in abeyance until WP/SRC complete its Task 83 "revision of Z7".)

Date of submission: 6 May 1999
By WP/SRC Chairman's e-mail

UR M24 "Requirements concerning use of crude oil or slops as fuel for tanker boilers"

Summary

This UR provides requirements for tankers where crude oil or slops are used as fuel for boilers. This revision clarifies that the UR will not be applicable when low flash point crude oil is used, and the design is subject to SOLAS regulation II-1/55.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev.2 (August 2023)	07 August 2023	1 January 2025
Rev.1 (1976)	No record	-
New (1975)	No record	-

- **Rev.2 (August 2023)**

1 Origin of Change:

☑ Other (*FUA No.9 of GPG 85 - update of the Rule linkage table)*

2 Main Reason for Change:

Revision 2 of UR M24 aims to clarify whether UR M24 shall be applied additionally with engineering analysis as stated in SOLAS regulation II-1/55 or the design and construction should follow SOLAS regulation II-1/55 or UR M24, i.e., when requirements in UR M24 are followed, it should be understood being complying with requirements in SOLAS regulation II-1/55.

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None.

4 History of Decisions Made:

1. Following a member suggestion, it was agreed M24.7 (renumbered to M24.8) should be referred to from UR P2.1 under task PM20906f (see PM20906aIMc).

2. Members agreed that UR M24 should not be directly applied to ship subject to IGF code (PM20906aIMb) and therefore new M24.1 was added to the UR.
Noting that the main point to consider for the application of UR M24 is then whether crude oil is low flash point or not and that generally crude oil is low flash point, members agreed to the proposed text for M24.1 stating that UR M24 is applicable to tankers where crude oil or slops are used as fuel for boilers except where there is

conflict with alternative design and arrangements required in accordance with SOLAS II-1/55 (PM20906aIMh).

5 Other Resolutions Changes:

As indicated in §4 History of decisions made, a reference to M24.8 will be referred to in UR P2.1.

6 Any hinderance to MASS, including any other new technologies:

None.

7 Dates:

Original Proposal	: 19 January 2021	(Ref: PM210906aIMa)
Panel Approval	: 03 May 2023	(Ref: PM20906aIMi)
GPG Approval	: 07 August 2023	(Ref: 23055_IGd)

- **Rev.1 (1976)**

No records available.

- **New (1975)**

No records available.

****

Part B. Technical Background

List of Technical Background (TB) documents for UR M24:

Annex 1. **TB for Rev.2 (August 2023)**

See separate TB document in Annex 1.

Note: There are no Technical Background (TB) documents available for New (1975) and Rev.1 (1976).

Technical Background (TB) document for UR M24 Rev.2 (August 2023)

1. Scope and objectives

To clarify application of the UR versus the alternative design and arrangements of SOLAS Reg. II-1/55.

2. Engineering background for technical basis and rationale

A review of UR M24 Rev.1 was undertaken by the Machinery Panel to identify any inconsistency with the IGF Code, considering as starting point whether crude oil or slops are regarded as low-flashpoint fuel defined in SOLAS Reg. II-2/2.30.

3. Source/derivation of the proposed IACS Resolution

The subject revision is an outcome of FUA No. 9 of GPG 85, which tasked the Machinery Panel to take action on records kept by IACS on the status of URs.

4. Summary of Changes intended for the revised Resolution:

An introductory paragraph has been inserted clarifying that where conflict is identified between the UR provisions and the alternative requirements of SOLAS Reg. II-1/55, the SOLAS requirements take precedence. Due to the new paragraph, the subsequent paragraphs have been renumbered.

5. Points of discussions or possible discussions

1. On a query whether crude oil/slops can never have a flash point equal to 60C or above, or they usually have a flash point (FP) of less than 60°C, according to received member's replies, the crude oil flash point is in general below 60°C , however there might be some cases in which the FP can exceed 60°C .

2. UR M24.1 newly added in the UR M24 (Rev.2) was provided on the basis of the conclusion that UR M24 should not be directly applied to ships subject to the IGF code. Therefore, what is important is not "whether crude oil is used as fuel", but "whether crude oil is low-flashpoint fuel".

   If crude oil used as fuel for boilers is not low-flashpoint fuel, then UR M24 will be applied, and if crude oil used as fuel for boilers is low-flashpoint fuel, then SOLAS II-1/55 will be applied taking precedence over UR M24. In the latter case, if there is a conflict between the requirements of UR M24 and SOLAS II-1/55, then it is necessary to follow SOLAS II-1/55, including engineering analysis.

6. Attachments if any

None.

UR M25 "Astern power for main propulsion"

Summary

UR M25 provides unified requirement for astern power for main propulsion. Rev.5 was issued to resolve the inconsistency between UR M25.1 and UR S10.2.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev.5 (Dec 2024)	21 December 2024	1 January 2026
Rev.4 (June 2017)	15 June 2017	1 July 2018
Rev.3 (July 2003)	-	-
Rev.2 (1997)	-	-
Rev.1 (1984)	-	-
New (1975)	-	-

- **Rev.5 (Dec 2024)**

.1 Origin of Change:

Task raised by a member during the 33rd IACS Machinery Panel Meeting held on 16 and 17 March 2021, who pointed out the following inconsistency between UR M25 and UR S10:

a. IACS UR M25.1 requires that "...main propulsion machinery is to be capable of maintaining in free route astern at least 70% of the ahead revolutions." We have received feedback from yacht builders that the requirement cannot be satisfied primarily due to their non-retractable stabilizers and highly skewed propellers and therefore suggest that the requirement should be related to the maximum astern speed of the vessel.

b. We would also bring members attention to the requirements in IACS UR S10.2 for determination of rudder forces and calculation of rudder scantlings, in which the astern calculation uses the greater of the maximum astern speed of the vessel or 0.5 x the ahead speed. This may (or may not) need to be considered in any proposed revision of the requirements.

.2 Main Reasons for Change:

No reliable information was available regarding the relationship between astern revolutions, engine power and ship astern speed. It was considered that operation astern at 70% of the MCR ahead revolutions would not cause the ship speed to exceed half of the maximum ahead speed.

The requirement to maintain, in free route astern, at least 70% of the ahead revolutions appeared to be solely a classification requirement, as the statutory instruments require the main propulsion machinery to be capable of reversing the direction of thrust so as to bring the ship to rest from the maximum service speed.

The "70% astern revolutions" was neither considered during design appraisal and it was not clear whether and how it should be verified. UR M25.1 did not mandate an astern trial, however somewhat paradoxically, this was stated as a requirement for steam turbine installations.

.3 Surveyability review of UR and Auditability review of PR

Not applicable to the proposed modification of Rev.5.

.4 Human Element issues assessment

Not applicable.

.5 List of non-IACS Member Classification Societies contributing through theTC Forum and/or participating in IACS Working Group:

None

.6 History of Decisions Made:

The work on amendments to UR M25 was taken up in the panel by correspondence, which were discussed and agreed by the panel.
First draft UR M25 Rev.5 was circulated to the Panel with Chair's message IMu dated 03/12/2024.

.7 Other Resolutions Changes

Changes were made to UR M51.

.8 Any hinderance to MASS, including any other new technologies:

None

.9 Dates:

Original Proposal:	Date: March 2021	Made by: Member society
Panel Approval:	Date: 03 December 2024	PM 18103b_IMu
GPG Approval:	Date: 21 December 2024	24208_IGb

- **Rev.4 (June 2017)**

.1 Origin of Change:

Based on Vessel Incident (Saffier and Key Bora)

.2 Main Reason for Change:

This task has been received from GPG (e-mail 12095_IGb dated 9 July 2012), which has requested the Machinery Panel to review the PIAIB report and to submit to GPG itsviews and the preferred possible course of actions. The MAIB report addresses the investigation of the failure of the controllable pitch propeller (CPP) of the cargo ship

Saffier resulting in heavy contact with a berthed tug in Immingham harbour on 25 June 2011.

In connection with the incident, it was agreed during the 18'h meeting of the Machinery Panel that:

a. developing a UR Zxx is the appropriate way to address this matter, and
b. the scope of this task should be extended to cover on-board tests required incase of retrofit of essential machinery, not limited to CPPs.

Additionally, another MAIB accident investigation report (No 31/2014) for KEY BORA,which made heavy contact with the jetty because the CPP's astern response was inadequate and did not develop sufficient astern thrust in time to stop the vessel, wasalso taken into consideration.
Consequently, it was agreed to develop:

a. a UR Zxx "On-board tests required during commissioning of essential equipmentand systems for propulsion", to address the on-board tests to be carried out for new essential equipment and systems and also for replacement, modification, repair or re-adjustment of existing essential equipment and systems for propulsion; and
b. new requirements for UR M25 to specifically address astern manoeuvring trials.

On 30 November 2016, the Survey panel Chairman informed machinery panel Chairman, by PM12601_PYb, that Survey Panel members unanimously agreed thatthere was no need to issue a new UR Zxx but the UR Z18 would be modified accordingly, in order to address the above matters, by the introduction of a new paragraph 4.2. This proposal was also agreed by machinery panel members by PM12601_IMr dated 26 December 2016.

.3 List of non-IACS Member Classification Societies contributing through theTC Forum and/or participating in IACS Working Group:

None.

.4 History of Decisions Made:

Panel discussed and agreed to:

- expand the scope of the task and develop a UR Zxx to address on-board testingduring commissioning of essential equipment and systems for propulsion, not limited to CPP systems

- to develop new requirements for UR M25 to specifically address asternmanoeuvring trials.

GPG required (under 14181_IAa dated 10 November 2014) the KEY BORA case to be addressed by the Panel.

Final versions of UR Zxx and UR lfl25 (Rev.4) were approved by Panel during the 23rd meeting in March 2016.

The final text of the new paragraph 4.2 of UR Z18 was agreed by machinery panel members by PM12601_IMs dated 27 February 2017 and communicated to the Survey panel chairman. On that occasion machinery panel members also agreed on the inclusion in the note of the draft UR M25 of the following statements which refers to UR

Z18:
"(b) ships other than those specified in the preceding (a) on which astern testing is carried out in accordance with Z18 on or after 1 July 2018."

Final version of UR M25 (Rev.4) was approved by Panel by PM12601_IMv dated 24 May 2017.

.5 Other Resolutions Changes

None

.6 Dates:

Original Proposal: 04 July 2013	Made by Machinery Panel Member
Panel Approval: 24 May 2017	(Ref: PM12601)

◄▲►

Technical Background (TB) document for UR M25 (Rev.3 July 2003)

WP/MCH Task 61 “Ml25.1 regarding duration of astern trials”. WP/MCH submitted proposed amendments to M25.1 requiring that the main propulsion machinery should be capable of reversing the direction of thrust so as to bring the ship to rest from maximum service speed.

NK Council clarified what should have been written in M25.2. Agreed.

Technical Background (TB) document for UR M25 (Rev.4 June 2017)

1. Scope and objectives

The objectives of the task were to:

a) Develop a UR Zxx "ON-BOARD TESTS REQUIRED FOR COMMISSIONING OF ESSENTIAL EQUIPMENT AND SYSTEMS FOR PROPULSION", to address the on- board tests to be carried out for:

- new essential equipment and systems intended for propulsion
- replacement, modification, repair or re-adjustment of existing essential equipment and systems for propulsion.

b) Develop new requirements for UR M25 to specifically address astern manoeuvring trials.

With reference to the objectives as per item a) above, in November 2016 Survey panel members agreed to introduce a new paragraph in UR Z18 instead of developing a new UR Zxx. This proposal was also agreed by machinery panel members by PM12601_IMr dated 26 December 2016

2. Engineering background for technical basis and rationale

This task was triggered by the UK MAIB and their report on the investigation of the failure of the controllable pitch propeller of the cargo ship Saffier. The MAIB requested IACS to develop a unified requirement stating that, during commissioning trials of new and existing CPP systems, the response times for ahead and astern pitch demand are also recorded and verified to be in accordance with the values expected by the CPP system manufacturer.

After discussions within the Panel, it was decided to expand the scope of the taskto on-board tests for commissioning essential equipment and systems for propulsion.

3. Source / derivation of the proposed IACS Resolution

- MAIB Report on the investigation of the failure of the controllable pitch propeller of the cargo ship Saffier resulting in heavy contact with a berthed tugin Immingham harbour on 25 June 2011, Report No. 9/2012, day 2012.
- MAIB accident investigation report (No. 31/2014) for KEY BORA, which made heavy contact with the jetty because the CPP's astern response was inadequate and did not develop sufficient astern thrust in time to stop the vessel.

4. Summary of Changes intended for the revised Resolution

- Addition of M25.4 requiring on-board tests to demonstrate the astern response characteristics of essential equipment and systems for propulsion.
- Rearrangement of Footnote 2 as Pl25.5.

5. Points of discussions or possible discussion

The position of one member was to require tests to demonstrate that the response time for any pitch change was acceptable. The Panel decided not to follow this position as UR Pl25 covers only the astern operation of the ship and accordingly, to limit the application of the requirement to astern pitch demand.

6. Attachments if any

None

Technical Background (TB) document for UR M25 (Rev.5 Dec 2024)

1. Scope and objectives

The objectives of the task were:

- to reconsider the requirement in M25.1 for the propulsion machinery to maintain in astern operation 70% of the ahead revolutions,
- to introduce requirements on the minimum astern power required by SOLAS regulation II-1/28.1,
- to introduce requirements on astern trials,
- to propose clarification for the maximum astern speed referred to in UR S10.2.

2. Engineering background for technical basis and rationale

No reliable information has been identified regarding the relationship between astern revolutions, engine power and ship astern speed.

The requirement for 70% astern rpm was contained in the previous editions of UR M51 and was removed from the current version (Rev.4) in February 2015. There is no reason to expose the plant to unnecessary risk, and 70% is not a SOLAS requirement. In addition, the Panel's understanding is that this 70% astern revolution requirement probably originates from steam turbines in order to properly dimension the astern turbine.

The revised UR M25 refers to the following:

- The **minimum astern power** required by SOLAS regulation II-1/ 28.1 to secure proper control of the ship in all normal circumstances. This minimum astern power is not to exceed the maximum permissible astern power (MPAP) for which the propulsion plant is designed.
- The **maximum permissible astern power,** which should not exceed the designed maximum astern power referred to in SOLAS regulation II-1 / 3.15. The maximum permissible astern power is to be considered for the design of the main steering gear and rudder stock as per SOLAS regulation II-1 / 29.3.4 and UR S10.2.1.1.

For astern trials, a reference to standard ISO 19019:2005, section 5.4: Astern trials has been introduced.

3. Summary of Changes intended for the revised Resolution

The following main changes were made in UR M25 Rev.4:

- The first sentence of UR M25.1 was more or less a copy of SOLAS regulations II-1 / 28.1 and 28.2 and was therefore deleted. The second sentence was substituted with the following text:

  The minimum astern power required by SOLAS regulation II-1 / 28.1 to secure proper control of the ship in all normal circumstances is to be determined by the ship designer and is not to exceed the maximum permissible astern power (MPAP) for which the propulsion plant is designed. Astern trials are to be conducted in accordance with the provisions of ISO 19019:2005, section 5.4: Astern trials.

- Existing M25.2 was revised as follows:

  M25.2 Where steam turbines are used for main propulsion, the astern trial is to demonstrate that they are to be capable of ~~maintaining~~ operating at their maximum permissible astern power (MPAP) ~~in free route astern at least 70% of the ahead revolutions[1]~~ for a period of at least 15 minutes. The astern trial is to be limited to 30 minutes or in accordance with manufacturer's recommendation to avoid overheating of the turbine due to the effects of "windage" and friction.

- The following Note were added:

  Note:

  The designed maximum astern power, as referred to in SOLAS regulation II-1 / 3.15, defining the maximum astern speed for the design of the main steering gear and rudder stock as per SOLAS regulation II-1 / 29.3.4 and UR S10.2.1.1, shall not to be taken less than the MPAP.

- Existing requirement M25.5 was deleted as deemed outside the scope of UR M25 (i.e. required astern power). In addition, for CPP propulsion systems, the reversing characteristics of the propulsion plant are covered by new UR M83: "Testing of the control system of controllable pitch propellers intended for main propulsion".

As regards UR M51, the following Note was proposed to be added in M51.4.4.3 and accepted by the Panel:

- For the engine load to be applied for the reverse direction test E), refer to UR M25.1.

As regards UR S10, the following Note was proposed to be added in S10.2.1.1:

- The "maximum astern speed" Vastern is not to be taken less than the speed corresponding to the "maximum permissible astern power (MPAP)" referred to in UR M25.1.

4. Points of discussions or possible discussion

A member proposed adding a requirement on torsional vibrations for astern operation. However, due to diverging opinions, it was decided not to introduce any requirement in UR M25, but to discuss this item under a possible revision of UR M68.

UR M31 "Continuity of electrical power supply for vessels with periodically unattended machinery spaces"

Summary

UR M31 who contains no additional requirements to SOLAS except for the "45 seconds" requirement was deleted.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Del (Jan 2023)	20 January 2023	-
New (1978)	1978	-

- **Del (Jan 2023)**

1 Origin of Change:

☑ Other (Periodical review carried out by Machinery Panel)

2 Main Reason for Change:

UR M31 who contains no additional requirements to SOLAS except for the "45 seconds" requirement was deleted.

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None

4 History of Decisions Made:

Taking into account the case where SOLAS regulations II-1/41.5 and II-1/53.2 are not applied to ships (e.g., non-SOLAS ships and ships to which *Alternative Design and Arrangements* as per Part E of SOLAS Chapter II-1 are applied), discussion was conducted on whether the "45 seconds" requirement should be retained in this UR subject to development of exemption clauses for the following ships: (1) ships subject to the said alternative design and arrangements and (2) ships whose propulsion and steering systems are independent from the main source of electrical power (including such ships to which SOLAS does not apply).

The Panel has, based upon its Members' (the qualified majority's) preference, decided to delete both the requirements in UR M31 duplicated to SOLAS and the "45 seconds" requirement, noting that this deletion does not affect IACS Members' decision to keep the latter requirement in an appropriate manner in their Rules i.e. they can specify more stringent requirements than those set out by URs in their Rules.

5 Other Resolutions Changes:

None

6 Any hinderance to MASS, including any other new technologies:

None

7 Dates:

Part B. Technical Background

List of Technical Background (TB) documents for UR M31:

Note: *There are no Technical Background (TB) documents available for the original version (1978) and Del (Jan 2023).*

WP/MCH Task 41
Technical Justification for revision of

M33 M37 M38 M39 M48

and

new UR M68

CIMAC established a working group (WG14) for the purpose of getting a unified practice among Classification Societies on the topic of shafting and permissible torsional vibrations.

This WG14 concluded the work by the end of 2002, however, with a more restricted scope than the original. The original scope included issues for both 4-stroke and 2-stroke plants, but it soon became clear that due to the limited time (all to be within 2002) only 2-stroke plants with fixed pitch propellers could be handled.

It was the intention of WG14 that the agreements of 2002 should be reflected in the rules of the participating societies (ABS, GL, LR and DNV).

During the IACS MCH meeting in London 2003, it was agreed that actions should be taken versus very old URs, meaning a) confirm b) revise or c) delete. Among other, the above mentioned URs were chosen because:

- All 5 UR are interconnected and partly repeat each other
- Reservations were made (e.g. DNV)
- Several societies practiced considerable deviations from the UR
- WG14 had concluded on something different (for 2-stroke)
- Design features for controllable pitch propellers lacking

After revising the technical contents of the 5 URs, it was intended to merge them into one UR. The 4-stroke issues of WG14 (that were not in the agreement of 2002) had little or no relevance for the revision of these URs which only dealt with shafts. Of that reason the revision should include all relevant kinds of shafts.

The draft UR replaces M33, M37, M38, M39 and M48.

Note: This UR applies to ships constructed for construction from 1 July 2006.

Submitted by WP/MCH Chairman
21 Dec 2004

UR M35 “Alarms, remote indications and safeguards for main reciprocating I.C. engines installed in unattended machinery spaces”

Summary

This UR provides requirements for alarms, remote indications and safeguards for main reciprocating I.C. engines installed in unattended machinery spaces

.1 Origin of Change:

☑ Suggestion by IACS member

.2 Main Reason for Change:

To align requirements of UR M35 with requirements of UR M10.8 regarding the use of engine bearing temperature monitors or equivalent devices instead of oil mist detection arrangement to protect the engine crankcases.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

The matter was offered and discussed at 27th Machinery Panel Meeting (27 Feb to 02 March 2018) and agreed during 28th Meeting (18 – 21 September 2018).

.5 Other Resolutions Changes

None

.6 Dates:

Original Proposal: February 2018 by Machinery Panel
Panel Approval: 28 November 2018 (Ref. PM18908_IMg)
GPG Approval: 23 January 2019 (Ref. 18141_IGh)

- **Rev 7 (Mar 2016)**

.1 Origin of Change:

☑ Suggestion by IACS member

.2 Main Reason for Change:

To make consistent with UR M73; UR M73.5 requires turbocharger speed alarm for Categories B and C turbochargers but UR M35 does not cover them.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

It was unanimously agreed to add the speed of turbocharger to monitoring item.

.5 Other Resolutions Changes

None

.6 Dates:

Original Proposal: November 2015 by Machinery Panel
Machinery Panel Approval: 2 February 2016 (Ref: PM15906)
GPG Approval: 4 March 2016 (Ref: 16028_IGb)

- **Rev 6 (July 2013)**

.1 Origin of Change:

☑ Suggestion by IACS member

.2 Main Reason for Change:

To exclude definitions for Low-, Medium- and High-Speed Engines and introduce terms “cross-head” and “trunk-piston” engines to describe the engine type to which the requirements apply.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

The matter was discussed by Machinery Panel under PM 12407 during 16th and 17th Meetings and all members agreed to the introduction of the terms "cross-head" and "trunk-piston" engines instead of introducing the definitions "Low-, Medium- and High-Speed engines made in UR M71 as was the reason for initiating the task.

.5 Other Resolutions Changes

None

Technical Background Document
Revision of UR M35 (Revision 5, August 2008)
Revision of UR M36 (Revision 3, September 2008)

Alarms, remote indications and safeguards for main reciprocating I.C. engines installed in unattended machinery spaces

Objective and Scope:

The aim of Task 5101 was to review the alarm requirements in UR M35 for oil mist detection (OMD) and turbocharger lubricating oil in comparison with slow speed engines and medium / high speed engines.
Further, to update the UR to reflect on modern engine design and to develop new requirements for fuel or hydraulic oil pressure monitoring of newly introduced electronically controlled diesel engines (E-engines).
Finally, the clarity of the information provided in the columns of Tables 1 and 2 was to be improved. For consistency reasons UR M36 was also to be reviewed with respect to requirements for fuel and hydraulic oil pressure monitoring on E-engines as well as the format of the table.

Background:

The background for the proposed modification / additions in the UR M35 has two aspects.
First: the harmonization of Table 1 and Table 2 of UR M35
and second: the development of new requirements for fuel or hydraulic oil pressure monitoring on E-engines.

Points of discussion:

A discussion developed around requirements for OMD. It has been pointed out that at present OMD is not regarded as a safety device and only required for unattended machinery spaces. Further, it has been suggested, that remote indication is needed to keep personnel away from the engine when an alarm is triggered. The Panel considered that there is still a problem with the reliability of the OMD alarm signal and that this needs to be taken into account when considering possible corrective action, such as engine slowdown or shutdown.
UR M35 was discussed in conjunction with UR M10 and there was a general view that OMD or alternative arrangements should be required for both attended and unattended machinery spaces. It has been agreed to introduce this in M10.

This would make the installation of OMD or alternative arrangements mandatory for all engines independent from the operational mode. The power limitation from Note 3 in Table 1 of UR M35 Rev.4 should also be added.

Finally, it has been decided to modify footnote 9 and 10 of table 1 and footnote 8 of table 2. With the changes in the footnotes M35 can be applied regardless of a different design of turbocharger lubrication.
To reflect on changes in the design of modern electronically controlled diesel engines there was agreement to introduce a low pressure alarm for common rail fuel oil and rail servo oil pressure.

Conclusion:

Following changes to Table 1 and Table 2 in UR M35 have been agreed:

<u>M35, Table 1 and 2, 1.0, add new item:</u>

- “Common rail fuel oil pressure”; alarm pressure low

<u>M35, Table 1 and 2, 2.0, add new item:</u>

- “Common rail servo oil pressure”; alarm pressure low

<u>M35, Table 1 9.0, change the wording to:</u>

- “Exhaust gas temp. after each cylinder”

<u>M35, Table 1, 3.0, add Notes 9 and 10:</u>

- 9) Unless provided with a self-contained lubricating oil system integrated with the turbocharger (also Note 5 in Table 2).
- 10) Where outlet temperature from each bearing cannot be monitored due to the engine/turbocharger design alternative arrangements may be accepted.

<u>M35, Table 2, 3.0, add new item and Note 8:</u>

- New item: Turbocharger lub. oil temperature each bearing
- 8) Where outlet temperature from each bearing cannot be monitored due to the engine/turbocharger design alternative arrangements may be accepted.

<u>M35, Table 1 and Table 2, Note 3:</u>

- Add reference to OMD requirements in UR M10.8 or SOALS Reg. II-1/47.2

<u>M36, Table 1:</u>

- Add low level alarm for common rail fuel and servo oil pressure

The changes have been agreed unanimously by Panel members.

GPG approval, UR M35(Rev.5): 28 August 2008, s/n 4069bIGh
GPG approval, UR M36(Rev.3): 22 September 2008, s/n 4069cIGb.

Technical Background (TB) document for UR M35 (Rev.6 July 2013)

1 Scope and objectives

Introducing definitions for Low-, Medium- and High-Speed Engines in the new UR M71 made it necessary to investigate the effect on other documents using these terms.

The changes introduced is not expected have any effect on the technical content of the UR, the sole purpose is to align the documents.

2 Engineering background for technical basis and rationale

Requirements in the URs applicable to I.C. engines do depend upon engine speed and engine design. It was therefore necessary to introduce definitions of engine speed in the newly developed UR M71.

3 Source / derivation of the proposed IACS Resolution

UR M71

4 Summary of Changes intended for the revised Resolution

It was considered in the panel that the applicability of different requirement respectively in Tab 1 and Tab2 is better defined by making reference to Engine Design, rather than engine speed.

5 Points of discussions or possible discussions

This task was triggered by IACS Machinery Panel as a result of discussion of a Member's proposal during 15th, 16th and 17th Panel Meetings. Definitions for Low-, Medium- and High-Speed Engines were introduced in the new UR M71 "Type Testing of I.C. Engines".

Technical Background (TB) document for UR M35 (Rev.8 Jan 2019)

1 Scope and objectives

To align requirements of UR M35 with requirements of UR M10.8 regarding the use of engine bearing temperature monitors or equivalent devices instead of oil mist detection arrangement to protect the engine crankcases.

2 Engineering background for technical basis and rationale

There is the discrepancy between requirements of UR M10.8 regarding the use of engine bearing temperature monitors or equivalent devices instead of oil mist detection arrangements to protect the engine crankcases and relevant fields in the Tables of parameters provided in UR M35 with regard to the respective alarms, shut-downs and slow-downs. UR M10.8 allows usage of engine bearing temperature monitors or equivalent devices instead of oil mist detection arrangements, however there is nothing in the relevant fields of UR M35.

Second and more important issue is the necessity to define the respective requirements for engine bearing temperature monitors and equivalent devices by the same way how it done for oil mist detector by introduction of UR M67. Due to increasing of demand for such monitors and devices and respective solutions existed on the market it is vital to provide the industry and Class Societies with common agreed requirements for approval of equivalent monitors/devices and further for unified and consistent application of the latter on the ship's main and auxiliary I.C. Engines

3 Source/derivation of the proposed IACS Resolution

UR M10

4 Summary of Changes intended for the revised Resolution

The items "2.0 Lubrication oil system" of Table 1 and Table 2 of UR M35 as well as the Note n.3 of Table 2 have been modified in order to be aligned with the text used in UR M10.8.

5 Points of discussions or possible discussions

The final text was agreed by correspondence.

IACS WP/MCH

TECHNICAL BACKGROUND DOCUMENT

Rev.2, M36 – Alarms and safeguards for auxiliary reciprocating internal combustion engines driving generators in unattended machinery spaces.

2.1 Scope and objectives

The item is covered by Task 41, and dealt with under item 6.2 at WP/MCH's 40th meeting. Main objective was to achieve agreement as to a revised UR M36 which could be accepted by all IACS parties without reservations.

2.2 Points of discussion

The subject was thoroughly discussed at WP/MCH's 40th meeting. In this respect it was expressed that:

- Continuous review and updating of both IACS UR M35 and M36 is foreseen necessary also for the future.
- With regards to IACS UR M35 and M36, the requirement "shut down" is to be considered as more conservative than "slow down". Accordingly each Society will be free to request "shut down" by their Rules where IACS UR request "slow down" only, without giving any reservation.

As to revision of current IACS UR M36 it was concluded (all parties agreed) to propose to GPG the following alterations to be made:

- *A new requirement (based on NK's proposal) to be included in Table 1 requesting Alarm (high and low value) for "Fuel oil viscosity before injection pumps or Fuel oil temp before injection pumps". A footnote to be added to said requirement stating: "For heavy fuel oil burning engines only".*
- *A new requirement (based on NK's proposal) to be included in Table 1 requesting Alarm (high) for "Exhaust gas temperature after each cylinder". A footnote to be added stating: " For engine power above 500 kW/cyl.*

2.2 Source/derivation of proposed requirements

Earlier discussions within WP/MCH, input from CIMAC and proposal from NK.

2.3 Decision by voting.

All WP/MCH members agreed in above.

Submitted by WP/MCH Chairman on 10 May 2000

Technical Background Document
Revision of UR M35 (Revision 5, August 2008)
Revision of UR M36 (Revision 3, September 2008)

Alarms, remote indications and safeguards for main reciprocating I.C. engines installed in unattended machinery spaces

Objective and Scope:

The aim of Task 5101 was to review the alarm requirements in UR M35 for oil mist detection (OMD) and turbocharger lubricating oil in comparison with slow speed engines and medium / high speed engines.
Further, to update the UR to reflect on modern engine design and to develop new requirements for fuel or hydraulic oil pressure monitoring of newly introduced electronically controlled diesel engines (E-engines).
Finally, the clarity of the information provided in the columns of Tables 1 and 2 was to be improved. For consistency reasons UR M36 was also to be reviewed with respect to requirements for fuel and hydraulic oil pressure monitoring on E-engines as well as the format of the table.

Background:

The background for the proposed modification / additions in the UR M35 has two aspects.
First: the harmonization of Table 1 and Table 2 of UR M35
and second: the development of new requirements for fuel or hydraulic oil pressure monitoring on E-engines.

Points of discussion:

A discussion developed around requirements for OMD. It has been pointed out that at present OMD is not regarded as a safety device and only required for unattended machinery spaces. Further, it has been suggested, that remote indication is needed to keep personnel away from the engine when an alarm is triggered. The Panel considered that there is still a problem with the reliability of the OMD alarm signal and that this needs to be taken into account when considering possible corrective action, such as engine slowdown or shutdown.
UR M35 was discussed in conjunction with UR M10 and there was a general view that OMD or alternative arrangements should be required for both attended and unattended machinery spaces. It has been agreed to introduce this in M10.

This would make the installation of OMD or alternative arrangements mandatory for all engines independent from the operational mode. The power limitation from Note 3 in Table 1 of UR M35 Rev.4 should also be added.

Finally, it has been decided to modify footnote 9 and 10 of table 1 and footnote 8 of table 2. With the changes in the footnotes M35 can be applied regardless of a different design of turbocharger lubrication.
To reflect on changes in the design of modern electronically controlled diesel engines there was agreement to introduce a low pressure alarm for common rail fuel oil and rail servo oil pressure.

Conclusion:

Following changes to Table 1 and Table 2 in UR M35 have been agreed:

<u>M35, Table 1 and 2, 1.0, add new item:</u>

- “Common rail fuel oil pressure”; alarm pressure low

<u>M35, Table 1 and 2, 2.0, add new item:</u>

- “Common rail servo oil pressure”; alarm pressure low

<u>M35, Table 1 9.0, change the wording to:</u>

- “Exhaust gas temp. after each cylinder”

<u>M35, Table 1, 3.0, add Notes 9 and 10:</u>

- 9) Unless provided with a self-contained lubricating oil system integrated with the turbocharger (also Note 5 in Table 2).
- 10) Where outlet temperature from each bearing cannot be monitored due to the engine/turbocharger design alternative arrangements may be accepted.

<u>M35, Table 2, 3.0, add new item and Note 8:</u>

- New item: Turbocharger lub. oil temperature each bearing
- 8) Where outlet temperature from each bearing cannot be monitored due to the engine/turbocharger design alternative arrangements may be accepted.

<u>M35, Table 1 and Table 2, Note 3:</u>

- Add reference to OMD requirements in UR M10.8 or SOALS Reg. II-1/47.2

<u>M36, Table 1:</u>

- Add low level alarm for common rail fuel and servo oil pressure

The changes have been agreed unanimously by Panel members.

GPG approval, UR M35(Rev.5): 28 August 2008, s/n 4069bIGh
GPG approval, UR M36(Rev.3): 22 September 2008, s/n 4069cIGb.

Technical Background (TB) document for UR M36 (Rev.4 July 2013)

1 Scope and objectives

Introducing definitions for Low-, Medium- and High-Speed Engines in the new UR M71 made it necessary to investigate the effect on other documents using these terms.

The changes introduced is not expected have any effect on the technical content of the UR, the sole purpose is to align the documents.

2 Engineering background for technical basis and rationale

Requirements in the URs applicable to I.C. engines do depend upon engine speed and engine design. It was therefore necessary to introduce definitions of engine speed in the newly developed UR M71.

3 Source / derivation of the proposed IACS Resolution

UR M71

4 Summary of Changes intended for the revised Resolution

It was considered in the panel that the applicability of different requirement respectively in Tab 1 and Tab2 is better defined by making reference to Engine Design, rather than engine speed.

5 Points of discussions or possible discussions

This task was triggered by IACS Machinery Panel as a result of discussion of a Member's proposal during 15th, 16th and 17th Panel Meetings. Definitions for Low-, Medium- and High-Speed Engines were introduced in the new UR M71 "Type Testing of I.C. Engines".

Technical Background (TB) document for UR M36 (Rev.6 Dec 2018)

1 Scope and objectives

To align requirements of UR M36 with requirements of UR M10.8 regarding the use of engine bearing temperature monitors or equivalent devices instead of oil mist detection arrangement to protect the engine crankcases.

2 Engineering background for technical basis and rationale

There is the discrepancy between requirements of UR M10.8 regarding the use of engine bearing temperature monitors or equivalent devices instead of oil mist detection arrangements to protect the engine crankcases and relevant fields in the Tables of parameters provided in UR M36 with regard to the respective alarms, shut-downs and slow-downs. URM10.8 allows usage of engine bearing temperature monitors or equivalent devices instead of oil mist detection arrangements, however there is nothing in the relevant fields of UR M36.

Second and more important issue is the necessity to define the respective requirements for engine bearing temperature monitors and equivalent devices by the same way how it done for oil mist detector by introduction of UR M67. Due to increasing of demand for such monitors and devices and respective solutions existed on the market it is vital to provide the industry and Class Societies with common agreed requirements for approval of equivalent monitors/devices and further for unified and consistent application of the latter on the ship`s main and auxiliary I.C. Engines

3 Source/derivation of the proposed IACS Resolution

UR M10

4 Summary of Changes intended for the revised Resolution

Table 1 of UR M36 as well as the Note n.3 of this table have been modified in order to be aligned with the text used in UR M10.8.

5 Points of discussions or possible discussions

The final text was agreed by correspondence.

WP/MCH Task 41
Technical Justification for revision of

M33 M37 M38 M39 M48

and

new <u>UR M68</u>

CIMAC established a working group (WG14) for the purpose of getting a unified practice among Classification Societies on the topic of shafting and permissible torsional vibrations.

This WG14 concluded the work by the end of 2002, however, with a more restricted scope than the original. The original scope included issues for both 4-stroke and 2-stroke plants, but it soon became clear that due to the limited time (all to be within 2002) only 2-stroke plants with fixed pitch propellers could be handled.

It was the intention of WG14 that the agreements of 2002 should be reflected in the rules of the participating societies (ABS, GL, LR and DNV).

During the IACS MCH meeting in London 2003, it was agreed that actions should be taken versus very old URs, meaning a) confirm b) revise or c) delete. Among other, the above mentioned URs were chosen because:

- All 5 UR are interconnected and partly repeat each other
- Reservations were made (e.g. DNV)
- Several societies practiced considerable deviations from the UR
- WG14 had concluded on something different (for 2-stroke)
- Design features for controllable pitch propellers lacking

After revising the technical contents of the 5 URs, it was intended to merge them into one UR. The 4-stroke issues of WG14 (that were not in the agreement of 2002) had little or no relevance for the revision of these URs which only dealt with shafts. Of that reason the revision should include all relevant kinds of shafts.

The draft UR replaces M33, M37, M38, M39 and M48.

Note: This UR applies to ships constructed for construction from 1 July 2006.

Submitted by WP/MCH Chairman
21 Dec 2004

WP/MCH Task 41
Technical Justification for revision of

M33 M37 M38 M39 M48

and

new UR M68

CIMAC established a working group (WG14) for the purpose of getting a unified practice among Classification Societies on the topic of shafting and permissible torsional vibrations.

This WG14 concluded the work by the end of 2002, however, with a more restricted scope than the original. The original scope included issues for both 4-stroke and 2-stroke plants, but it soon became clear that due to the limited time (all to be within 2002) only 2-stroke plants with fixed pitch propellers could be handled.

It was the intention of WG14 that the agreements of 2002 should be reflected in the rules of the participating societies (ABS, GL, LR and DNV).

During the IACS MCH meeting in London 2003, it was agreed that actions should be taken versus very old URs, meaning a) confirm b) revise or c) delete. Among other, the above mentioned URs were chosen because:

After revising the technical contents of the 5 URs, it was intended to merge them into one UR. The 4-stroke issues of WG14 (that were not in the agreement of 2002) had little or no relevance for the revision of these URs which only dealt with shafts. Of that reason the revision should include all relevant kinds of shafts.

The draft UR replaces M33, M37, M38, M39 and M48.

Note: This UR applies to ships constructed for construction from 1 July 2006.

Submitted by WP/MCH Chairman
21 Dec 2004

WP/MCH Task 41
Technical Justification for revision of

M33 M37 M38 M39 M48

and

new <u>UR M68</u>

CIMAC established a working group (WG14) for the purpose of getting a unified practice among Classification Societies on the topic of shafting and permissible torsional vibrations.

This WG14 concluded the work by the end of 2002, however, with a more restricted scope than the original. The original scope included issues for both 4-stroke and 2-stroke plants, but it soon became clear that due to the limited time (all to be within 2002) only 2-stroke plants with fixed pitch propellers could be handled.

It was the intention of WG14 that the agreements of 2002 should be reflected in the rules of the participating societies (ABS, GL, LR and DNV).

During the IACS MCH meeting in London 2003, it was agreed that actions should be taken versus very old URs, meaning a) confirm b) revise or c) delete. Among other, the above mentioned URs were chosen because:

- All 5 UR are interconnected and partly repeat each other
- Reservations were made (e.g. DNV)
- Several societies practiced considerable deviations from the UR
- WG14 had concluded on something different (for 2-stroke)
- Design features for controllable pitch propellers lacking

After revising the technical contents of the 5 URs, it was intended to merge them into one UR. The 4-stroke issues of WG14 (that were not in the agreement of 2002) had little or no relevance for the revision of these URs which only dealt with shafts. Of that reason the revision should include all relevant kinds of shafts.

The draft UR replaces M33, M37, M38, M39 and M48.

Note: This UR applies to ships constructed for construction from 1 July 2006.

UR M42 "Steering Gear"

Summary

In Rev.6 of this Resolution, the definition of hydraulic locking has been clarified.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev.6 (Mar 2022)	03 March 2022	1 July 2023

- ### Rev.6 (Mar 2022)

1 Origin of Change:

☑ Suggestion by IACS member

2 Main Reason for Change:

To clarify the definition of hydraulic locking.

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None

4 History of Decisions Made:

The Revision 6 was discussed by correspondence and agreed at the 34th Panel Meeting (from 31th August to 2th September 2021)

5 Other Resolutions Changes:

UR E25(Rev.2)

6 Any hinderance to MASS, including any other new technologies:

None

.7 Dates:

Original Proposal	: 11 May 2020	(Ref: PM20801_IMa)
Panel Approval	: 20 January 2022	(Ref: PM20801_IMl)
GPG Approval	: 03 March 2022	(Ref: 22013_IGc)

• Corr.1 (Oct 2021)

1 Origin of Change:

☑ Suggestion by IACS member

2 Main Reason for Change:

Application statement No. 1 needed clarification that it applies to Rev.4 of this UR.

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None

4 History of Decisions Made:

It was agreed that application statement No. 1 should be clarified. The way to refer to specific SOLAS regulations was also changed.

5 Other Resolutions Changes:

None

6 Any hinderance to MASS, including any other new technologies:

None

7 Dates:

Original Proposal	: 16 June 2021	(Ref: PM20906lIMa)
Panel Approval	: 06 October 2021	(Ref: PM20906lIMc)
GPG Approval	: 22 October 2021	(Ref: 20206dIGd)

• Rev.5 (Feb 2021)

1 Origin of Change:

☑ Other (Periodical review to ascertain that the Resolution is suitable for the latest developments in technology)

2 Main Reason for Change:

There was a need to ascertain that this UR is suitable for the latest developments in technology.

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None

4 History of Decisions Made:

None

5 Other Resolutions Changes:

None

6 Any hinderance to MASS, including any other new technologies:

None

7 Dates:

Original Proposal:	28 October 2019 (Ref: PM18939_IMd)
Panel Approval:	9 November 2020 (Ref: PM20906_IMf)
GPG Approval:	12 February 2021 (Ref: 20206dIGb)

- **Rev.4 (June 2011)**

1 Origin of Change:

☑ Based on IMO Regulation (SOLAS II-1 regulation 29.3.2 & 29.4.2)

2 Main Reason for Change:

To develop a UI in respect of SOLAS Regulations II-1/29.3.2 and 29.4.2 and establish conditions for ships which cannot achieve deepest seagoing draught at the trial to replace the alternative requirement in UR M42.15(i).

3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

4 History of Decisions Made:

PT agreed that no amendment to SOLAS II-1 regulation 29 would be necessary and that the draft UI to be developed by the team would be sufficient to meet the objectives of the task.

Review of DNV proposed method completed and the need for experimental data confirmed as necessary to verify the predicted steering gear loads for steering gear when rudders are partially submerged.

Reference to ISO 19019:2005 Sea-going vessels and marine technology – Instructions for planning, carrying out and reporting sea trials agreed by the PT as the reference procedure for all ships which are not at deepest seagoing draught. Draft UI and Proposed amendment to URM42 developed to support this reference.

Additional conditions were developed by the team to be applied when testing steering gear in accordance with the ISO instructions on all occasions when ships were not at the deepest draught for the trial, in order to establish reliable and consistent test methodology.

5 Other Resolutions Changes:

UI SC246 (New June 2011) developed in respect of the panel task in conjunction with the UR amendment proposal.

Annex 4. **TB for Rev.6 (Mar 2022)**

See separate TB document in Annex 4.

Note:

There is no separate Technical Background (TB) document for UR M42 New (1981).

Technical Background for UR M42 Rev.4, June 2011

1. Scope and objectives

To establish alternative steering gear trial conditions for vessels which cannot be tested at their deepest seagoing draught and to develop a UI in respect of SOLAS Regulations II-1/29.3.2 and 29.4.2 and based on this interpretation consider whether/how UR M42.15(i) is compatible with UI and propose amendments to M42.15(i) as necessary.

2. Engineering background for technical basis and rationale

The SOLAS regulations require that the main steering gear and rudder stock shall be:
- of adequate strength and capable of steering the ship at maximum ahead service speed which shall be demonstrated; and
- capable of putting the rudder over from 35° on one side to 35° on the other side with the ship at its deepest seagoing draught and running ahead at maximum ahead service speed and, under the same conditions, from 35° on either side to 30° on the other side in not more than 28 s

Alternative steering gear trial conditions to those where the vessel is at the deepest sea going draught, which is normally equal to the summer load line, are considered necessary for certain ship types in order to provide acceptable testing conditions. In order to establish a sound and uniform practice, the draft UI is suggested to refer to ISO 19019:2005 and through a proposed amendment to UR M42 allow the trial requirements contained in the ISO instructions to replace the requirement for alternative testing provided that the loading condition specified will result in predictable trial conditions in compliance with UR M42.15(i) as proposed for amendment.

The extant ISO 19019:2005 Sea-going vessels and marine technology – Instructions for planning, carrying out and reporting sea trials contains a procedure to demonstrate the performance requirements of SOLAS regulations for steering gear and refers to the loading condition for the ship to be as close as practical to full load displacement. This procedure is referenced to replace the specially considered clause in M42.15, subject to additional conditions developed by the team to establish consistent and reliable testing for ships not tested at the deepest sea-going draught.

3. Source/derivation of the proposed IACS Resolution

For ships not at the deepest sea-going draught for the steering gear trial ISO 19019:2005 Sea-going vessels and marine technology – Instructions for planning, carrying out and reporting sea trials is referenced. The following extracts are relevant and applicable:

6.1 Steering gear trials
6.1.1 Purpose
Steering gear trials are performed to verify the performance of the steering gear and to demonstrate its efficiency.

6.1.2 Trials specification
If the loading condition is not contractually specified, steering gear trials shall be conducted at a displacement as close as reasonably possible to full-load displacement for merchant ships and warships.
and;
6.1.5.1 Ahead-steering-gear trial
With the main propulsion engines delivering maximum continuous rating ahead or at the corresponding shaft speed, the following rudder manoeuvres shall be executed. The first direction of rudder movement, i.e. port or starboard, shall be at the discretion of the trial captain, considering the conditions in the area. The following description is for first rudder deflection to port.
a) Amidships to 35° port — Hold for sufficient duration in order to record time taken, at the steering gear,
between rudder amidships and 30°;
b) 35° port to 35° starboard — Hold approximately 10 s; record time taken, at the steering gear, between
35° hardover to 30° to the opposite side (as the steering gear is slowing down between 30° and hardover);
c) 35° starboard to 35° port — Hold approximately 10 s; record time taken between 35° starboard and 30° port;
d) 35° port to amidships — Record time taken between 35° port and rudder amidships;
e) trial completed.

This trial shall be repeated for each power unit of the steering gear and, if possible, for both units acting together. For emergency power units, trials shall be performed at reduced speed and reduced rudder angles. Setting of the propulsion plant of a single-screw main propulsion system shall not be changed during the trial; however, change in throttle adjustment or propeller pitch in the case of a controllable-pitch propeller plant or multi-screw main propulsion systems is permissible during the trial to avoid overload or overspeed. If the maximum rudder angle is less than 35°, the maximum possible rudder angle shall be used, with time determined to the maximum angle minus 5°, as above.

The additional requirements to be satisfied during the trial were developed and agreed by the PT to establish consistent and reliable trial conditions for all occasions when the trial is undertaken with the ship not at the deepest sea-going draught.

4. Summary of Changes intended for the revised Resolution:

To replace the 'alternative trial conditions may be specially considered' term in UR M42.15(i) with specific requirements when the loading condition for the ship at the steering gear trial is contractually specified to be other than the deepest seagoing draft or the ship cannot achieve deepest draught to test in accordance with ISO 19019:2005 subject to additional conditions for consistent and reliable testing.

Proposed amendment
15. Trials
The steering gear should be tried out on the trial trip in order to demonstrate to the Surveyor's satisfaction that the requirements of the Rules have been met. The trial is to include the operation of the following:

(i) the steering gear, including demonstration of the performances required by Regulation 29.3.2 and 29.4.2. For controllable pitch propellers, the propeller pitch is to be at the maximum design pitch approved for the maximum continuous ahead R.P.M. at the main steering gear trial.
If the vessel cannot be tested at the deepest draught, ~~alternative~~ trial conditions ~~may be specially considered~~ as stated in Section 6.1.5.1 of ISO 19019:2005 *Sea-going vessels and marine technology – Instructions for planning, carrying out and reporting sea trials* are to be applied.
If the loading condition is such that the ship is not at the deepest draught, steering gear trials shall be conducted at a displacement as close as reasonably possible to full-load displacement as required by Section 6.1.2 of ISO 19019:2005 on the conditions that either the rudder is fully submerged (zero speed waterline) and the vessel is in an acceptable trim condition, or the rudder load and torque at the specified trial loading condition have been predicted and extrapolated to the full load condition.

In this case for the main steering gear trial, the speed of ship corresponding to the number of maximum continuous revolution of main engine ~~could~~ is to apply.

5. Points of discussions or possible discussions

SOLAS II-1/29.3.2 and 29.4.2
Reviewed by the PT in order to generate a UI for the performance requirements for the main and auxiliary steering gear

UR M42.15(i)
Reviewed by the PT in order to establish requirements to replace the alternative trial conditions with specific reference to ISO 19019:2005 *Sea-going vessels and marine technology – Instructions for planning, carrying out and reporting sea trials* subject to additional conditions developed by the PT.

From work specification items for the panel task:
A review of the DNV proposal "Steering gear test with partly submerged rudder" was completed and an evaluation of the need for experimental data was completed, it was considered necessary that experimental data would be required to verify the proposed method.

Technical Background (TB) document for UR M42 (Rev.6 Mar 2022)

1. Scope and objectives

To clarify the definition of hydraulic locking based on the guidance note which has been deleted from UI SC 94 Rev.1.

2. Engineering background for technical basis and rationale

UR M42 12.2 specifies that an audible and visual alarm shall be provided on the navigating bridge, where hydraulic locking. In addition, it specifies two cases as triggers to activate the hydraulic locking. Regarding this requirement, a panel member found that a manufacturer had the following misunderstanding:

"Even if operating with only one hydraulic system, when either of the two cases specified in M42 12.2 is detected, it will lead to a situation that falls under the definition of hydraulic locking."

A panel member pointed out that UI SC 94 Rev.1 had specified "hydraulic locking" as the following guidance note.

"Hydraulic locking means all situations where two hydraulic systems (usually identical) oppose each other in such a way that it may lead to loss of steering. It can either be caused by pressure in the two hydraulic systems working against each other or by hydraulic "by-pass" meaning that the systems puncture each other and cause pressure drop on both sides or make it impossible to build up pressure."

Based on the above, the definition of hydraulic locking is added to UR M42 based on the guidance note which has been deleted from UI SC 94 Rev.1 to avoid misunderstanding.

3. Source/derivation of the proposed IACS Resolution

None

4. Summary of Changes intended for the revised Resolution:

The definition of hydraulic locking is added in UR M42 Appendix 1 based on the guidance note which has been deleted from UI SC 94 Rev.1.

In addition, the definition of steering gear control system in UR M42 Appendix 1 is aligned with the definition given in IACS SC94 to cover "the equipment required to control the steering gear power actuating system".

5. Points of discussions or possible discussions

None

6. Attachments if any

UR M43 "Bridge control of propulsion machinery"

Summary

This UR provides requirements for the bridge control systems for propulsion machinery, for attended and unattended machinery spaces. In this revision requirements existing in SOLAS II-1/49 have been removed. Additionally, it includes requirements of attended machinery spaces which were in UR M47.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev.1 (Feb 2024)	02 February 2024	01 January 2025
New (1982)	No record	-

- **Rev.1 (Feb 2024)**

1 Origin of Change:

☑ Other (FUA N°9 of GPG 85 - update of the Rule linkage table)

2 Main Reason for Change:

Revision 1 of UR M43 aims at removing from the UR the requirements which can be considered as a duplication of what is required in SOLAS II-1/49. Additionally, UR M47 was referring to UR M43 and it was decided to transfer its requirements to UR M43.

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None.

4 History of Decisions Made:

1) Members agreed that paragraphs M43.1, M43.5, M43.9; M43.10, M43.11, M43.12, M43.13 and M43.14 can be deleted as they are considered as duplication of SOLAS II-1/49 requirements (PM20906dIMc).

2) Considering the current wording of UR M47 saying that UR M43 applies to the bridge control of propulsion machinery for all machinery spaces (unattended and attended) with the exception of clause M43.7 relating to steam turbines, members agreed that UR M47 can be transferred to UR M43.7 (Rev.0) and the title of UR M43 is changed to "Bridge control of propulsion machinery" instead of "Bridge control of propulsion machinery for unattended machinery spaces" (PM20906dIMc).

3) Members disagreed to delete requirements M43.2 (Rev. 0) but to modify it considering deletion of M43.1 (PM20906dIMd).

4) Members considered the risk that M43.8 (Rev. 0) could be seen as a relaxation of SOLAS II-1/49.5. It was decided to keep the requirements and modify it for ships not covered by the SOLAS convention (PM20906dIMg).

5 Other Resolutions Changes:

UR M47 is deleted as its requirements are now included in UR M43.
UR M3 is referring to deleted requirements of UR M43 and to UR M47.
These references are to be deleted.

6 Any hinderance to MASS, including any other new technologies:

The UR M43 requires control from bridge which precludes MASS operations.

7 Dates:

Original Proposal	: 01 February 2021	(Ref: PM20906dIMa)
Panel Approval	: 10 January 2024	(Ref: 23186_PMa)
GPG Approval	: 02 February 2024	(Ref: 23186_IGc)

- **New (1982)**

No record available.

Part B. Technical Background

List of Technical Background (TB) documents for UR M43:

Annex 1. **TB for Rev. 1 (Feb 2024)**

See separate TB document in Annex 1.

Technical Background (TB) document for UR M43 (Rev 1 Feb 2024)

1. Scope and objectives

To delete requirements considered as duplication of SOLAS II-1/49, and to incorporate the exclusion provided by UR M47 in UR M43.

2. Engineering background for technical basis and rationale

None.

2a. Specification of the data utilised in the development/revision of the proposed IACS Resolution, if any

N/A.

3. Source/derivation of the proposed IACS Resolution

The subject revision is an outcome of FUA No. 9 of GPG 85, which tasked the Machinery Panel to take actions on records kept by IACS on the status of URs.

4. Summary of Changes intended for the revised Resolution:

Requirements considered as duplication of requirements existing in SOLAS II-1/49 are deleted: M43.1, M43.5, M43.9; M43.10, M43.11, M43.12, M43.13 and M43.14.

Requirements M43.2 and M43.8 have modified in order they cannot be considered as a duplication or a relaxation to existing SOLAS requirements. M43.8 is kept for ships not covered by the SOLAS convention.

By incorporating UR M47 requirement in a Note of UR M43.7 (renumbered as M43.5), the title of the UR has been modified.
Following the above modification, paragraphs have been renumbered.

5. Points of discussions or possible discussions

The main point of discussion was concerning M43.8 (renumbered as M43.6) as some members found that there is a risk that M43.8 may be regarded as a relaxation to SOLAS regulation II-1/49.5 since, while the said regulation requires the preset speed and direction of thrust of the propeller to be maintained until local control is in operation unless the Administration considers it impracticable, UR M43.8 allows a change in propulsion power or direction of propeller rotation if it is not major and sudden under the condition of lack of power (electric, pneumatic, hydraulic).

While some members considered that lack of power could be a different failure mode from power failure, most members agreed that M43.8 is covered by SOLAS as the failure modes "lack of power (electric, pneumatic, hydraulic)" are part of the potential failures of a bridge control system covered by SOLAS II-1/49.5.

Finally, members decided to add an introductory sentence in the opening part of M43.8 without modification of other part of M43.8, which is advisable to avoid the risk that the remainder of M43.8 without the text of SOLAS Regulation II-1/49 may be regarded as a relaxation to SOLAS regulation as if it does not require to maintain preset speed and direction and permits a change in propulsion power or direction of propeller rotation.

Other deleted requirements are covered by SOLAS II-1/49.

6. Attachments if any

None.

UR M44 "Documents for the Approval of Reciprocating Internal Combustion Engines"

Summary

This UR provides requirements for the approval of drawings and specifications for engines and their sub-systems. Revision 11 of this resolution has been restructured to align with the new UR, 'Certification Scheme for Reciprocating Internal Combustion Engines,' and certification requirements previously contained in M44 have now been merged into M87 accordingly.

New (1982)	1982	-

- **Rev.11 (Apr 2025)**

1 Origin of Change:

☒ Request by non-IACS entity (CIMAC)

2 Main Reason for Change:

CIMAC WG2 believes that existing UR M51 and UR M71 need revision and updating, and proposes the development of a new UR, 'Certification Scheme for Engines.'
The Machinery Panel has decided to evaluate these proposals and to improve URs related to Internal Combustion (I.C.) Engines, including M44, 'Documents for Approval of I.C. Engines

3 Surveyability review of UR and Auditability review of PR

Draft document of UR has been reviewed with Survey Panel for surveyability items.

4 Human Element issues assessment

N/A due to the relevant task initiation date.

5 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None

6 History of Decisions Made:

CIMAC proposed a revision of the URs related to I.C. Engines. The Machinery Panel reviewed these proposals at its 30th meeting in 2019 and decided that a dedicated Project Team (PT) was necessary to evaluate them further.

The PT PM19102 established principles for developing or amending IACS URs related to I.C. engines during its first workshop in 2020. The development of these URs was primarily based on IACS members' expertise and experience, with consideration given to CIMAC's proposals.
A new UR, 'Certification Scheme for Reciprocating Internal Combustion Engines,' was developed based on section M44 '5 Certification Process' and CIMAC's input.
UR M44 was then revised to cover only document approval requirements. The terms, definitions, and certification requirements were incorporated into a new UR, M87.

As a result, five URs, including M44, were drafted at the PT's second workshop in 2021 and submitted to the Machinery Panel for review. UR M44 was updated and restructured to align with other URs related to engine certification.
From 2021 to 2023, these URs were discussed and revised according to feedback from the Machinery Panel.

7 Other Resolutions Changes

The following URs have been amended in parallel:

- M87: Certification Scheme for Reciprocating Internal Combustion Engines (new)
- M71: Type Testing of Reciprocating Internal Combustion Engines (revised)
- M51: Factory Acceptance Test of Reciprocating Internal Combustion Engines (revised)
- M88: Shipboard Trial of Reciprocating Internal Combustion Engines (new, derived from M51)

8 Any hinderance to MASS, including any other new technologies:

None.

8 Dates:

Original Proposal:	05 September 2019 Made by Machinery Panel
Panel Approval:	23 October 2024 (Ref: PM19102_IMzv)
GPG Approval:	20 April 2025 (Ref: 24205_IGc)

- **Corr.1 (Feb 2022)**

1 Origin of Change:

☑ Other (A correction to make the UR M44 uniform with UR M60)

2 Main Reason for Change:

To delete footnote 5 of Tale 1 “The FMEA reports required will not be explicitly approved by the Classification Society” and an unpreferable phrase “by IMO resolutions up to MSC.472(101)” in Appendix 3.

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None

4 History of Decisions Made:

During the review of UR M60 (Rev.1), a Member pointed out that UR M44, Table1, Footnote 5, states "The FMEA reports required will not be explicitly approved by the Classification Society." However, there is no such mention in the draft revised UR M60(Rev.1). The Member further opined that, this statement should either be introduced in the draft UR M60(Rev.1) as well or be removed from UR M44, to maintain uniformity.

GPG noted that the documents listed in Table 1 in UR M44 (as the title of the table says) are for information only and not for approval (Documents for approval are listed in Table 2). Therefore, in Footnotes 5. of Table 1, 'The FMEA reports required will not be explicitly approved by the Classification Society' is considered redundant. Therefore, GPG decided to delete the above-mentioned text from UR M44.
Also, an unpreferable phrase “by IMO resolutions up to MSC.472(101)” in Appendix 3 has been deleted.

5 Other Resolutions Changes:

None

6 Any hinderance to MASS, including any other new technologies:

None

7 Dates:

Original Proposal: 08 November 2021 (Ref: 21163_IRa, Made by IACS Member)
Panel Approval: 10 February 2022 (Ref: PM20002b)
GPG Approval: 28 February 2022 (Ref: 21163aIGb)

- **Rev.10 (Feb 2021)**

1 Origin of Change:

☑ Other (Update to comply with the required format when industry standards are referred to)

2 Main Reason for Change:

There was a need to update this UR to comply with the following format when industry standards are referred to:

[Standard Designation], [version/revision, if applicable], [year of publication] (examples: API Spec 2F, 6th Edition, 1997; ISO 4624, 2002), where [version/revision, if applicable] and/or [year of publication] are decided by IACS and are not necessarily to be the current/latest version.

To take this opportunity, references to IMO instruments have been specified in the following format based upon confirmation of amendments up to the latest one:

regulation/paragraph x.x.x of SOLAS Chapter X/MARPOL Annex X/the XXX Code, as amended by IMO resolutions up to MSC.xx(xx)/MEPC.xx(xx)

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None

4 History of Decisions Made:

None

5 Other Resolutions Changes:

None

6 Any hinderance to MASS, including any other new technologies:

None

7 Dates:

Original Proposal: 28 October 2019 (Ref: PM18939_IMd)
Panel Approval: 9 November 2020 (Ref: PM20906_IMf)
GPG Approval: 12 February 2021 (Ref: 20206dIGb)

- **Corr.2 (Oct 2016)**

1 Origin of Change:

☑ Suggestion by a Machinery Panel Member

2 Main Reason for Change:

a. UR M44 (Corr.1) defines the documentation to be submitted for approval in Table 2, particularly Item Nos. 20 and 21 require submission of drawings of construction of accumulators and common accumulators for electronically controlled engines with common rail fuel injection system. However, some electronically controlled diesel engines (e.g. those designed by MAN Diesel & Turbo) are equipped with one complete electro-mechanical hydraulic pump system per cylinder – i.e. each cylinder is provided with one accumulator, and therefore no longer of "common rail" design since the term "common rail" refers to a single common fuel rail that supplies fuel oil under pressure to all the cylinders of a diesel engine, which is nothing more than a pressure accumulator.

20	Construction of accumulators (common rail) (for electronically controlled engine)
21	Construction of common accumulators (common rail) (for electronically controlled engine)

The wording "common rail" with parentheses in Item Nos. 20 and 21 can be misinterpreted that submission of those drawings is not required in the case where electronically controlled engines adopt fuel injection systems other than common rail system; however, since accumulators are essential components for electronically controlled engines, drawings of construction of accumulators should be submitted for approval when obtaining a Type Approval Certificate.

b. For reference purpose, a member Society's system corresponding to Alternative Certification Scheme (ACS) is added to the list in the definition column of UR M44 – Appendix 1 – Glossary.

3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

4 History of Decisions Made:

Deletion of "(common rail)" in Item Nos. 20 and 21 of UR M44 (Corr.1) Table 2 was agreed at the 24th Machinery Panel Meeting for the sake of clarity.

5 Other Resolutions Changes:

None

6 Any hinderance to MASS, including any other new technologies:

None

7 Dates:

Original Proposal: 25 July 2016 Made by Machinery Panel
Panel Approval: 31 October 2016 (Ref: PM9906c)
GPG Approval: 14 November 2016 (Ref: 16200_IGb)

- **Corr.1 (June 2016)**

1 Origin of Change:

☑ Suggestion by a Machinery Panel Member

2 Main Reason for Change:

UR M44 (Rev.8) and M44 (Rev.9) contain provisions related to engine certification process (production) which require re-type approval of diesel engines with an existing type approval. To avoid future troubles caused by understandings diverse among Societies/licensors/licensees/shipowners, it was found necessary to publish a corrigendum for further clarification.

3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

4 History of Decisions Made:

During discussion, it was found out that UR M44 (Rev.8) and M44 (Rev.9) can be read that also existing types of diesel engines with an existing type approval need to be retype approved as a part of engine certification process (production), as far as literally reading the provisions in a rigorous manner. Thus, it was concluded necessary to publish a corrigendum in order to clarify that such re-type approval is not necessary and that certification process (production) for individual engines whose application is dated on or after 1 July 2016 is to be carried out in this UR accepting the existing type approval, etc.

5 Other Resolutions Changes:

None

6 Any hinderance to MASS, including any other new technologies:

None

7 Dates:

Original Proposal: 02 November 2015 Made by Machinery Panel
Panel Approval: 15 April 2016 (Ref: PM9906a)
GPG Approval: 3 June 2016 (Ref: 16088_IGc)

- **Rev.9 (Dec 2015)**

1 Origin of Change:

☑ Request by non-IACS entity (Suggestion by CIMAC)

2 Main Reason for Change:

The task was triggered by CIMAC WG2's request to provide a harmonised application form across IACS members for approval of IC engines because experience shows an increasing number of different application forms from different classification societies.
While developing the harmonised application form, CIMAC WG2 was invited to review the draft for comments and the Panel has taken into account CIMAC's comments as appropriate. The updated draft was also presented to CIMAC WG2 representatives at the 11th Joint Meeting between IACS MP and CIMAC WG2 held on 9 September 2015 during the 22nd Machinery Panel Meeting.

3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

4 History of Decisions Made:

This harmonized application form and data sheet are intended to replace Appendix 3 of UR M44 (Rev.8) which was approved by GPG when the Rev.8 of the UR was published.

There was an argument over deleting "Society Logo" initiated by CIMAC WG2's request encouraging IACS members to use the same form hereby simplifying the work process of filling in forms. In the continued discussion, the Panel came to the conclusion to removing "Society Logo" to leave the space in blank and therefore an individual Society may choose to add the Society's logo respectively to comply with its document policy, if necessary. In connection with this, CIMAC also supported removal of Society's logo, hereby enabling the societies to print the application form on paper with their respective company logo.

5 Other Resolutions Changes:

None

6 Any hinderance to MASS, including any other new technologies:

None

7 Dates:

Original Proposal: 29 July 2013 made by CIMAC WG2 (Ref: ST-12-066)
Panel Approval: 30 October 2015 (Ref: PM13926)
GPG Approval: 14 December 2015 (Ref: 14086_IGc)

- **Rev.8 (Dec 2015) – Complete Revision**

1 Origin of Change:

☑ Request by non-IACS entity (Suggestion by CIMAC)

2 Main Reason for Change:

The revision of IACS UR M44 was discussed at the September 2009 joint meeting between IACS MP and CIMAC WG 2 – Classification Societies – Diesel. An ad-hoc group from WG2 was tasked to revise UR M44. In recent years in some parts of East Asia there have been repeated discussions between engine manufacturers and local Class Representatives regarding approval status of drawings for engine components. Often times these discussions are the result of differences in the identification between drawings requested in the present UR M44 and the corresponding drawing identification used during survey of components. The drawings listed in UR M44 might be assembly drawings whereas the drawings used for survey might be detailed manufacturing drawings. On other occasions the local Class Surveyors are often requesting the engine manufacturer and/or sub-suppliers to provide Class stamped drawings prior to or at survey, even though no stamped drawings are distributed to all licensees and their sub-suppliers; but, just lists of approved/reviewed drawings.

3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

4 History of Decisions Made:

A Member lead incorporation of proposed revisions into UR M44. The Machinery Panel commented on proposed revisions by correspondence and at regularly scheduled meetings.

Form A was agreed in the Panel in December 2011.
Form A approved by GPG in December 2011.

5 Other Resolutions Changes:

None

6 Any hinderance to MASS, including any other new technologies:

None

7 Dates:

Part B. Technical Background

List of Technical Background (TB) documents for UR M44:

Annex 1. **TB for Rev.6 (Nov 2003)**

See separate TB document in Annex 1.

Annex 2. **TB for Rev.7 (May 2004)**

See separate TB document in Annex 2.

Annex 3. **TB for Rev.8 (May 2015)**

See separate TB document in Annex 3.

Annex 4. **TB for Rev.10 (Feb 2021)**

See separate TB document in Annex 4.

Annex 5. **TB for Rev.11 (Apr 2025)**

See separate TB document in Annex 5.

Note:

There are no Technical Background (TB) documents available for New (1982), Rev.1 (1983), Rev.2 (1984), Rev.3 (1986), Rev.4 (1989), Rev.5 (1992), Rev.9 (Dec2015), Corr.1 (June 2016) and Corr.2 (Nov 2016).

Technical Background

UR M44 Rev.6 and P2 Rev.5

The UK MAIB report on its investigation of the causes of an engine fire in the high-speed ferry 'Stena Explorer' concluded that it was due to the incorrect reassembly of a compression fitting in a high pressure fuel line.

IACS did not concur in the MAIB recommendation to discontinue the use of such fittings, and so advised the MAIB in a letter from the GPG Chairman on 15 September 2003 (3051_IGb).

However WP/MCH proposed amendments to UR M44 and P2 to enhance relevant requirements for approval and maintenance.

They are:

UR M44:

i) Add suffix 7 to Item 33,

ii) Add FOOTNOTE 7.
7. operation and service manuals are to contain maintenance requirements (servicing and repair) including details of any special tools and gauges that are to be used with their fitting/settings together with any test requirements on completion of maintenance.

iii) Add NOTE 5.
5. Where the operation and service manuals identify special tools and gauges for maintenance purposes (see footnote 7.) refer to UR P2.7.4.14.

UR P2:

i) add P2.7.4.14: The installation of mechanical joints is to be in accordance with the manufacturer's assembly instructions. Where special tools and gauges are required for installation of the joints, these are to be supplied by the manufacturer.

ii) Add sentence above P2.7.4.1 :
The application and pressure ratings of different mechanical joints are to be approved by the Classification Society. The approval is to be based on Type Approval procedure in P2.11.

The amendments were approved by GPG on 30 September 2003 (3051aIGb)

Technical Background to Revision of M44 – Documents for the approval of diesel engines (Rev. 7, 2004)
WP/MCH Task 65

Background:
The object of the revision to UR M44 is update the document with respect to documents required for approval of current engine designs and the related scope of approval activities carried out by classification societies.

UR M44 provides a list of documents which are to be submitted to a classification society for the approval of a diesel engine. The first table in this UR identifies the requirements for submission of documents and the related activity concerning what will be carried out by classification societies after submission by the engine manufacturer.

Details:
It is generally understood that for a plan or design information to be approved there needs to be detailed criteria in the form of rules or specification, against which the design is appraised, and hence approval based upon. On this basis, a unified approach for the approval of diesel engines is achieved. During the 44th meeting of WP/MCH a detailed review of the existing plans list of UR M44 was carried out and a consensus reached on the validity of plans and information to be submitted, and their designation for approval, or for information. Additionally, it was proposed that a new designation. 'A*' be adopted, requiring that the plan be submitted to the classification society for approval of materials and weld procedure specifications. This designation recognises that it may not be possible to approve a particular design due to there being no defined approval criteria, but the materials used in construction and welding procedures are important and may impact on the component and engine integrity.

At the meeting and during subsequent correspondence between members the opportunity was taken to propose several minor amendments to the nomenclature of engine components used in UR M44 to reflect current industry terminology.

It was acknowledged that diesel engine technology is rapidly moving and with the development of electronically controlled engines it is apparent that the rules for diesel engines need to address electronic control systems, which are undeniably complex systems for controlling the operation of the engine and all of its essential services. A crucial facet in the approval of an engine, its support systems including the engine's control system itself, is ensuring that failure of a control system will not cause the loss of essential services for operation of the engine, or degrade the engine performance beyond an acceptable level. Failure Mode and Effects Analysis (FMEA) is a tool now widely being adopted within the marine industry to carry out a structured analysis of the effects of loss of function. By applying an FMEA the critical failure modes of a system can be identified and consequently, where unacceptable levels of risk are present, mitigating steps can be taken such as introducing redundancy into the system. The requirement for submission of an FMEA, as supporting documentation for the approval of plans, has been introduced into UR M44 where the engine incorporates an electronic control system. The requirement extends to all services which are considered essential to the operation of the engine.

Points of discussion

The draft was agreed without reservations or statements.

GPG

Approved GPG without amendment 7 May 2004, 4069aIGb.

Council

Adopted Council without amendment 26 May 2004, 4069aICa.

****

Technical Background (TB) document Rev 8 (Mar 2015)

1 Scope and objectives

Develop a revised UR M44 organized to:

- Describe the approval process and document flow;
- Identify the relationships between the Classification Society's engineering and survey staff and the engine designer (licensor), the licensee and their sub-suppliers and the shipyard;
- Account for licensor/licensee protocols so the attending Classification Society Surveyors are provided with evidence that the relevant design drawings reviewed by engineering are shown to be equivalent to the manufacturing drawings developed by the licensee for the use of the attending Surveyor.

2 Engineering background for technical basis and rationale

In recent years in some parts of East Asia, there have been repeated discussions between engine manufacturers and local Class Representatives regarding approval status of drawings for engine components. Often times these discussions are the result of differences in the identification between drawings requested in the present UR M44 and the corresponding drawing identification used during survey of components. The drawings listed in UR M44 might be assembly drawings whereas the drawings used for survey might be detailed manufacturing drawings. On other occasions the local Class Surveyors are often requesting the engine manufacturer and/or sub-suppliers to provide Class stamped drawings prior to or at survey, even though no stamped drawings are distributed to *all* licensees and their sub-suppliers; but, just lists of approved/reviewed drawings.

Based on the proposals in CIMAC WG 2 – Classification Societies – Diesel, letter of 11 July 2010 Revision of IACS UR M44 for I.C. Engines (ST-10-33) UR M44 was proposed to be expanded and reformatted from two tables listing documents to be submitted and diesel engine data to requirements listing information and data to be submitted along with a detailed explanation of the engine certification process describing engineering review and survey during manufacture and erection at the shipyard. This proposed reorganization resulted in this format:

M44.2:	Definitions
M44.3 :	Overview - Approval process, Document flow
M44.4 :	Type Approval Process
M44.5 :	Certification Process

Definitions were added to UR M44 to clarify various terms used in the diesel engine certification process. The initial set of terms was developed by CIMAC WG 2 and forwarded with their letter ST-10-33. These were reviewed by the MP and in some cases the definitions were further clarified. The definitions are in Appendix 1.

An overview of the procedures to obtain an Engine Certificate is summarized in M44.3. The process is based on current practice by the IACS members. There is presently much misunderstanding between the engine licensee and the attending Surveyor at the manufacturing plant because design drawings developed by the engine designer (licensor) are used by the classification society during the drawing review. The licensee uses the design drawings to create their manufacturing drawings. These drawings are highly detailed. In almost all cases, the licensee's drawing numbers and titles do not match the design drawings reviewed by the classification society causing the Surveyor to request the drawings be stamped.

A new Appendix 2 indicates the document flow for Type Approval (TA) and Factory Acceptance Testing (FAT). CIMAC WG 2 initiated these document flow diagrams to provide a visual aid to users to show which offices of the classification society, engine designer, component suppliers and engine manufacturer act on or use the drawings. The final diagrams were the result of much discussion between the MP and CIMAC WG 2.

M44.4 lists the requirements for the Type Approval process for new or revised engine designs. M44.5 lists the requirements for the certification process for a Type Approved engine. These requirements are based on current practices of the IACS members.

The Data Sheet and Engine Particulars in Appendix 3 have been reformatted. Dimensional data related to the reciprocating components in the engine cylinders and the crankshaft have been deleted. Material specifications for the crankshaft have been deleted. Data related to supercharging devices, over-speed protection, electronic control systems, crankcase safety devices, starting systems, cylinder overpressure, allowable fuels, engine attached filters and driven pumps and main engine emergency operation capabilities have been added.

A new Appendix 4 provides the format related to information required for the comparison list for the licensor and licensee’s drawings. A new Appendix 5 provides the format for information required of the licensee to obtain confirmation from the licensor of any modifications to the engine’s design by the licensee.

3 Source / derivation of the proposed IACS Resolution

CIMAC WG2 dated 11 July 2010, Subject: Revision of IACS UR M44 for I.C. Engines and incorporate appropriate proposals.

4 Summary of Changes intended for the revised Resolution

The existing table has been reorganized into Tables 1 and 2 per the comments of the CIMAC WG2 letter. New Tables in the appendices have been added such as:

Appendix 1 – New Glossary
Appendix 2 – Representative document flow diagrams providing an aid to all parties involved in the engine certification process as to their roles and responsibilities
Appendix 3 –Updated and reformatted data sheet
Appendices 4 and 5 – New forms providing guidance for licensee/licensor drawing list comparison and licensor acceptance of licensee revisions to the engine design.

5 Points of discussions or possible discussions

During the development of Revision 8, CIMAC WG2 made several comments to the draft M44. The comments and MP responses are listed below for reference purposes only.

Clause / Sub-clause / Paragraph	CIMAC WG2 Comment	IACS MP Response
M44.3.1.2	This drawing comparison process is not achievable for high-volume marine engine production (thousands of certified marine engines annually). This level of documentation cannot be supported; we simply do not have the resources to support this administrative burden.	The intent of this requirement is to allow the attending surveyor to establish that the engine being assessed is the same as that approved by the society. The surveyor will as part of this check that the production drawings used for survey are the same as those approved and where there are any differences, that they have been agreed with the society. The drawing comparison process is <u>only required once for each engine type</u> and then at any change in production drawings. And for the engine assembly and testing, please see M44.5.6. There is a reference to UR Z26 for Alternative Certification Schemes which also resolve this comment.
M44.3.2.2.3	If the designer acceptance is not confirmed, the engine is to be regarded as a different engine type and is to be subjected to the complete Type Approval Process by the Licensee. This shall be struck/erased This is a violation of copy rights Licensee cannot Type Approve Engine an engine - all components are the property of the Licensor.	As this requirement prevents the builder/ licensee from deviating from the approved licensor's drawings without the designer's acceptance, it satisfies the commenter's concerns.
M44.3.2.2.4	Identical comment for M44.3.1.2	There appears to be a misinterpretation of 3.2.2.4. As stated in 3.1.2, the drawing comparison is done once. Then all future built engines requiring certification are certificated by the Classification Society. If there are several variations of a base model, administration is to be decided by the individual Society. One approach we apply is to have the designer/licensee submit all the engine variations for one model initially. Then there will be no delay.

M44.3.2.2.5	High-volume engine production cannot have a built in delay waiting for approval before the engine is built. Engines are built exactly the same in series, and submittal for the unit certificate is typically after engine build and test is complete. Most plants are under Alternative System of Certification.	
M44.3.2.2.7	This is not the process for high-volume engines built in plants with ASC.	See M44.5.6 and response to Item 1.
M44.4.6	Substantive modifications or Major modifications or Major changes: Design modifications which lead to alterations in the stress levels, operational behaviour, fatigue life or an effect on other components or characteristics of importance such as emissions.	This definition is based in part on CIMAC letter WG2/ST-10-33 dated 11.07.2010 As follows: Design modifications which might lead to alterations in stresses, running behaviour application of other components or other changes of importance
	The inaccuracy of the above definition, much more evident in the second part, might lead to stresses between the manufacturer, the Class HO, and the Class site offices.	Regarding emissions, 'substantial modification' in NTC/1.3.2 is applicable. Emission behaviour is not a class issue.
	What has for instance a design assessment to share with emission?	
	How does one define an operational behaviour change?	Operational behaviour change relates to output power, speed, temperatures for any cooling fluids, gas temperatures, fluid or gas pressure changes, etc. Any parameter that is measurable.
	It seems there are no unique parameters to judge whether a change is substantive or not.	There are numerous parameters adhered to in manufacturing an engine such as tolerances. The Societies are concerned with the major dimension for various components. Any changes to an engine design need to be discussed with the Society.

M44.4.8	This is not reasonable There is no longer a fixed rule for allowable uprating for a TAC, so a new TAT is required?	Requests for increased ratings are in UR M71.3 Note 2 which is proposed. Here is the proposed text: 2) The engine is approved for the tested rating and pressures (100% corresponding to MCR). Provided documentary evidence of successful service experience is submitted, an increase (if design approved) may be permitted without a new type test if the increase from the type tested engine is within: - 5% of the maximum combustion pressure, or - 5% of the mean effective pressure, or - 5% of the rpm.
	The TAC will be INVALID? The substantial modification definition is too generic for stating that a TAC is invalid if there are substantial modifications in the design.	M44, Appendix 1 without approval by the Society will invalidate the TAC for that particular engine. Follow on engines designed in accordance with the Rules will be able to be certificated applying the applicable TAC.
M44.4.9.2	Proposed The Classification Society, if considered necessary, may request further documents to be submitted to the Classification Society, only in case they differ from the ones required as per Tables 1, 2, 3, and anyhow upon a precise and written motivation. The motivation must be linked to safety issues.	MP understands the issue for CIMAC is to limit requests for additional technical details to those drawings listed in Tables 1, 2 and 3. MP agrees with that in principal along with the requirement for written request from the Society to the engine manufacturer. However, MP disagrees with the last sentence. The request for additional information is to be based on verifying compliance with the Rule requirements because of a lack of information in the submitted drawings

M44 Table 2, Item 27	This is a new M44 requirement which is too broad in scope as written.	This request is from CIMAC letter WG2/ST-10-33 dated 11.07.2010, Section No.2 Item 5, “Requirements according to IACS UR P2 for mechanical joints.” The failure of any engine piping systems will lead to degraded performance or complete loss of power which is unacceptable to all the Societies.
M44 Figure 2	This drawing comparison process is not achievable for high-volume marine engine production (thousands of certified marine engines annually). This level of documentation cannot be supported; we simply do not have the resources to support this administrative burden.	See response to M44.3.1.2
M44 Appendix 1	There is no longer a fixed rule for allowable uprating for a TAC, so a new TAT is required?	Requests for increased ratings are in UR M71.3 Note 2 which is proposed. See full response in Item 8
M44 Appendix 1, Modifications	The explanation given is not a clear definition.	
M44 Appendix 1, Substantive modifications or Major modifications or Major changes	Design modifications which lead to alterations in the stress level, fatigue life and/or to the definition of engine type according to IACS M32.	See response to M44.4.8
M44 Appendix 3	New M44 requirement to state "Performance Data" in terms of IACS UR M28 ambient reference conditions. A study of available marine diesel engine power data shows most companies are referencing power to ISO 15550 (clause 5) standard reference conditions (and same from ISO 3046-1 clause 5). Apparently this is to determine "service power" as defined in ISO 15550 section 3.3.8 at the UR M28 ambient reference conditions.	ISO 15550 states; 1.2 This International Standard applies to engines used for: a) land, rail-traction and marine use as defined in ISO 3046-1. ISO 3046-1 references the IACS nominal ambient conditions stated in UR M28. It is understood that ‘continuous power’ (Type of power application) as used in the referred ISO standards (see ISO 3046, 11.3) is equivalent to the MCR as used throughout the IACS UR Ms.

CIMAC WG2/ST-10-33 letter to Machinery Panel dated 11 July 2010, Subject: Revision of IACS UR M44 for I.C. Engines

CO-ORDINATING WORKING GROUP

"CLASSIFICATION SOCIETIES – DIESEL"

(WG2)

Proposal towards IACS Machinery Panel

St. Stutz/Secretary WG2/ST-10-33 11.07.2010

Subject: Revision of IACS UR M44 for I. C. Engines

Background

On the occasion of the last Joint Meeting between IACS MP and CIMAC WG2 in September 2009 the revision of IACS UR M44 was subject to negotiations.
It was decided that the revision work shall be taken up by a small working group composed of A. Smith, C. Hadler, K. B. Hansen and St. Stutz.
One of the reasons behind the necessity to revise IACS UR M44 is that mainly in some parts of East Asia repeatedly discussions are coming up between engine manufacturers and local Class Representatives with regard to whether engine components were built in accordance with approved drawings or not. The problem is often caused by differences in the identification between drawings requested in IACS UR M44 and the corresponding drawing identification used for inspection of components, as the drawings mentioned in IACS UR M44 might be assembly drawings and the drawings for inspection might be detail drawings.
An other argument for revising IACS UR M44 is that local surveyors are often requesting the engine manufacturers and/or sub-suppliers to provide Class stamped drawings for inspection, even we have to realize that in normal cases no stamped drawings are distributed around the world but just lists of appoved/appraised drawings.
With this proposal the responsabilities and actions shall be streamlined.
The proposal has been developed as follows:

- Section 1 and 2 are common for both 2 and 4-stroke manufacturers,
- Section 3 focuses exclusively on engine produced on the license ,
- Section 4 focuses on agreements not covered by section 3

Proposal

M44 Certification of I.C. Engines

M44.1 *Definitions*

The definitions as given in IACS UR M44, Appendix 1 shall clarify the meaning of the various specific expressions and lead to common understanding.

M44.2 *Type Approval Process (TAP)*

A Type Approval Process consists of the following steps:

M44.2.1 *Design Approval/Appraisal (DA)*

DA's are valid as long as no substantial modifications have been implemented and might be extended/renewed based on evidence that all current rules and requirements are still covered.

M44.2.2 *Manufacturer Approval*

The assessment shall comprise manufacturing facilities and -process, machining tools, quality assurance, testing facilities etc.
Conformity with the Class requirements will be covered by a Class Approval document.

M44.2.3 *Type Approval Test*

A Type Approval Test (TAT) required according to IACS UR M32 should be carried out in accordance with IACS UR M50 and shall be witnessed by Class.

M44.2.4 *Type Approval Certificate*

After the above steps have successfully been passed the Classes will issue a Type Approval Certificate (TAC).
An extension/renewal of such certificates will be granted upon the submission of modified or new drawings (substantial modifications) compared to the former submission(s) for DA.
A renewal can be granted when a declaration that no substantial modifications have been applied since the last submission is made.

M44.3 *Procedures*

M44.3.1 *Documents to be submitted to the Class Societies for Engine Information, Approval, Test and Inspection Purposes*

For each type of engine the documents listed in the following sections and if applicable to the type of engine are to be submitted to the Classification Societies for information, approval, recalculation or inspection for one (1) cylinder only if not otherwise specified.

Note:

In those cases in which a Licensor – Licensee agreement does NOT apply, an "Engine Designer" should be understood as the entity that has the Design Rights or is delegated by whom has the design rights to modify the design.

Documents for information, ref. to section 1, are to be submitted to the Classification Societies by Licensor.

Documents for approval and /or recalculation, ref. to section 2, are to be submitted to the Classification Societies by Engine Designer / Licensor.

Documents for inspection purposes, ref. to section 3, to be made available by Engine Builder / Licensees for the Class representative in charge of inspection.

After the design approval of an engine type has been given by a Classification Society for the first time, only those documents as listed in the section 1, 2, 3/4 which have undergone substantial modifications or new documents replacing existing documents will have to be submitted for consideration of the Class Society.

Section No.: 1 - Documents for information		
The group consists of basic descriptive information so the Class can get a general impression of the engine and its design and relevant engine data and performances. Besides that, the section describe necessary aux. systems belonging to the engine, installations aspects, list of capacities/tech. specifications/requirements and information needed for maintenance and operating of the engine. Documents to be submitted by **engine designer/lincensor**.		
	List of drawings to be submitted for Information	**Item Nos. ref. to existing IACS UR M44**
1	Engine particulars [1]	1
2	Engine cross section	2
3	Thrust bearing, assembly (if applicable)	5
4	Cylinder cover, assembly	9
5	Cylinder liner, assembly	10
6	Connecting rod, assembly	17
7	Crosshead, assembly (if applicable)	18
8	Piston, assembly	20
9	Camshaft / chain drive, assembly (where applicable)	21
10	Schematic layout or other equivalent documents of starting air system [2]	24
11	Schematic layout or other equivalent documents of fuel oil system [2]	25
12	Schematic layout or other equivalent documents of lube oil system [2]	26
13	Schematic layout or other equivalent documents of cooling water system [2]	27
14	Schematic layout or other equivalent documents of hydraulic system [2]	
15	Schematic diagram of engine control and safety system	28
16	Operation- and Service Manuals (as soon as available)	32
17	FMEA (for electronically controlled engines) [3]	
18	Type Test Report after the TAT	34
19	Shielding and insulation of exhaust pipes, assembly	29
20	Production specifications for castings and welding (sequence)	
21	Material specifications of main parts with information on NDT, pressure tests etc.	22

1) Project Guide/ Marine Installation Manual

2)with main dimensions, operating media, max . working pressure, if not include in engine particulars

3) Common platform required. To be decided in collaboration IACS MP/CIMAC WG 15

Section No.: 2 – Documents for Class approval or recalculation.			
The group contains documents and drawings which have to be approved by the Class. The documents are to be submitted to the Class by engine designer/licensor.			
List of documents for Class approval and/or recalculation		**Item Nos. ref. to existing IACS UR M44**	**Remarks**
1	Crankshaft calculations (for each cylinder configuration) according to the enclosed data sheet and to IACS UR M53	11-14	
2	Results of calculation for crankcase explosion relief valves	31	
3	Requirements according to IACS UR M9 for crankcase explosion relief valves		M9.12
4	Requirements according to IACS UR M10 for oil mist detection and/or alternative alarm arrangements		M10.18
5	Requirements according to IACS UR P2 for mechanical joints.		
6	Shielding of high pressure fuel/gas pipes, assembly		
7	Welding instruction		
8	Compliance with inclination limits		
9	Engine frames, welding drawings (if applicable)		
10	Bedplate/oil sump welding drawings		
11	Results from environmental tests, control components		
12	according to IACS UR E10		
	Documents as required in IACS UR E22		
13	Type test program to be approved before TAT		

Section No.: 3 – Documents for inspection of components and systems
This section applies only to those Realities governed by Licensor – Licensee type of agreements. The section contains documents (drawings & production- quality specifications) needed for inspection and testing of the engine, engines parts and systems in the production. Only for inspection purpose and upon request for clarification, the **Licensee** has to show to the Class representative the relevant detail drawings, production quality control specifications and acceptance criteria. The **Licensee** must be prepared to provide the Class representative with a "List of Comparison" which compares **Licensee** drawing Id. to **Licensor** drawing Id. If there are differences in the technical content on the Licensee drawing compared to the similar **Licensor** drawing the **Licensee** must provide the Class Representative with a list "Request for Alternative Execution" approved by **Licensor** and signed by **Licensee** and Licensor. At any time the **Licensee** is responsible for the accuracy of the List of Compared drawing Id. and the content on the List of Request for Alternative Execution.

List of Component Drawings and systems drawings as far as requested by the relevant Class, for which the Licensee must make available detail drawings for Inspection		**Drawings**	**Specifications for Inspection**
1	Crankshafts (pins, journals, flanges etc.)	The relevant detail drawings are to be shown upon request to every individual local Class Representative for inspection purpose.	Relevant quality and production specification for every individual item must be made available upon request. In case of devia-tions between the approved docu-mentation and the documentation according to which the engine is being built, the **Licensee** has to provide as well those modifi-cation notices showing the **Licensors** handling codes.
2	Pistons, piston rods		
3	Connecting rods		
4	Crossheads, if applicable		
5	Cylinder liners		
6	Cylinder covers		
7	Cylinder blocks		
8	Engine blocks		
9	Engine frames, if applicable		
10	Bedplates, if applicable		
11	Bolts for crankshaft couplings		
12	Tie rods, if applicable		
13	Valve bodies, if applicable		
14	Bolts for crosshead, if applicable		
15	Bolts for cylinder covers/heads		
16	Bolts for main bearings		
17	Bolts for connecting rod		
18	Camshaft drive wheels		
19	High pressure pipes		
20	Pumps, if applicable		

Section No.: 4 – Documents for inspection of components and systems

This section applies to Self-Manufacturing Companies, Assembly Shops and to those Realities (such as Joint Ventures) governed by agreements different from the Licensor – Licensee type.

The section contains documents (drawings & production - quality specifications) needed for inspection and testing of the engine, engines parts and systems in the production.
Only for inspection purpose and upon request for clarification the Engine Builder has to show to the Class representative the relevant detail drawings, production quality control specifications and acceptance criteria.
The **Engine Builder** must be prepared to provide the Class representative with a "List of Comparison" which compares **Engine Builder** drawing Id. to **Engine Designer** drawing Id.
If there are differences in the technical content on the Engine Builder drawing compared to the similar Engine Designer drawing, the **Engine Builder** must provide to the Class Representative evidence of the equivalence and agreement with Engine Designer.
At any time the **Engine Builder** is responsible for the accuracy of the "List of Comparison" of drawing Id.

M44.3.2 Comparison List
(see attachment 1)

M44.3.3 List of alternative Execution
(see attachment 2)

M44.3.4 Data Sheet
(see attachment 3)

M44.4 Acceptance of Components/Certification

Whenever a manufacturer of internal combustion engine components is purchasing lots of materials which can not be identified for specific projects or Classes due to the time frame until the material is used up as well as when producing for spare parts stocks, the IACS members accept that the materiel identification and certification will be carried by one single Class and that all other IACS members will accept the respective documents issued by this specific Class.
It goes without saying that the material supplier will call up Classes in turns.
Furthermore, the IACS members accept that the presence of a surveyor is not always necessary when pieces of such lots are being cut for specific projects.

M44.5 Certification of Parts subject to Class Approval

Under such components we understand parts, which are fitted to an engine and which are subject to a Class approval, as well as parts,
which shall be carried on board as replacement parts (Spare Parts) for components which might fail during operation of the engine or are subject to wear and tear and which, call for change in situ to keep the vessel moving.

Engine Designer and Engine Builder must define and agree the procedure according to which they select, evaluate and reevaluate such Part Manufacturers and declare such companies as approved suppliers

DATA SHEET

for calculation of Crankshafts for I.C. Engines

– based on IACS UR M 53 –

1	Engine Builder		
2	Engine Type Designation		
3	Stroke-Cycle	☐ 2 SCSA	☐ 4 SCSA
4	Kind of engine ☐ In-line engine ☐ V-type engine with adjacent connecting rods ☐ V-type engine with articulated-type connecting rods ☐ V-type engine with forked/inner connecting rods ☐ Crosshead engine ☐ Trunk piston engine		
5	Combustion Method ☐ Direct injection ☐ Precombustion chamber ☐ Others: ____________________		
6	 Fig. 1 Designation of the cylinders		
7	Sense of Rotation (corresponding to Item 6) ☐ Clockwise ☐ Counter clockwise

Expression	Definition
Acceptance criteria	The set of values or criteria which a design, product, service or process is required to conform with, in order to be accepted
Accepted	Status of a design, product, service or process, which has been found to conform to specific acceptance criteria
Action- or activity code	Instruction in a modification notice under which circumstances a design modification is to be implemented
Alternative System of Certification (ASC)	A system, by which a society evaluates a manufacturers quality assurance and quality control arrangements for compliance with Rule requirements, then authorizes a manufacturer to undertake and witness testing normally required to be done in the presence of a surveyor. The alternative System of Certification as presently administrated by the Member Societies is generally known as: ABS: Product Quality Assurance BV: Alternative Survey Scheme CCS: Quality System Approval DNV: Manufacturing Survey Arrangement GL: Alternative System Certification????????????? KR: Quality Assurance System LR: LR Quality Schemes NK: Approved Survey Scheme RINA: Alternative Survey Scheme RS: Recognition of Manufacturers
Appraisal	Refers to the evaluation by a competent body
Approval	The granting of permission for a design, product, service or process to be used for a stated purpose under specific conditions based upon a satisfactory appraisal
Assembly	Equipment or a system made up of components or parts
Assess	Determine the degree of conformity of a design, product, service, process, system or organization with identified specifications, rules, standards or other normative documents
Audit	Planned systematic and independent examination to determine whether the activities are documented. The documented activities are implemented. The results meet the stated objectives
Auditor	Individual who has the qualifications and experience to perform audits
Certificate	A formal document attesting compliance of a design, product, service or process with the specified requirements
Certification	A procedure whereby a design, product, service or process is approved in accordance with specified requirements
Class	Short for Classification Society
Class Approval	Approved by means of a Class Certificate
Classification	Is that specific type of certification, which relates to the Rules of the relevant Classification Society
Classification Mark/	Assignment of a classification mark or notation. The relevant components and materials
Notation	may require certification with the applicable Rules of the Society
Classification Process	Essentiel part of the classification process is the initial and periodic certification of materials and components to the Rules of the relevant Classification Society
Competent Body	Organization recognized as having appropriate knowledge and expertise in a scific area
Component	Part, Member of Equipment or System
Conformity	Where a design, product, process or service demonstrates compliance with its specific requirements
Construction Mark	A Construction Mark identifies the type of surveillance made prior to the issuance of the Certificate of Classification to a ship Ships which are built in accordance with the requirements of the Rules and under the survey of the Society Ships built under the survey of other authorities and which have been assigned by such authorities a Class deemed equivalent to a Class described in the Rules Ships are built under the survey of the Society but do not meet some provisions of the Rules One of the marks here above is also assigned , followed by the symbol of the corresponding additional Class Notation, to classed automated installations, refrigerating plants, lifting appliances and generally to any installation for which a certificate or an annex to the certificate is issued
Contract	Agreement between two or more parties relating to the scope of service

Expression	Definition
Contractor	see supplier
Customer	Party who purchases or receives goods or services from another
Delegation of Authority	See IMO
Design	All relevant plans, documents calculations described in the performance, installation and manufacturing of a product
Design Analysis	Investigative methodology selectively used to assess the design
Design appraisal	Evaluation of all relevant plans, calculations and documents related to the design
Design approval	Process whereby permission is granted for the design to be used for a stated purpose under specific condition
Design Examination Certificate	See IEU Marine directive for definition
Design review	Part of the appraisal process to evaluate specific aspects of the design
Directive	See EU
Documentation	The provision of appropriate documental evidence to support an assessment
Drawings appoval/ plan approval	Part of the design approval process which relates to drawings and plans
Equipment	Part of a system assembled from components
Equivalent	An acceptable, no les effective alternative to specified criteria
Evaluation	Systematic examination of the extent to which a design, product, service or process satifies specific criteria
Examination	Assessment by a competent person to determine compliance with requirements
Inspection	Examination of a design, product service or process by an Inspector
Inspection Plan	List of tasks of inspection to be performed by the Inspector
Installation	The assembling and final placement of components, equipment and subsystems to permit operation of the system
Manufacturer	Party responsible for the manufacturing and quality of the product
Manufacturing process	Systematic series of actions directed towards manufacturing a product
Manufacturing process approval	Approval of the manufacturing process adopted by the manufacturer during production of a specific product
Material	Goods supplied by one manufacturer to another manufacturer that will require further forming or manufacturing before becoming a new product
Modification	Alimited change that does not affect the current approval
Modification notice	Information about a design modification with new mod. index or new drawing number replacing the former drawing
Mutual recognition	The result of an arrangement between two or more bodies that consider that an approval or a certification granted by one of them, under special conditions, is acceptable to the others
Original Spare Parts	Parts produced fully in line with the engine designer's drawings, specifications and quality requirements. The supplier must be approved by the engine designer and/or -manufacturer and Classes. The respective documents are to be purchased in a legal proper way.
Performance test	Technical operation where a specific performance characteristic is determined
Producer	See manufacturer
Product	Result of the manufacturing process
Prototype Test	Investigations on the first or one of the first new engines with regard to optimization, fine tuning of engine parameters and verification of the expected running behaviour
Quality Assurance	All the planned and systematic activities implemented within the quality system, and demonstrated as needed to provide adequate confidence that an entity will fulfil requirements for quality. Ref. ISO 8402
Regulation	Rule or order issued by an executive authority or regulatory agency of a government and having the force of law
Repair	Restore to original or near original condition the results of wear and tear or damages for a product or system in service
Requirement	Specified characteristics used for evaluation purposes
Review	Systematic evaluation
Revision	Means to record changes in one or more particularsof design drawings or specifications
Specification	Technical data or particulars which are used to establish the suitability of materials, products, components or systems for their intended use

Expression	Definition
Substantial or major modifications/changes	Design modifications which might lead to alterations in stresses, running behaviour application of other components or other changes os importance
Subsupplier/ subcontracter	One who contracts to supply material to another supplier
Supplier	One who contracts to furnish materials or design, products, service or components to a customer or user
Test	A technical operation that consists of the determination of one or more characteristics or performance of a given product, material, equipment, organism, physical phenomenon, process or service according to a specified procedure. A technical operation to determine if one or more characteristic(s) or performance of a product, process or service satisfies specific requirements
Traceability	Ability to follow back through the design and manufacturing process the origine
Type Approval	1. Evaluation of a design to determine conformance with specifications 2. Witnessing manufacture and testing of a type of product to determine compliance with the specification 3. Evaluation of the manufacturingarrangements to confirm that the product can be consistently produced in accordance with the specification
Type Test	Last step of the type approval procedure. Test program in accordance with M50
Witness	To be physically present at a test and being able to record and give evidence about it's outcome

Technical Background (TB) document for UR M44 (Rev.10 Feb 2021)

1. Scope and objectives

UR M44(Rev.9) does not reflect the agreed format for referencing the ISO standards. Rev.10 has been developed to comply with the agreed format.

2. Engineering background for technical basis and rationale

A) Format for references to Industry standards

Format:
[Standard Designation], [version/revision, if applicable], [year of publication] (examples: API Spec 2F, 6th Edition, 1997; ISO 4624, 2002), where [version/revision, if applicable] and/or [year of publication] are decided by IACS and are not necessarily to be the current/latest version.

B) Format for references to IMO instruments (where the number of amendments is large)

Format:
regulation/paragraph x.x.x of SOLAS Chapter X/MARPOL Annex X/the XXX Code, as amended by IMO resolutions up to MSC.xx(xx)/MEPC.xx(xx)

3. Source / derivation of the proposed IACS Resolution

None

4. Summary of Changes intended for the revised Resolution:

UR M44 has been updated to specify the revision/version of the ISO standards and MSC resolutions as follows:

ISO standards	**Replaced by**
ISO 9000 series	ISO 9001:2015
ISO 9001	ISO 9001:2015
ISO 8216	ISO 8216-1:2017
MSC resolutions	**Replaced by**
MSC.81(70)	MSC.81(70), as amended by IMO resolutions up to MSC.472(101)

5. Points of discussions or possible discussions

None

6. Attachments if any

None

Technical Background (TB) document for UR M44 (Rev.11 Apr 2025)

1. Scope and objectives

To develop a revised UR M44 that contains the requirements for the approval of drawings and specifications for engines and sub-systems, in alignment with IACS UR M87, 'Certification Scheme for Reciprocating Internal Combustion Engines.'

This UR specifies the following items:

- Documents to be submitted for type approval or design evaluation of an engine design,
- Documents to be submitted for use during manufacturing and installation,
- The document flow between the engine designer, Classification Society approval centre, engine manufacturer, and Classification Society Surveyors, and
- Documents required for the approval of sub-systems

.

2. Engineering background for technical basis and rationale

CIMAC proposed a revision of the URs related to I.C. Engines, leading to the development of a new UR, M87, 'Certification Scheme for Reciprocating Internal Combustion Engines,' as a base standard for engine certification.

The existing M44, 'Documents for the Approval of Diesel Engines,' currently covers requirements for document submission and approval, as well as requirements for engine type approval and certification.
Accordingly, the certification-related content of M44 will be merged into M87, and M44 will be restructured and aligned with other URs related to engine certification, drawing on experience gained from implementing the existing URs M44, M71, and M51.

2a. Specification of the data utilised in the development/revision of the proposed IACS Resolution, if any

None.

3. Source/derivation of the proposed IACS Resolution

IACS UR M44 (Rev.10 Corr.1 Feb 2022).

4. Summary of Changes intended for the revised Resolution:

A) To coordinate with new UR M87 “Certification Scheme of Reciprocating Internal Combustion Engines”, the UR M44 focuses on topics about documentation submission and approval. The following contents relating engine certification in existing M44 was removed and merged into M87 “Certification Scheme for Reciprocating Internal Combustion Engines”.

- M44 3.1 approval process （M87 5.1, 6）
- M44 3.3 Approval of diesel engine components (M87 6)
- M44 4 (except for 4.1 and 4.2 and 4.9) type approval process (M87 5)
- M44 5 (except for 5.1 and 5.2 and 4.9) Certification process (M87 6)

- M44 Appendix 1, Glossary (M87 Appendix 1, Definitions)

B) The structure of UR M44 was harmonized with the other URs considering CIMAC's proposals as far as practicable. Item M44.1 "General", M44.3 "Objectives" was added to be consistent with other URs.

C) Structure is optimized in M44 as below,
M44.5 Documents approval for obtaining type approval
-documents flow
-documents to be submitted
-Submission format of documentation
M44.6 Documents approval for obtaining product certificate
-documents flow
-documents to be submitted
-Submission format of documentation
M44.7 Documents required for approval of sub-systems

D) To coordinate with new UR M87 "Certification Scheme of Reciprocating Internal Combustion Engines", because the term of "licensor-licensee agreement" was a particular business cooperation model, general terms of "engine designer/manufacturer" were preferable. New definitions were added in M87 Appendix 1. When a licensor-licensee agreement is applied, "designer/manufacturer" could be regarded as the "licensor/licensee".

E) In item M44.5 "Documents approval for obtaining Type approval or Design Evaluation Certificate", the "Design Evaluation Certificate" was added to be corresponding with M87.

F) Because the existing M44 mainly considered the circumstance of 2-stroke engine inspection, in M44.6 we clarified that it was not necessary to submit drawings for approval repeatedly for the approved engines without design modification, especially for 4 stroke engines.

G) To coordinate with the application of the concept of "sub-system" in new M87, documents approval for sub-system was added as M44.7, taking consideration of CIMAC's proposals and with reference to M44 table 1,2,3.

H) In M44 8, an approval letter was proposed to be issued, but at the discretion of each Society.

I) M44 Footnote7 under Table 1 was added, because it was not necessary to submit common documents for different engine type.

J) M44 Footnote7 under Table 2 clarified that the test program could be submit later but before the test.

K) CIMAC suggested to add the joint venture in note of paragraph 6 which agreed by the Panel members.

L) CIMAC suggested adding the paragraph 7.2 which agreed by the Panel members.

7.2 If the subsystem is either already certified for the relevant engine type or type-approved by the Classification Society or has already been applied and approved for another engine type, The documents normally required for submission in 7.1 can then be omitted at the discretion of each classification society, unless otherwise there are modifications.

M) CIMAC suggests changing “Fuel oil” to “Fuel” only in tables 1, 2 and 3 and adding fuel injection to appendix 2 table to covering any type of fuel which agreed by the Panel members.

N) CIMAC asked for clarity on paragraph 6 and table 3 which specified the list of documents which are required to be made available for surveys during inspections. Machinery Panel slightly modified paragraph 6 accordingly.

O) CIMAC proposed to modify paragraph 6.1.3 as follow;

Existing 6.3.1: “If the designer’s acceptance is not confirmed, the engine is to ~~be regarded as a different engine type and is to be~~ subjected to the ~~complete~~ type approval process ~~by the licensee~~ under the responsibility of the manufacturer.

CIMAC suggests, add:
Consent from the Engine Designer for the build of such modified engine must be provided to avoid IP infringement. Without such consent modified engine design cannot be regarded as legible for assessment, build and Type Test.

Machinery Panel members agreed that concerns raised by CIMAC has already addressed in paragraph 6.1.2 the confirmation/acceptance from engine designer requested.
Based on above and given that the details of specific applications may vary and could fall under contractual agreements between the designer and manufacturer, the Panel has agreed to remove the entire paragraph of section 6.1.3.

P) CIMAC suggests that reference to the applicable and available documents can be indicated in a new raw "30" in the Table 1, Panel members agreed to incorporate the comment and table 1 item 30 added.

5. Points of discussions or possible discussions

Document has been reviewed by **SuP** without comment.

Documents has been reviewed by **CIMAC** with comments and the panel has thoroughly evaluated the technical suggestions and comments provided by CIMAC.

Some of these have been incorporated as outlined above, while others, particularly those related to the structural arrangement of the UR, have been deemed not to require immediate revision at this time.

6. Attachments if any

Part B. Technical Background

List of Technical Background (TB) documents for UR M45:

Annex 1. **TB for Rev.2 (Feb 2011)**

See separate TB document in Annex 1.

Note: There are no separate Technical Background (TB) documents for New (1982), Rev.1 (1987) and Del (Nov 2022).

Technical Background for UR M45 Rev.2, Feb 2011

1. Scope and objectives

To modify the existing UR M45 in order for Member Societies to uniformly implement the requirement for continuous ventilation of machinery spaces in all weather conditions on the Load Line convention.

- To clarify the application UR M45 to the Machinery spaces
- Revise "UR M45 Ventilation of Machinery Spaces" to Clarify the "Machinery spaces" mentioned in UR M45

2. Engineering background for technical basis and rationale

- International Convention on Load Lines, 1966, as amended by the Protocol of 1988(ICLL mentioned below) has entered into force on 1 January 2005. Annex I Chapter II Regulation 17(3) of ICLL states: "… ventilators necessary to continuously supply the machinery space shall have coamings of sufficient height to comply with regulation 19(3), without having to fit weathertight closing appliances. Ventilators necessary to continuously supply the emergency generator room, if this is considered buoyant in the stability calculation or protecting opening leading below, shall have coamings of sufficient height to comply with regulation 19(3), without having to fit weathertight closing appliances."

- SOLAS Reg. II-1/35 states : "Machinery spaces of category A shall be adequately ventilated so as to ensure that when machinery or boilers therein are operating at full power in all weather conditions, including heavy weather, an adequate supply of air maintained to the spaces for the safety and comfort of personnel and the operation of the machinery. Any other machinery space shall be adequately ventilated appropriate for the purpose of that machinery space."

- From abovementioned regulations, it is understood that only machinery spaces of category A shall be ventilated continuously. But the existing UR45 requires all machinery space to be ventilated continuously in all weather conditions. Furthermore, the title of UR M45 (engine room) is not consistent with the title of SOLAS Regulation II-1/35 (machinery space). So it was agreed to modify the existing UR M45 to clarify which machinery space is to be ventilated continuously in all weather conditions.

3. Source/derivation of the proposed IACS Resolution

None

4. Summary of Changes intended for the revised Resolution:

The following description of UR M45 has been updated to clarify the "Machinery spaces".

- The title of UR M45 has been updated to be consistent with the title of SOLAS Regulation II-1/35 (machinery space instead of engine room)
- The existing first paragraph of UR M45 has been removed and replaced with "The ventilation of machinery spaces shall be according to the principles laid down in SOLAS Regulation II-1/35", so that UR M45 is aligned with SOLAS Regulation II-1/35.
- The new sentence "The Machinery spaces are those defined in SOLAS Regulation II-1/3.16" has been added for clarification, so that the definition of machinery spaces within UR M45 is aligned with the definition of machinery spaces within SOLAS Regulation II-1/3.16.

5. Points of discussions or possible discussions

- "Machinery spaces" whether including the "Machinery spaces of category A". This is the requirements of SOLAS Reg. II-1/35.

- The revision is to be submitted to respective Conventions for evaluation; for example ICLL and SOLAS

6. Attachments if any

None

UR M46 "Ambient conditions – Inclinations and Ship Motions"

Summary

Note 3 to M46.2 is updated accommodating the reference clause nos. of the IGC Code and the IBC Code that were previously specified in UI SC6 and UI SC290.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev.4 (August 2024)	26 August 2024	1 January 2026
Rev.3 (August 2023)	09 August 2023	1 January 2025
Rev.2 (Dec 2018)	19 December 2018	1 January 2020
Rev.1 (June 2002)	No records	-
New (1982)	No records	-

- **Rev.4 (August 2024)**

1 Origin of Change:

☑ Suggestion by IACS member

2 Main Reason for Change:

Reference clause nos. of the IGC Code and the IBC Code which are the main part of interpretation in UI SC6 and UI SC290 have been transferred to UR M46 (Note 3 to M46.2).

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None.

4 History of Decisions Made:

The Panel considered the revision of UI SC6, UI SC290 and UR M46, and after deliberations decided to delete the redundant UIs (i.e. UI SC6 and UI SC290) and add reference clause nos. of the IGC Code and the IBC Code to UR M46 (Note 3 to M46.2).

In the course of discussion, it was found that similar requirements as Note 3 to M46.2 is present in item 8 of UR E10 (inclination test), and the Panel decided to update relevant part of UR E10 as well.

5 Other Resolutions Changes:

- UI SC6

- UI SC290
- UR E10

6 Any hinderance to MASS, including any other new technologies:

None.

7 Dates:

Original Proposal:	19 January 2024	(Ref: PM24002_RIa)
Panel Approval:	02 July 2024	(Ref: PM24002_IMf)
GPG Approval:	26 August 2024	(Ref: 21036aIGd)

- **Rev.3 (August 2023)**

1 Origin of Change:

☑ Suggestion by IACS member

2 Main Reason for Change:

To establish and add requirements for verification.

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None.

4 History of Decisions Made:

Issue raised as a potential New Work Item by a member during the 29th Machinery Panel meeting (March 2019)
Revised UR M46 agreed by Machinery Panel (PM19923_IMu dated 07/07/2023)

5 Other Resolutions Changes:
None.

6 Any hinderance to MASS, including any other new technologies:
None.

7 Dates:

Original Proposal	: 06 May 2019	(Ref: PM19923_IMa)
Panel Approval	: 07 July 2023	(Ref: PM19923_IMu)
GPG Approval	: 09 August 2023	(Ref: 21036_IGf)

- **Rev.2 (Dec 2018)**

1 Origin of Change:

☑ Suggestion by IACS member

2 Main Reason for Change:

Perceived conflict between Note 1 in UR M46 Rev.1 and UR E10 Rev.6

3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None.

4 History of Decisions Made:

Issue raised by a member at the 27th Machinery Panel meeting (March 2018)
Revised UR M46 agreed by Machinery Panel (PM18911_IMd dated 26/10/2018)

5 Other Resolutions Changes

None.

6 Dates:

Original proposal: March 2018
Panel Approval: 26 October 2018 (Ref: PM18911_IMd)
GPG Approval: 19 December 2018 (Ref: 18185_IGe)

- ## Rev.1 (June 2002)

No records available.

****

Part B. Technical Background

List of Technical Background (TB) documents for UR M46:

Annex 1. **TB for Rev.2 (Dec 2018)**

See separate TB document in Annex 1.

Annex 2. **TB for Rev.3 (August 2023)**

See separate TB document in Annex 2.

Annex 3. **TB for Rev.4 (August 2024)**

See separate TB document in Annex 3.

Note: There are no Technical Background (TB) documents available for New (1982) and Rev.1 (June 2002).

Technical Background (TB) document for UR M46 Rev.2 (Dec 2018)

1. Scope and objectives

To remove a possible conflict between Note 1 in UR M46, Rev.1 and test no. 8 in UR E10, Rev.6.

2. Engineering background for technical basis and rationale

Note 1 of UR M46, Rev.1 requires for switch gear, electrical and electronic appliances that no undesired switching operations or operational changes may occur up to an angle of inclination of 45 deg. while test no. 8 of UR E10 stipulates static and dynamic inclination angles of 22.5 deg. in the test specification for type approval. These two requirements appear to be at variance. Upon consideration the Panel qualified majority concluded that the type test requirements in UR E10 should apply and that the inclination angle of 45 deg. in Note 1 in UR M46 may be deleted.

3. Source/derivation of the proposed IACS Resolution

Members practice in the application of UR M46 and UR E10.

4. Summary of Changes intended for the revised Resolution:

Deletion of the required inclination angle of 45 deg. from Note 1.

5. Points of discussions or possible discussions

Two members considered that the requirements in UR M46 and UR E10 are distinctly different in that UR M46 requires that switches and controls are to remain in their last set position and this is seen as an additional requirement.

One member was of the view that Note 1 of UR M46 may be added to UR E10, however, another member considered that this was not appropriate since UR E10 specifies test requirements whereas Note 1 in UR M46 gives a requirement, however, without stipulating tests.

6. Attachments if any

None.

Technical Background (TB) document for UR M46 (Rev.3 August 2023)

1. Scope and objectives

It was proposed to revise UR M46 to ensure clarity of the static and dynamic inclinations that the machinery is expected to perform at. This new task will address the concerns and uncertainties of compliance with UR M46. The objective of the revision was essentially in three parts.

1. To require the dynamic conditions under which essential machinery and equipment is required to operate satisfactorily to be determined.
2. To establish acceptable approaches by which machinery and equipment manufacturers can demonstrate satisfactory operation under the conditions described in the UR.
3. To establish acceptable approaches by which ship builders can demonstrate satisfactory operation when installed onboard under the conditions described in the UR.

2. Engineering background for technical basis and rationale

IACS UR M46 defines the ambient conditions "to be applied to the layout, selection and arrangement of all shipboard machinery, equipment and appliances to ensure proper operation" and in particular the dynamic angles of inclination due to ship motion.

Recent in-service experience, external feedback and ensuing discussions with industry suggests that, from a machinery and equipment manufacturing perspective, the definition of dynamic inclinations as stated in the UR is unclear and arguably incomplete, and therefore needs further definition.

A series of recent main engine fuel gas compressor in-service failures has been attributed to compressor components (conrods) unsuited to the higher accelerations to which deck mounted (LNGC compressor room located) compressors are subject to in heavy weather.

Additionally, it has become evident that there is also unclarity with regards to how machinery and equipment manufacturers and the means by which shipbuilders would be expected to demonstrate compliance with the requirements in respect of their scope of supply, which therefore needs establishing.

The failures highlighted the need for verification of machinery and equipment for operation under dynamic inclinations and the accelerations resulting therefrom. During the ensuing discussions within the IACS Machinery Panel, the need for defining a consistent approach to the verification of both static and dynamic inclinations became apparent.

2a. Specification of the data utilised in the development/revision of the proposed IACS Resolution, if any

None.

3. Source/derivation of the proposed IACS Resolution

Members practice in the application of UR M46 and in-service feedback from recent relevant failures.

4. Summary of Changes intended for the revised IACS Resolution:

Change of UR title to better reflect scope.
In 46.1 word 'all' deleted to reflect the applicability of the UR more accurately.
New 46.3 added indicate when information is required to be submitted for verification by Class.
New 46.4 added to specify a documentation requirement for ship builders, with a view to ensuring that expected accelerations and ship motions periods are to be within machinery and equipment manufacturers requirements.
New 46.5 added to indicate information required to be submitted.

5. Points of discussions or possible discussions

Much discussion between IACS members during the development of the revised UR. Comments and concerns raised by members included the scope of applicability i.e. which machinery and equipment the UR applied to, the methods by which dynamic ship motions may be established recognising that SOLAS II-1, 26.6 does not fully define the dynamic motions e.g. rolling and pitching periods are undefined, the difficulty and cost to the industry in demonstrating compliance with the UR and the application date of the UR given the significant implications for the industry.
Also much discussed was the current approach of members to the verification or the existing UR (Rev.2) which revealed wide differences between members.

Draft Rev.3 of UR has been consulted with Hull Panel for estimation ship's acceleration and motion methodology.
As estimation acceleration method in CSR and the CSS Code is far less specific than content of M46.2 and further to upcoming new revision of CSR which will refer to roll period only and not pitch and heave period, then qualified majority in Machinery Panel agreed to do not recommend any methodology for estimation ship's acceleration and motion in the Rev.3 of UR.

Draft Rev.3 of UR has been shared with CIMAC for their view and feedback, which their feedback implemented to draft Rev.3 of UR.

6. Attachments if any

None.

Technical Background (TB) document for UR M46 (Rev.4 August 2024)

1. Scope and objectives

It was proposed to consider revision of the two UIs (i.e. UI SC6 and UI SC290), either to delete UI SC6 and update UI SC290 both covering 1983 & 2014 IGC Code, or to simply delete the two UIs recognizing that the requirement is sufficiently addressed by UR M46 and possibly to update UR M46 (Note 2 to M46.2) adding references to IGC Code and IBC Code.

2. Engineering background for technical basis and rationale

The inclination requirement for emergency source of electrical power on gas carriers and chemical tankers is addressed in UI SC6 and UI SC290. The two UIs are dealing with the same issue and the same contents, with the only difference of the reference clause nos. for IGC Code between old and new IGC Code, i.e. UI SC6 refers to 1983 IGC Code and UI SC290 mentions 2014 IGC Code.

The duplication of the UIs is thought to be originated from GPG instruction (ref. 18902_IGe and PM5901fIMl: "creating UIs that will be published as "new" and also revising the old UIs by adding the references to the old IGC Code that will be published as Revisions").

This panel is of the view that the instruction would be applicable when specific requirement of old IGC Code has been revised or replaced by new IGC Code. However, in this case, the requirement is same and the two UIs are just indicating the re-adjusted clause number of old & new IGC Code, thus not advisable.

In the meantime, it is observed that the same inclination requirement is already covered by UR M46 (Note 3 of M46.2).

Still, it was found that similar requirements as Note 3 to M46.2 is present in item 8 of UR E10 (inclination test).

2a. Specification of the data utilised in the development/revision of the proposed IACS Resolution, if any

None.

3. Source/derivation of the proposed IACS Resolution

UI SC6, UI SC 290
SOLAS II-1/Reg.43.6
1983 IGC Code, clause 2.9.2.2
2014 IGC Code, clause 2.7.2.2
IBC Code, clause 2.9.3.2

4. Summary of Changes intended for the revised IACS Resolution:

Note 3 to M46.2 has been updated, adding reference clause nos. of the IGC Code (both 1983 IGC Code and 2014 IGC Code) and the IBC Code. By the transfer of the reference clauses, UI SC6 and UI SC290 have been deleted.

5. Points of discussions or possible discussions

It was suggested to also update UR E10 item 8 referencing Note 3 to M46.2. One member opined that the update of UR E10 could be addressed at a later stage. Following the qualified majority, UR E10 is also updated.

6. Attachments if any

None.

UR M47 "Bridge control of propulsion machinery for attended machinery spaces"

Summary

UR M47 requirements are transferred to UR M43 and is therefore deleted.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Del (Feb 2024)	02 February 2024	
New (1983)	1983	

- **Del (Feb 2024)**

1 Origin of Change:

☑ Other (FUA N°9 of GPG 85 - update of the Rule linkage table)

2 Main Reason for Change:

UR M47 was referring to UR M43 and it was decided to transfer its requirements to UR M43.

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None.

4 History of Decisions Made:

Considering the current wording of UR M47 saying that UR M43 applies to the bridge control of propulsion machinery for all machinery spaces (unattended and attended) with the exception of clause M43.7 (Rev.0) relating to steam turbines, members agreed that UR M47 can be transferred to UR M43.7 (Rev.0), which is renumbered as UR M43.5 (Rev.1) (PM20906dIMc).

5 Other Resolutions Changes:

UR M43 includes now the requirements of UR M47 and UR M43 title is changed to "Bridge control of propulsion machinery" instead of "Bridge control of propulsion machinery for unattended machinery spaces".

6 Any hinderance to MASS, including any other new technologies:

None.

7 Dates:

- **New (1983)**

No record available.

Part B. Technical Background

List of Technical Background (TB) documents for UR M47:

Note: *There are no Technical Background (TB) documents available for the original version (1983) and Del (Feb 2024).*

UR M51 "Factory Acceptance Test of Reciprocating Internal Combustion Engines"

Summary

This UR provides requirements for factory acceptance tests of engines in general. Revision 5 of this resolution has been restructured and is now associated with the new UR 'Certification Scheme for Reciprocating Internal Combustion Engines.' The existing UR M51 has been divided to focus specifically on the factory acceptance test on the test bed, while requirements relating to shipboard trials have been relocated to a new UR, designated M88.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev.5 (Apr 2025)	20 Apr 2025	01 January 2027
Corr.1 (Oct 2018)	08 October 2018	-
Rev.4 (Feb 2015)	27 February 2015	1 July 2016
Rev.3 (Jan 2008)	15 January 2008	1 January 2009
Rev.2 (July 2003)	16 July 2003	-
Corr.1 (1997)	12 May 1997	-
Rev.1 (1990)	No records	-
New (1987)	No records	

- **Rev. 5 (Apr 2025)**

1 Origin of Change:

☒ Request by non-IACS entity (CIMAC) and other non-IACS (union of Greek Shipowners)

2 Main Reason for Change:

2.1 CIMAC WG2 holds the view that the existing UR M51 and UR M71 should be revised and updated in line with technological advancements, also considering operational aspects. The Machinery Panel has decided to assess these proposals and enhance URs related to Reciprocating Internal Combustion Engines.

2.2 It became evident that there was uncertainty about how to address the requirements under UR M51.4.5.1, Corr.1 Rev.4. Consequently, concerns arose regarding the impact of these uncertainties on the marine industry's confidence in predicting and, where necessary, achieving a satisfactory service life for main propulsion shafting and associated components. These concerns and uncertainties have been addressed by updating UR M51.4.5.1 to provide clarity and a consistent approach to predicting and measuring barred speed range passage time. Additionally, the M51.4.5.1 requirements for measurements have been transferred to a new UR M88 covering the shipboard trials of Reciprocating Internal Combustion Engines.

3 Surveyability review of UR and Auditability review of PR

Draft Rev.5 of UR M51 has been reviewed by Surveyor Panel for surveyability items.

4 Human Element issues assessment

Not applicable

5 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

- ☒ CIMAC WG2
- ☒ 2-stroke engine manufacturer

6 History of Decisions Made:

6.1 CIMAC proposed revisions to the URs relating to internal combustion (I.C.) engines. The Machinery Panel reviewed CIMAC's proposals at its 30th meeting in 2019 and decided that a dedicated Project Team (PT) was necessary to consider these proposals.

The PT PM19102 established principles for developing or amending IACS URs related to I.C. engines at its first workshop in 2020. The UR development primarily relied on the knowledge and experience of PT members, while also taking CIMAC's proposals into account.
As a result, five URs, including UR M51, were drafted during the PT's second workshop in 2021 and submitted to the Machinery Panel for review. As per CIMAC's proposal, UR M51 was split to cover only Factory Acceptance Tests (FAT), with the shipboard trial requirements moved to a new UR, designated UR M88, titled 'Shipboard Trials of I.C. Engines.'

From 2021 to 2023, the URs were further discussed and revised based on comments from the Machinery Panel. Several amendments were accepted, including requirements for testing engines that drive controllable pitch propellers and integration testing of sub-systems.

6.2 While the initial proposal aimed to develop calculation methodologies to predict BSR passage time and the service life of main propulsion shafting and associated components, this approach was found to be overly complex. Discussions with CIMAC WG2 indicated that a simpler industry approach would be to develop calculation methodologies for determining the allowable BSR passage time. This would account for the service life of the main propulsion shafting and associated components, as well as the vibratory stress characteristics during passage through the barred speed range.

During the development of this review, it was also decided to establish minimum power margin set values at the lower and upper limits of the BSR, and to transfer this requirement to the new UR M88 covering the shipboard trials of Reciprocating Internal Combustion Engines.

7 Other Resolutions Changes

7.1 The following additional URs have been amended in parallel:
- M87 Certification Scheme for Reciprocating Internal Combustion Engines (new)
- M44 Documents for the Approval of Reciprocating Internal Combustion Engines (revision)
- M71 Type Testing of Reciprocating Internal Combustion Engines (revision)
- M88 Shipboard Trial of Reciprocating Internal Combustion Engines (new, from M51)

7.2 Panel Members have agreed on a series of future tasks, as detailed in Annex 4.

8 Any hinderance to MASS, including any other new technologies:

None.

9 Dates:

Original Proposal	: 09 September 2016	(Made by:PM16101_IMa)(PM19102)
Panel Approval	: 05 November 2024	(Ref: PM19102_IMzzb)
GPG Approval	: 20 April 2025	(Ref:24205aIGc)

- **Corr.1 (Oct 2018)**

.1 Origin for Change:

☒ Suggestion by IACS member

.2 Main Reason for Change:

-

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

The reference to UR M51.3.3.2 in UR M51.3.3.4 was changed to UR M51.3.3.3 for the reason that the operational profile of the engines driving generators for auxiliary purposes was evaluated to be more similar to that of the engines driving generators for electric propulsions (UR M51.3.3.3) rather than to that of the propulsion engines driving propeller or impeller only (UR M51.3.3.2).

TB document is not required for this corrigenda

.5 Other Resolutions Changes

None

.6 Dates:

Panel Approval: 17 September 2018 (Ref: PM18908)

GPG Approval: 08 October 2018 (Ref: 18141_IGc)

- **Rev.4 (Feb 2015)**

.1 Origin for Change:

☒ Request by non-IACS entity *(*CIMAC*)*
☒ Suggestion by IACS members

.2 Main Reason for Change:

There existed differences between the current practices of diesel engine design and manufacture, and the current URs requirements. These discrepancies needed to be resolved through updating and revising the current UR M51.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

The text of M51 was revised after the Kick-off PT meeting and was discussed during the later three PT meetings. The revised draft was agreed at the last PT meeting.
The draft UR prepared by the PT was further discussed by the Panel during the 14th, 15th and 16th meeting and by correspondence.

.5 Other Resolutions Changes

Other UR M files were also reviewed and edited (under subject number 7569_).

.6 Dates:

Original Proposal: 02 April 2010 (Made by: IACS Members) Panel
Approval: 08 January 2015 (By: IACS Machinery Panel) GPG
Approval: 27 February 2015 (Ref: 7569_IGw)

- **Rev.3 (Jan 2008)**

Refer to the TB document in Part B.

- **Rev.2 (July 2003)**

Refer to the TB document in Part B.

- **Corr. (1997)**

Typographical error of paragraph number 2.12 was corrected to read as 2.1.2.

- **Rev.1 (1990)**

No history files or TB document available.

- **Original resolution (1987)**

  No history files or TB document available.

Technical Background (TB) document for Rev.3 (Jan 2008)

UR M50 (Rev.3, Jan 2008) ***"Programme for type testing of non-mass produced I.C. engines"***
and
UR M51 (Rev.3, Jan 2008) ***"Programme for trials of i.c. engines to assess operational capability"***

Machinery Panel Tasks PM5102 and PM6102

Objective and Scope:

The aim of Task PM5102 was to reconsider UR M50 and UR M51 for electronically controlled two stroke and four stroke diesel engines especially in view of performance of the type approval test as required by the current UR M50 and the factory acceptance test as required by the current UR M51.
The aim of Task PM6102 was to clarify the text of UR M51 2.1.3 and 2.1.4 to avoid different interpretations regarding the tests to be carried out on engines used for ship's electrical propulsion.
It has been decided by the Panel to combine both tasks to one Revision only.

Points of discussion:

In Task 5102 three issues have been identified to be reflected in UR M50 and UR M51:

a) Reference to the FMEA required by UR M44 for the type approval test in M50.
b) A possible waiver for specific tests for an engine type which already has been type tested as conventional mechanical diesel engine (e.g. turbo charger cutoff test) in M50.
c) Reference to FMEA for the FAT and other tests in UR M51.

During the discussion the preference of the group was not to mention the turbocharger cut-off test explicitly, but rather to include a more generic statement.

As far as testing on board is concerned in UR M51 2.1.3 the wording "Main engines driving generators for propulsion" is not intended to include engines driving generators, which also supply electrical power to the ship network.

The intention of this paragraph is to address the tests to be carried out when an engine drives a generator, which is dedicated to the supply of an electric propulsion motor.

Engines driving generators supplying electrical power to the ship network (even if electrical propulsion is included among the network electrical users) are to be tested as required in UR M51 2.1.4.

The need to revise the wording to meet the above interpretation was discussed. In addition during the discussion it has been recognized that also the wording "rated power" in UR M51

2.1.3 a) may lead to different interpretations, since it is not immediate to understand if reference is made to rated power of the engine, of the generator or of the propulsion motor. It has been agreed that the intent of the requirement is referred to the rated power of the propulsion motor.

Conclusion:

Following changes are proposed:

UR M50: insert in 3.3 Functional tests

“3.3.5 Integration Test

For electronically controlled diesel engines integration tests shall verify that the response of the complete mechanical, hydraulic and electronic system is as predicted for all intended operational modes. The scope of these tests shall be agreed with the Society for selected cases based on the FMEA required in UR M44.”

M50.5 Notes

“5.3 If an electronically controlled diesel engine has been type tested as a conventional engine the Society may waive tests required by this UR provided the results of the individual tests would be similar.”

UR M51: Include a new paragraph 1.5 with the same text as in 3.3.5 above.

Based on the discussion of Task 6102 a new wording has been agreed for UR M51, Paragraph 2.1.3 :
“2.1.3 Single main engine driving generator for propulsion”

UR M51 2.1.3 a) shall read:
“100% power (rated propulsion power): at least 4 hours"

and the relevant note has to be modified to:

"Tests are to be based on the rated electrical powers of the electric propulsion motor."

The changes have been agreed unanimously by Panel members.

Submitted by Machinery Panel Chairman
22 November 2007

(**Permanent Secretariat note:** *Approved by GPG 15 January 2008, ref. 7720_IGc*)

Annex 3 Technical Background (TB) document

Technical Background (TB) document for Rev.4 (Feb 2015)

Scope and objectives

The valid version (January 2008) does not contain any safety precautions or test bed requirements. Test requirements for engine plants with power take off were also lacking.
Important testing of the entire propulsion plant when passing through barred speed ranges and system stability are not addressed in the present version.

It was decided to edit the revision in a chronological order, i.e. starting with safety precautions and general requirements.

Engineering background of changes and additions.

The following descriptions of technical backgrounds follow the sequence of the proposed revision.

A) Requirements to safety of personnel were taken over from the revised UR on type testing.

B) Recording of parameters to be taken during the FAT needed to be clarified. It was decided to require almost the same level as for type testing.

C) In item 3.3.1 the main objective of the overload test is to establish the margin between turbocharger speed at 110% load under stable conditions and turbocharger overspeed.

D) In item 3.3.2 and 3.3.3 the objectives of the 110 % overload requirement are explained (old text being unclear).

E) Item 3.3.4 is new and defines the required overload. The difference to gensets is that the overload refers to propulsion together with 110 % generator overload. This is clarified in the text.

F) Item 3.4 is new and deals with turbocharger surge margins for propulsion engines. In this chapter, the matching of the turbocharger with the engine is considered based upon member practices. Turbochargers shall have a compressor characteristic that allows the engine, for which it is intended, to operate without surging during all operating conditions. For category C turbochargers used on propulsion engines the methods for surge margin testing during the engine workshop testing are specified. Although confirmation of surge margins using actual engines is preferable, using a compressor chart is allowed as an alternative verification method for 2-stroke engines because testing using actual engines can be difficult for reasons such as cost, etc.

G) Start up tests is removed from the FAT to the Shipboard trials since this is a matter of starting media capacity.

H) The previous reference to running-in under Shipboard trials is moved to the beginning of FAT.

I) Under Shipboard trials in 4.1 the objectives are explained. The old M51 dealt with the engine only. The new and expanded text deals with the engines' compatibility with the entire plant and its control systems.

J) In item 4.4.1 (propulsion engines with fixed pitch propeller) the important change is that the previous requirement of 70 % astern rpm is removed. For the same reason the sub-item on stopping tests contains a warning and a reference to 4.5.1 which deals with torsional vibrations in barred speed ranges. Passing through a barred speed range can lead to excessive torsional vibration (more than theoretically estimated) and cause slippage of a keyless fitted propeller (and even bent shafts), unless the passage is made in a proper way. This is particularly important when operating the engine in the astern direction. The torque-rpm characteristic can be different from forward, especially if the ship is moving slowly forward. This affects the propeller damping which usually is the major damping source. Therefore the previous testing requirement of 70 % astern rpm is removed. There is no reason to expose the plant to unnecessary risk, and the 70 % is not a SOLAS requirement.
Note: The 70 % requirement probably originated from steam turbines in order to dimension the astern turbine properly.

K) Item 4.4.3 is new and deals with engines driving generators for electric propulsion and/or auxiliary. It was discussed whether a single engine driving a generator for propulsion should be a separate item, but since the selected requirements were identical it was considered there was no need for it. This requirement applies irrespective of whether an engine is used either:

- as part of a common power generation system used for both propulsion and auxiliary power; or
- exclusively to generate power for electric propulsion.

L) Item 4.4.4 is also new and deals with propulsion engines having PTO. The chosen requirements are analogous to the corresponding items in 4.4.

M) Item 4.5.1 (passing through a barred speed range) is new. The background is explained in J) above.
Both up and down passage are to be recorded since either of them can lead to the highest vibration level.
The ship's draft and speed are also important parameters. The slowest passage (and thus highest vibration level) will occur at maximum draft and

with hull fouling. This has to be considered in connection with the various acceptance criteria by the Societies.
Last but not least, a stable fuel index is very important. The influence of even small fuel index oscillations on the torsional vibration level is often severely underestimated. Even more important than the oscillation amplitude is the phase angle. As the latter is not visible, the acceptance level for the (double) amplitude of oscillation is conservatively set.

Technical Background (TB) document for Rev.5 (Apr 2025)

1. Background

A common approach to achieving Phase 1 implementation of the Energy Efficiency Design Index (EEDI), effective from 1 January 2015, has generally involved installing a directly coupled, de-rated two-stroke main propulsion diesel engine for applicable vessel types and sizes.

In such cases, it is possible that the typical rapid transit time through the barred speed range (BSR) is extended, which could have implications for the service life of the main propulsion shafting and associated components.

This concern was supported by correspondence from the Union of Greek Shipowners to IACS, which highlighted examples of extended BSR transit times and requested the establishment of a new Unified Requirement.

Issues related to BSR passage and system stability were initially addressed through IACS UR M51, 'Factory Acceptance Test and Shipboard Trials of I.C. Engines,' Rev.4, February 2015, section 4.5 on Torsional Vibrations, specifically 4.5.1 on the Barred Speed Range. This update also coincided with the implementation of the EEDI initiative.

Since the adoption of IACS UR M51 Rev.4, it has become evident that uncertainty remains regarding how to address the required submission of the predicted BSR transit time. Consequently, concerns have emerged over how these uncertainties might affect confidence within the marine industry in predicting and, where necessary, achieving a satisfactory service life for main propulsion shafting and associated components.

The updated requirement transferred to the new UR M88 covering the shipboard trials of Reciprocating Internal Combustion Engines.

2. Scope and objectives

2.1 The Factory Acceptance Test is part of the 'Certification Scheme for Reciprocating Internal Combustion Engines.' Its purpose is to verify that the engine's design parameters and functions align with those of the type-approved engine.

The existing UR M51 “Factory Acceptance Test of I.C. Engines” covers the test requirements of Factory Acceptance Test and Test on board. M51 is proposed to focus on the Factory acceptance test on test bed and be aligned with M71, M87 and M88 in structure.

2.2 The objectives of this update were to address the concerns of the marine industry regarding implementation of ‘4.5.1 Barred speed range’ of UR M51 Rev.4 Feb 2015 through the provision of clarity and consistency of approach to the prediction and measurement of barred speed range passage time and to define the requirements for measurements.

On that respect, a Project Team formed by four Classification Societies, defined the scope of work as follows:

1. Requirement for BSR Passage Time Estimation
2. Requirements for fatigue estimations
3. Requirements for measurement of BSR Passage time

3. Engineering background for technical basis and rationale

CIMAC WG2 believes that UR M51 and UR M71 need revision and updates to reflect technological advancements and operational considerations.
CIMAC submitted proposed documents to the Machinery Panel (MP) for review, including revised versions of M51 and M71, as well as two new URs, M87 and M88.
Project Team PM19102 was tasked with organizing URs related to I.C. Engine approval, drawing primarily on members' expertise and incorporating CIMAC's proposals.
As part of CIMAC's recommendation, UR M51 was split to cover only Factory Acceptance Tests (FAT), while a new UR, designated M88, was created to address 'Shipboard Trials of I.C. Engines.'
The structures of the new UR M51 and UR M88 have been aligned with related URs, including M87, M44, and M71, where applicable.
Several amendments were also made based on insights gained from implementing the existing URs M71 and M51.
These changes include requirements for testing engines driving controllable pitch propellers and integration testing of subsystems.

3a. Specification of the data utilised in the development/revision of the proposed IACS Resolution, if any

<u>3a.1 Requirement for BSR Passage Time Estimation and Measurment</u>

The update BSR's requirement transfer to the new UR M88.

4. Source/derivation of the proposed IACS Resolution

Feedback from CIMAC WG2 and classification societies.

5. Summary of Changes intended for the revised Resolution:

A) The existing M51 is split to focus on the Factory acceptance test of I.C Engines on test bed. And at the same time, a new UR M88 "Shipboard Trials of I.C. Engines" is established for the test on board.
B) The structure of UR M51 was harmonized with the other URs considering CIMAC's proposals as far as practicable. M51.1 "General", M51.2 "Scope" was added to be consistent with other URs.
C) M51.3, the objectives of the FAT were extended to verify the operating parameters and functions and integrated test of sub-system according to CIMAC's proposal.
D) M51.5.2 is proposed by CIMAC and accepted to clarify an internal test before Factory Acceptance Test is required, and a test program is to be agreed before the test.
E) M51.5.2 Documentation to be submitted are clarified as the proposals from CIMAC.

F) M51.6 is proposed by CIMAC, to clarify that the engine parameters are to be recorded within the specification.
G) M51.7.1, test items and requirements of safety device are given as requested by customer.
H) In existing M51, test requirements of engines driving controllable pitch propeller was missing, so load test requirements depending on application were developed M51 7.2.1 D) as below,
- in accordance with the nominal propeller curve, for an engine driving a fixed pitch propeller, water jet or controllable pitch propeller with variable speed and pitch. Or
- in accordance with modified propeller curve for an engine driving controllable pitch propeller with variable speed and pitch. Or,
- at constant speed for an engine driving a controllable pitch propeller with constant speed.
I) To coordinate with the application of the concept of "sub-system", M51 7.4 Integration tests of sub-system are supplemented. Because the integration test in existing UR is mainly used for electronical engine control system but now is extended to all kinds of subsystem, typical tests items are also clarified.
J) M51 7.4 Engine with multiple running mode is proposed to test at each running mode.

6. Points of discussions or possible discussions

<u>6.1 Structure of UR</u>

CIMAC proposed dividing the current tests into three stages A, B, and C structured similarly to type approval tests, primarily for formal purposes. However, IACS did not find that structuring tests into stages A, B, and C would provide significant benefits or convenience to engine manufacturers. Consequently, the CIMAC proposal was not adopted.

6.2 Panel members agreed to integrate the requirements for BSR transit time published within 7.7.1 of UR M51 rev. 5 into UR M68.5 as they would best place within the requirements for permissible torsional vibration stresses. The formula developed gives no credit to multi-radii flange fillets. This is due to the fact that UR M68 does not incorporate these types of designs. A further task proposed is to incorporate multi-radii fillets into UR M68; this is agreed by all panel members. It is proposed to use this task to develop a common approach for testing BSR passage time for CPP systems.

A further task is agreed by Panel Members for the development of requirements which accommodate an inability to test at fully laden draughts and development of requirements for alarms to signal exceedance of the minimum transit time of the barred speed range and transfer it to New UR M88 covering the shipboard trials of Reciprocating Internal Combustion Engines.

6.3 Draft document of UR reviewed by CIMAC as well as Survey Panel for Surveyable items.

The Machinery Panel reviewed CIMAC's comments and agreed to incorporate them into the draft UR M51, as outlined above.

7. Attachments if any

None.

UR M52 'Length of aftmost propeller shaft bearing'

Summary

The purpose of the present revision is to emphasize that the bearing length application is only valid for the aftmost propeller shaft bearing, next to and carrying the propeller, to state that type approval is required for all synthetic materials for aftmost propeller shaft bearings, and to reference the new UR M85 for the type approval testing requirements of synthetic materials.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable

Rev.2 (Nov 2019)	21 November 2019	1 January 2021
Rev.1 (Jan 2019)	7 January 2019	1 January 2020
New (1986)	-	

- **Rev. 3 (Nov. 2024)**

1 Origin of Change:

☑ Suggestion by IACS member

2 Main Reason for Change:

During the revision of UR M52 (Rev.2, Nov 2019) regarding the determination of aftmost propeller shaft bearing lengths and type approval requirements of synthetic material used in aftmost propeller shaft bearings:

- one member proposed to make it clear that the bearing length defined by UR M52 only applies to the aftmost propeller shaft bearing. (see UR M52 Scope)
- one member proposed to emphasize that synthetic materials for application as oil and water lubricated bearings, whether in the aft or forward bearing of the stern tube or the strut must be type approved. (see UR M52 2.2&3.2)

- members proposed to reference the new UR M85 for type approval testing requirements of synthetic materials used in aftmost propeller shaft bearing. (see UR M52 2.4&3.4)

3 Survey ability review of UR and Auditability review of PR

Revision 3 of UR M52 found no relevant item to be reviewed by SuP for survey ability with respect to scope of revision.

4 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

5 History of Decisions Made:

UR M52 Rev.3 agreed during the 39th meeting of the Machinery Panel.

- **Rev. 2 (Nov 2019)**

1 Origin of Change:

☑ Suggestion by IACS member

2 Main Reason for Change:

During the revision of UR M52 (Rev.1, Jan 2019) regarding water lubricated bearings:

- one member proposed to introduce requirements in UR M52 for grease lubricated bearings, arguing that such bearings could be found on some small ships.

- one member proposed to introduce a clause requiring the type approval of synthetic materials intended for oil lubricated stern tube bearings, in the same way as for water lubricated stern tube bearings (see UR M52.3.3).

3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

Technical Background (TB) document for UR M52 Rev.1 (Jan. 2019)

1 Scope and objectives

The UR was revised to resolve a reservation by one member against requirements for lignum vitae as bearing material.

2 Engineering background for technical basis and rationale

The Panel agreed unanimously to remove paragraph 3 from this UR, noting that the requirement is from 1986 and that water lubricated bearings of lignum vitae are no longer installed in current designs.

3 Source/derivation of the proposed IACS Resolution

UR aligned with current industry practice

4 Summary of Changes intended for the revised Resolution

Removal of paragraph 3 relating to water lubricated bearings of lignum vitae

One Member Society proposed to modify the existing paragraph M52.4 on "Water lubricated bearings of synthetic material", renumbered in Revision 1 as M52.3, in order to generalize the 4 times criteria for water lubrication bearings subject to the special consideration for bearings of synthetic materials. The proposal was finally agreed by the qualified majority to read as follow:

"M52.3 Water lubricated bearings

3.1 The length of the bearing is to be not less than 4.0 times the Rule diameter of the shaft in way of the bearing.

3.2 For a bearing of synthetic material, consideration may be given to a bearing length not less than 2.0 times the Rule diameter of the shaft in way of the bearing, provided the bearing design and material is substantiated by experiments to the satisfaction of the Society.

3.3 Synthetic materials for application as water lubricated stern tube bearings are to be Type Approved."

5 Points of discussions or possible discussions

- One Member Society proposed to introduce requirement in UR M52 for grease lubricated bearings and proposed the following wording to be added in the UR:

“M52.3 Grease lubricated bearings

The length of grease lubricated bearings is generally to be not less than 4 times the rule diameter of the shaft in way of the bearing.

For installations with adequate sealing / gland devices, the minimum length of the bearings may be determined in accordance with M52.1 or M52.2, as applicable.”

The qualified majority of Members agreed to introduce such requirements in the UR M52 but also agreed to reconsider the matter at the next revision of the UR.

- One Member Society proposed to modify para 1.2 as follow:

“1.2 The length of the bearing may be less provided the normal bearing pressure is not more than 8 bar as determined by static bearing reaction calculation taking into account shaft and propeller weight which is deemed to be exerted solely on the aft bearing divided by the projected area of the shaft and if the results of the operational check are satisfactory. However, the minimum length is to be not less than 1,5 times the actual diameter."

But the proposal was not supported by the qualified majority.

6 Attachments if any

None

Technical Background (TB) document for UR M52, Rev.2 (Nov. 2019)

1 Scope and objectives

The UR M52 was revised to:

- introduce requirements for grease lubricated stern tube bearings,
- require synthetic materials for oil lubricated stern tube bearings to be type approved.

2 Engineering background for technical basis and rationale

The Panel, on the basis of the members' experience, agreed to require a minimum length for a grease-lubricated bearing of not less than 4.0 times the rule diameter of the shaft in way of the bearing.

The Panel also agreed that synthetic materials, which are required to be type approved for application as water lubricated stern tube bearings (see UR M52.3.3), should also be required to be type approved for application as oil lubricated bearings.

3 Source/derivation of the proposed IACS Resolution

The new requirements for grease lubricated stern tube bearings and for the type approval of synthetic materials for oil lubricated stern tube bearings are aligned with industry practice.

4 Summary of Changes intended for the revised Resolution

The Panel decided to introduce the following text:

- "M52.4 Grease lubricated bearings

  4.1 The length of a grease lubricated bearing is to be not less than 4.0 times the rule diameter of the shaft in way of the bearing."

- "2.3. Synthetic materials for application as oil lubricated stern tube bearings are to be Type Approved."

5 Points of discussions or possible discussions

- One member proposed to add the following relaxation for grease lubricated stern tube bearings:
  "For installations with adequate sealing / gland devices, the minimum length of the bearings may be determined in accordance with M52.1 or M52.2, as applicable."

  This proposal was, however, not supported by the qualified majority.

- One member proposed adding requirements for bearings made of synthetic materials and intended for applications such as pintle, stock and carrier disc bearings in rudders and possibly in other ship equipment e.g. fins stabilizers.

  This proposal was, however, not supported by the qualified majority.

- One member proposed to develop criteria for the type approval of synthetic materials used for oil lubricated and water lubricated bearings.

  This proposal was supported by the qualified majority and the Panel decided to develop a new UR to address it.

6 Attachments if any

N/A

Technical Background (TB) document for UR M52, Rev.3 (Nov. 2024)

1 Scope and objectives

The UR M52 was revised to:

- clarify that the bearing length criterion only applies to the aftmost propeller shaft bearing,
- require synthetic materials for oil and water lubricated for all aftmost propeller shaft bearings to be type approved,
- reference the new UR M85 for the type approval testing requirements of synthetic materials used for aftmost propeller shaft.

2 Engineering background for technical basis and rationale

The Panel, based on the members' experience, agreed to change the title of UR M52 and add a scope that states the bearing length application to clear up misunderstandings among designers and shipyards.

The Panel agreed that all synthetic materials, that are inside the aftmost propeller shaft bearings (see UR M52.2.3&3.3), should be required to be type-approved.

The Panel also agreed that tests for synthetic materials for the aftmost propeller shaft should be carried out according to the new UR M85. (see UR M52.2.4&3.4)

2a. Specification of the data utilised in the development/revision of the proposed IACS Resolution, if any

None.

3 Source/derivation of the proposed IACS Resolution

Elimination of misunderstandings regarding the application of bearing length (for example: In a strut system, trying to comply with this length rule for the stern tube bearings that no longer have the aftmost bearing, or not being able to find a rule to apply for the aftmost strut bearing).

Clarifying the type approval requirements for all synthetic materials used for aftmost propeller shaft bearings.

Determining that synthetic material testing should be performed in accordance with the new UR M85.

4 Summary of Changes intended for the revised Resolution

The Panel decided to introduce the following text:

- Title "**Length of aftmost propeller shaft bearing"**
- Scope: The length requirements of this UR are valid only for the aftmost propeller shaft bearing, next to and carrying the propeller, whether the bearing is in a stern tube or in a strut (aftmost propeller shaft bearing).
- 2.3. Synthetic materials used for oil lubricated aftmost propeller shaft bearings are to be Type Approved. The type approval requirements in this clause apply to all aftmost propeller shaft bearings made of synthetic materials.
- 2.4. For type approval testing requirement of synthetic material for the aftmost propeller shaft bearing, refer to UR M85.
- 3.3. Synthetic materials used for water lubricated aftmost propeller shaft bearing are to be Type Approved. The type approval requirement in this clause apply to all aftmost propeller shaft bearings made of synthetic materials.
- 3.4. For type approval testing requirements of synthetic material for the aftmost propeller shaft bearing, refer to UR M85.

5 Points of discussions or possible discussions

- Two members proposed to make necessary updates for UR M85 which refers to "stern tube bearings" so that it does not limit its application to stern tube bearings only.

  This proposal evaluated within the scope of PM20101 with necessary correction on UR M85.

- Some later modifications were made based on GPG comments to specify that the requirement applies to the aftmost propeller shaft bearing, ensuring clarity for all readers. MP members agreed that the content of the UR is applicable to the aftmost propeller shaft bearing.

- The aftmost propeller shaft bearing is the bearing positioned immediately adjacent to and supporting the propeller. This critical bearing can either be located within the stern tube or mounted in a strut.

Rev.1 (Dec 2004)	Dec 2004	1 Jan 2007
New (1986)	1986	-

• Rev.6 (April 2025)

1 Origin of Change:

☑ Request by IACS Members
☑ Based on IACS Requirements (UR M78)

2 Main Reason for Change:

The Machinery Panel noted that torsional vibration characteristics may be higher for some engine types when operating on some gases or low-flashpoint fuels. As given by UR M53.2.2.1, it is for the manufacturer to specify the maximum applicable nominal alternating stresses. Calculations may be expected for all fuels on which an engine (and shafting system) is designed to operate.
The Panel agreed that acceptance would be based on approval for the worst-case scenario.

3 Surveyability review of UR and Auditability review of PR

No surveyability has been found with respect to the content of revision.

4 Human Element issues assessment

Not applicable.

5 List of non-IACS Member Classification Societies contributing through the TC Forum and/or participating in IACS Working Group:

None.

6 History of Decisions Made:

1) Initial proposal submitted by PTPM43 while preparing draft revision 3 of UR M78 in July 2024 to the Panel for further consideration.
2) On December 2024 Machinery Panel agreed to final proposed amendment of UR M53.2.2.
3) The UR M53 (Rev. 6) was agreed by correspondence in Machinery Panel.

7 Other Resolutions Changes

None

8 Any hinderance to MASS, including any other new technologies:

None

9 Dates:

Original Proposal:	22 July 2024	(Ref. PM18914)
Panel Approval:	12 December 2024	(Ref: PM24023_IMk)
GPG Approval:	20 April 2025	(Ref: 23053aIGc)

• Rev.5 (May 2023)

1 Origin of Change:

☑ Request by non-IACS entity (CIMAC)

2 Main Reason for Change:

CIMAC proposed to modify the formula for the calculation of the acceptability factor (Q) for crankpin fillet and journal fillet in UR M53 (Rev.4, Aug 2019) Appendix IV, paragraph 4.3 for the reason that the use of the maximum principal equivalent stress formulation was evaluated to be more appropriate than the multi-axial Gough-Pollard formulation.

3 List of non-IACS Member Classification Societies contributing through the TC Forum and/or participating in IACS Working Group:

None

4 History of Decisions Made:

4) Initial proposal submitted by CIMAC in February 2021 (Ref. PM21903_IMa dated 16/02/2021)
5) On December 2022 Machinery Panel requested to CIMAC to clarify the technical points and support of the proposed modification.
6) The UR M53 (Rev. 5) was agreed by correspondence in Machinery Panel

5 Other Resolutions Changes

None

6 Any hinderance to MASS, including any other new technologies:

None

7 Dates:

Original Proposal:	February 2021	(Ref. PM21903_IMa dated 16/02/2021)
Panel Approval:	21 April 2023	(Ref: PM21903_IMf)
GPG Approval:	25 May 2023	(Ref: 22053_IGd)

• Rev.4 (Aug 2019)

1 Origin of Change:

☑ Request by non-IACS entity (CIMAC)

2 Main Reason for Change:

CIMAC proposed to modify the formula for the calculation of the acceptability factor (Q) for crankpin oil bore in UR M53 (Rev.3, June 2017) Appendix IV, paragraph 4.3

for the reason that the use of the maximum principal equivalent stress formulation was evaluated to be more appropriate than the multi-axial Gough-Pollard formulation.

3 List of non-IACS Member Classification Societies contributing through the TC Forum and/or participating in IACS Working Group:

None

4 History of Decisions Made:

7) Initial proposal submitted by CIMAC in May 2018 (Ref. PM18916_IMa dated 07/05/2018)
8) On October 2018 and later on January 2019 (Ref. PM18916_PMa dated 01/10/2018 and PM18916_PMc dated 15/01/2019) the Machinery Panel requested to CIMAC significant examples in support of the proposed modification.
9) The UR M53 (Rev. 4) was agreed by correspondence

5 Other Resolutions Changes:

None

6 Any hinderance to MASS, including any other new technologies:

None

7 Dates:

Original Proposal: May 2018 (Ref. PM18916_IMa dated 07/05/2018)
Panel Approval: 22 July 2019 (Ref: PM18916_IMf)
GPG Approval: 13 August 2019 (Ref: 19145_IGb)

• Rev.3 (June 2017)

1 Origin of Change:

☑ Request by non-IACS entity (CIMAC)

2 Main Reason for Change:

CIMAC has proposed changes of existing UR M53 (Rev.2) with the inclusion of new Appendices allowing to:

a. provide methods using Finite Elements calculations in order to evaluate stress concentration factors, in addition to existing empirical formulae used presently.
b. provide methods in order to evaluate stress in oil bore and fillets when surface treatment process is applied.
c. provide methods in order to evaluate fatigue strength by experiment

3 List of non-IACS Member Classification Societies contributing through the TC Forum and/or participating in IACS Working Group:

None

4 History of Decisions Made:

- Initial proposal submitted by CIMAC in February 2011
- Appendix VI submitted by CIMAC in May 2012
- IACS comments to CIMAC proposal sent to CIMAC in November 2013
- Revised documents submitted by CIMAC in February 2014
- UR M53 revised in accordance with CIMAC comments and adopted by the Machinery Panel in April 2015
- Revised UR M53 submitted to CIMAC in April 2015
- CIMAC comments received in June 2015. CIMAC agreed that the examples would not be introduced in the UR but in the Technical Background.
- Final version of UR M53 (Rev.3) adopted by the Machinery Panel at the 22_{nd} meeting in March 2016

5 Other Resolutions Changes

None

6 Dates:

Original Proposal: Feb 2011 Made by CIMAC Panel
Approval: 24 May 2017 (Ref: PM11100)
GPG Approval: 15 June 2017 (Ref 12184_IGc)

• Rev.2 (Jan 2011)

1 Origin of Change:

☑ Request by non-IACS entity (CIMAC)

2 Main Reason for Change:

CIMAC raised the issue that the empirical stress concentration factors in the calculation rules in the UR M53 do not cover some of the currently used crankshaft designs. Therefore in order to assist, the alternative method for calculation of Stress Concentration Factors in the web fillet radii of crankshafts by utilizing Finite Element Method was agreed.

3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

4 History of Decisions Made:

CIMAC submitted its proposal during the IACS-CIMAC (WG2) Sept. 2008 meeting. The proposal was then discussed in the Machinery Panel. After reviewing the proposal the Machinery Panel had comments which were later clarified by CIMAC. However the

IACS Machinery Panel had concerns with the extent of validation, as the validation was
made for one test previously and that no further validation data was available. After further discussion it was agreed to insert it as an appendix and use it as an alternative approach when the prescriptive method does not apply.

5 Other Resolutions Changes

None

6 Dates:

Original Proposal: September 2008 Made by CIMAC (WG2)
Panel Approval: September 2010
GPG Approval: 06 January 2011 (Ref: 10171_IGc)

• Rev.1 (Dec 2004)

See TB in Part B.

• New (1986)

No TB document available.

Part B. Technical Background

List of Technical Background (TB) documents for UR M53:

Annex 1 **TB for Rev.1 (Dec 2004)**

See separate TB document in Annex 1.

Annex 2 **TB for Rev. 2 (Jan 2011)**

Annex 5 **TB for Rev. 5 (May 2023)**

See separate TB document in Annex 5.

Annex 6 **TB for Rev. 6 (April 2025)**

See separate TB document in Annex 6

Note: There is no separate Technical Background (TB) document for New (1986).

CIMAC Crankshaft Working Group (WG4)
Documentation and remarks to IACS WP/MCH comments
July 2. 2003, M. W. Rasser / Chairman

CIMAC Proposal for Revised M53
IACS WP/MCH Comments

Comments have been received from members and these essentially stem from the need to provide technical justification for the changes and new requirements.

For the proposals to be accepted and incorporated as Unified Requirements we have to provide a technical justification for the requirements and it is noted that we have not received any additional technical documentation other than the 30 pages expanded from the original 15.

Identification of the changes and the background to each change and addition is required as part of the technical justification.

Some comments received include:

1) Fig 5 and Fig 7
For crankshafts with overlap and recessed fillets, the web thickness W appears to be taken at the outside of the web which is different from that indicated in Fig 5 for a crankshaft without overlap, where W is taken from the centre of the recessed fillet.

CIMAC remark:
The definition of W for cranks with overlap is identical to M53-issue 1986, and is taken from the outside of the web.
The definition of W for cranks without overlap is newly introduced, see Fig. 5.
The newly introduced definition of W is proposed based on the fact that all 2-stroke manufacturers have crankshafts in operation for long time which do not fulfil the M53 with respect to the limitation of TH (TH ≤ RH).
The proposal is therefore to define a reduced web thickness in such a way that it ends at the centre of RH. The definition also matches the relevant cross section more closely.

2) M53.2.2.2

Statement there are to be no barred speed ranges above a speed ratio of $\lambda>0.8$ of rated speed. It is not unusual to have barred speed ranges above a speed ratio of $\lambda>0.8$ for the one cylinder misfiring condition in two stroke engines and it is suggested that the sentence should be modified to read. There are to be no barred speed ranges above a speed ratio of $\lambda>0.8$ for normal firing conditions.

CIMAC remark:
Agreed. The wording is included in the latest draft M53 revision.

3) M53.6

- K factor for cast steel crankshaft (was 0.93) has been removed and replaced by "is to be agreed between engine manufacturer and the Classification Society." No technical justification has been given about the inadequacy of the previous value considering that semi-built cast steel crankshafts are widely used. It is considered that a specific value should be established in the UR. Also it is considered necessary to establish basic requirements regarding fatigue testing of crankshafts or specimens and to include these in the UR.

CIMAC remark:
The K factor for cast steel cranks has been removed and replaced by the comment on agreement between engine builders and Classification Society. The wording was agreed between CIMAC and the IACS representative Mr. E. Sandberg in a meeting held on 15/16 April 1999.
The reason for the modified wording was that the previous figure of 0.93 was not considered realistic according to crankshaft manufacturer data. In current practice only 2-stroke engines use cast steel cranks with special treatment (e.g. stroke peening). Those engines never use the K figure, as given in UR M53 – issue 1986, but get individual approval from Classification Societies.
The wording as proposed is now consistent with the procedures followed since many years.

- Regarding the provision of alternative means of determining of fatigue strength based on testing of specimens taken from a full size crankthrow it is proposed a size correction factor should be established, or to develop procedures for specimen testing in order to provide for a common basis of acceptance of such fatigue test results.

CIMAC remark:
CIMAC see the development of a common basis for the acceptance of fatigue test results outside the scope of the UR M53 revision. The wording in M53.6 as proposed is now consistent with the procedures followed since many years.

4) M53.2.1.3
The calculation of alternating bending stress does not take into account alternating axial stress. For crosshead type engines LR Rules take into account axial alternating stress derived from forced-damped calculations.
The section includes a procedure for calculating alternating bending and torsional stresses in outlet of oil bore. LR Rules do not publish a procedure but require that a fatigue strength calculation or alternative fatigue test results may be required to demonstrate acceptability of the design. Whilst no objection is raised to the proposed approach its accuracy is crucially dependent on the evaluation of the stress concentration for the oil hole. In the absence of a detailed justification, LR would continue to require, perhaps as an alternative to the proposed calculation method full fatigue analysis or experimental results.

5) M53.3
The dimensional ratio r lower limit is extended to 0.015, LR Rules limit this to 0.03. It is not clear on what grounds this extension is proposed.

CIMAC remark:
The discussion to extended the range of the parameter “r” from the current value of 0.03 down to lower values dates back some years. Meanwhile technical progress has obviated this range extension, as it is unlikely that modern crankshaft designs show fillet radii with the parameter “r” below 0.03.

The latest draft M53 therefore goes back to the original range for the parameter “r” with a lower limit of 0.03.

6) M53.4
These stresses indicate that the misalignment component considered is $\forall 10\text{N} / \text{mm}^2$ and that for the crosshead engines, assuming the same level of misalignment the axial component is $\forall 20\text{N} / \text{mm}^{2.}$
LR would recommend that the value of $\forall 20\text{N} / \text{mm}^2$ should be used only as guidance where no axial vibration calculations are available. It is considered that this value may be too high for a majority of systems operating away from axial or torsional (cross coupled effect should be considered) natural frequencies.

CIMAC remark:
CIMAC agree with this recommendation, nevertheless the wording of the UR M53 – issue 1986 is carried over to the latest draft M53.

7) M53.8
The background to the expression in paragraph 8.2 is requested.

CIMAC remark:

M53.8 para 8.2 21/1/2002 MWR

M_{max} ... Maximum torque [Nm]

D_S ... Shrink fit diamer [mm]

D_{BG} ... Bore diameter [mm]

S_R ... Safety against slipping [-]

μ ... friction coefficient [-]

Area of pressfit

$A = D_S \cdot l_S \cdot \pi$ [mm^2]

Contact pressure (necessary)

Tangential force : $F_T = \frac{M_{max} \cdot S_R \cdot 2}{D_S}$

Friction force : $F_R = p \cdot A \cdot \mu$

$\Downarrow$

$$p = \frac{M_{max} \cdot S_R \cdot 2 \cdot 1000}{\mu \cdot \pi \cdot D_S^2 \cdot l_S}$$

Tangential stress at inner bore diameter

$$\sigma_V = -\frac{2 \cdot p}{1-\left(\frac{D_{BG}}{D_S}\right)^2} = -\frac{M_{max} \cdot S_R \cdot 4000}{\mu \cdot \pi \cdot D_S^2 \cdot l_S \cdot \left(1-\left(\frac{D_{BG}}{D_S}\right)^2\right)}$$

σ_V must be lower than σ_{SP}

$$\Rightarrow D_{BG} = D_S \cdot \sqrt{1 - \frac{M_{max} \cdot S_R \cdot 4000}{\mu \cdot \pi \cdot D_S^2 \cdot l_S \cdot \sigma_{SP}}}$$

$\Rightarrow$ represents the maximum bore diameter, where σ_{SP} is reached

The method uses the linear elastic theory to calculate stresses.

Literature

- „Auslegung elastisch-plastisch beanspruchter Pressverbände“ Author Franz Gustav Kollmann published in "Forschung Ing.-Wes." Vol. 44 (1978) NR. 1, p. 1 – 11
- DIN 7190 "Pressverbände, Berechnungsgrundlagen und Gestaltungsregeln"

A reply to the points raised a copy of the development process for the proposed changes that include technical justifications would assist in the final acceptance of the proposals by the WP / MCH.

UR M53 REVISED EDITION

MAIN DIFFERENCE
BETWEEN DECIDED WORDING DURING
CIMAC W.G. MEETING (15/16th APRIL 1999)
AND FINAL WORDING PRESENTED
IACS/CIMAC COMMON MEETING
(11th NOVEMBER 1999)

⇓

§ 53.2.2.2. « CALCULATION OF NOMINAL ALTERNATING TORSIONAL STRESS »

NEW TEXT IS ONLY CLEARER
ON DEFINITION, METHOD
AND USE OF METHOD.

PRESENTATION OF CIMAC W.G. C.D. WORK

DURING COMMON MEETING CIMAC/IACS

HELD IN OSLO 11th OF NOVEMBER 1999

UR M53

CIMAC PROPOSAL SYNTHESIS

WHAT WAS NOT CHANGED

- CALCULATION PRINCIPLE

- NOMINAL STRESS CALCULATIONS

- STRESS CONCENTRATION FACTORS CALCULATIONS

- FATIGUE STRENGTH FORMULA

- SHRINKFIT CALCULATIONS IN CASE OF SEMI-BUILT CRANKSHAFT

- MINIMUM SAFETY COEFFICIENT FACTOR FIGURE

UR M53

CIMAC PROPOSAL SYNTHESIS

WHY NO CHANGE ?

- **AFTER YEARS OF EXPERIENCE, PRESENT METHOD GIVES GENERALLY PRETTY GOOD RESULTS ON THE SAFE SIDE.**

- **IT MINIMIZES AMOUNT OF WORK.**

- **IT SHOULD BE EASIER TO COME TO AN AGREEMENT ON UPDATED VERSION BETWEEN BOTH PARTIES.**

UR M53

CIMAC PROPOSAL SYNTHESIS

WHY CHANGES ?

- **IN ORDER TO HAVE A SAFER DESIGN OF CRANKSHAFT (SAFETY FACTOR AROUND OIL HOLE).**

- **IN ORDER TO BE MORE WELL SUITED TO NOWADAYS CRANKSHAFT DESIGN (EXTENSION OF CONCENTRATION FACTOR RANGE AND GEOMETRICAL PARAMETERS OF SEMI-BUILT CRANKSHAFT).**

- **IN ORDER TO AVOID MISTAKE IN APPLYING THE U.R. BY AVOIDING AMBIGUOUS DEFINITIONS.**

- **IN ORDER TO OPEN THE U.R. TO ALTERNATIVE ASSESSMENT PROCEDURES (SURFACE TREATMENT, FATIGUE STRENGTH, F.E. CALCULATIONS, …).**

UR M53

CIMAC PROPOSAL SYNTHESIS

MAIN IMPROVEMENTS ALREADY PRESENTED TO IACS AND DOCUMENTED

- **SAFETY FACTOR CALCULATION AROUND CRANKPIN OIL HOLE (ONLY IN CASE OF DIAMETRAL ONE).**

- **EXTENSION OF SOME CONCENTRATION FACTORS RANGE (ONLY WHEN FEASIBLE ACCORDING TO PREVIOUS EXPERIMENTAL RESULTS).**

- **IMPROVED DEFINITIONS OF CALCULATION PRINCIPLE, VARIOUS STRESSES AND STRESS CONCENTRATION FACTORS.**
  (IN CONSISTENCY WITH ANALYSIS METHOD USED AT CREATION OF PRESENT U.R.).

- **CLARIFICATION CONCERNING GEOMETRIC PARAMETERS OF CRANKSHAFT.**
  (SPECIALLY IN CASE OF 2 STROKES ENGINES)

UR M53

CIMAC PROPOSAL
SYNTHESIS

WHAT WAS IMPROVED SINCE OUR LAST MEETING ACCORDING TO IACS/WP REQUESTS

- **MORE PRECISE DEFINITION OF EQUIVALENT ALTERNATING STRESSES USED IN U.R.**

  THESE DEFINITIONS ARE SUPPORTED BY 2 APPENDIXES INCLUDED IN CIMAC PROPOSED TEXT :

  - **APPENDIX 1 FOR STRESSES IN FILLETS**
  - **APPENDIX 2 FOR STRESSES AROUND OIL HOLE**

- **NEW PARAGRAPH CONCERNING FATIGUE STRENGTH OF CRANKSHAFT TO ALLOW – AS AN ALTERNATIVE – CLASSIFICATION SOCIETY APPROVED EXPERIMENTAL METHODS BASED ON SAMPLE RESULTS (AND NOT ON FULL SCALE CRANKTHROW).**

UR M53

IACS POSITION AFTER PRESENTATION OF CIMAC UR M53 REVISED TEXT :

- **NEW PROPOSAL IS CLEARER AND DOES NOT NEED MUCH INTRODUCTION AND SUPPORT INFORMATION.**

- **SOME PRECISIONS AND MODIFICATIONS ARE STILL ASKED TO CIMAC C.D. W.G.**

- **DETAILED REVIEW AND EVALUATION OF PROPOSAL IS REQUESTED TO EACH MEMBER OF IACS/WP/MCH BEFORE END OF YEAR 2000.**

Revision of Unified Requirements UR M53, Calculation of Crankshafts for Internal Combustion Engines – Task 8.

Mr. Bertrand, chairman CIMAC WG-Crankshaft Dimensions (CD) gave a presentation on the subject and informed about the new CIMAC proposal for revised UR M53. It was emphasized that fundamental parts had not been altered, but that weak areas had been improved and volume thus increased from earlier 15 pages to now 30.

In the presentation and the subsequent discussion the following was highlighted :

- The **new proposal is clearer than earlier versions and do not need much introduction and support** information. However, when submitting the final proposal to WP/MCH**, CIMAC was requested to provide documentary evidence of :**

(a) **Specific reasons for individual requirement changes**.
(b) **That the changes have the full support of all associated manufacturers of 2 and 4 stroke engines**.

- Current proposal is to be considered as a temporary proposal. Even when accepted and included in the IACS UR, the work within CIMAC, aiming at further improvements, will continue in line with the technical development.

- Shrink fit criteria are not covered by the current proposal. This is a task for future development/revisions.

- The new proposal is covering steel crankshafts, and is not suitable for crankshafts made from cast iron.

- It is important that criteria are well defined. GL's experience from last IACS audit clearly illustrated how difficult it could be to explain to an auditor on what basis approval was made when not in compliance with current UR M53.

- The new proposal (ref. top of page 4) have a paragraph which opens for the use of other criteria than those given in the UR itself. A number of WP/MCH's members found this somewhat confusing and expressed that lack of common minimum requirements, could involve that members in principle were free to accept designs on a subjective basis. This could mean that **we do not have Unified Requirements, but Unified Recommendations. Is this considered sufficient for crankshafts ?**

- With basis in above, **it was considered mandatory that the UR M53 gave clear criteria/definition as to what could be considered as « equivalent methods ».** Accordingly, and upon request, Mr. Sandberg, DNV produced a proposal for definition/interpretation of the term « equivalent » intended applied for the new proposal to UR M53. The proposal with ref. to M53, page 4, amendment to 1.1 scope : ……. equivalence to these rules, reads : ***« Equivalence is understood as : No alteration in principles affecting non apparent safety factors, i.e. the assumption of max bending and max torsion coinciding in time and position is to be maintained together with the acceptability factor. Empirical methods as e.g. calculation of nominal stresses, stress concentration factors, combination of stresses, fatigue strength, etc may be replaced by more relevant methods of ……… »***

It was agreed that :

0. *Copy of the presentation given by Mr. Bertrand should be submitted WP/MCH's chairman (preferably in electronic form) for distribution to the WP/MCH members***. Status : Not yet received. Reminder is hereby given.**

1. *All WP/MCH members should evaluate above definition together with the already distributed proposal for revision of UR M53.*

2. ***All WP/MCH members should perform a detail review of the proposal submitted*** *(together with above definition of equivalency) and revert with their comments to WP/MCH's chairman within end of this year. In this respect due attention should also be paid to the language and terms used. (In some places, translation to English (from French and German) have resulted in some unfortunate terms/wording, which need to be evaluated and considered corrected, e.g. W is defined as second moment of area).*

SHORT HISTORY OF UR M53
TECHNICAL EVOLUTION (1986 – 1999)

- **SEPT. 91 (PARIS) :**

  → First discussions about oil hole safety factor calculation.

- **JUNE 92 (PARIS) :**

  → Definition, then edition, of « Basic Documents » on which are based the original version of UR M53.

  → Discussion on the range of validity for SCF parameters.

- **JUNE 93 (PARIS) :**

  → Proposal for introducing plasticity criteria in shrinkfit.

  → Approval of oil hole method.

  → Approval of decisions concerning SCF parameters extension range.

- **OCT. 94 (WINTERTHUR) :**

  → Discussion about new definition for W and B.

  → Proposal for calculation of shrinkfit with plasticity.

- **JUNE 97 (PARIS) :**

  → Approval of modification concerning W, B and shrinkfit calculations with plasticity.

- **<u>JUNE 98</u> (COPENHAGEN) :**

  → 1st complete rewording of UR M53 incorporating :

  *** Oil hole safety coeff. calculation method**

  *** Extension range of SCF factors**

  *** Clear definitions of various parameters consistently with « Basic Documents »**

  *** Cancellation of proposed method about plasticity effects during shrinkfit**

  → 1st discussion about future of UR M53

- **<u>APRIL 99</u> (ST NAZAIRE) :**

  → Definitive revision of UR M53 agreed by all W.G. members with addition of :

  *** Appendix for clear explanation of SCF.**

  *** Possibility of σ_{DW} determination by alternative experimental method.**

  → State of art in crankshaft design presented by each W.G. member.

- **<u>OCT. 99</u> :**

  → Presentation to IACS WP/MCH of previous revised edition of UR M53 (with only one editorial modification).

Technical Background for UR M53 Rev.2, Jan 2011

1. Scope and objectives

The present UR M53 does not cater for some of the current designs of crankshaft and the Industry through CIMAC have proposed an alternative calculation procedure.

2. Engineering background for technical basis and rationale

The analytical method in UR M53 is based on empirical formulae developed from strain gauge measurements of various crank geometries. Use of these formulae beyond any of the various validity ranges can lead to erroneous results in either direction, i.e. results that are more inaccurate than indicated by the mentioned standard deviations. Therefore the FEM-based method is highly recommended and this Technical Background is taken from the work undertaken by CIMAC.

The SCF's calculated according to the rules of this document are defined as the ratio of stresses calculated by FEM to nominal stresses in both journal and pin fillets. When used in connection with the present method in M53 von Mises stresses shall be calculated for bending and principal stresses for torsion or when alternative methods are considered.

3. Source / derivation of the proposed IACS Resolution

See Proposal by CIMAC WG4 ST-08-044 dated 29.06.2009.

4. Summary of Changes intended for the revised Resolution:

See Proposal by CIMAC WG4 ST-08-044 dated 29.06.2009.

5. Points of discussions or possible discussions

Proposal by CIMAC WG4 ST-08-044 dated 29.06.2009 was subject to extensive discussion regarding the validity of the proposal. A major concern was the lack of far reaching validation offered. It was for this reason that the proposal has been accepted as an alternative only where the current prescriptive rules in UR M53 are out of bounds and not as a means to replace UR M53 in its entirety.

IACS UR M53, Appendix III

“Guidance for calculation of

Stress Concentration Factors

in the web fillet radii of crankshafts by utilizing Finite Element Method”

Index

1. General

The objective of the analysis is to substitute the analytically calculated Stress Concentration Factors (SCF) at the crankshaft fillets by suitable Finite Element Method (FEM) calculated figures. The analytical method is based on empirical formulae developed from strain gauge measurements of various crank geometries. Use of these formulae beyond any of the various validity ranges can lead to erroneous results in either direction, i.e. results that are more inaccurate than indicated by the mentioned standard deviations. Therefore the FEM-based method is highly recommended.

The SCF's calculated according to the rules of this document are defined as the ratio of stresses calculated by FEM to nominal stresses in both journal and pin fillets. When used in connection with the present method in M53 von Mises stresses shall be calculated for bending and principal stresses for torsion or when alternative methods are considered.

The procedure as well as evaluation guidelines are valid for both solid cranks and semibuilt cranks (except journal fillets).

The analysis is to be conducted as linear elastic FE analysis, and unit loads of appropriate magnitude are to be applied for all load cases.

The calculation of SCF at the oil bores is at present not covered by this document.

It is advised to check the element accuracy of the FE solver in use, e.g. by modelling a simple geometry and comparing the stresses obtained by FEM with the analytical solution for pure bending and torsion.

Boundary Element Method (BEM) may be used instead of FEM.

2. Model requirements

The basic recommendations and perceptions for building the FE-model are presented in 2.1. It is obligatory for the final FE-model to fulfil the requirement in 2.3.

2.1. Element mesh recommendations

In order to fulfil the mesh quality criteria it is advised to construct the FE model for the evaluation of Stress Concentration Factors according to the following recommendations:

- The model consists of one complete crank, from the main bearing centreline to the opposite side main bearing centreline.
- Element types used in the vicinity of the fillets:
  - 10 node tetrahedral elements
  - 8 node hexahedral elements
  - 20 node hexahedral elements
- Mesh properties in fillet radii. The following applies to ±90 degrees in circumferential direction from the crank plane:

- Maximum element size $a=r/4$ through the entire fillet as well as in the circumferential direction. When using 20 node hexahedral elements, the element size in the circumferential direction may be extended up to 5a. In the case of multi-radii fillet *r* is the local fillet radius. (If 8 node hexahedral elements are used even smaller element size is required to meet the quality criteria.)
- Recommended manner for element size in fillet depth direction
  - First layer thickness equal to element size of ***a***
  - Second layer thickness equal to element to size of **2*a***
  - Third layer thickness equal to element to size of **3*a***

o Minimum 6 elements across web thickness.

o Generally the rest of the crank should be suitable for numeric stability of the solver.

o Counterweights only have to be modelled only when influencing the global stiffness of the crank significantly.

o Modelling of oil drillings is not necessary as long as the influence on global stiffness is negligible and the proximity to the fillet is more than 2*r*, see figure 2.1.

o Drillings and holes for weight reduction have to be modelled.

o Submodeling may be used as far as the software requirements are fulfilled.

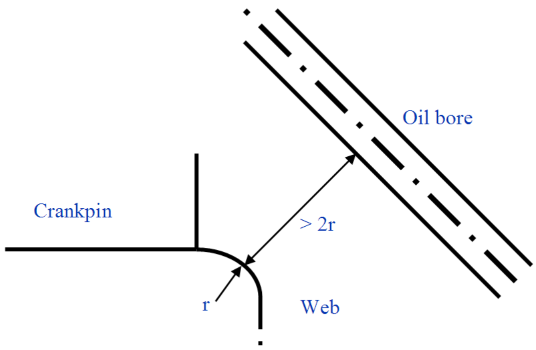

Figure 2.1. Oil bore proximity to fillet.

2.2. Material

UR M53 does not consider material properties such as Young's Modulus (*E*) and Poisson's ratio (ν). In FE analysis those material parameters are required, as strain is primarily calculated and stress is derived from strain using the Young's Modulus and Poisson's ratio. Reliable values for material parameters have to be used, either as quoted in literature or as measured on representative material samples.

For steel the following is advised: $E = 2.05 \cdot 10^5$ MPa and $\nu=0.3$.

2.3. Element mesh quality criteria

If the actual element mesh does not fulfil any of the following criteria at the examined area for SCF evaluation, then a second calculation with a refined mesh is to be performed.

2.3.1. Principal stresses criterion

The quality of the mesh should be assured by checking the stress component normal to the surface of the fillet radius. Ideally, this stress should be zero. With principal stresses σ_1, σ_2 and σ_3 the following criterion is required:

$$\min(|\sigma_1|,|\sigma_2|,|\sigma_3|) < 0.03 \cdot \max(|\sigma_1|,|\sigma_2|,|\sigma_3|)$$

2.3.2. Averaged/unaveraged stresses criterion

The criterion is based on observing the discontinuity of stress results over elements at the fillet for the calculation of SCF:

- Unaveraged nodal stress results calculated from each element connected to a $node_i$ should differ less than by 5 % from the 100 % averaged nodal stress results at this $node_i$ at the examined location.

3. Load cases

To substitute the analytically determined SCF in UR M53 the following load cases have to be calculated.

3.1. Torsion

In analogy to the testing apparatus used for the investigations made by FVV the structure is loaded pure torsion. In the model surface warp at the end faces is suppressed.

Torque is applied to the central node located at the crankshaft axis. This node acts as the master node with 6 degrees of freedom and is connected rigidly to all nodes of the end face.

Boundary and load conditions are valid for both in-line and V-type engines.

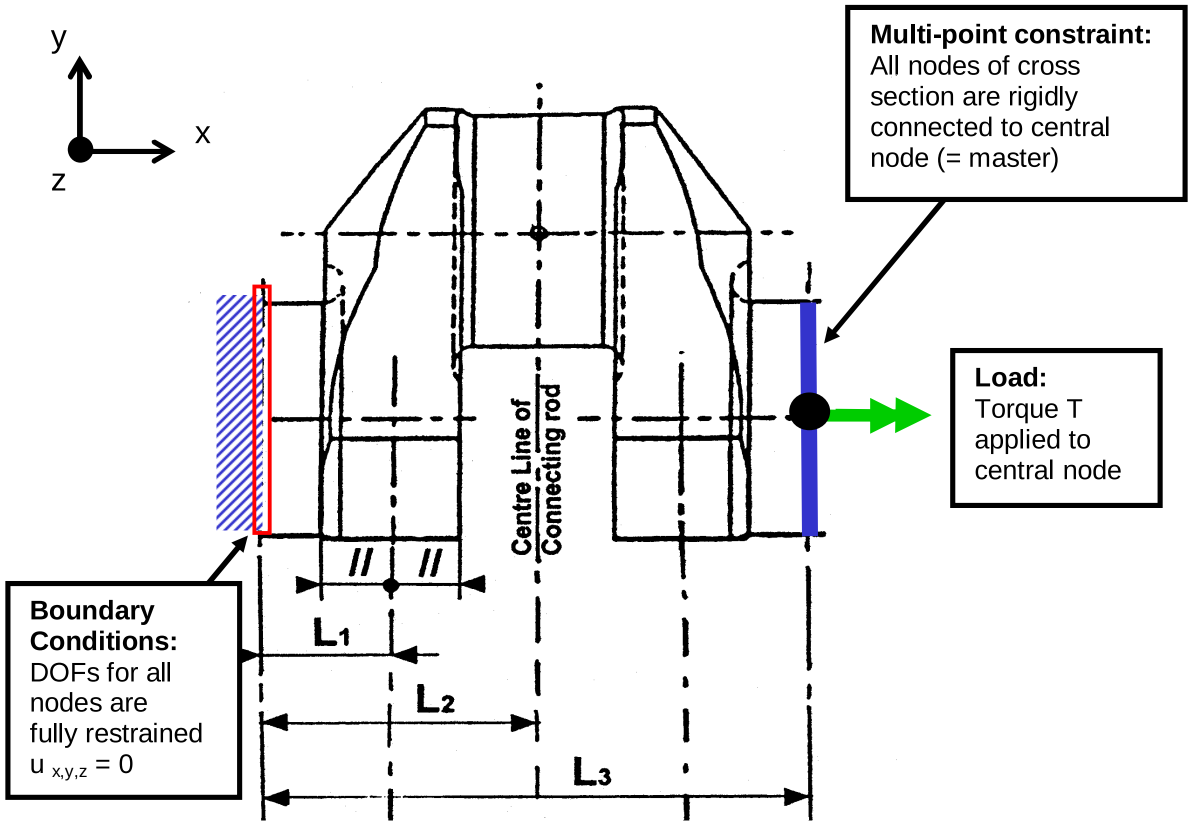

Figure 3.1 Boundary and load conditions for the torsion load case.

For all nodes in both the journal and crank pin fillet principal stresses are extracted and the equivalent torsional stress is calculated:

$$\tau_{equiv} = \max\left(\frac{|\sigma_1 - \sigma_2|}{2}, \frac{|\sigma_2 - \sigma_3|}{2}, \frac{|\sigma_1 - \sigma_3|}{2}\right)$$

The maximum value taken for the subsequent calculation of the SCF:

$$\alpha_T = \frac{\tau_{equiv,\alpha}}{\tau_N}$$

$$\beta_T = \frac{\tau_{equiv,\beta}}{\tau_N}$$

where τ_N is nominal torsional stress referred to the crankpin and respectively journal as per UR M53 2.2.2 with the torsional torque *T*:

$$\tau_N = \frac{T}{W_P}$$

3.2. Pure bending (4 point bending)

In analogy to the testing apparatus used for the investigations made by FVV the structure is loaded in pure bending. In the model surface warp at the end faces is suppressed.

The bending moment is applied to the central node located at the crankshaft axis. This node acts as the master node with 6 degrees of freedom and is connected rigidly to all nodes of the end face.

Boundary and load conditions are valid for both in-line- and V- type engines.

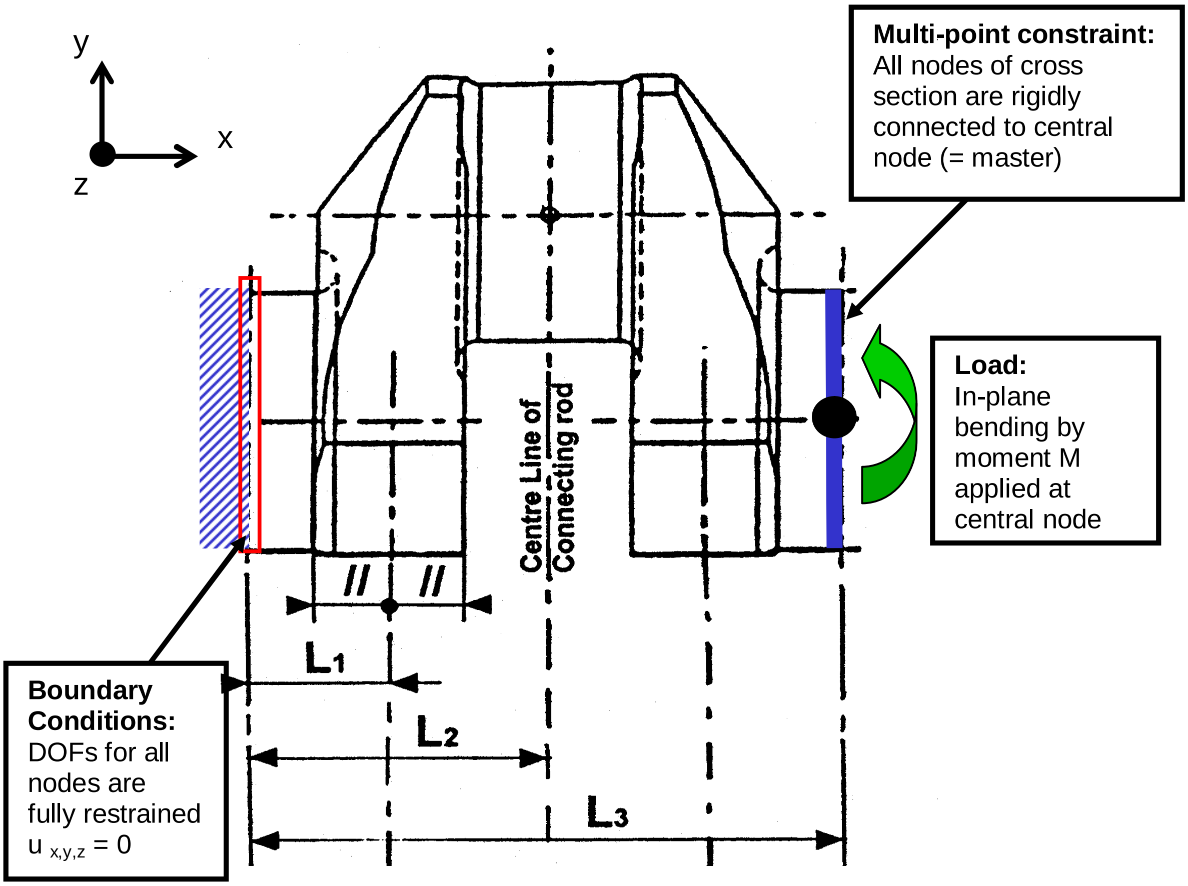

Figure 3.2 Boundary and load conditions for the pure bending load case.

For all nodes in both the journal and pin fillet von Mises equivalent stresses σ_{equiv} are extracted. The maximum value is used to calculate the SCF according to:

$$\alpha_B = \frac{\sigma_{equiv,\alpha}}{\sigma_N}$$

$$\beta_B = \frac{\sigma_{equiv,\beta}}{\sigma_N}$$

Nominal stress σ_N is calculated as per UR M53 2.1.2.1 with the bending moment M:

$$\sigma_N = \frac{M}{W_{eqw}}$$

3.3. Bending with shear force (3-point bending)

This load case is calculated to determine the SCF for pure transverse force (radial force, β_Q) for the journal fillet.

In analogy to the testing apparatus used for the investigations made by FVV, the structure is loaded in 3-point bending. In the model, surface warp at the both end faces is suppressed. All nodes are connected rigidly to the centre node; boundary conditions are applied to the centre nodes. These nodes act as master nodes with 6 degrees of freedom.

The force is applied to the central node located at the pin centre-line of the connecting rod. This node is connected to all nodes of the pin cross sectional area. Warping of the sectional area is not suppressed.

Boundary and load conditions are valid for in-line and V-type engines. V-type engines can be modelled with one connecting rod force only. Using two connecting rod forces will make no significant change in the SCF.

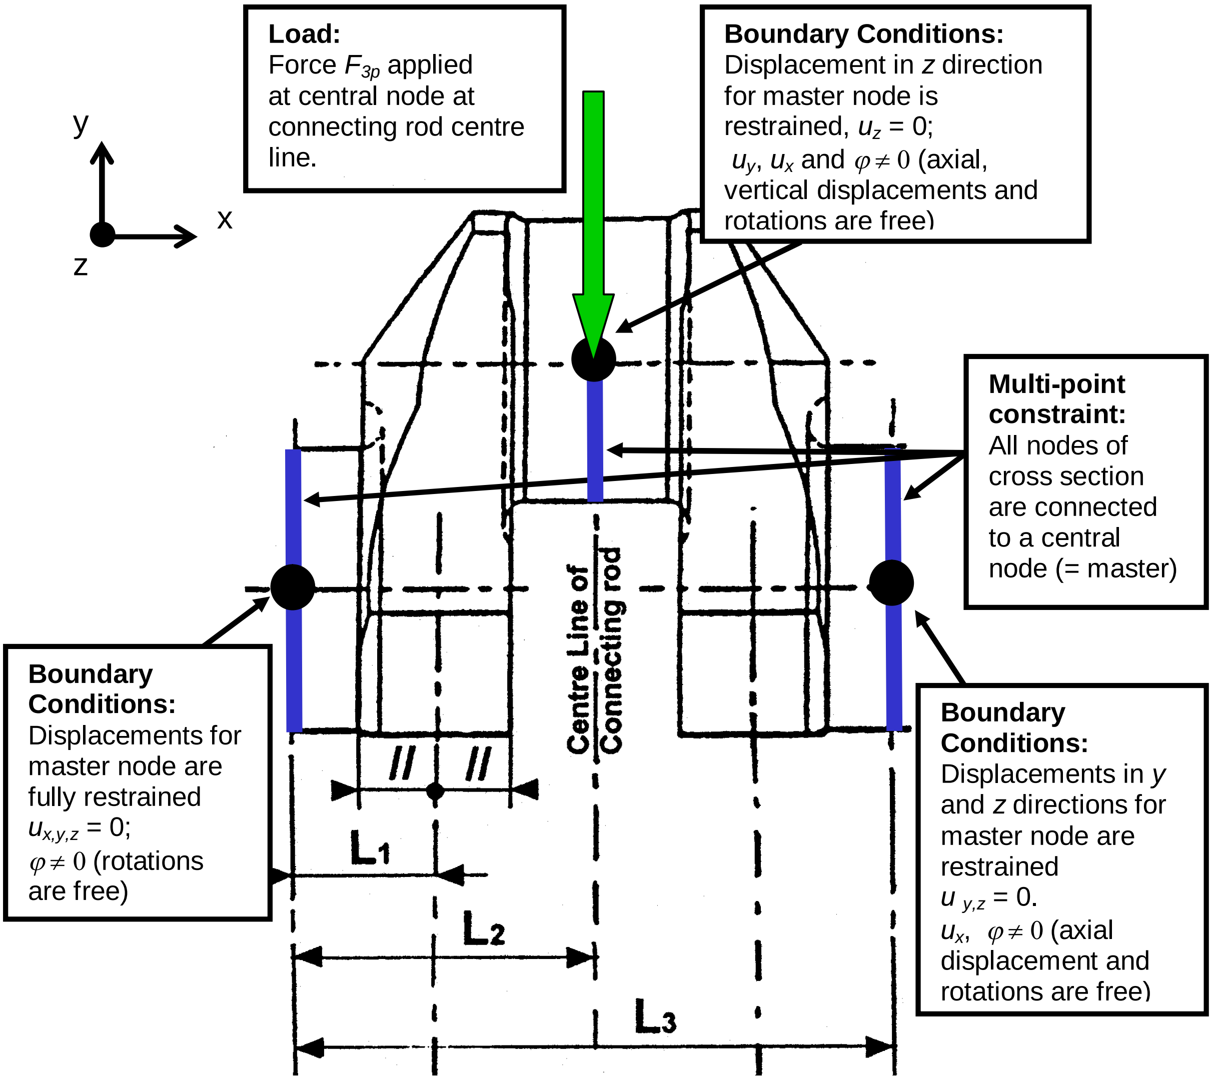

Figure 3.3. Boundary and load conditions for the 3-point bending load case of an in-line engine.

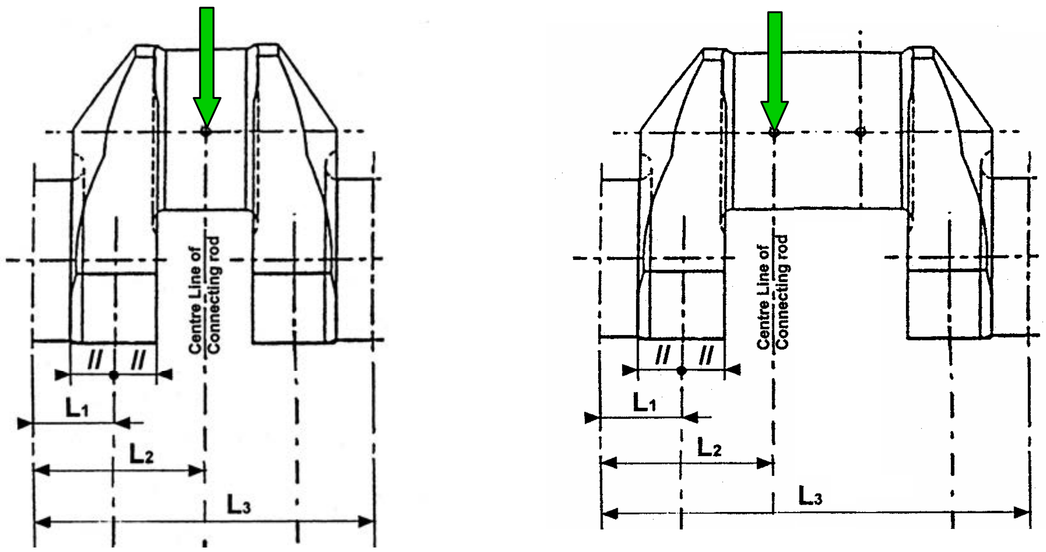

Figure 3.4 Load applications for in-line and V-type engines.

The maximum equivalent von Mises stress σ_{3P} in the journal fillet is evaluated. The SCF in the journal fillet can be determined in two ways as shown below.

3.3.1. Method 1

This method is analogue to the FVV investigation. The results from 3-point and 4-point bending are combined as follows:

$$\sigma_{3P} = \sigma_{N3P} \cdot \beta_B + \sigma_{Q3P} \cdot \beta_Q$$

where:

- σ_{3P} as found by the FE calculation.
- σ_{N3P} Nominal bending stress in the web centre due to the force F_{3P} *[N]* applied to the centre-line of the actual connecting rod, see figure 3.4.
- β_B as determined in paragraph 3.2.
- σ_{Q3P} $= Q_{3P}/(B \cdot W)$ where Q_{3P} is the radial (shear) force in the web due to the force F_{3P} *[N]* applied to the centre-line of the actual connecting rod, see also figures 3 and 4 in M53.

3.3.2. Method 2

This method is **not** analogous to the FVV investigation. In a statically determined system with one crank throw supported by two bearings, the bending moment and radial (shear) force are proportional. Therefore the journal fillet SCF can be found directly by the 3-point bending FE calculation.

The SCF is then calculated according to

$$\beta_{BQ} = \frac{\sigma_{3P}}{\sigma_{N3P}}$$

For symbols see 3.3.1.

When using this method the radial force and stress determination in M53 becomes superfluous. The alternating bending stress in the journal fillet as per UR M53 2.1.3 is then evaluated:

$$\sigma_{BG} = \pm \left| \beta_{BQ} \cdot \sigma_{BFN} \right|$$

Note that the use of this method does not apply to the crankpin fillet and that this SCF must not be used in connection with calculation methods other than those assuming a statically determined system as in M53.

Technical Background (TB) document for UR M53 (Rev.3 June 2017)

1. Scope and objectives

The objective of this task is to introduce additional requirements to UR M53 Rev.2 on the basis of the changes proposed by CIMAC, covering the following items:

a. evaluation of stress concentration factors (SCF) by finite elements calculation,
b. evaluation of stress in oil bore and fillets when surface treatment process is applied,
c. evaluation of fatigue strength by experiment (fatigue tests).

2. Engineering background for technical basis and rationale

The engineering background has been provided by CIMAC and is summarized below:

<u>a) Calculation of SCF factors</u>

The objective of the analysis is to substitute the analytically calculated Stress Concentration Factor (SCF) at the oil bore outlet by suitable Finite Element Method (FEM) calculated figures. The analytical method is based on empirical formulae developed from strain gauge or photo-elasticity measurements of various round bars.
Use of these formulae beyond any of the various validity ranges can lead to erroneous results in either direction, i.e. results that more inaccurate than indicated by the mentioned standard deviations.
The SCF calculated according to CIMAC method is defined as the ratio of stresses calculated by FEM to nominal stresses calculated analytically. When used in connection with the present method in M53 Rev.2, von Mises stresses are to be calculated for bending and principal stresses for torsion.
The analysis is to be conducted as linear elastic FE analysis. It is advised to check element accuracy of the FE solver in use, e.g. by modelling a simple geometry and comparing the stresses obtained by FEM with the analytical solution.

<u>b) Calculation of surface treated fillets and oil bore outlets</u>

The basic principle is that the alternating working stresses shall be below the local fatigue strength (including the effect of surface treatment) wherein non-propagating cracks may occur. This is then divided by certain safety factor. This applies through the entire fillet or oil bore contour as well as below the surface to a depth below the treatment-affected zone – i.e. to cover the depth all the way to the core.
Consideration of the local fatigue strength shall include the influence of the local hardness, residual stress and mean working stress. The influence of the 'giga-cycle effect', especially for initiation of subsurface cracks, should be covered by the choice of safety margin.
It is of vital importance that the extension of hardening/peening in an area with concentrated stresses be duly considered. Any transition where the hardening/peening is ended is likely to have considerable tensile residual stresses. This forms a 'weak spot' and is important if it coincides with an area of high stresses. Alternating and mean working stresses must be known for the entire area of the stress concentration as well as to a depth of about 1.2 times the depth of the treatment.

c) Evaluation of fatigue tests

Fatigue testing can be divided into two main groups: testing of small specimens and full size crank throws.
For crankshafts without fillet surface treatment, the fatigue strength can be determined by testing small specimens taken from a full size crank throw. One advantage is the rather high number of specimens which can be then manufactured. Another advantage is that the tests can be made with different stress ratios (R-ratios) and / or different modes e.g. axial, bending and torsion, with or without a notch. This is required for evaluation of the material data to be used with critical plane criteria.
For crankshafts with surface treatment, the fatigue strength can only be determined through testing of full size crank throws. For cost reasons, this usually means a low number of crank throws. The load can be applied by hydraulic actuators in a 3- or 4-point bending arrangement, or by an exciter in a resonance test rig. The latter is frequently used, although it usually limits the stress ratio to R = 1.
Testing can be made using the staircase method or a modified version thereof, where the first specimen is subjected to a stress level that is most likely well below the average fatigue strength. When this specimen has survived 10^7 cycles, this same specimen is subjected to a stress level one increment above the previous. The increment should be selected to correspond to the expected level of the standard deviation. This is continued with the same specimen until failure. Then the number of cycles is recorded and the next specimen is subjected to a stress that is at least two increments below the level where the previous specimen failed.

3. Source / derivation of the proposed IACS Resolution

CIMAC WG4 proposal "IACS UR M53, Appendix IV, Guidance for evaluation of Fatigue Tests", dated 16.10.2009.

CIMAC WG4 Proposal "IACS UR M53, Appendix V, Guidance for calculation of Surface Treated Fillets and Oil Bore Outlets", dated 03/12/2010.

CIMAC WG4 Proposal "IACS UR M53, Appendix VI, Guidance for calculation of Stress Concentration Factors in the oil bore outlets of crankshafts by utilizing Finite Element Method", dated 03.12.2010.

4. Summary of Changes intended for the revised Resolution

The main changes to UR M53 Rev.2 consist in adding the following new Appendixes:
- Appendix IV: Guidance for evaluation of Fatigue Tests,
- Appendix V: Guidance for calculation of Surface Treated Fillets and Oil Bore Outlets,
- Appendix VI: Guidance for calculation of Stress Concentration Factors in the oil bore outlets of crankshafts by utilizing Finite Element Method.

5. Points of discussions or possible discussions

A) The following comments have been made by the Machinery Panel to the documents submitted by CIMAC:

Appendix IV : Guidance for evaluation of fatigue tests :

a) Paragraph 1
"For crankshafts without any fillet surface treatment, the fatigue strength can be determined by testing small specimens taken from a full size crank throw".

While there are the introduced advantages in Chapter 1 on testing small specimens taken from a full size crank throw, it is not considered that the fatigue strength can determined only by testing small specimens taken from a full size crank throw unless the following are not shown by the technical documents.

i) There is the difference of the stress gradient by the size effect in comparison between the test result by the small specimen taken from a full size crank throw and the test result by the full size crank throws as it is.

ii) There is a problem whether the direction of the principle stress on the full size crank throw is the same as the one on small specimen taken from crank throw or not.

iii) It should be mentioned that this does not apply to crankshafts without fillet surface treatment but with other parts treated which could induce residual stress in the neighbourhood of fillet.

b) Chapter 5
In case where the size or configuration etc. of the full size crank throw is different, there is the possibility that the fatigue strength vary by the above i) and ii) compared with the existing results for similar crankshaft.

Therefore, it is necessary that enough technical data are also submitted for the classification review so as to complement the above possibility.

c) Cleanliness steel
Regarding the high and super clean steel described in Chapter 3 and the cleanliness steel described in Chapter 5, to take in the evaluation of the fatigue strength of the cleanliness steel based on this Appendix IV may be premature due to the lack of discussion.

Therefore, it is necessary to have another argument from the beginning stage such as definition and manufacturing process etc. for this kind of steel.

Appendix V : Surface treated Fillets and oil Bore outlets

One example on each case shall be submitted (at least induction hardening and shot peening), in order to evaluate what kind of documents can be produced by Manufacturers in order to fulfil these guidelines.

"acceptability factor" issue mentioned on § 3.3 : limit value of 1.15 is mentioned but in the last paragraph, door is opened to accept other (lower?) value and to call it a "safety factor". Example illustrating this should be provided.

B) CIMAC answers together with revised versions of Appendix IV and Appendix V were deemed satisfactory and UR M53 was updated accordingly by the Machinery Panel. It should be noted that Examples 2.1 and 2.2 in Appendix IV have not been included in the UR but in the present TB (see below).

C) The updated version of UR M53 was submitted to CIMAC. Minor corrections were made by the Machinery Panel in accordance with the comments received from CIMAC.

Attachment 1
Evaluation of fatigue tests results
Calculation of sample mean and standard deviation – Example 2.1

Hypothetical test results may look as shown in Figure 2.1. The processing of the results and the evaluation of the sample mean and the standard deviation are shown in Figure 2.2.

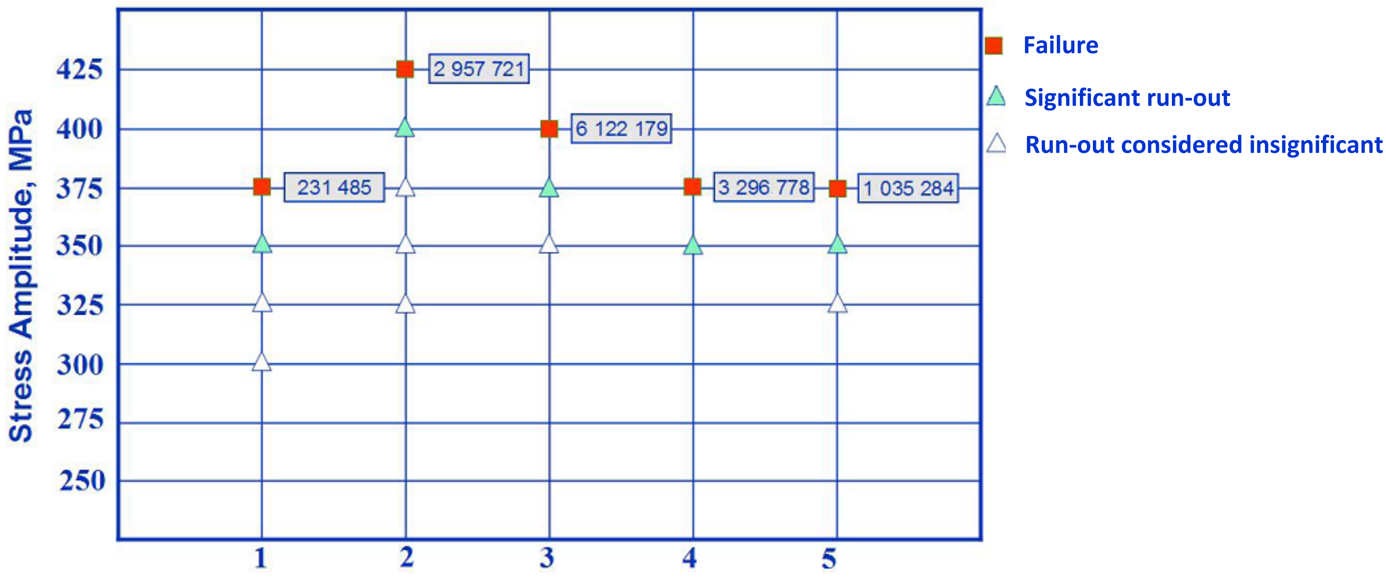

Figure 2.1. Log sheet of a modified staircase test.

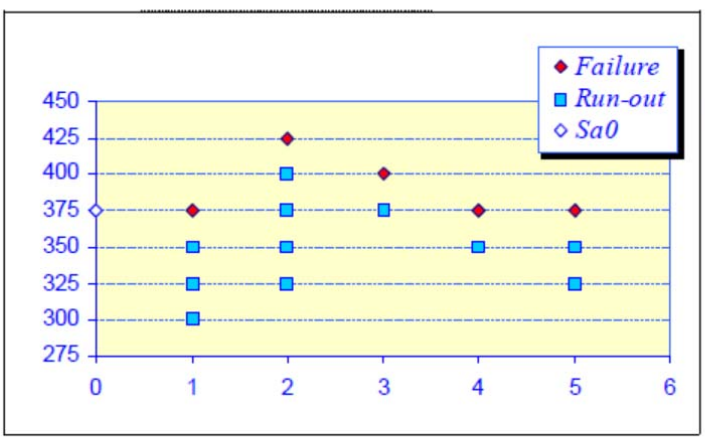
Stress level 0, $S_{a0} := 375 \cdot MPa$

Stress increment, $d := 25 \cdot MPa$



i	fi	i*fi	i^2*fi
2	1	2	4
1	1	1	1
0	3	0	0
Σ	5	3	5
	F	*A*	*B*

$F = \sum f_i$

$A = \sum i \cdot f_i$

$B = \sum i^2 \cdot f_i$

$i = 0,1,2,...$ is the stress level numbering, the numbering ususally starts from zero

f_i is number of test specimen at stress level, i

Level 0 *is the lowest value of the less frequent occurrence in the test results.*

$F := 5$

$A := 3$

$B := 5$

Sample mean

Sample mean,

$$S_a := \begin{cases} S_{a0} + d\cdot\left(\dfrac{A}{F} - \dfrac{1}{2}\right) & \text{if } C = 1 \\ S_{a0} + d\cdot\left(\dfrac{A}{F} + \dfrac{1}{2}\right) & \text{if } C = 2 \end{cases} \qquad S_a = 377.5\ MPa$$

Standard deviation

Sample standard deviation,

$$s := 1.62\cdot d\cdot\left(\frac{B\cdot F - A^2}{F^2} + 0.029\right) \qquad s = 27.09\ MPa$$

Standard deviation ratio,

$$s_r := \frac{s}{S_a} \qquad s_r = 0.072$$

Figure 2.2. Processing of the staircase test results.

Attachment 2
Evaluation of fatigue tests results
Confidence interval for mean fatigue limit – Example 2.2

Applying a 90 % confidence interval (α = 0.1) and *n* = 10 (5 failures and 5 run-outs) leads to $t_{\alpha,n-1}$ = 1.383, taken from a table for statistical evaluations (E. Dougherty: Probability and Statistics for the Engineering, Computing and Physical Sciences, 1990. Note that ν = *n* - 1 in the tables.). Hence:

$$S_{a90\%} = S_a - 1.383 \cdot \frac{s}{\sqrt{n}} = S_a - 0.4373 \cdot s$$

To be conservative, some authors would consider *n* to be 5, as the physical number of used specimen, then to $t_{\alpha,n-1}$ = 1.583.

Technical Background (TB) document for UR M53 (Rev.4, Aug 2019)

Example (2) in Page 2 was updated on 11 Sep 2019 – Ref: 19145_IGc

1. Scope and objectives

The objective of this task is the modification of the formula for the calculation of the acceptability factor (Q) for crankpin oil bore in UR M53 (Rev.3, June 2017) Appendix IV, paragraph 4.3 for the reason that the use of the maximum principal equivalent stress formulation was evaluated to be more appropriate than the multi-axial Gough-Pollard formulation.

2. Engineering background for technical basis and rationale

- In the CIMAC opinion the use of the maximum principal equivalent stress formulation is more appropriate than the multi-axial Gough-Pollard formulation, because bending and torsional loads lead to an uni-axial stress state (see Appendix II); this would have the same logic as chapter 5 of M53 (i.e calculate the equivalent stress at the oil bore according to chapter 5.2 (maximum principal stress) and compare it to the tensile fatigue strength from torsional testing only, σ_{DWOT}).
  According to their opinion CIMAC proposed to modify the formula for the calculation of the acceptability factor for the crankpin oil bore as follow:

Related to crankpin oil bore:

$$Q = \left(\sqrt{\left(\frac{\sigma_{BO}}{\sigma_{DWOT}}\right)^2 + \left(\frac{\tau_{TO}}{\tau_{DWOT}}\right)^2}\right)^{-1} \xleftarrow{\text{replace}} Q = \frac{\sigma_{DWOT}}{\sigma_v}; \qquad \sigma_v = \frac{1}{3}\sigma_{BO}\cdot\left[1+2\sqrt{1+\frac{9}{4}\left(\frac{\sigma_{TO}}{\sigma_{BO}}\right)^2}\right]$$

where:

σ_{DWOT}	fatigue strength by bending testing	$\xleftarrow{\text{replace}}$	σ_{DWOT}	fatigue strength by means of largest principal stress from torsion testing
τ_{DWOT}	fatigue strength by torsion testing	$\xleftarrow{\text{delete}}$		

  The details of the Technical Background offered by CIMAC, regarding their proposal, are enclosed in the Attachment 1 to Annex 4.

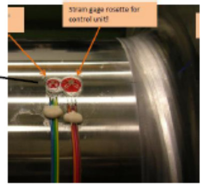
- On 01/10/2018, CIMAC was requested by IACS to provide significant examples in order to have a comparison between the results obtained from the current acceptability factor calculation and those obtained from the new proposed one and CIMAC provided the following three (3) examples:

CIMAC THE INTERNATIONAL COUNCIL ON COMBUSTION ENGINES

Example (1)

strength

- Strain gauge measurements from torsional test leads to a nominal alternating torsional strength: $\tau_n = 141 MPa$



- There are no bending test results available, because crank never fails at oil bore during bending test.
- At the oil bore, there is a 1D uni-axial stress state (torsional load leads to tensile strength only, see M53, 2.2.3 and App. II)

$$\tau_{DWOT} = N/A$$
$$\sigma_{DWOT} = \gamma_t \cdot \tau_n = 3.7 \cdot 141 MPa = 522 MPa$$

stress

- Stress concentration factors from M53 lead to alternating bending stress σ_{BO} (2.1.4) and alternating torsional stress σ_{TO} (2.2.3):

$$\sigma_{BO} = 118 MPa$$
$$\sigma_{TO} = 244 MPa$$

CIMAC THE INTERNATIONAL COUNCIL ON COMBUSTION ENGINES

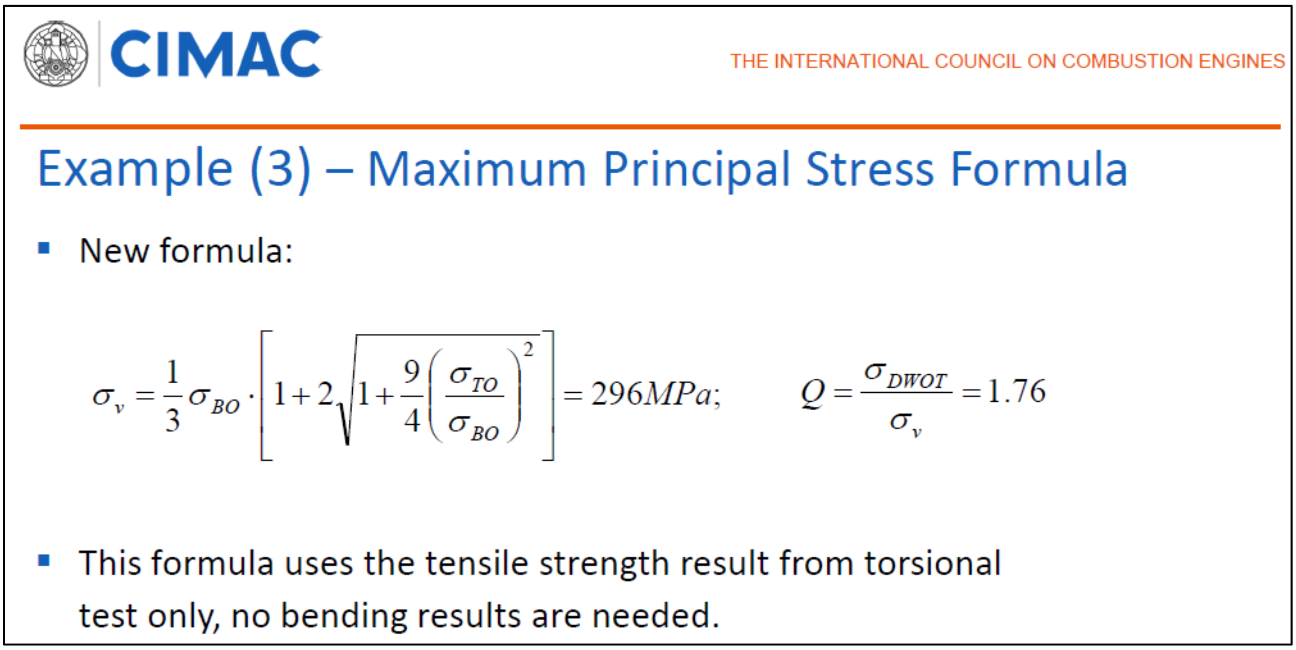
Example (2) – Gough - Pollard Formula

- Current formula:

$$Q = \left(\sqrt{\left(\frac{\sigma_{BO}}{\sigma_{DWOT}}\right)^2 + \cancel{\left(\frac{\tau_{TO}}{\tau_{DWOT}}\right)^2}}\right)^{-1} = \left(\sqrt{\left(\frac{\sigma_{BO}}{\sigma_{DWOT}}\right)^2}\right)^{-1} = 4.42$$

reduce multi-axial formula to 1D case ($\tau_{TO} = 0$)

- This acceptability factor is too large.
And, not correct, because the Gough-Pollard formula can only be applied to multi-axial stress states.



Regarding the examples provided by CIMAC some Machinery Panel Members commented that these examples are more representative of theoretical test cases and do not, therefore, demonstrate how the proposed revision to the calculation of the acceptability factor might affect specific in-service crankshafts.

- On 15/01/2019, CIMAC was requested by IACS to provide more examples related to specific in-service crankshaft designs, ideally demonstrating the effect across a range of sizes; in this regard CIMAC advised as follow:

"None of the engine manufacturers present has crankshaft in the field, which have been submitted for approval according to M53 App. IV. Therefore, we are not able to satisfy your request.

We still are convinced that the proposed correction of the oil bore formula is indispensable and therefore ask you to change App. IV according to our proposal. The proposed revision is meant to correct our own mistake.
DNVGL has already incorporated this proposal in the draft of their next revision of CG-0037"

- In the light of the above, the unanimity of the Machinery Panel Members, after reconsideration of the proposal, agreed to revise the formula for the calculation of the acceptability factor (Q) for crankpin oil bore in UR M53 (Rev.3, June 2017) Appendix IV, paragraph 4.3 according to the CIMAC proposal, as it was observed that the formula is already used in UR M53 (M53.5.2 combined with the acceptability criteria of M53.7).

3. Source / derivation of the proposed IACS Resolution

CIMAC WG4 proposal "CIMAC_WG4_2018-0504_AppIV_OilBore.pdf", dated 07/05/2018.

4. Summary of Changes intended for the revised Resolution

- The text of UR M53 (Rev.3, June 2017) Appendix IV, paragraph 4.3 has been modified as follow:

"In order to combine tested bending and torsion fatigue strength results in calculation of crankshaft acceptability, see M53.7, the Gough-Pollard approach and the maximum principal equivalent stress formulation can be applied for the following cases:"

- The formula for the calculation of the acceptability factor (Q) for **crankpin oil bore** in UR M53 (Rev.3, June 2017) Appendix IV, paragraph 4.3 has been replaced by the following one:

$$Q = \frac{\sigma_{DWOT}}{\sigma_v}; \qquad \sigma_v = \frac{1}{3} * \sigma_{BO} * \left[1 + 2 * \sqrt{1 + \frac{9}{4} * \left(\frac{\sigma_{TO}}{\sigma_{BO}}\right)^2}\right]$$

And the definition of σ_{DWOT} has been amended as follow:

σ_{DWOT} fatigue strength by means of largest principal stress from torsion testing fatigue ~~strength by bending testing~~

5. Points of discussions or possible discussions

The UR M53 (Rev.4) has been agreed by correspondence.

Attachment 1

CIMAC WG 4, UR M53 App. IV, Comment on Oil Bore Analysis

CIMAC THE INTERNATIONAL COUNCIL ON COMBUSTION ENGINES

Introduction

- Fatigue strength and acceptability factor from
  - UR M53
  - DNVGL-CG-0037 (Class Guideline)
  - Full scale fatigue testing (App. IV)
- Proposal for acceptability factor calculation from fatigue test data at oil bore.

CIMAC THE INTERNATIONAL COUNCIL ON COMBUSTION ENGINES

Acceptability Factors (screenshot from UR M53)

M 53.5 CALCULATION OF EQUIVALENT ALTERNATING STRESS

5.1 General

In the fillets, bending and torsion lead to two different biaxial stress fields which can be represented by a Von Mises equivalent stress with the additional assumptions that bending and torsion stresses are time phased and the corresponding peak values occur at the same location (see Appendix I).

As a result the equivalent alternating stress is to be calculated for the crankpin fillet as well as for the journal fillet by using the Von Mises criterion.

At the oil hole outlet, bending and torsion lead to two different stress fields which can be represented by an equivalent principal stress equal to the maximum of principal stress resulting from combination of these two stress fields with the assumption that bending and torsion are time phased (see Appendix II).

The above two different ways of equivalent stress evaluation both lead to stresses which may be compared to the same fatigue strength value of crankshaft assessed according to Von Mises criterion.

- Von MISES is the wrong equivalent stress evaluation for oil bore outlets

CIMAC THE INTERNATIONAL COUNCIL ON COMBUSTION ENGINES

Acceptability Factors (UR M53)

- Equivalent stress:
  - cpf, mjf (von MISES): $\sigma_V = \pm\sqrt{(\sigma_{BH}+\sigma_{add})^2 + 3\bullet\tau_H^2}$; $\sigma_V = \pm\sqrt{(\sigma_{BG}+\sigma_{add})^2 + 3\bullet\tau_G^2}$
  - oil bore (max. principal): $\sigma_V = \pm\frac{1}{3}\sigma_{BO}\bullet\left[1+2\sqrt{1+\frac{9}{4}\left(\frac{\sigma_{TO}}{\sigma_{BO}}\right)^2}\right]$
- Fatigue strength (von MISES):

$$\sigma_{DW} = \pm K\bullet(0.42\bullet\sigma_B + 39.3)\bullet\left[0.264 + 1.073\bullet D^{-0.2} + \frac{785-\sigma_B}{4900} + \frac{196}{\sigma_B}\bullet\sqrt{\frac{1}{R_X}}\right]$$

- Acceptability factor: $Q = \frac{\sigma_{DW}}{\sigma_V}$ $\quad Q \geq 1.15$

CIMAC THE INTERNATIONAL COUNCIL ON COMBUSTION ENGINES

Acceptability Factors (DNVGL-CG-0037)

- Stress: bending and torsional stress from SCF
- Fatigue strength:
  - cpf, mjf: $\sigma_f = K_b \cdot f(\sigma_B;\sigma_{0.2}) \cdot f(R_a) \cdot f(\chi) \cdot f(\sigma_M)$

    $\tau_f = K_t \cdot \frac{1}{\sqrt{3}} \cdot f(\sigma_B;\sigma_{0.2}) \cdot f(R_a) \cdot f(\chi) \cdot f(\tau_M)$
  - oil bore: $\sigma_{fh} = K_h \cdot f(\sigma_B;\sigma_{0.2}) \cdot f(R_a) \cdot f(\chi) \cdot f(\sigma_M)$
- Acceptability factor: $S = 1{,}15$
  - cpf, mjf (GOUGH-POLLARD): $\left(\frac{\sigma_H}{\sigma_{fH}}\right)^2 + \left(\frac{\tau_H}{\tau_{fH}}\right)^2 \leq \frac{1}{S^2}$; $\left(\frac{\sigma_G}{\sigma_{fG}}\right)^2 + \left(\frac{\tau_G}{\tau_{fG}}\right)^2 \leq \frac{1}{S^2}$
  - oil bore (max. principal): $\frac{1}{3}\cdot\sigma_{BO}\cdot\left|1+2\sqrt{1+\frac{9}{4}\left(\frac{\sigma_{TO}}{\sigma_{BO}}\right)^2}\right| \leq \frac{\sigma_{fO}}{S}$

CIMAC THE INTERNATIONAL COUNCIL ON COMBUSTION ENGINES

Full Scale Fatigue Testing

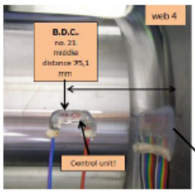
- Full scale (single crank) fatigue testing is done for bending and torsional load separately.
- Appendix IV defines a modified staircase method which leads to a bending **and** torsional fatigue strength.
  Strictly speaking, the fatigue test leads to "damage torque load" and strain gauge measured stress at different locations for the damage case. From these, fatigue strength at critical locations (cpf, mjf, oil bore) is calculated.
- The fatigue strength in the oil bore outlet σ_{DWOT} is calculated as the alternating **tensile** stress for the damage case under torsional load with SCF (see M53 chap. 2.2.3).
- The crank will fail at the weakest of the critical locations (assumed cpf below).

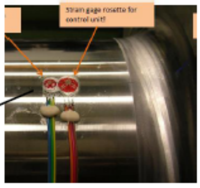
CIMAC THE INTERNATIONAL COUNCIL ON COMBUSTION ENGINES

Acceptability Factors (UR M53 App. IV)

- Strain gauge measured fatigue strength (from full scale pulse test):

bending test | torsional test





$\tau_n = ***MPa$

	bending test	torsional test
– oil bore:		$\sigma_{DWOT} = \gamma_T \cdot \tau_n$
– crank pin fillet:	$\sigma_{DWCT} = ***MPa$	$\tau_{DWCT} = \alpha_T \cdot \tau_n$
– main journal fillet:	$\sigma_{DWJT} = ***MPa$	$\tau_{DWJT} = \beta_T \cdot \tau_n$

CIMAC THE INTERNATIONAL COUNCIL ON COMBUSTION ENGINES

Acceptability Factors (UR M53 App. IV)

- Stress: bending and torsional stress from SCF
- Fatigue strength (from full scale pulse test):

	cpf	mjf	oil bore
bending test	σ_{DWCT}	n/a	x
torsional test	τ_{DWCT}	n/a	σ_{DWOT} = alternating tensile stress in outlet of journal oil bore due to torsion

- Acceptability factor (GOUGH-POLLARD): $Q \geq 1.15$
  - cpf: $$Q = \left(\sqrt{\left(\frac{\sigma_{BH}}{\sigma_{DWCT}}\right)^2 + \left(\frac{\tau_{BH}}{\tau_{DWCT}}\right)^2} \right)^{-1}$$
  - mjf $$Q = \left(\sqrt{\left(\frac{\sigma_{BG}}{\sigma_{DWJT}}\right)^2 + \left(\frac{\tau_{G}}{\tau_{DWJT}}\right)^2} \right)^{-1}$$
  - oil bore: $$Q = \left(\sqrt{\left(\frac{\sigma_{BO}}{\sigma_{DWOT}}\right)^2 + \left(\frac{\tau_{TO}}{\tau_{DWOT}}\right)^2} \right)^{-1}$$

τ_{DWOT} not available from test ?

CIMAC THE INTERNATIONAL COUNCIL ON COMBUSTION ENGINES

Acceptability Factors: Inconsistencies

- Von MISES is the wrong equivalent stress formulation for oil bore outlets and in consequence is GOUGH-POLLARD the wrong multi-axial criterion for acceptability factor calculation.
- Formula to calculate acceptability factor for oil bore outlet in UR M53 App. IV chap. 4.3 uses:

σ_{DWOT} fatigue strength by bending testing
τ_{DWOT} fatigue strength by torsion testing

where only “fatigue strength by torsional test” can be determined, and leads to tensile fatigue strength.

CIMAC THE INTERNATIONAL COUNCIL ON COMBUSTION ENGINES

Acceptability Factors
(Proposal: use max. principal stress for oil bore)

- Stress: bending and torsional stress from SCF
- Fatigue strength (from full scale pulse test):

	cpf	mjf	oil bore
bending test	σ_{DWCT}	n/a	x
torsional test	τ_{DWCT}	n/a	σ_{DWOT}

= alternating tensile stress in outle of journal oil bore due to torsion

- Acceptability factor: Q ≥ 1.15
  - cpf (GOUGH-POLLARD): $$Q=\left(\sqrt{\left(\frac{\sigma_{BH}}{\sigma_{DWCT}}\right)^2+\left(\frac{\tau_{BH}}{\tau_{DWCT}}\right)^2}\right)^{-1}$$
  - mjf (GOUGH-POLLARD): $$Q=\left(\sqrt{\left(\frac{\sigma_{BG}}{\sigma_{DWJT}}\right)^2+\left(\frac{\tau_{G}}{\tau_{DWJT}}\right)^2}\right)^{-1}$$
  - oil bore (max. principal): $$Q_{OT}=\frac{\sigma_{DWOT}}{\sigma_v};\qquad \sigma_v=\frac{1}{3}\sigma_{BO}\cdot\left[1+2\sqrt{1+\frac{9}{4}\left(\frac{\sigma_{TO}}{\sigma_{BO}}\right)^2}\right]$$

CIMAC THE INTERNATIONAL COUNCIL ON COMBUSTION ENGINES

Conclusion

- At the oil bore outlet the maximum principal equivalent stress formulation is more appropriate than the **multi**-axial GOUGH-POLLARD formulation, because bending and torsional loads lead to a **uni**-axial stress state (see App. II / B and App. VI / F). To use a different approach for oil bore compared to fillets is in alignment with DNVGL-CG-0037.

Proposal for Change of UR M53 App. IV (page 48)

Related to crankpin oil bore:

$$Q = \left(\sqrt{\left(\frac{\sigma_{BO}}{\sigma_{DWOT}}\right)^2 + \left(\frac{\tau_{TO}}{\tau_{DWOT}}\right)^2} \right)^{-1} \xleftarrow{\text{replace}} Q = \frac{\sigma_{DWOT}}{\sigma_v}; \quad \sigma_v = \frac{1}{3}\sigma_{BO} \cdot \left[1 + 2\sqrt{1 + \frac{9}{4}\left(\frac{\sigma_{TO}}{\sigma_{BO}}\right)^2} \right]$$

where:

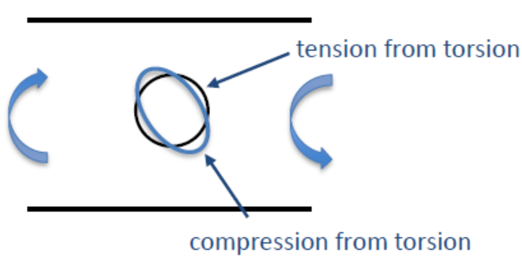
σ_{DWOT} fatigue strength by bending testing $\xleftarrow{\text{replace}}$ σ_{DWOT} fatigue strength by means of largest principal stress from torsion testing

τ_{DWOT} fatigue strength by torsion testing $\xleftarrow{\text{delete}}$

Appendix – Uni-axial Stress State at Oil Bore

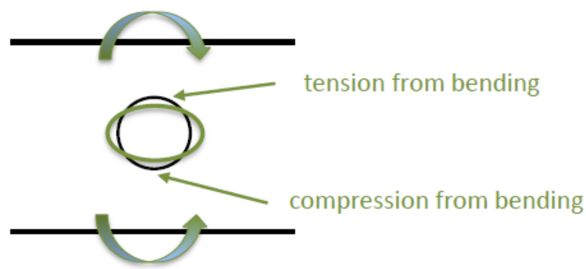
Uni-axiality at Edge of Oil Bore

- Torsion of the crankpin leads to ovalization of the oil bore.
- This leads to tensile stress only



- Bending of the crankpin leads to ovalization of the oil bore.
- This leads to tensile stress only.

- In combination, there is only an uni-axial stress state. There is only tensile stress $\sigma(\alpha)$ at the edge of the oil bore – no shear stress (see App. II).

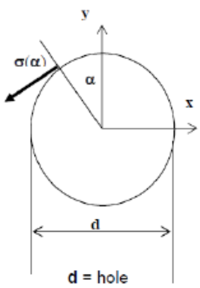


CIMAC THE INTERNATIONAL COUNCIL ON COMBUSTION ENGINES

Uni-axiality at Edge of Oil Bore (App. II)

Stress Concentration Factors and stress distribution at the edge of oil drillings **Appendix II**

M53
(cont)



d = hole diameter

Stress type	Nominal stress tensor	Uniaxial stress distribution around the edge	Mohr's circle diagram
Tension	$\begin{bmatrix} \sigma n & 0 \\ 0 & 0 \end{bmatrix}$	$\sigma_\alpha = \sigma_n \gamma_B / 3\,[1+2\cos(2\alpha)]$ 	 $\gamma_B = \sigma_{max}/\sigma_n$ for $\alpha = k\pi$
Shear	$\begin{bmatrix} 0 & \tau n \\ \tau n & 0 \end{bmatrix}$	$\sigma_\alpha = \gamma_T\, \tau_n \sin(2\alpha)$ 	 $\gamma_T = \sigma_{max}/\tau_n$ for $\alpha = \frac{\pi}{4} + k\frac{\pi}{2}$
Tension + shear	$\begin{bmatrix} \sigma n & \tau n \\ \tau n & 0 \end{bmatrix}$	$\sigma_\alpha = \frac{\gamma_B}{3}\sigma_n\left\{1+2\left[\cos(2\alpha)+\frac{3}{2}\frac{\gamma_T}{\gamma_B}\frac{\tau_n}{\sigma_n}\sin(2\alpha)\right]\right\}$ 	 $\sigma_{max} = \frac{\gamma_B}{3}\sigma_n\left[1+2\sqrt{1+\frac{9}{4}\left(\frac{\gamma_T}{\gamma_B}\frac{\tau_n}{\sigma_n}\right)^2}\right]$ for $\alpha = -\frac{1}{2}\mathrm{tg}^{-1}\left(\frac{3\gamma_T\tau_n}{2\gamma_B\sigma_n}\right)$

Technical Background (TB) document for UR M53 (Rev.5 May 2023)

1. Scope and objectives

The purpose is to revise UR M53 (Rev.4 Aug 2019), applicable to ships complying with the crankshafts whose application for design approval is dated on or after 1 January 2021.

2. Engineering background for technical basis and rationale

Revision 5 proposed by CIMAC with technical justification and effect to design of crankshafts.

3. Source/derivation of the proposed IACS Resolution

None.

4. Summary of Changes intended for the revised Resolution:

The Rev.5 of the UR M53 was developed for correction Q formula.

5. Points of discussions or possible discussions

5.1 CIMAC WG4 proposed a change to App.IV which indicating the maximum principal equivalent stress formulation is more appropriate than the multi-axial Gough-Pollard formulation. The proposal accepted by IACS machinery panel on Rev.4 of UR M53.

Later, three errors found in the formula which have been taken over from Rev.3

- The alternating torsional stress in crankpin fillet τH is defined on page 14. while τBH is not defined at all in M53. Therefore: τBH agreed to be replaced by τH.
- Chapter 4 (page 21) explains the use of the additional stress σadd together with the alternating bending stresses in the fillets: σBH and σBG. Therefore, the additional bending stress σadd agreed to be included.
- Introductory text for the equations for stress at the crankpin and journal needed to be updated to clarify that they are done at the fillet.

5.2 Machinery Panel asked CIMAC to provide specific on the effect of modification to the calculation formulae.

5.3 CIMAC clarified effect of modifications as follows;

Proposed modifications give more correct results for the acceptability factors because now “further bending stresses due to misalignment and bedplate deformation as well as due to axial and bending vibrations” are considered. With this, the formulas in App. IV are consistent to M53 chapter 5.

M53
(cont)

M 53.4 ADDITIONAL BENDING STRESSES

In addition to the alternating bending stresses in fillets (see item M 53.2.1.3) further bending stresses due to misalignment and bedplate deformation as well as due to axial and bending vibrations are to be considered by applying σ_{add} as given by table:

Type of engine	σ_{add}[N/mm²]
Crosshead engines	± 30 (*)
Trunk piston engines	± 10

5.4 Machinery Panel evaluated the scope of modifications and agreed on Revision 5 of UR M53.

6. Attachments if any

None

Technical Background (TB) document for UR M53 (Rev.6 April 2025)

1. Scope and objectives

The scope and objective of Revision 6 of UR M53 are to address concerns related to elevated torsional vibration characteristics observed in certain engine types when operating on low-flashpoint fuels or specific gas compositions to mitigating potential risks associated with these fuel types.

2. Engineering background for technical basis and rationale

The proposal initiated by the Machinery Panel project team while developing the draft Rev.3 of UR M78 that to consider concern in calculation of alternating torsional stresses for some engine type operating on low-flashpoint fuels or specific gas compositions.

3. Source/derivation of the proposed IACS Resolution

None.

4. Summary of Changes intended for the revised Resolution:

The following is a summary of changes in the revised UR M53 Rev.6:

The manufacturer shall specify the maximum nominal alternating torsional stress <u>for all fuels and operation modes on which an engine (and shafting system) is designed to operate</u>.

<u>Acceptance shall be based on approval of the worst-case scenario, which may include the highest nominal alternating torsional stress.</u>

5. Points of discussions or possible discussions

5.1 The Machinery Panel noted that torsional vibration characteristics may be elevated for certain engine types when operating on specific gases or low-flashpoint fuels.

As specified in UR M53.2.2.1, it is the manufacturer's responsibility to define the maximum permissible nominal alternating stresses.

Calculations should be provided for all fuel types on which the engine and shafting system are designed to operate.

The Panel understands that acceptance criteria should be based on the approval of the worst-case operational scenario.

The Panel consider updating UR M53 to explicitly address the submission and verification requirements for permissible torsional vibration stresses, covering all fuels for which they are designed.

5.2 The proposed amendment to UR M53.2.2 was as follows.

The torsional vibration characteristics may be higher for some engine types when operating on some gases or low-flashpoint fuels.

The calculation for nominal alternating torsional stresses is to be undertaken by the engine manufacturer according to the information contained in item M 53.2.2.2.

The manufacturer shall specify the maximum nominal alternating torsional stress for all fuels and operation modes on which an engine (and shafting system) is designed to operate.

Acceptance shall be based on approval of the worst-case scenario, which may include the highest nominal alternating torsional stress.

Some Members expressed that first sentences not necessary as already included on "… for all fuels and operation modes on which an engine (and shafting system) is designed to operate."

The Panel found it appropriate to consider the suggestion and agreed with the final amendment as currently presented in Rev.6 of UR M53.

- **Rev.4 (Feb 2021)**

1 Origin of Change:

☑ Other (Update to comply with the required format when industry standards are referred to)

2 Main Reason for Change:

There was a need to update this UR to comply with the following format when industry standards are referred to:

[Standard Designation], [version/revision, if applicable], [year of publication] (examples: API Spec 2F, 6th Edition, 1997; ISO 4624, 2002), where [version/revision, if applicable] and/or [year of publication] are decided by IACS and are not necessarily to be the current/latest version.

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None

4 History of Decisions Made:

None

5 Other Resolutions Changes:

None

6 Any hinderance to MASS, including any other new technologies:

None

7 Dates:

Original Proposal:	28 October 2019	(Ref: PM18939_IMd)
Panel Approval:	9 November 2020	(Ref: PM20906_IMf)
GPG Approval:	12 February 2021	(Ref: 20206dIGb)

- **Rev.3 (Oct 2015)**

1 Origin of Change:

☑ Suggestion by IACS Member

2 Main Reason for Change:

Clarification on field application of UR M56.

3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

4 History of Decisions Made:

Suggestion from a Machinery Panel Member was discussed by correspondence within Machinery Panel and during the 20th meeting.

5 Other Resolutions Changes:

None

6 Dates:

Original Proposal: 19 March 2014	made by a Member
Panel Approval: 8-11September 2015	(22nd Panel Meeting)
GPG Approval: 8 October 2015	(Ref. 15154_IGb)

- **Rev.2 (Oct 2013)**

1 Origin of Change:

☑ Suggestion by IACS Member

2 Main Reason for Change:

The previous revision 1 was based on the 1996 edition of International Standards ISO 6336. These standards were revised during 2006 through 2008 introducing very important changes, compared with their previous edition, that have a significant influence to the calculation outcome. Consequently, the UR M56 had to be brought inline with the currently valid edition of ISO 6336 standards.

3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None.

4 History of Decisions Made:

GPG approved the task PM 11918 on 2012-03-11 (12031_IGb)

Machinery panel agreed the revision 2 on 2013-09-06.

GPG adopted the revision 2 on 2013-10-11.

5 Other Resolutions Changes:

None

6 Dates:

Original Proposal: 24 October 2012	made by a Member
Panel Approval: 06 September 2013	(By Machinery Panel)
GPG Approval: 11 October 2013	(Ref. 12031_IGf)

- **Corr.1 (1996)**

See separate TB document in Annex 2.

Annex 3. **TB for Rev.4 (Feb 2021)**

See separate TB document in Annex 3.

Annex 4. **TB for Corr.1 (Oct 2021)**

See separate TB document in Annex 4.

Annex 5. **TB for Corr.2 (Mar 2023)**

See separate TB document in Annex 5.

Note:

There are no separate Technical Background (TB) documents for the New (1990), Rev.1 (1994) and Corr.1 (1996).

Technical Background Document for UR M56 (Rev. 2 Oct 2013)

1 Scope and objectives

Revision 2 reflects changes in the calculation of surface durability (pitting) and tooth root bending strength of gears introduced by the international standards series ISO 6336 by their editions in 2006 through 2008.

Since the time the revision 1 of UR M56 was adopted, these standards have undergone their important updates. These updates can in certain cases have a significant influence to the decision whether a gear pair is acceptable or not.

2 Engineering background for technical basis and rationale

Changed procedure for calculations of some factors in the new edition of standards.

3 Source/derivation of the proposed IACS Resolution

International standards

- ISO 6336-1:2006 & Corr. 1:2008, Calculation of load capacity of spur and helical gears - Part 1: Basic principles, introduction and general influence factors;
- ISO 6336-2:2006 & Corr. 1:2008, Calculation of load capacity of spur and helical gears - Part 2: Calculation of surface durability (pitting);
- ISO 6336-3:2006 & Corr. 1:2008, Calculation of load capacity of spur and helical gears - Part 3: Calculation of tooth bending strength;
- ISO 6336-5:2003, Calculation of load capacity of spur and helical gears - Part 5: Strength and quality of materials

4 Summary of Changes intended for the revised Resolution

Revision 2 of the UR M56 introduces a few additional formulae for the calculation of gear pair geometrical values.

Revision 2 changes procedure for calculation of factors K_v (partially), Z_W and $Y_{\delta relT}$.

Revision 2 corrects formulae for calculation of factors Z_B, Z_D, Z_β and Y_{RrelT}. Different formula for Z_β in the new edition of standards and its background actually initiated work on revision 2.

Revision 2 keeps only reference to the standards in the procedure for calculation of factors K_v (partially), $K_{H\beta}$, $K_{H\alpha}$, $K_{F\alpha}$, Y_F, Y_S as in the previous revision, rather than reproducing the text from the standards. This keeps the UR text compact, though not completely stand-alone. The same was done in the revision 1.

Revision 2 introduces new factors Y_B and Y_{DT} based on the new edition of standards.

5 Points of discussions or possible discussions

Load sharing factor K_γ and design factor Y_d do not exist and are not referenced to either in the present editions of the standards, or in the previous one. However, they are kept in the revised UR, having a real significance in the calculation of marine gears.

6 Attachments if any

None.

Technical Background Document for UR M56 (Rev.3 Oct 2015)

1 Scope and objectives

Clarification on field application of UR M56.

2 Engineering background for technical basis and rationale

The task was triggered by the proposal of a Member Society of establishing threshold values for application of IACS UR M56, since small size equipment are mass produced according to standardized design criteria widely experienced in service and built by specialized manufacturers.

Additionally, for gears intended to auxiliary services, it appear unfeasible to apply the UR to any kind of equipment without a minimum size threshold, because this would make very small equipment (e.g. windshield wipers, watertight doors closing gears) subject to approval, thus causing an excessive burden.

3 Source/derivation of the proposed IACS Resolution

None.

4 Summary of Changes intended for the revised Resolution

Rev.3 has modified section 1.2 "Scope and field of application" introducing threshold values respectively for gears intended for main propulsion and for essential auxiliary services.

5 Points of discussions or possible discussions

Several options were considered pertaining to setting specific threshold values for gears intended for main propulsion and for essential auxiliary services-i.e. one option was "220 kW for main propulsion and 110kW for auxiliary services"; and the other was "110 kW for both main propulsion and auxiliary services". Although some members preferred introducing "110 kW for both main propulsion and auxiliary services", in the continued discussion, Machinery Panel concurred that setting "220 kW for main propulsion and 110kW for auxiliary services" would be more appropriate considering the fact that member societies may freely impose stricter limitation than "220 kW for main propulsion and 110kW for auxiliary services".

UR M60 “Control and Safety of Gas Turbines for Marine Propulsion Use”

Summary

In Rev.1 of this UR, requirements have been updated, taking into account gas turbine manufacturers’ requests.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev.1 (Nov 2021)	24 November 2021	1 January 2023
New (1997)	1997	-

- **Rev.1 (Nov 2021)**

1 Origin of Change:

☑ Suggestion by IACS member

2 Main Reason for Change:

The item was triggered by a suggestion from a Machinery Panel Member. The following requests regarding gas turbines were received from manufacturers:

(1) IACS UR M60.2.2b) should be limited to forced lubrication systems, and,

(2) Whether each safety device of a gas turbine should be examined based upon FMEA in reference to UR M78 and UR M44.

Regarding the above requests, Machinery Panel considered the revision of IACS UR M60.

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None

4 History of Decisions Made:

Form A was approved on 13 July 2021 by Machinery Panel.

5 Other Resolutions Changes:

None

6 Any hinderance to MASS, including any other new technologies:

None

7 Dates:

Original Proposal	: 25 June 2020	(Ref: PM20002bIMb)
Panel Approval	: 13 July 2021	(Ref: PM20002bIMh)
GPG Approval	: 24 November 2021	(Ref: 21163_IGb)

- **New (1997)**

No records are available

****

Part B. Technical Background

List of Technical Background (TB) documents for UR M60:

Annex 1. **TB for Rev.1 (Nov 2021)**

See separate TB document in Annex 1.

◄▼►

Note: *There is no Technical Background (TB) document available for the New (1997).*

Technical Background (TB) document for UR M60 (Rev.1 Nov 2021)

1. Scope and objectives

To review existing UR M60 and update it as requested from manufacturers.

2. Engineering background for technical basis and rationale

The Panel has discussed whether each safety device of gas turbines should be based upon FMEA, because the monitoring and safety systems for DF or GF engines have been based upon FMEA in the fifth paragraph of 2.2.7 of UR M78.
As a result, it was concluded that the safety devices of gas turbine should also be based upon FMEA.

There was a request that the safety device in response to unacceptable lubricating oil pressure drop in UR M60.2.2b) should be limited to the case of the forced lubrication systems. However, it was concluded that all safety devices should be covered by FMEA.

3. Source/derivation of the proposed IACS Resolution

None.

4. Summary of Changes intended for the revised Resolution:

1) The following additional text has been added in paragraph 2.1:

"Unless the FMEA required by this UR proves otherwise, the alarm and shutdown functions for gas turbines are to be provided in accordance with Table 1 of this UR in addition to the general monitoring and safety system functions given by the Classification Societies."

2) The note regarding implementation date has been added.

3) The requirement in paragraph 3.1 has been amended to make it clear that alarm devices can be added or omitted depending on the result of FMEA.

4) The requirement in paragraph 3.2 has been moved to footnotes in Table 1.

5) The marks in Table 1 have been changed in the same way as UR M35 and M36 (e.g. high, low, x).

5. Points of discussions or possible discussions

There was a concern that an additional paragraph in M60.2.1 would lead to misunderstanding that performing FMEA could be omitted. After discussion, Rev.1 of UR has been unanimously agreed by Machinery Panel Members based upon the Panel consensus that performing FMEA is mandatory and that this amendment is not intended to omit FMEA.

6. Attachments if any

None.

UR M61 "Starting Arrangements of Internal Combustion Engines"

Summary

The requirements for engine starting in this UR M61 have been updated to include a cross reference to the newly developed UR M84 - Capacity and availability of compressed air for essential services to ensure that the new requirements in UR M84 relating to compressed air for essential services are also fully considered together with the requirements for engine starting.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev.3 (Feb 2024)	20 February 2024	01 July 2025
Rev.2 (Aug 2023)	04 August 2023	01 January 2025
Rev.1 (Feb 2022)	04 February 2022	01 January 2023
New (Dec 2003)	Dec 2003	-

- **Rev.3 (Feb 2024)**

1 Origin of Change:

☑ Suggestion by IACS member

2 Main Reason for Change:

As part of the development of UR M84 - *Capacity and availability of compressed air for essential services* carried out under task PM23200 which addresses the capacity and availability of compressed air for essential services and which cross references UR M61 - *Starting Arrangements of Internal Combustion Engines*, it was considered appropriate to make a corresponding reciprocal update to UR M61 since both UR's are concerned with compressed air for essential services.

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None

4 History of Decisions Made:

UR M61 Rev.3 agreed by correspondence.

See separate TB document in Annex 4.

Technical Background –

(New) UR M61 'Starting arrangements of internal combustion engines'

deletion of
UR M49 'Availability of machinery' and
UR E8 'Starting arrangements of internal combustion engines'

1. General

There had been a long discussion in 1998-1999 with respect to the definitions of "deadship" and "blackout". The main reason was that the SOLAS definitions of blackout and deadship condition were quite different from those given in UR M49 (Rev.1, 1996).

2. UR M 49

At present, Rev.1 of M49 (1996) is effective.

In 1998, WP/MCH suggested that a footnote be added to UR M49.1 in order to make reference to SOLAS II-1/42.3.4 and 43.3.4. GPG 44 (1998) also considered that the existing UR M49.1 was to be isolated from M49.2, the latter together with UR E8 being relocated as new UR M61.

At the same time, GPG 44 decided that approval of Rev.2 of UR M49 be put in abeyance until the development of UI SC 124 was finalized.

UR M49 (Rev.2) and M61(New), so prepared by the Permanent Secretariat, were passed to WP/MCH for review. In particular, WP/MCH was to clarify the scope of application of **M49** and **M61** to non-SOLAS ships (part of WP/MCH Task 41).

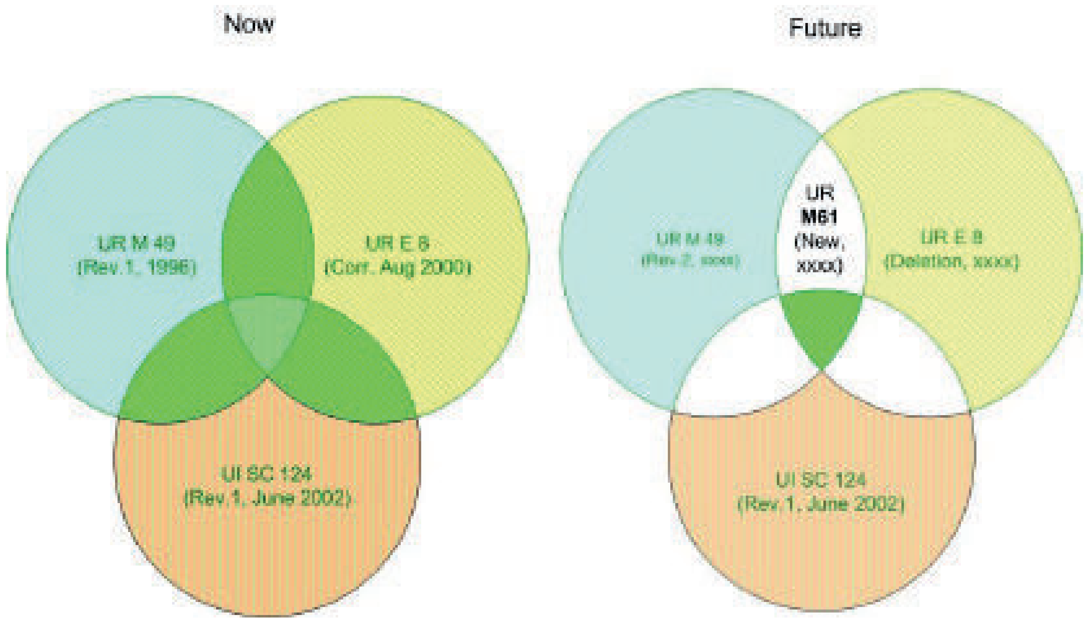
WP/MCH reported to GPG 52 (March 2002) that M49 should apply to all ships subject to further debate. WP/MCH consequently suggested in March 2003 (GPG 54) that an application note should be added to UR M49 to the extent that M 49 applies to non-SOLAS vessels. The draft footnote read: *These requirements (M49) apply only to ships required to comply with SOLAS [and ships above 200 GRT].* WP/MCH Chairman later confirmed in consultation with experts that the square bracket be removed. However, Council did not approve it (June 2003).

3. UI SC 124

GPG 44 (1998) found that the draft text of SC 124 did not clarify the definition of "deadship" and "blackout". UI SC 124 was then withdrawn and WP/MCH was tasked to develop an interpretation of the two terms with a view to elaborating a definition to be used in UR M49 and SC 124 and if necessary other resolutions. However, WP/MCH failed to reach a common understanding of the term "deadship condition" in 1998.
Hence, GPG 46 (1999) attempted to develop a generally agreeable definition. With assistance from the WP/MCH, GPG/Council finally approved UI SC 124 in

May 1999. It was submitted to IMO DE (DE 43/Inf.5). Revised in June 2002 and submitted to IMO MSC 76.

Status at this point



4. Tasking of WP/MCH

In August 2003 GPG tasked WP/MCH to consider

M49:

a. whether the text of UR M49.1(draft Rev.2, xxxx) should be amended in light of UI SC 124(Rev.1, June 2002) ;
b. whether the wording [and ships above 200GRT] should be deleted from the note to UR M49(draft Rev.2, xxxx) or retained;

M61:

c. whether the text of new draft UR M61 is appropriate, taking into account 7225_NVc of 26 May 98 from the then GPG Chairman.

5 WP/MCH submission

The WP concluded that text of UR M 61 is not adequate and changes suggested previously by GPG need to be introduced. However with the introduction of these changes M61.3 would become a word by word copy of SOLAS regulation II-1/44. Therefore WP did not see any need for this requirement as a class one and proposed to GPG to delete M61.3.

IMO has adopted MSC / Circ.736 (which is recommendatory) that interpreted SOLAS regulation II-1 / 44.1. There was a need to draft a UI that would simply reference the relevant paragraphs of this circular with respect to the regulation in question. This arrangement will create uniform application on behalf of the Flags in cases where a particular Flag is silent on circular application.

With the publication of the revised SC124 the need for UR M49 as it stands were now be brought into question. The origins of the UR M49 stem from SOLAS II-1 / 26.4 with the need to define what "dead ship" conditions entailed. In view of the latest SC124 it would now seem sensible to make a new UIs for SOLAS II-1 / 26.4 and HSC 9.1.5 and delete M49. In doing this it would make it clear that the requirements are only applicable to SOLAS / HSC vessels and obviate the discussions regarding the notes to M49. The definition of "dead ship" in the new UIs would be consistent with SC124.

With the above in mind WP / MCH:

i) proposed to delete M61.3,
ii) suggested to draft a UI that would reference relevant paragraphs of SOLAS Reg. II-1 / 44.1 and MSC / Circ.736,
iii) sought approval for the deletion of UR M49 and drafting of UI for SOLAS II-1 / 26.4 and HSC 9.1.5.

GPG concurred and approved the subsequent drafts and deletion of UR M49 and UR E8 (as per 3097cIGf of 12 November 2003; tacit 19 November) .

****

Permanent Secretariat 21 November 2003.

Technical Background (TB) document for UR M61 (Rev.1 Feb 2022)

1. Scope and objectives

Review of the required number of starts for internal combustion engines.

2. Engineering background for technical basis and rationale

Engine starting test is generally performed during Sea trials (some members require it in the mooring trials) to verify the total capacity of the air receivers to provide not less than 12 consecutive starts for an engine of reversible type (6 starts for an engine of non-reversible type). It has, however, been acknowledged that it is difficult to conduct the test with the engine in a cold condition because the engine is ready for start in a warm condition.

3. Source/derivation of the proposed IACS Resolution

None

4. Summary of Changes intended for the revised Resolution:

The requirements mentioning the engine conditions (such as cold conditions and warm running condition) have been deleted.

5. Points of discussions or possible discussions

Original version of UR M61 provides the requirement for the number of starting engines based on the cold condition and additional starting for the engine in a warm running condition. However, it does not provide a piece of specific advice for a required additional number of starts or definition of the warm running condition.

In this point, one member tried to find the reference for the additional number of starts in the warm running condition and proposed to delete the text if a detail requirement cannot be provided.

The majority members agree to delete the text, but the following opinions have been raised by other members:

a. One member expressed concerns about the temperature of engine room, which may have effects on the number of starts or may not be sufficient as contained mass of air in air bottles (at high temperature, say 55’C as example only) tends to exhaust rapidly without achieving the required number of starts.

   Some members agree with the concerns. On the other hand, the majority is of the view that the required test in UR M61 had been developed depending on the engine condition whether it is in cold or warm and the engine room temperature should be controlled taking into account UR M28 and M40.

b. One member proposed developing the guideline for improvement of wording and clarification on the total capacity of air receivers covering adverse conditions (cold starting, minimum air pressure, etc.), for instance:

the total capacity of air receivers > the required number of starts x the capacity of compressed air of P_{min} required for 1 starting attempt in the coldest condition anticipated for the engine

However, the qualified majority deems that there is no need for the starting test to be conducted in the coldest condition anticipated for the engine and the aforementioned proposal has not been reflected in the UR.

Besides, Members have confirmed that Rev.1 of UR M61 should also apply to gas turbines, which fall under the category "internal combustion engines".

6. Attachments if any

None

Technical Background (TB) document for UR M61 (Rev.2 August 2023)

1. Scope and objectives

Review of the requirements for the ratio of capacity of each starting air compressor to the total capacity.

2. Engineering background for technical basis and rationale

In a design in which the starting air receivers are also used for the control system, a third air compressor with a smaller capacity may be installed in addition to two air compressors with almost the same capacity in order to minimize the voltage fluctuation when the air compressor starts. (e.g. Total capacity is divided by a ratio of 40:40:20)
The UR was reviewed as it was not clear whether such a design complied with the requirements of the previous M61.1.2 and M61.1.3.

3. Source/derivation of the proposed IACS Resolution

None

4. Summary of Changes intended for the revised Resolution:

The requirements for the ratio of capacity of each starting air compressor to the total capacity have been clarified.

5. Points of discussions or possible discussions

It was confirmed that the percentage of air compressor capacity described in paragraph 2 was acceptable by members. But it was considered that it could conflict with the requirement of M61.1.2 quoted below. It was therefore decided to amend the text of M61.1.2.

"M61.1.2 Where the main engine is arranged for starting by compressed air, two or more air compressors are to be fitted. At least one of the compressors is to be driven independent of the main propulsion unit and is to have the capacity not less than 50 % of the total required."

On the other hand, although M61.1.3 states that "The capacity is to be approximately equally divided between the number of compressors fitted", it was agreed that this does not prohibit the above percentages.

6. Attachments if any

None

Technical Background (TB) document for UR M61 (Rev.3 Feb 2024)

1. Scope and objectives

To ensure that all UR's relating to compressed air for essential services, including engine starting, are readily apparent to industry.

2. Engineering background for technical basis and rationale

The changes introduced in Rev.3 of UR M61 recognise that the arrangements for the supply of compressed air for essential services in UR M84 are applicable to compressed air for engine starting which is the subject of this UR.

3. Source/derivation of the proposed IACS Resolution

Suggestion by member.

4. Summary of Changes intended for the revised Resolution:

A reference to 'low pressure compressed air systems' is added in UR M61.1.5 together with a cross reference to the new UR M84.2.2 - *Capacity and availability of compressed air for essential services.*

5. Points of discussions or possible discussions

Suggestion was agreed.

6. Attachments if any

None

UR M63 "Alarms and safeguards for emergency internal combustion (I.C.) engines"

Summary

In Rev.1 of this UR, the scope of required alarms and safeguards for fuel oil leakage in UR M63 has been clarified compared with UR M35 and M36.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev.1 (Jan 2023)	17 January 2023	1 January 2024
New (Jan 2005)	January 2005	-

- **Rev.1 (Jan 2023)**

1 Origin of Change:

☑ Suggestion by IACS member

2 Main Reason for Change:

Clarify the scope of required alarms and safeguards for fuel oil leakage in UR M63 compared with UR M35 and M36

Part B. Technical Background

List of Technical Background (TB) documents for UR M63:

Annex 1. **TB for New (Jan 2005)**

See separate TB document in Annex 1.

Annex 2. **TB for Rev.1 (Jan 2023)**

See separate TB document in Annex 2.

Technical Background (TB) document for UR M63 (New Jan 2005)

Current Unified requirements address, to a limited extent alarms and safeguards for emergency diesel engines. The purpose of an emergency diesel engine is to act as an alternative source of power for essential services for the safety of the ship in the event of the main source(s) being out of action or unavailable. It was therefore considered that requirements for automatic shutdown of such engines should be investigated to ensure consistent application of requirements regarding provision of automatic safeguards.

The WP/MCH has been tasked to investigate, develop and propose Unified requirement for alarms and safeguards for emergency diesel engines, including:

- requirements for alarms for the engine operating parameters that could affect the prolonged operation of the engine (e.g. high cooling temperature, LO low pressure and leakage of FO injection pipe).
- requirements for automatic shutdown of the engine when immediate breakdown of the engine (e.g. overspeed) is imminent.
- requirements for automatic shutdown in other cases (e.g. low cooling water pressure and use of over-ride arrangements).

In addressing the above, the WP reviewed SOLAS requirements applicable to emergency diesel engine operation, has established philosophy for alarms and safeguards for emergency diesel engines, has considered safeguards contained in URs M2, M3.2, M36 and of SOLAS regulation II-1/27.5, as a possible basis when determining safeguards applicable for emergency diesel engines.

The initial draft UR had been agreed by the WP, approved by GPG in March 2002 and submitted to Council in May 2002. Subsequently, in light of comments raised by Council Members the draft had been referred to WP/EL and WP/FP&S for their review and comments to WP/MCH.

Having received in September 2004 the comments from these two WGs, WP/MCH unanimously agreed the second drat UR which was submitted to GPG on 16 November 2004.

15/12/2004
KP

Technical Background (TB) document for UR M63 (Rev.1 Jan 2023)

1. Scope and objectives

Clarify the scope of required alarm and safeguards for fuel oil leakage in UR M63 compared with UR M35 and M36

2. Engineering background for technical basis and rationale

According to table 1 of UR M63, 'Fuel oil leakage from pressure pipes' shall be monitored and activated alarm irrespective of engine power for emergency diesel engines. The required parameter is intended for the prolonged operation of the engine, taking into account the technical background of M63.

On the other hand, a similar parameter, but applying to high pressure pipes, for main and auxiliary internal combustion engine is required in accordance with UR M35 and M36 respectively. For the UR M36, the parameter 'Fuel oil leakage from high pressure pipes' at table 1 had been amended from 'pressure pipe' at the Rev.3 in September 2008. Even if a background of Rev.3 was not traceable, it seems that the parameter was maybe amended depending on comparison with UR M35. And the goal seems for the fire protection like the SOLAS II-2/Reg.4.2.2.5.2.

3. Source/derivation of the proposed IACS Resolution

UR M35, M36

4. Summary of Changes intended for the revised Resolution:

Update the parameter "Fuel oil leakage from pressure pipes" in table 1 to "Fuel oil leakage from high pressure pipes" (adding the 'high' in the expression).

The parameter "Oil mist concentration in crankcase" is also updated by an expression same as in UR M35 and M36.

Update the table 1 to be presented by texts (e.g. high, low, x) instead of figure for improvement of understanding and further potential maintenance.

The term "I.C. engines" is modified to "reciprocating I.C. engine". And regarding the change of term, one member requested to clarify the application of UR M63 whether it can be applied to engines using other non-traditional fuel oil such as gas, ammonia, LPG, bio-derived fuels, and a flashpoint below 60℃. It is clarified that UR M63 applies to engines using fuels covered by ISO 8217.

5. Points of discussions or possible discussions

Regarding the addition part for application of UR M63.1,

- One member suggested applying the UR M63 to engine using distillate marine fuel covered by ISO 8217:2017.

- One member has been of the opinion that the expression for clarification does not need, because the SOLAS convention limits fuel with a flashpoint of not less than 43℃.

Both understandings are not wrong, but the Panel decided to add the text, taking into account the industrial practice and needs of clarification.

Regarding the parameter for fuel oil leakage in Table 1, the expression ‘fuel injection pipes and common rails’ is added to clarify the scope of high pressure pipes.

One Member questioned whether the F.O. leakage alarm of Table 1 of this UR should be applied to engines with unit injector, but the Panel confirmed that the said alarm should not be applied to unit injectors.

(IACS UR M64, 2003)
Technical background to the adoption of the new IACS UR M64

The scope of this new IACS UR has been derived from the investigations into the "IEVOLI SUN" casualty and possible lessons to be considered. This chemical tanker had installed an integrated cargo and ballast system driven by a hydraulic power pack. The power supply to the circuit was common with other consumers located in the forecastle space. The flooding of the forecastle space caused short circuit in an electric switch of component of the bow thruster thus determining the automatic shutdown of the integrated system. Due to this emergency stop, both the cargo and ballast pumps became inoperable. The activation of the ballast pumps would have delayed and/or mitigated the consequences of progressive flooding of the double hull spaces through the air vents due to reduction of freeboard.

The "IEVOLI SUN" had neither the power pack supply nor the control panel located in the fore flooded compartments. However, there are other installations on existing tankers where the power pack or control panels are located in the forward spaces, which might be at risk in the event of damage and flooding of these spaces due to extreme weather conditions.

The matter could generally be relevant to any integrated hydraulic or electric system used to drive both cargo and ballast pumps. This type of integrated systems is extensively installed on new tankers. Manufacturers of these systems have been consulted and have agreed the scope and general principles of the IACS UR, which, as intended, is to be applied to new designs of integrated cargo and ballast systems installed on new tankers, irrespective of their size.

The identified design features are intended to address designer's attention to the fact that in the event of failure of the automatic or remote control system, a secondary means of control is to be made available for the operation of the integrated cargo and ballast system. However, other design features can be found to achieve the same objective.

Finally, some of the design features indicated in this IACS UR might be applicable to all remotely controlled cargo and ballast systems and not only integrated systems. Through this IACS UR, designers should become aware that, in general, the operation of remotely controlled cargo and ballast systems may be necessary, under certain emergency circumstances or during the course of navigation, to enhance the safety of tankers.

Note: A proposal to establish a lower limit of size application (..tankers of 1,000 DWT and above…) in M64.1 was not agreed by GPG.

Submitted by the Chairman of the CG/ICB

Date: March 2003

Technical Background Document for new draft UR for Draining and Pumping Forward Spaces in Bulk Carriers

1. Scope and Objective

MSC 76 adopted new SOLAS regulation XII/13 on the availability of pumping arrangements. Thereafter IACS has identified a need for a Unified Interpretation of this regulation that would interpret the arrangements necessary to bring into operation the means for draining and pumping of spaces covered by the regulation.

However the argument was put forward, and accepted as valid, that the regulation lacks the requirements for the capacity of dewatering system. Subsequently it was agreed that these requirements are to be additional to the SOLAS regulation, should be applicable to new ships and thus take the form of an IACS UR.

The draft UR is written to apply to all new bulk carriers as defined by regulation XII/1.1, of single or double side skin construction, and has no ship length limitations.

2. Points of discussion

The first draft was given to the WP by GPG with a task to review the draft in light of GPG Members' comments. These comments had focused on one aspect of the draft UR that had proposed to regulate the capability of the dewatering system by means of specifying the speed of removing water through a piping system.

WP Members had reviewed their GPG Members' objections to that aspect of the draft. Two Members (ABS and NK) did not consider it necessary to specify a minimum speed for removing the water from the forward spaces, as per item 1. b) of the original draft, in addition to the dewatering rate specified under item 1.a).

3. Source/derivation of proposed amendments

MARIN reports made available to the Derbyshire Formal Inquiry include identification of testing that in typhoon "Orchid" conditions with the ship in its intact state, initial flooding through one open 500mm diameter hole could be as much as 63 tonnes per hour. Once flooding had commenced, the rate could increase rapidly to values between 100 to 650 tonnes per hour. For the purpose of identifying a realistic dewatering rate as a minimum requirement, the 63 tonnes per hour through a 500 mm opening has been used as a basis for any size opening. In round figures, 320 A m3/hr equates to 63 tonnes/hr through a 500 mm opening.

4. Decision

As mentioned in section 2 above, 2 Members have explicitly agreed to the draft UR subject to deletion of the speed of dewatering requirement. With tacit acceptance by the remaining Members the draft was agreed by consensus.

KP

UR M66 "Type Testing for Crankcase Explosion Relief Valves"

Summary

In Rev.4 Corr.1 of this Resolution, references to industry standards have been corrected.

There are no separate TB documents for Rev.1 Corr.1 (Mar 2007) and Rev.2 Corr.1 (Oct 2007).

Technical Background

Revision UR M9 (Rev.3) and M10(Rev.2)
New URs (M 66 & M67) for Type Testing Crankcase Explosion Relief Valves and Oil Mist Detection Arrangements

1. WP/MCH Task 55 was established to review the requirements in URM9 "Safety valves for crankcases of internal combustion engines" and M10 "Protection of internal combustion engines against crankcase explosions" for applicability and suitability to modern diesel engines.

2. The work specification included the following:
    - Review crankcase explosion reports for the past 10 years.
    - Review SOLAS requirements applicable to diesel engine crankcase safety.
    - Establish philosophy for a holistic approach to crankcase safety.
    - Consider the applicability of the safeguards in M9 and M10 for crankcase to all types of modern diesel engines – (high speed, medium speed and large slow speed engines + "large" and "small" bore engines).
    - Propose a set Unified Requirements for crankcase safety that include:
        - Requirements for submission of plans and particulars
        - Assessment of engine arrangements
        - Design of equipment
        - Testing of equipment and safety arrangements
        - Type testing requirements
        - Monitoring arrangements
        - Protection of engine and personnel
        - Through life survey and inspection

3. The background to the task was that there have been a number of serious incidents involving crankcase explosions in large diesel engines in the past 5-6 years that have resulted in loss of life and major damage to ships and their machinery. Questions have been raised regarding the adequacy of current standards for crankcase safety with engine builders and ship-owners pressing for revision/re-assessment of the current the standards that essentially stem from the Reina del Pacifico incident in 1947.

4. UR M9 has been extended to address design requirements for explosion relief valves in terms of a required provision of a flame arrester that prevents the passage of flame following a crankcase explosion and for valve to be type tested. The possible effects of shielding on relief valve efficacy have been recognised with a requirement for testing if such shielding is fitted.

5. The revised M9 also includes requirements for a manufacturer's installation and maintenance manual with instructions installation, maintenance and actions required to be followed after a crankcase explosion. Requirements for marking of the valves have also been included.

6. UR M10 has been revised to remove requirements for the explosion relief valve (moved to M9) and clarify the existing text. The revised M10 now includes requirements for type testing of oil mist detection/monitoring systems and compliance with the oil mist manufacturer's instructions. Requirements for arrangements and installation onto the engine have been defined and also for system testing.

7. UR M10 also addresses alternative methods of preventing the build-up of oil mist and methods of assessment.

8. To support the extensive revisions to M9 and M10 new Unified Requirements for type testing explosion relief valves and for oil mist monitoring/detection arrangements have been developed. These URs provide a common standard against which relief valves and oil mist monitoring/detection systems cane be assessed. They define the scope, purpose, test facilities, processes, assessment and reporting.

Note by the Permanent Secretariat:

1. GPG added the following implementation statement to the URs:

> "Engines are to be fitted with components and arrangements complying with this UR when:
> 1) an application for certification of an engine is dated on/after 1 January 2006; or
> 2) installed in new ships for which the date of contract for construction is on or after 1 January 2006."

2. The URs (M 66 & 67, M9(Rev.2) and M20(Rev.3)) do not apply to existing engines on the existing ships.

Submitted by WP/MCH Chairman 24th August 2004

Technical Background Document
UR M9(Rev.3, Corr.1, November 2005)
UR M10(Rev.2, Corr.1, November 2005)
UR M66(New, Corr.1, November 2005)
UR M67(New, Corr.1, November 2005)

1. These UR Ms were adopted in Jan 2005 for implementation from 1 Jan 2006.

2. However, IACS was requested, via the Machinery Panel, by CIMAC and MAN/B&W, to postpone the 1 Jan 06 implementation date for the type testing requirements for crankcase explosion relief valves and crankcase oil mist detection/monitoring and alarm arrangements contained in IACS URs M66 and M67, respectively.

3. This discussion led to re-issuance of these UR Ms, changing the implementation statements.

These UR Ms were re-issued as ‘Corr.1’ on 29 Nov 2005.

4. GPG Chairman’s message (4069gIGk, 14/11/2005) contains a more detailed background for this amendment.

For records, GPG/Council Chairmen’s messages are attached to the TB document for the January 2005 versions.

Subject: 4069gICd: UR M66, M67 - application date

Date: 23 Nov 05

TO: IACS Council Members

TO: IACS GPG Chairman & Members

TO: IACS Permanent Secretary: Mr. R. Leslie

TO: IACS Machinery Panel Chairman: Dr. U. Petersen

FROM: R. D. Somerville
File Ref: T-12-2

Subject: 4069gICd: UR M66, M67 - application date

1. All Members have replied to ICc. Eight Members have supported the proposed course of action in IGk.

2. Lloyd's, supported by RINA, proposes that the URs need not be withdrawn, as proposed in IGk, but that only the implementation date need be changed. LR proposed posponement to 1 July 06 -- instead of 1 Jan 07, as proposed in IGk.

2.1 Regarding the implementation date of 1 July 06 vs. 1 Jan 07, this had already been debated in GPG and the strong majority supported 1 Jan 2007. I conclude 1 January 2007 is agreed.

2.2 Regarding whether to "withdraw" the URs or "postpone" their date of application, to my understanding either approach is acceptable and will result in the same outcome.

3. Therefore to accomodate the request that the URs not be withdrawn, I conclude that the agreed course of action is:

3.1 **Perm Sec** is to revise the uniform application statements for the URs, as follows, reissue them, and post them on the IACS website:

3.1.1 For URs M66 and M67:

"Note: Engines are to be fitted with components and arrangements complying with this UR when:
1) an application for certification of an engine is dated on/after 1 January 2007; or
2) installed in new ships for which the date of contract for construction is on or after 1 January 2007."

3.1.2 For UR M9, Rev.3:

"2. Engines are to be fitted with components and arrangements complying with Revision 3 of this UR, except for M9.8, when:

1) an application for certification of an engine is dated on/after 1 January 2006; or
2) installed in new ships for which the date of contract for construction is on or after 1 January 2006.
The requirements of M9.8 apply, in both cases above, from 1 January 2007."

3.1.3 For UR M10, Rev.2:

"2. Engines are to be fitted with components and arrangements complying with Revision 2 of this UR, except for M10.8, when:
1) an application for certification of an engine is dated on/after 1 January 2006; or
2) installed in new ships for which the date of contract for construction is on or after 1 January 2006.
The requirements of M10.8 apply, in both cases above, from 1 January 2007."

3.2 **Machinery Panel** is to:
a. inform CIMAC and MAN/B&W of the postponed application of URs M66 and M67, and the intention to update them;
b. update URs M66 and M67, as quickly as possible, taking account of CIMAC's, MAN/B&W and Panel Member's inputs;
c. once adopted at Panel level, send the revised URs to CIMAC for quick review/comment and notification to the equipment suppliers;
d. further update the URs as needed in light of any comments received from CIMAC;
e. submit the revised URs to GPG for approval not later than the end of the 1st Q 2006.

3.3 Upon adoption of the revised URs by IACS Council, **Machinery Panel** is to send them to CIMAC for their information and requesting that CIMAC notify the equipment suppliers of the requirements.

Regards,
Robert D. Somerville
IACS Council Chairman

CC: IACS Permanent Secretary: Mr. R. Leslie

FROM: S.R. McIntyre

File Ref: T-12-2

Subject: 4069gIGk: UR M66, M67 - application date

1. IACS has been requested, via the Machinery Panel, by CIMAC and MAN/B&W, to postpone the 1 Jan 06 implementation date for the type testing requirements for crankcase explosion relief valves and crankcase oil mist detection/monitoring and alarm arrangements contained in IACS URs M66 and M67, respectively. Their request is to give the equipment manufacturers and the engine builders more time to adapt to the new requirements. Industry has also recommended the need for some improvements/clarifications in the two URs, which the Machinery Panel has agreed are needed/appropriate.

1.1 Since CIMAC was involved in the IACS decision, some years ago, to develop these URs, in retrospect it would have been advisable to submit the URs for external review by CIMAC before their adoption to ensure that CIMAC would be fully aware of the requirements and the timetable for their implementation--and working with IACS Societies to ensure that their suppliers were apprised of and complying with the new requirements. Unfortunately, this was not done.

1.2 The type testing requirements of URs M66 and M67 are invoked in recent revisions of M9 and M10, respectively.

2. The Machinery Panel recommended that GPG postpone implementation of URs M66 and M67 and advised GPG that both URs need to be updated/clarified.

2.1 Several Members have also advised that they needed more time for initial implementation and could not implement the two URs from 1 Jan 06 as had been originally agreed by Council.

3. Having carefully considered the input from CIMAC, MAN/B&W, the Machinery Panel and Members, GPG agrees that IACS should postpone the implementation of these URs by one year to give time for updating them, vetting the changes with CIMAC, notifying industry and for Members to process the related rule changes. Therefore, GPG requests Council's agreement to the following course of action:

3.1 URs M66 and M67, along with M9.8 of M9, Rev.3 and M10.8 of M10, Rev.2 are to be withdrawn pending the updating of M66 and M67, which needs to be accomplished as quickly as possible (ie. the target date of 1st Q 2006 for revising M66, agreed at GPG 59, needs to be accelerated);

3.2 The updated URs, once adopted at Panel level are to be sent to CIMAC by the Machinery Panel for quick review/comment by CIMAC, and then further updated by the Panel in light of any comments received, prior to submission to GPG/Council;

3.3 The updated URs M66 and M67, once adopted by GPG/Council, are to be issued as "Corr" (since the initial versions will never have been implemented)--with uniform application from 1 Jan 2007 (instead of 1 Jan 2006);

3.4 M9, Rev.3 without M9.8, and M10, Rev. 2, without M10.8, are to be reissued as "Corr" until the updated M66 and M67 are adopted by Council, at which time M9.8 and M10.8 are to be included in M9, Rev.4 and M10, Rev.3, respectively for application from 1 Jan 2007.

4. Council Chairman is kindly requested to seek Council's agreement to this course of action as soon as possible.

Regards,
S.R. McIntyre
IACS GPG Chairman

Technical Background Document
UR M66 Rev.1 (October 2006)
Type Testing Procedure for Crankcase Explosion Relief Valves

Scope and objectives

UR M66 is currently issued as 'Corr.1' with an application from 1 January 2007. During discussions at the joint Machinery Panel/CIMAC meeting in September 2005 it was the common view that UR M66 requires some further improvements/ clarifications. Accordingly, a new task for the Machinery Panel was raised (PM5104) and the Panel tasked to revise M66 with a view to address CIMAC concerns and to remove errors and ambiguities.

Points of discussion or possible discussions

Changes to UR M66 are mainly of an editorial nature to clarify specific requirements. In the course of the review process comments were received from CIMAC, Penn-Troy Manufacturing and Pyropress (see Appendix).

CIMAC's comments were discussed at the joint Machinery Panel/CIMAC meeting in September 2005 and again at the CIMAC WG2 meeting on 7 September 2006 and at the joint Machinery Panel/ CIMAC meeting on 19 September 2006. The Panel's response is indicated in the attached CIMAC proposal of 22 September 2005. All comments were taken into consideration by the Panel in the review process.

Penn-Troy Manufacturing approached IACS with a concern about the applicability of UR M66 to their explosion relief valves which feature internal oil wetting of the flame arrester as part of the design. The Machinery Panel considered this issue and agreed to add a 'Note' under paragraph 1.2 allowing for this feature.

Pyropress UK approached IACS with concerns about the M66 requirement for a free area of explosion relief valves of not less than 115 sq cm per cubic metre of crankcase gross volume as their valves are designed for a ratio of typically 700 sq cm per cubic metre. The Panel agreed that as long as the purpose in item 3 of M66 is verified the prescriptive requirements relating to the 115 ratio need not be insisted upon. To that effect a new 'Note 2' was introduced in paragraph 4.1.11.

LR recalled that the origins of the minimum standard of 115 sq cm per cubic metre for crankcase relief stem from work carried out in the late 1940s and 1950s and theory presented by Benson and Burgoyne on ignition in closed spherical vessels with central ignition.

The final draft text of M66 was sent to CIMAC on 21 July 2006 with a four week deadline for comments. A corrigendum for item 7.2.1.1 was sent on 17 August 2006. CIMAC reverted on 1 September 2006 with a proposal to modify item 9 'Design series qualification' (see Appendix). This proposal was discussed at the CIMAC WG2 meeting on 7 September 2006 and at the joint Machinery Panel/ CIMAC meeting on 19 September 2006 and further modified as reflected in the new paragraphs 9.3 and 9.4.

The Panel at its 4th meeting (19 – 22 September 2006) considered whether the new paragraphs 9.3 and 9.4 constitute technical changes rather than clarifications. It was the Panel's view that they are relaxations compared with the previous requirements and should therefore not affect the implementation date of 1 January 2007.

Source/derivation of proposed requirements
N/A

Decision by Voting (if any)
The revised text was agreed unanimously by Panel members.

Appendix
The following comments from industry were received in the course of the revision of M66 (attached):
- CIMAC (22 September 2005)
- Penn-Troy Manufacturing (26 May 2006)
- Pyropress (9 March 2006)
- CIMAC (1 September 2006)

Machinery Panel Chairman

<u>Permanent Secretariat Note:</u>
Subject no. 4069g – agreed by GPG and Council 16 October 2006 (IGq).

CIMAC CWG „CS-D“ WG2

Proposal towards IACS Machinery Panel

St. Stutz/Secretary WG2 22.09.2005

Subject: New Unified Requirement IACS UR M66

Background

As the final text in IACS UR M66 has not been discussed with Cimac CWG2 before coming in force and in the light of a usually good cooperation between IACS and Cimac we kindly ask IACS MP to take the below comments into consideration and reconsider the final text and the date for coming in force.

For the valve makers it might be difficult to overcome the situation in time as they should get the possibility to prepare themselves (get familiarized) with the new situation.

Proposal

The date of coming into force of the new UR M66 is strongly recommended to be postponed until a common text has been agreed between IACS, CIMAC and the valve makers and enable the valve makers to prepare themselves.

Following M66 items are recommended to be revised taking into consideration the respective comments below:

5.1

We feel that the pressure 0.2 bar is an unnecessary requirement as the valves have to open at 0.05bar and not at 0.2bar (full open at 0.2 bar)

Panel: *Wording changed to ".... The pressure in the test vessel is to be not less than atmospheric and is not to exceed the opening pressure of the relief valve."*

6.2

The requirements for 0.2bar have been discussed with N. Rattenbury several times. He accepted to specify a lower opening pressure. The IACS requirement 0.2bar means a pressure where the valve is fully open. But it has to be taken into consideration that these 0.2bar are rather related to the spring characteristic and thus we do not see any inconsistency of a pressure between 0.05 and 0.2bar.

-2-

Furthermore, some trunk engines shall have a higher opening pressure of 0.1bar. For which engines then M66 should be valid?

***Panel**: Wording changed to "…. demonstrate that the opening pressure is in accordance with the specification within a tolerance of +/- 20 % and …"*

The tolerance level of 20% was selected on the basis of the valve manufacturer's published data. It is considered that it is the valve manufacturer rather than the user who should provide the technical data relevant to the product. It is not clear why CIMAC members should wish to re-define the OEM's specification.

7.2.2.3

We propose to revise the text as follows:
"Provided that the first explosion test successfully demonstrated that there was no indication of combustion outside the flame arrester, a second explosion test without the polythene bag arrangement is to be carried out in as rapid sequence as possible. During the second explosion the valve is to be monitored by video recording and preferably by recording with a heat sensitive camera.

***Panel**: Covered by 7.1.3 and 4.1.5*

7.2.2.4

Under this item it is proposed to maintain the valve closed for 10 seconds but under 6.2 a time of 30 seconds is mentioned. Why this discrepancy?

***Panel**: The Panel clarifies that the different time periods required in paragraphs 7.2.2.4 and 6.2 apply to different test conditions (cf. Minutes of joint Machinery Panel/CIMAC meeting, September 2005).*

8.1.2

How to check the valve lift?

***Panel**: The Panel clarifies that the objective of this paragraph is to determine the cross sectional area and lift after an explosion (cf. Minutes of joint Machinery Panel/CIMAC meeting, September 2005).*

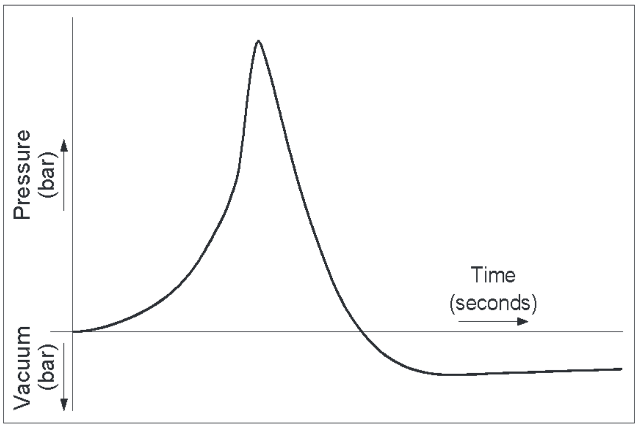
8.1.7

Where do these values come from "0.3bar underpressure for 10 seconds"?
See also 7.2.2.4.

***Panel**: These values have been determined from actual field tests/measurements and are considered to provide an acceptable baseline for assessment purposes. The following explanation was provided to CIMAC:*

<u>Typical Crankcase Pressure/Time Curve – Crankcase Explosion</u>

The diagram below shows a typical pressure/time with a simulated crankcase explosion. There will be an under-pressure (vacuum) following the pressure rise due to the explosion as air and combustion products are expelled through the relief valve during the explosion sequence. The explosion sequence takes place over a very short period of time and the recording equipment needs to be capable of recording at a very fast rate which requires a large memory. Recording of the pressure variation over ten seconds time duration from the start of the ignition sequence is achievable with readily available equipment and is considered to sufficient to ascertain that the valve has re-seated after an explosion. The 0.3 bar under pressure (vacuum) is consistent with what has been found during testing of the different valves.



NR
16th November 2005

<u>9.1</u>

We propose to revise the text as follows:
“A series of valves can be approved on the bases of a single test of one device of a medium size if all geometric features of the valve can be scaled linear and that all valves have the same nominal opening pressure and flame arrester fulfil the requirement 9.2”.

***Panel**: Propose to keep paragraph 9.1, subject to editorial corrections (cf. Minutes of joint Machinery Panel/CIMAC meeting, September 2005).*

<u>9.2</u>

“flame screen” is to be changed to “flame arrester” in first and fourth line.

***Panel**: Agreed, the term ‘flame arrester’ will be used.*

Dr. Petersen

Thank you for your reply. I too have been traveling and I am sorry for the delay in responding to you.
Penn-Troy has done testing some years ago showing the effectiveness of the oil wetted BICERA flame trap. The BICERA Internal Flame Trap was originally researched and patented by BICERA. (now BICERI) In part, their research was in response to a crankcase explosion aboard the REINA DEL PACIFICO. (See link: http://brew.clients.ch/engine.htm)

The oil wetting of the screen comes from the normal splash and spray of oil in a crankcase. It is important that when testing that the oil wetting also be simulated. When Penn-Troy did testing, it was with a small oil pump spraying an oil mist on the screen to simulate a normal crankcase environment. Flame emission was determined by film and direct observations.

Regarding the US Coast Guard specifications, they require relief valves with a screen type flame arrestor and also require a minimum of 1.5 in2 of relief area for each cubic foot of crankcase volume.
(345 cm2/ 1 Meter3) This is three times the minimum relief area stated in the IACS specifications.

One question that has come up is the means of adjusting the volume of the test vessel. In our testing, Penn-Troy regulated the required test vessel volume by adding oil or water to the vessel to reduce the internal air volume of an oversize vessel to match the size valve being tested. I assume that this same method can be used to reduce the internal air volume of the test tanks used for IACS testing. It is a practical way of maintaining the correct volume per section 4.1.12 of M66.

Greg Powers

----- Original Message -----**From:**MCH-Panel **To:** gwpowers@epix.net **Cc:** GYH **Sent:**Wednesday, June 07, 2006 5:52 AM **Subject:** UR M66, Task 5104

Date: 7 June 2006

Dear Mr Powers, first of all my apologies for the delayed response, I have been out of the office most of the time recently. Regarding your enquiry please be advised as follows:

1. Engines are to be fitted with components and arrangements complying with UR M66 when: a) an application for certification of an engine is dated on/ after 1 January 2007, or b) installed in new ships for which the date of contract for construction is on or after 1 January 2007.

1 IACS decided on the application date 1 January 2007 to give industry sufficient time to prepare for the test procedure. Currently the IACS Machinery Panel revises the text of January 2005 to respond to specific feedback from industry. The review is not intended to introduce substantive changes but rather to improve the clarity of certain requirements. The review is due to be completed shortly.

2 The objectives of the test procedure in UR M66 are fourfold:

3.1 To verify the effectiveness of the flame arrester,
3.2 To verify that the valve closes after an explosion,
3.3 To verify that the valve is gas/air tight after an explosion, and
3.4 To establish the level of over pressure protection provided by the valve. The test procedure laid down in UR M66 does not make specific reference to oil wetting of internal flame arresters. In this context it would be of interest to learn which test specification Penn-Troy Manufacturing uses for its flame arresters, what kind of tests are conducted and how it is verified that no flame passes through the valve. I note from the literature enclosed with your emails that Bicera valves meet specifications from the U.S. Coast Guard, ABS and other classification societies. Which specifications are these? Do they relate to the pressure relief capability or also to the flame arrester? I look forward to hearing from you,

Regards,
Dr Ulf Petersen
IACS Machinery Panel Chairman

-----Ursprüngliche Nachricht----**Von:** Greg Powers [mailto:gwpowers@epix.net]
Gesendet: Freitag, 26. Mai 2006 15:30 **An:** MCH-Panel **Betreff:** Fw: Reference: UR M66, Task 5104

Dear Dr. Petersen / Machinery Panel

Could you update me with your progress on revisions to M66, Crankcase Relief Valves?

Our company is concerned with a couple of issues:

1 UR M66 seems to make no provision in the test for oil wetting of the flame suppression screen of relief valves with internal flame traps. Our Bicera Valve has an internal flame trap. The normal oil splash of a crankcase wets the surface of the flame suppression screen and enhances it's effectiveness substantially. The new testing criteria should make allowance for this feature if internal flame traps are used.
2 The Bicera Valve was designed from the beginning to incorporate an internal, oil wetted flame arrestor as well as an external cover to direct the exhaust. The large, external flame arrestor of some valves make it difficult and cumbersome to add a deflector cover because the external flame arrestor takes up so much area. To give the exhausting gasses room to flow between the flame arrestor and the deflector cover would require a very large cover relative to the valve size. The Bicera Valve

does not have any external flame arresting components to inhibit the flow of the gases. The internal flame arrestor has a large surface area relative to the size of the valve, and it's efficiency is increased by oil wetting from the normal oil splash present in crankcases.

Please let me know if I can provide any further information.

Gregory Powers
Penn-Troy Manufacturing

To: jennydeedman@iacs.org.uk
Subject: explosion relief valve, M66

Jenny Thank you for your e-mail and copy of M66.
However I have some additional quires which I have initially directed to Collin Wright as the contact I was passed to ref. my telephone conversation 3.3.06.

For the attention of Collin Wright.
Collin. Reference our recent telephone conversation I have a query concerning IACS standard M66. I understand you may be more of a tank rather than a case expert however if you can help, I have a project of updating and re-certifying our crankcase explosion relief valves. Our valves originated from BICERI (British Internal Combustion Engine Research Institute) from whom we manufactured under licence, these valves have a long track record and have been shown to be affective within the design parameters laid down. We are now looking for registration with relevant approval and with testing to IACS M66. One major difference between the two standards is the relief area to cubic volume. M66 calls for 115 cm sq /M.cu; this relates to a BICERI figure of 700 cm sq /M.cu.

M66 section 4.1.12 gives 115 as a minimum " relief valve to be not less than 115 cm sq/ M cu of the gross volume." This would indicate larger relief areas are acceptable, but the testing volume is then tied down to +15% to 10% from the 115 volume ratio.
This effectively restricts all valves designed to BICERI criteria, which are fit for purpose if sized appropriately.

I would be grateful if you could give any information on the origins of 115 cm sq/ M cu for flame arresters and whether M66 is likely to be amended to accommodate larger relief area valves.

Regards

Martin Elver

CIMAC comment on final draft UR M66, 1 September 2006

To: Dr. Ulf Petersen, Chairman IACS Machinery Panel

Subject: IACS UR M66, comments to final draft version of 17 Aug. 2006

Dear Mr. Petersen,

Referring to your e-mail of 17 August 2006, we ask you kindly to consider the following (very late) comments.

We appreciate your effort to finalize the wording on IACS UR M66, and in general, we agree to the text. However, we believe some areas could be defined more precisely.

Our objective is that the tests should result in approved valves to be used on diesel engines. For example, on some two-stroke engines valve sizes from “173” to “735” are used.

During the tests in 1999, we tested the two sizes of valves “173” on a 1.6 m3 test vessel, and a valve size “420” on a 10 m3 test vessel.

Those tests formed the basis for approval of the whole series of valves.

We presume that similar test procedure can be used again; however, in Item 3 (Purpose) on page 1, four purposes are mentioned that is 3.1.1 to 3.1.4.

In the present IACS UR M 66 revision of August 2006, only Item 3.1.1 is taken in consideration in Item 9.

Therefore, we are suggesting the following modifications of Item 9.1 and 9.2:

9.1 A series of valves can be approved on the basis of a single test of one device of a medium size, if all geometric features of the valves are scaled linear, and that all valves have the same nominal opening pressure. In addition, it has to be documented that the spring characteristics ensure that the valve will be completely open at a pressure of 0.2 bar, and that the flame arrester fulfils the requirement in 9.2

9.2 The qualification of quenching devices to prevent the passage of flame can be evaluated for other similar devices of identical type where one device has been tested and found satisfactory.
The quenching ability of a flame arrester depends on the total mass of quenching lamellas/mesh. Provided the materials, thickness of materials, depth…………etc.

Beside our comments to item 9, we have a small whish to change the texts in item 7.2.2.3. We believe that the wording “and there are no signs of damage to the flame arrester or valve” will course many arguments regarding what is considered a damage (?). Conclusively, if the valve is able to function during the second test, then it should be accepted. Nevertheless, we will recommend our customers to replace the flame arrester after a crankcase explosion.

For your further information, Cimac WG 2 will have an ordinary group meeting on 7 September 2006, at MTU in Friedrichshafen.

Mr. C Hardler participates as a Cimac member, and Mr. Norman Rattenbury as an IACS representative.
The topic IACS UR M 66 is on the Cimac agenda.

Best regards,
Kjeld B Hansen
Cimac WG2 Chairman

Technical Background, Internal

UR M66, Rev.2 (Sept 2007)

Scope and objectives

UR M66 Corr. 1 as currently published on the IACS website has been used as a basis for tests of crankcase explosion relief valves at FTZU in Ostrava, Czech Republic in April 2007. During the tests it became apparent that the location of the flange at 1/3 distance from the end of the test vessel may lead to unstable and not reproducible conditions inside the test vessel after ignition of the methane in air mixture. Furthermore, the flame arresting capability of the valves could not always be clearly determined from observations and video recordings. It was considered necessary by all parties attending the tests (class representatives from LR, GL and RS, engine designers MAN and Wartsila and experts from the test laboratory) to record tests with a heat sensitive camera to identify any possible flame transmission.

Valve manufacturers requested fewer valve sizes of one particular design to be tested in order to obtain a balanced requirement for valve sizes to be tested given the considerable effort involved in the tests.

The Panel has addressed the points above and made corresponding modifications in Corr. 2 of M66. In addition, some editorial improvements and clarifications were introduced.

Points of discussion

<u>UR M66 Corr. 2</u>
The RS Panel member made two proposals for changes to the M66 Corr. 2. The first relates to tolerances in 4.1.3 (-2.5% instead of -1%). The second suggestion relates to means of ignition in 5.4 (proposal to add ‘or equal alternative means of ignition’). RS indicated that these proposals could also be considered in future revisions of M66 and that they did not insist on their implementation at this point in time (PM7101_RSb of 6 June 2007). Since LR and GL explicitly did not support these proposal and no further comments were received from Panel members it was concluded not to adopt these proposals now but to re-consider them in a future revision of M66.

Externally, the changes in M66 Corr. 2 were discussed with representatives from MAN and Wartsila at a meeting arranged by GL on 10th May 2007. Both engine builders supported the changes.

<u>Implementation date</u>
The implementation date of M66, Corr. 1 as published on the IACS website is 1st July 2007. Hoerbiger in particular has expressed concerns about this date, stating that they require 12 to 18 months to set up a new production line and requesting an unspecified extension for the implementation date (cf. Annex 1). Taking into account these concerns RS, KR, NK, DNV and ABS supported a new implementation date for M66, Corr. 2 of 1 January 2008. In principle LR and GL also agreed to this date, however, there was still some discussion in the Panel about the interpretation of the application statement which would then read:

Quote
Note: Engines are to be fitted with components and arrangements complying with this UR when:
1) an application for certification of an engine is dated on/after 1 January 2008; or
2) installed in new ships for which the date of contract for construction is on or after 1 January 2008.
Unquote

LR, GL and ABS are anxious to implement M66 Corr. 2 at the earliest possible opportunity. In 2006 GL recorded several instances of crankcase explosions while LR recorded 143 crankcase explosions in its classed fleet in the period 1990 to 2001 and several more since. Other members also report crankcase explosions on vessels classed by them. As further discussions about the interpretation of the above Note remained inconclusive, and in view of the urgency of the matter, it was concluded to revert back to GPG and seek advice about the exact wording of the application statement.

Source/derivation of proposed requirements

Experience gained from tests conducted at FTZU in Ostrava in April 2007.

Decision by voting

The revised text of M66 was supported by all members commenting (with the RS concerns outlined above)

Regarding the implementation date the positions were as follows:
Support for 1 January 2008: RS, KR, NK, DNV, ABS, LR, GL
Support for 1 July 2007: CCS
Both dates acceptable: IRS
No comments: BV, RINA

The wording of the application statement remained inconclusive at the time of writing.

Hamburg, 26 June 2007
Chairman IACS Machinery Panel

Permanent Secretariat note (September 2007):

GPG discussion

By 2/3 majority (RS disagreed, DNV did not reply) GPG decided that the new version of UR M66 should be a Rev.2 rather than a Corr.2 since the technical content of the UR has been changed. The technical content of the revised UR M66 was agreed by all replying members.

After discussion GPG agreed on the following implementation statement for UR M66 Rev. 2:

"Engines are to be fitted with components and arrangements complying with this UR when:
1) the engine is installed on existing ships (i.e. ships for which the date of contract for construction is before 1 January 2008) and the date of application for certification of the engine is on or after 1 January 2008; or
2) the engine is installed on new ships (i.e. ships for which the date of contract for construction is on or after 1 January 2008)."

ABS proposed to withdraw all previous versions of UR M66 since they all appear to be flawed, however as BV currently has files under review which are being certified against UR M66 Corr.1, it was concluded that this was not possible and UR M66 Rev.2 would simply replace Corr.1 for projects covered by the aforementioned implementation statement.

UR M66 Rev.2 was approved 14 September 2007, ref. 4069gIGv.

Subject: **Type Approval for Explosion Relief Valves & New IACS Rules**

Dear Mr. Petersen,

Since many years Hoerbiger Vienna manufactures explosion relief valves for marine diesel engines. Per year we supply more than 20.000 relief valves for the engine industry. These valves are often inspected by external classification authorities based on valid type approvals.

Since 2005 (when IACS updated the rule M66) Hoerbiger has spent substantial effort to improve the existing valves to fulfil the rules. We have performed several tests at the testing institute FTZU, but we did not pass so far. You may already have received the information that the new rules require substantial higher strength of existing explosion relief valves.

After a long phase of tests and improvements we finally informed members of the IACS authority mid April 2007 during a meeting in Ostrava, that Hoerbiger will design a complete new relief valve to fulfil the new rules. At the same meeting discussions have been held if the test procedures (as defined in M66) shall be modified in some points.

HOERBIGER

Next week Hoerbiger is going to do internal tests with the new design at FTZU and as a next step we plan to invite the classification societies for official type approval tests within 2 months. To prepare the official tests we kindly ask you to inform us if the IACS rule M66 is going to be modified in the near future based on the discussions held in Ostrava.

If the new design passes the official tests successfully Hoerbiger will require a 12 to 18 month time frame to setup new production and assembly lines. Since the new design builds larger some engine manufacturers will have to adapt their frame constructions to incorporate our valves.

We kindly ask you to extend the due date in the M66.

Please inform us, if there will be any official statement by IACS in this regard.

Best regards

TECHNICAL BACKGROUND

UR M66, Rev.3 – January 2008

1. IACS has received several letters from Industry raising concerns about the application of revision 2 of UR M66. As a result of that GPG members were asked to comment on the following issues:

   (i) Support or disagreement to CCS proposal to move the date in the application statement to 1 July 2008;

   (ii) Support or disagreement to NK proposal to substitute "the date of application for certification of the engine" with "application for registration of classification (new construction)" in the application statement.

2. With respect to change of the application statement to 1 July 2008:

- ABS were very reluctant to put back the application statement for the revision of UR M66, but said that "if Members are going to reserve on the application date then the only way to get unanimous, uniform application of the revised UR may be to again set back the application date".

- GL were also reluctant and not in favour of extending the application date for this safety relevant device in general. But they were prepared to grant a period of grace for flame arresters until 30 June 2008.

- CCS, NK, DNV, RS, BV, KR, RINA and LR could accept to change the date in the application statement to 1 July 2008. RINA proposed a new text as shown below.

It was therefore concluded to change the implementation note in rev.2 of UR M66 according to RINA's proposal.

3. With respect to NK's proposal to substitute "the date of application for certification of the engine" with "application for registration of classification (new construction)", ABS, RS, GL, KR, LR and RINA explicitly objected. CCS and DNV did not comment upon it, and LR said that "we fail to recognise what "application for registration of classification (new construction)" means contractually. For classification purposes there is only one date that counts - date of "contract for construction" of the ship as defined in PR 29".

ABS proposed to define the "date of application for certification of the engine" as "the date of whatever document the Society requires/accepts as an application or request for certification of an individual engine". DNV, RS, BV, GL, KR, LR and RINA agreed they could support this. Thus the definition was by majority accepted to be incorporated in RINA's aforementioned proposal for a new implementation note.

4. Therefore the revised Item 1) of the implementation Note, incorporating RINA and ABS's proposals, reads as follows:

Technical Background (TB) Document for UR M66 (Rev.4 Feb 2021)

1. Scope and objectives

UR M66(Rev.3) does not reflect the agreed format for referencing the EN, ISO and VDI standards. Rev.4 has been developed to comply with the agreed format.

2. Engineering background for technical basis and rationale

Format for references to Industry standards

> ***Format:***
> *[Standard Designation], [version/revision, if applicable], [year of publication] (examples: API Spec 2F, 6th Edition, 1997; ISO 4624, 2002), where [version/revision, if applicable] and/or [year of publication] are decided by IACS and are not necessarily to be the current/latest version.*

3. Source/derivation of the proposed IACS Resolution

None

4. Summary of Changes intended for the revised Resolution

UR M66 has been updated to specify the revision/version of the EN, ISO and VDI standards as well as MSC Circulars as follows:

EN, ISO and VDI standards	**Replaced by**
EN 12874:2001	EN 12874:2002
ISO/IEC EN 17025:2005	ISO/IEC 17025:2017
EN 1070:1998	EN 1070:2018
VDI 3673	VDI 3673:2002
MSC Circulars	**Replaced by**
MSC/Circular 677	MSC/Circ.677 as amended by MSC/Circ.1009 and MSC.1/Circ.1324

5. Points of discussions or possible discussions

None

6. Attachments if any

None

Technical Background (TB) Document for UR M66 (Corr.1 Oct 2021)

1. Scope and objectives

References to some of industry standards referred to from this UR needed corrections as agreed by Machinery Panel.

2. Engineering background for technical basis and rationale

None

3. Source/derivation of the proposed IACS Resolution

None

4. Summary of Changes intended for the revised Resolution

Corrections of references to industry standards are as follows:

EN standards	Correction
EN 12874:2002	ISO 16852:2016
EN 1070:2018	ISO 12100:2010

5. Points of discussions or possible discussions

None

6. Attachments if any

Note: No Technical Background (TB) document is available for Corr.1 (Oct 2007).

Technical Background

Revision UR M9 (Rev.3) and M10(Rev.2)
New URs (M 66 & M67) for Type Testing Crankcase Explosion Relief Valves and Oil Mist Detection Arrangements

1. WP/MCH Task 55 was established to review the requirements in URM9 “Safety valves for crankcases of internal combustion engines” and M10 “Protection of internal combustion engines against crankcase explosions” for applicability and suitability to modern diesel engines.

2. The work specification included the following:
   - Review crankcase explosion reports for the past 10 years.
   - Review SOLAS requirements applicable to diesel engine crankcase safety.
   - Establish philosophy for a holistic approach to crankcase safety.
   - Consider the applicability of the safeguards in M9 and M10 for crankcase to all types of modern diesel engines – (high speed, medium speed and large slow speed engines + “large” and “small” bore engines).
   - Propose a set Unified Requirements for crankcase safety that include:
     - Requirements for submission of plans and particulars
     - Assessment of engine arrangements
     - Design of equipment
     - Testing of equipment and safety arrangements
     - Type testing requirements
     - Monitoring arrangements
     - Protection of engine and personnel
     - Through life survey and inspection

3. The background to the task was that there have been a number of serious incidents involving crankcase explosions in large diesel engines in the past 5-6 years that have resulted in loss of life and major damage to ships and their machinery. Questions have been raised regarding the adequacy of current standards for crankcase safety with engine builders and ship-owners pressing for revision/re-assessment of the current the standards that essentially stem from the Reina del Pacifico incident in 1947.

4. UR M9 has been extended to address design requirements for explosion relief valves in terms of a required provision of a flame arrester that prevents the passage of flame following a crankcase explosion and for valve to be type tested. The possible effects of shielding on relief valve efficacy have been recognised with a requirement for testing if such shielding is fitted.

5. The revised M9 also includes requirements for a manufacturer’s installation and maintenance manual with instructions installation, maintenance and actions required to be followed after a crankcase explosion. Requirements for marking of the valves have also been included.

6. UR M10 has been revised to remove requirements for the explosion relief valve (moved to M9) and clarify the existing text. The revised M10 now includes requirements for type testing of oil mist detection/monitoring systems and compliance with the oil mist manufacturer's instructions. Requirements for arrangements and installation onto the engine have been defined and also for system testing.

7. UR M10 also addresses alternative methods of preventing the build-up of oil mist and methods of assessment.

8. To support the extensive revisions to M9 and M10 new Unified Requirements for type testing explosion relief valves and for oil mist monitoring/detection arrangements have been developed. These URs provide a common standard against which relief valves and oil mist monitoring/detection systems cane be assessed. They define the scope, purpose, test facilities, processes, assessment and reporting.

Note by the Permanent Secretariat:

1. GPG added the following implementation statement to the URs:

> "Engines are to be fitted with components and arrangements complying with this UR when:
> 1) an application for certification of an engine is dated on/after 1 January 2006; or
> 2) installed in new ships for which the date of contract for construction is on or after 1 January 2006."

2. The URs (M 66 & 67, M9(Rev.2) and M20(Rev.3)) do not apply to existing engines on the existing ships.

Submitted by WP/MCH Chairman 24th August 2004

Technical Background Document
UR M9(Rev.3, Corr.1, November 2005)
UR M10(Rev.2, Corr.1, November 2005)
UR M66(New, Corr.1, November 2005)
UR M67(New, Corr.1, November 2005)

1. These UR Ms were adopted in Jan 2005 for implementation from 1 Jan 2006.

2. However, IACS was requested, via the Machinery Panel, by CIMAC and MAN/B&W, to postpone the 1 Jan 06 implementation date for the type testing requirements for crankcase explosion relief valves and crankcase oil mist detection/monitoring and alarm arrangements contained in IACS URs M66 and M67, respectively.

3. This discussion led to re-issuance of these UR Ms, changing the implementation statements.

These UR Ms were re-issued as 'Corr.1' on 29 Nov 2005.

4. GPG Chairman's message (4069gIGk, 14/11/2005) contains a more detailed background for this amendment.

For records, GPG/Council Chairmen's messages are attached to the TB document for the January 2005 versions.

Subject: 4069gICd: UR M66, M67 - application date

Date: 23 Nov 05

TO: IACS Council Members

TO: IACS GPG Chairman & Members

TO: IACS Permanent Secretary: Mr. R. Leslie

TO: IACS Machinery Panel Chairman: Dr. U. Petersen

FROM: R. D. Somerville
File Ref: T-12-2

Subject: 4069gICd: UR M66, M67 - application date

1. All Members have replied to ICc. Eight Members have supported the proposed course of action in IGk.

2. Lloyd's, supported by RINA, proposes that the URs need not be withdrawn, as proposed in IGk, but that only the implementation date need be changed. LR proposed posponement to 1 July 06 -- instead of 1 Jan 07, as proposed in IGk.

2.1 Regarding the implementation date of 1 July 06 vs. 1 Jan 07, this had already been debated in GPG and the strong majority supported 1 Jan 2007. I conclude 1 January 2007 is agreed.

2.2 Regarding whether to "withdraw" the URs or "postpone" their date of application, to my understanding either approach is acceptable and will result in the same outcome.

3. Therefore to accomodate the request that the URs not be withdrawn, I conclude that the agreed course of action is:

3.1 **Perm Sec** is to revise the uniform application statements for the URs, as follows, reissue them, and post them on the IACS website:

3.1.1 For URs M66 and M67:

"Note: Engines are to be fitted with components and arrangements complying with this UR when:
1) an application for certification of an engine is dated on/after 1 January 2007; or
2) installed in new ships for which the date of contract for construction is on or after 1 January 2007."

3.1.2 For UR M9, Rev.3:

"2. Engines are to be fitted with components and arrangements complying with Revision 3 of this UR, except for M9.8, when:

1) an application for certification of an engine is dated on/after 1 January 2006; or
2) installed in new ships for which the date of contract for construction is on or after 1 January 2006.
The requirements of M9.8 apply, in both cases above, from 1 January 2007."

3.1.3 For UR M10, Rev.2:

"2. Engines are to be fitted with components and arrangements complying with Revision 2 of this UR, except for M10.8, when:
1) an application for certification of an engine is dated on/after 1 January 2006; or
2) installed in new ships for which the date of contract for construction is on or after 1 January 2006.
The requirements of M10.8 apply, in both cases above, from 1 January 2007."

3.2 **Machinery Panel** is to:
a. inform CIMAC and MAN/B&W of the postponed application of URs M66 and M67, and the intention to update them;
b. update URs M66 and M67, as quickly as possible, taking account of CIMAC's, MAN/B&W and Panel Member's inputs;
c. once adopted at Panel level, send the revised URs to CIMAC for quick review/comment and notification to the equipment suppliers;
d. further update the URs as needed in light of any comments received from CIMAC;
e. submit the revised URs to GPG for approval not later than the end of the 1st Q 2006.

3.3 Upon adoption of the revised URs by IACS Council, **Machinery Panel** is to send them to CIMAC for their information and requesting that CIMAC notify the equipment suppliers of the requirements.

Regards,
Robert D. Somerville
IACS Council Chairman

Subject: 4069gIGk: UR M66, M67 - application date

Date: 14 Nov 05

TO: Mr. R.D. Somerville, IACS Council Chairman

CC: IACS Council Members
CC: IACS GPG Members

CC: IACS Machinery Panel Chairman: Dr. U. Petersen

CC: IACS Permanent Secretary: Mr. R. Leslie

FROM: S.R. McIntyre

File Ref: T-12-2

Subject: 4069gIGk: UR M66, M67 - application date

1. IACS has been requested, via the Machinery Panel, by CIMAC and MAN/B&W, to postpone the 1 Jan 06 implementation date for the type testing requirements for crankcase explosion relief valves and crankcase oil mist detection/monitoring and alarm arrangements contained in IACS URs M66 and M67, respectively. Their request is to give the equipment manufacturers and the engine builders more time to adapt to the new requirements. Industry has also recommended the need for some improvements/clarifications in the two URs, which the Machinery Panel has agreed are needed/appropriate.

1.1 Since CIMAC was involved in the IACS decision, some years ago, to develop these URs, in retrospect it would have been advisable to submit the URs for external review by CIMAC before their adoption to ensure that CIMAC would be fully aware of the requirements and the timetable for their implementation--and working with IACS Societies to ensure that their suppliers were apprised of and complying with the new requirements. Unfortunately, this was not done.

1.2 The type testing requirements of URs M66 and M67 are invoked in recent revisions of M9 and M10, respectively.

2. The Machinery Panel recommended that GPG postpone implementation of URs M66 and M67 and advised GPG that both URs need to be updated/clarified.

2.1 Several Members have also advised that they needed more time for initial implementation and could not implement the two URs from 1 Jan 06 as had been originally agreed by Council.

3. Having carefully considered the input from CIMAC, MAN/B&W, the Machinery Panel and Members, GPG agrees that IACS should postpone the implementation of these URs by one year to give time for updating them, vetting the changes with CIMAC, notifying industry and for Members to process the related rule changes. Therefore, GPG requests Council's agreement to the following course of action:

3.1 URs M66 and M67, along with M9.8 of M9, Rev.3 and M10.8 of M10, Rev.2 are to be withdrawn pending the updating of M66 and M67, which needs to be accomplished as quickly as possible (ie. the target date of 1st Q 2006 for revising M66, agreed at GPG 59, needs to be accelerated);

3.2 The updated URs, once adopted at Panel level are to be sent to CIMAC by the Machinery Panel for quick review/comment by CIMAC, and then further updated by the Panel in light of any comments received, prior to submission to GPG/Council;

3.3 The updated URs M66 and M67, once adopted by GPG/Council, are to be issued as "Corr" (since the initial versions will never have been implemented)--with uniform application from 1 Jan 2007 (instead of 1 Jan 2006);

3.4 M9, Rev.3 without M9.8, and M10, Rev. 2, without M10.8, are to be reissued as "Corr" until the updated M66 and M67 are adopted by Council, at which time M9.8 and M10.8 are to be included in M9, Rev.4 and M10, Rev.3, respectively for application from 1 Jan 2007.

4. Council Chairman is kindly requested to seek Council's agreement to this course of action as soon as possible.

Regards,
S.R. McIntyre
IACS GPG Chairman

Technical Background

Revision UR M9 (Rev.3) and M10(Rev.2)
New URs (M 66 & M67) for Type Testing Crankcase Explosion Relief Valves and Oil Mist Detection Arrangements

1. WP/MCH Task 55 was established to review the requirements in URM9 “Safety valves for crankcases of internal combustion engines” and M10 “Protection of internal combustion engines against crankcase explosions” for applicability and suitability to modern diesel engines.

2. The work specification included the following:
   - Review crankcase explosion reports for the past 10 years.
   - Review SOLAS requirements applicable to diesel engine crankcase safety.
   - Establish philosophy for a holistic approach to crankcase safety.
   - Consider the applicability of the safeguards in M9 and M10 for crankcase to all types of modern diesel engines – (high speed, medium speed and large slow speed engines + “large” and “small” bore engines).
   - Propose a set Unified Requirements for crankcase safety that include:
     - Requirements for submission of plans and particulars
     - Assessment of engine arrangements
     - Design of equipment
     - Testing of equipment and safety arrangements
     - Type testing requirements
     - Monitoring arrangements
     - Protection of engine and personnel
     - Through life survey and inspection

3. The background to the task was that there have been a number of serious incidents involving crankcase explosions in large diesel engines in the past 5-6 years that have resulted in loss of life and major damage to ships and their machinery. Questions have been raised regarding the adequacy of current standards for crankcase safety with engine builders and ship-owners pressing for revision/re-assessment of the current the standards that essentially stem from the Reina del Pacifico incident in 1947.

4. UR M9 has been extended to address design requirements for explosion relief valves in terms of a required provision of a flame arrester that prevents the passage of flame following a crankcase explosion and for valve to be type tested. The possible effects of shielding on relief valve efficacy have been recognised with a requirement for testing if such shielding is fitted.

5. The revised M9 also includes requirements for a manufacturer’s installation and maintenance manual with instructions installation, maintenance and actions required to be followed after a crankcase explosion. Requirements for marking of the valves have also been included.

6. UR M10 has been revised to remove requirements for the explosion relief valve (moved to M9) and clarify the existing text. The revised M10 now includes requirements for type testing of oil mist detection/monitoring systems and compliance with the oil mist manufacturer's instructions. Requirements for arrangements and installation onto the engine have been defined and also for system testing.

7. UR M10 also addresses alternative methods of preventing the build-up of oil mist and methods of assessment.

8. To support the extensive revisions to M9 and M10 new Unified Requirements for type testing explosion relief valves and for oil mist monitoring/detection arrangements have been developed. These URs provide a common standard against which relief valves and oil mist monitoring/detection systems cane be assessed. They define the scope, purpose, test facilities, processes, assessment and reporting.

Note by the Permanent Secretariat:

1. GPG added the following implementation statement to the URs:

> "Engines are to be fitted with components and arrangements complying with this UR when:
> 1) an application for certification of an engine is dated on/after 1 January 2006; or
> 2) installed in new ships for which the date of contract for construction is on or after 1 January 2006."

2. The URs (M 66 & 67, M9(Rev.2) and M20(Rev.3)) do not apply to existing engines on the existing ships.

Submitted by WP/MCH Chairman 24th August 2004

Technical Background Document
UR M67 Rev.1 (October 2006)
Type Testing Procedure for Crankcase Oil Mist Detection and Alarm Equipment

Scope and objectives

UR M67 is currently issued as 'Corr.1' with an application from 1 January 2007. During discussions at the joint Machinery Panel/CIMAC meeting in September 2005 it was the common view that UR M67 requires some further improvements/ clarifications. Accordingly, a new task for the Machinery Panel was raised (PM5105) and the Panel tasked to revise M67 with a view to address CIMAC concerns and to remove errors and ambiguities.

Points of discussion or possible discussions

Changes to UR M67 are mainly of an editorial nature to clarify specific requirements. In the course of the review process comments were received from Schaller Automation, Maersk and Kidde Fire Protection UK (see Appendix). These were taken into consideration by the Panel in the review process. The following changes of a technical nature were made:

5.1.2 (j)	Delete reference to moving parts as also other fluids in pipes or components may cause problems (Schaller comment)
8.1.3	Clarification of orientation and adding reference to equipment manufacturer's specification (Schaller and Maersk comment)
12.2.4	Clarification of Functionality tests (Maersk comment)

Regarding Maersk's comment on paragraph 5.1.1(j) the Panel considered that moving parts are those that are free to move when the equipment is inclined under static and dynamic ship movements. The terminology is consistent with that used for other equipment and stems from IACS UR E10 for inclination testing which is well understood by industry.

With respect to the requirement in paragraph 6.3 the Panel clarified the intention as follows:

- Paragraph 6.4 stipulates a maximum alarm set point of 5% of the LEL. In paragraph 6.3 the lower and upper detection limits are set to 0% and 10% respectively, the maximum detection limit hence corresponding to twice the maximum alarm set point.
- Should a manufacturer design an OMD with an oil mist concentration alarm set point below 5% (e.g. 3%) then the lower and upper detection limits are required to be 0% and twice the alarm set point respectively, in this example 6%.

The Panel at its 4th meeting (19 – 22 September 2006) examined the nature of the changes made and considered that the new requirements in 6.7 and 6.8 are of a technical nature rather than purely editorial. The changes are in response to feedback received from industry (Kidde Fire Protection and Schaller Automation). Consequently, a new Note 3 was added setting the implementation date for paragraphs 6.7 and 6.8 to 1 January 2008.

The draft text of the UR was sent to CIMAC on 21 July 2006 with a four week deadline for comments. As of 11 September 2006 no comments were received from CIMAC.

Source/derivation of proposed requirements

N/A

Decision by Voting (if any)
The revised text was agreed unanimously by Panel members.

Appendix
The following comments from industry were received in the course of the revision of M67 (attached):
- Kidde Fire Protection UK (25 April 2006)
- Schaller Automation (28 June 2006)
- Maersk (15 July 2006)

Subject no. 4069g – agreed by GPG and Council 10 October 2006 (IGp).

Kidde Products

Commentary on M67 from Kidde.

Kidde is fully in support of the aims of M67 in its aim to test the ability of oil mist detectors for use in monitoring engine crankcases to perform to specification and withstand the expected environment. Kidde does, however, oppose the details of the testing methodology for good technical reasons. All currently approved oil mist detectors operate by detecting the effects of light scattered by the oil mist, either by detecting the scattered light directly or by detecting the reduction in intensity of a light beam projected through the mist. Thus, the detected signal is a measure of the light scattering properties of the oil mist and not a direct measure of the mass density of the oil mist. The relationship between the amount of light scattered and the mass density is a complicated function of particle size distribution in the mist, the physical properties of the oil and the wavelength of light used to make the measurement. In particular, the particle size distribution has a strong effect and this can be changed by the chemical composition of the oil, the temperature of the hot surface from which it is evaporated and the environmental conditions in and around the oil mist detector. The particle size distribution of an aerosol, of which an oil mist is an example, can also undergo changes with time after formation due to evaporation, agglomeration or settling. Testing any detector against an oil mist quantified in terms of mass density, therefore, introduces a number of uncertainties which can change the apparent sensitivity of the detector when its properties have remained stable. This problem has been addressed over many years in the approval testing of smoke detectors (an oil mist detector can be considered as a special class of smoke detector) and the agreed methodology is to use an obscuration meter of defined type as a reference instrument. A suitable device is defined, for example, in BS EN 54-7:2001 Annex C. This has the additional advantage of making calibration measurement much more precise, convenient and with continuous real time output. Apart from the uncertainties described above, aerosol mass density measurements by filter sampling is difficult experimentally, relatively time consuming and only provides an average measurement over the sampling period.

Of course, in order to calibrate oil mist detectors against an obscuration meter, an agreed calibration of the meter to oil mist mass density under a set of defined conditions needs to be defined. At present, each manufacturer has their own calibration, obtained under different conditions at different test sites, which have been maintained over long periods. It would be useful to the industry and would increase the confidence of end-users if such a calibration was carried out by an independent laboratory under the direction of the IACS.

Remarks / Questions to the Unified requirements M67 of IACS:

Type Testing Procedure For Crankcase Oil Mist Detection/Monitoring and Alarm Arrangements

3.1.5 *To verify time delays between mist extraction from crankcase and alarm activation*

Time between injection of oil mist and alarm or leaving the engine and alarm?

5.1.2 *Range of tests for the detectors*

(i) *Static and dynamic inclinations, if moving parts are contained*
Not only mechanical moving parts can produce problems under certain inclinations of the ship (engine) but also fluids like water or oil inside the device or pipes.

6. Functional test process
6.2 The concentration of oil mist in ***the test vessel*** *is to be measured in the top and bottom of the vessel and is not to differ by more than 10%*

Test vessel, a container, filled with oil mist?
Acc. 4.1.1.4 of the UR M67 it`s necessary to have more than 2 m³ of oil mist, only to check the oil mist concentration inside the vessel?

Other methods, to produce oil mist with a certain concentration are allowed, for e. to evaporate a certain quantity of oil in a box with a certain volume?

6.3 ....The LEL corresponds to an oil mist concentration of approximately 50mg/l ***(13% oil-air mixture)***
13% = V%? Calculation is not clear

8.1.2.1 Oil mist detection / Monitoring devices are to be tested in the orientation in which they intended to be installed on an engine or gear case.

Under consideration of the possible inclination?

8.1.2.2 Type testing is to be carried out for ***each range of oil mist detection/monitoring devices*** *that a manufacturer requires classification approval*

Range = type of oil mist detectors or diff. sensitivity levels on an oil mist detector?

C.c.:			

Dear Sirs,

IACS UR M10 & UR M67

We have been studying your unified requirements M10 & M67.

We do not feel that these documents are describing their intension sufficiently. We have therefore made some comments and questions to the individual paragraphs where definitions or descriptions need to be improved. Please see attachment.

We will appreciate if you can bring these comments to the right forum and look forward to get a feedback.

We are at your disposal if further clarification to our comments is needed.

Yours faithfully,
for MAERSK SHIP DESIGN A/S

Søren P. Arnberg /Per Hother Rasmussen

IACS Unified Requirements M10 / M67 questions / comments.

M10.12
We understand it as one central covering more engines is acceptable, when alarm indication is clearly showing which engine is having the alarm / shut-down condition.

M10.13
Acceptable test procedures.
We find that the Class Societies shall define / describe the test procedures required in order to ensure uniform acceptance by the various surveyors attending.

A smoke test shall be performed at shop trial for every engine equipped with an oil mist detector.

M10.15
"Provide an alarm indication in the event of a foreseeable functional failure"
Does that cover the wording used in e.g. LR Part 6, Chapter 1, section 2.4.6 ?
"The safety system is to be designed to "fail-safe". The characteristics of the "fail-safe" operation are to be evaluated on the basis not only of the safety system and its associated machinery, but also the complete installation. Failure of a safety system is to initiate an audible and visual alarm."

M10.19
Please see comments for M10.13

M10.20
"Time to be as short as reasonable practicable"
We find that a maximum time elapsing from mist generation starts until detector reacts on same should be defined. Could e.g. be 10 secs from any point of detection on an engine.

M67-5.1.1 j
Static and dynamic inclinations, if moving parts are contained.
Kindly specify what is understood as a "moving" part.

M67-8.1.2.1
Operating orientation, detector shall be able to operate in both operating directions.

M67-12.2.4 b
Maintenance & test manual, Functionality tests.
How to make a test as realistic as possible? (M10.19)

Technical Background for UR M67 (Rev.2, Feb 2015)

1. Scope and objectives

The review of M67, Type Testing Procedure for Crankcase Oil Mist Detection and Alarm Equipment identified the following concerns:
• Toxicity of mineral oil mists;
• Difference in alarm set point requirements between obscuration and light scattering detection methods;
• Test required to demonstrate detection of an obscured sensor as required by M10.16;
• Sedimentation method used to calculate oil droplet is prone to error;
• Gravimetric method for oil mist droplet density requires clean laboratory conditions;
• The specification does not clearly record the sensitivity or precision of the sensor;
• The "dirty oil" to test for obscuration is imprecise;
• Test chamber temperature is as not recorded;
• No self-test requirement;
• No standard test report.

2. Engineering background for technical basis and rationale

INTRODUCTION

The initial research into crankcase explosions and oil mist was funded by The British Internal Combustion Engine Research Association (BICERA) and the British Shipbuilding Research Association (BSREA) in 1950s. Most subsequent research has been more general looking into the behaviour of aerosols. Research into the carcinogenic effect of mineral based oil mists has lead to strict exposure limits being set in a number of countries, including UK and USA.

OIL MIST

Early experiments found:
• Oil mist created is when oil in droplet or liquid vaporises on contact with a hot surface. On cooling a mist (cloud of droplets) forms, like a meteorological fog, it may stratify due to temperature variations in the space.
• Oil mist forms with a droplet size mainly <20μm;
• Lower Explosion Limit almost constant for droplets in the range 0.4μm 21.6μm (48.6 mg/L to 55.8 mg/L) and is effected by:
  - o Droplet size
  - o Oil mist density
  - o Volatility of oil
  - o Ambient temperature; a 23°C to 100°C rise increases the velocity by 30%
• No Upper Explosive Limit has been established; even very dense mists propagate flames.
Definitions for different oil mists are:
• < 1μm "smoke", blue. Formed from contact with hot surface, > 800°C;
• 1 – 10μm, "mist", white. Mechanically generated, at between 200C and 600°C;
• > 50μm "spray", mechanically generated, e.g. from damaged pipe work.

Oil Mist Combustion

There is no single theory for the combustion of aerosols and sprays. The main theories found were:
• Evaporation of droplets;

• Turbulence;
• Flame propagation in aerosols.
The following key points are made across the research reviewed;
• Smaller droplets evaporate quickly before the flame front and eventually burn as gas;
• Mid-sized droplets completely burn in their own gas atmosphere; and
• Large droplets burn only partially on the surface and a drop of the core is left unburned.
• Flame front propagation is effected by:
    o heat transfer between droplets, which is related to droplet size and distance;
    o Volatility and its density, which also affect “rain out” due to gravity;
• The oil/ air ratio defines whether explosion is possible;
• Oil mists explosions can occur with hotspots of 650°C;
• Increasing oil mist density and temperature increases the power of explosions but not the frequency;
• Usual temperature at which explosions occurred is at around 820°C;
• It is the presence of vapour and not droplets, which determines ignitability;
• Some research suggests that it may be the ignition of gasses rather than oil vapour or mist that leads to explosions;
• Age of Oil has not been found to have any effect.

Delayed ignition
• Research shows there are two areas of spontaneous combustion for two distinct temperature ranges for a range of oil mist vapour densities.
    o ~270°C to 350°C for 13 to 18% air/ oil ratios;
    o ~350°C to ~ 400°C dead band where no ignition occurs;
    o ~400°C upwards with air/ oil rations of 4 to 17%.
• This may explain reports where ignition has occurred after the oil mist has been detected and engines have been slowed or shutdown.
• Oxidation and cracking of the oil due to temperature leads to gasses and vapours more dangerous than oil mist. The movement of air on restarting an engine can cause the gases to ignite on contact with hot surfaces.

Engine size
The likelihood of an explosion in a small engine is less than a large engine and is thought to be due to increased relative surface area cooling and mass of metal to receive heat.

OIL MIST DETECTORS
There are two main types of OMD:
• Light scattering devices have a linear output and therefore can present a real-time measurement of the oil mist concentration;
• The obscuration devices detect a percentage obscuration. By comparing deviations from average values for an engine, an alarm is triggered when the alarm level is exceeded;
To determine the performance of an OMD the following needs be known:
• Oil droplet size: to verify that the oil mist is representative of the oil mists found within engine crankcases;
• Oil mist concentration, to benchmark OMD under test against.

Determination of droplet size

The measurement of droplet size is a complex process and prone to experimental error. The difficulties encountered are:

- Variation in droplet size;
- Range of speeds of the droplets;
- Changes on droplet size with time due to coalescence.

The two main methods of determining the size of droplets are sedimentation or optical methods. These methods do not produce identical results; this is thought to be due to the differences in the rate of coalescence of oil droplets. The optical methods report smaller droplet size compared with the sedimentation method.

Sedimentation method

This yields an average droplet size value using Stokes Law, which relates the radius of the droplet to the droplet settling velocity, the force acting upon the droplets, the viscosity of the carrier medium and the difference in densities of the oil droplet and the carrier medium.

To minimise boundary the effects of the tank walls, convective currents and thermal gradients a volume of at least 1m3 is needed. A high density of oil mist is needed to ensure the boundary layer of the mist can be easily seen. 30 to 60 minutes are needed to ensure accurate results, and need to be repeated at least 3 times to ensure consistent results have been obtained. The ambient temperature also has an effect.

Optical methods

A number of different techniques exist such as Photo Analysis, Laser diffraction, Phase Doppler, Mie Light Scattering; which are available as commercial laboratory equipment. Their cost is considerably higher compared to the sedimentation tank. They do enable a significantly smaller test volume, whilst accurately determining the droplet size distribution. Optical methods can use a number of numerical methods to calculate the droplet size. For comparison with the sedimentation method, the arithmetic mean diameter should be used.

Determination of Oil Mist Concentration

A number of different methods can be used to calculate the oil mist concentration:

- Gravimetric Method: A known volume of oil mist is drawn through a filter, which is then weighed. This requires specialist scales and rigorous environmental controls to prevent contamination of the sample;
- Volumetric method: A known volume of oil used to generate the oil mist and to calculate the density of oil mist;
- Flow method: A flow meter calculates the volume of oil mist injected into the test volume.

Variations in coalescence are believed to accounts for the discrepancies between the methods.

SAFETY ISSUES ASSOCIATED WITH OIL MIST

Health Effects

Mineral based oil mists are carcinogenic. The UK and US regulatory bodies have set “permissible exposure limits” of 0.005mg/litre, to be time weight averaged over an 8-hour period. The UK has set short term exposure limits of 15 minute exposure limit of

0.01 mg/L, limited to 4 times per day, with a minimum interval between exposures of 60 minutes. These levels are considerably below the levels required for OMD testing. Commercial smoke generators used for fire and accident simulation and film and drama productions use low toxicity oils, with PEL well below that of mineral oils reducing the hazard and allowing much greater exposure levels and times. These oils are available in a range of viscosities including ones equivalent to the SAE 40 specified by UR M67.

Risk of Explosions
There is a possibility that during testing the LEL could be exceeded and an explosion could occur. The use of "white" oils, with aromatics removed, greatly reduces the risk. The use of either a 28.3% carbon dioxide or 45% nitrogen enrichment increases the LEL to a level where explosions are not possible. Nitrogen with a density close to air is preferred as it has less impact on the dynamics of the oil mist.

TEST EQUIPMENT

Oil Mist Generator
There is a range of methods for creating oil mist: dropping defined quantity oil onto a "hot plate", temperature controlled crucible; or pneumatic oil mist generators as used in stage productions and fire simulators.

Commercial oil mist generators can produce oil mists with a known initial droplet size of 0.2 to 5 µm. Droplet sizes rapidly change after creation due to coalescence.

Test Chamber
When the sedimentation and gravimetric methods are to be used, a minimum 1m3 test chamber is needed to minimise boundary effects. Smaller volumes may be acceptable with optical methods.

3. Source / derivation of the proposed IACS Resolution

Feedback from a manufacturer raising the issue of oil mist hazards preventing testing to M67. This prompted a research exercise into addressing issues associated with toxicity and flammability of oil mist during testing, and other issues as identified during investigation.

4. Summary of Changes intended for the revised Resolution

AMENDMENTS TO UR M67

6.3 Detector Span Range
The current range specified is not appropriate for OMDs using light scattering techniques. The setting of the alarm limit is dependent upon the detector location, engine arrangement and vessel type, which all impact the degree of background oil mist within the sump of the engine. An oil mist concentration range should be specified that it is suitable for both optical and obscuration modes of detection.

7.2 Lens obscuration
Detector and alarm equipment to be tested, clause 7.2 to be amended to require repeatable method of lens obscuration to be used. And at a level which will

prevent false alarms, which can lead to operator complacency and a failure for the system to detect dangerous levels of oil mist. The manufacturer is to define the percentage obscuration to be used and provide an independent report verifying the obscuration medium.

8 Method
8.1.1.1 Test Oil: Acceptance use of nontoxic oils with equivalent viscosity and density properties to SAE 40 monograde mineral oil.
Test Chamber: Minimum size to be 1m3.
Maximum Oil Mist Droplet Size: Alternative means of droplet sizing should be accepted, the method used to be declared.
• Atmosphere/propellant of oil mist to take into account the associated explosion risk;
• Droplet size <20μm with an average value of 5μm.

NEW REQUIREMENTS

6.6 OMD Specification
Accuracy, precision, resolution, resolution and response time to be assessed as part of the type testing. This will help define the performance of OMDs and assist ensuring a level playing field between manufacturers.

Definitions taken from the Joint Committee for Guides in Metrology (JCGM)

• Accuracy: accuracy of measurement, accuracy closeness of agreement between a measured quantity value and a true quantity value of a measurand.
• Precision: precision closeness of agreement between indications or measured quantity values obtained by replicate measurements on the same or similar objects under specified conditions.
• Sensitivity of a measuring system: sensitivity quotient of the change in an indication of a measuring system and the corresponding change in a value of a quantity being measured.
• Resolution: smallest change in a quantity being measured that causes a perceptible change in the corresponding indication.
• Response time: the time between measurand being measured and detector indicating a change.

6.10 Self test: An alarm to indicate system failure either a through build-up of dirt or component failure to be required.

6.4 Alarm set points to be set allowed, appropriate to detector technology.

8 Ambient temperature: to be set at -15°C to 55°C.

9.1.2 Assessment: The maximum percentage level of lens obscuration to be recorded.

11 The Report: common test report with OMD performance details to be included on Class Societies type approvals certificate. The report to include the following:

• Serial numbers of sample sensors and associated control and monitoring equipment under test;

• Serial numbers and calibration certificates of test equipment used;
• Specification of test oil used;
• Oil mist propellant, if used;
• Ambient temperature of test;
• Performance of OMD in mg/L;
• Accuracy of OMD;
• Precision of OMD;
• Range of OMD;
• Resolution of OMD;
• Response time of OMD;
• Sensitivity of OMD;
• Obscuration of sensor detection, declared as percentage of obscuration. 0% totally clean, 100% totally obscure;
• Detector failure alarm;

5. Points of discussions or possible discussions

Paragraph	Summarised comments from industry and other IACS Members
General comments	
	Comments from a number of parties raised concerns over continued specification of SAE 80 grade oil and requested SAE 40 is specified and agreed by the panel.
	Comments from manufacturers – detailed in separate files held by the IACS Machinery Panel
Specific comments	
8.1.1.1	C. Proposed that a minimum height of the test chamber is stipulated as this is the critical factor in the sedimentation method. A value of 1.0 meter was proposed and implemented.
	C. Specify how oil mist is generated. A. Change not agreed as a single method could cause excessive costs to manufacturers.
	C. The temperature influences the lifetime of droplets significantly. Proposed to require a constant temperature in the chamber during tests (range 20 to 25 deg C. is suggested as practicable). A. It was agreed that the ambient temperature is to be set for the test chamber and its local environment prior to testing. It is practical to require the temperature to be controlled and monitored during testing. Commercial oil mist generators all appear to heat the oil, this includes commercial smoke generators. As such the temperature is likely to rise inside the chamber. The temperature is likely to vary dependent on the device used.
	C. The term "or equivalent" should be removed, unless the scope of equivalency is defined. A. This was not implemented as the scope is already linked to viscosity.

	C. Information on the on importance of droplet size? Engine oil mists appears to be given as in the range of 1 to 20 microns, but how important is it for detector testing? The smaller the droplet size the greater the obscuration, the explosion risk appears to be fairly constant up to 20 microns. Droplet size in crankcases said to be typically 1 to 13 microns. Total obscuration of a light source from a few cms away occurs at 4-5mg/L. A. A droplet size < 5 μm is considered as most important contributor to fire. Therefore, the detector is to be tested to verify the exact indication of this droplet size. The droplet size of the oil mist used for the test is an important parameter to be regulated in the UR; considering that "The smaller the droplet size the greater the obscuration", the minimum droplet size should have to be established (to test the sensor on worst case) instead of the "maximum droplet size of 5 um" Immersion methods have been accepted as an alternative method for measuring droplet sizes based upon meeting with manufacturers. Both of the sedimentation method and direct measure method can be used to measure droplet sizes.
	C. What, if any, alternatives to the sedimentation method have been used for measuring droplet sizes? What was the basis for acceptance? A definition for "suitable equivalent" to sedimentation method should be given. (Alternatively replace by "sedimentation method or other methods traceable to recognized standards or referable to the sedimentation method"; a metrology expert should give his advice in this respect). A. Both of the sedimentation method and direct measure method can be used to measure droplet sizes. The terms "equivalent" and "equivalence" are used in the Oct 2007 version of the UR. It is considered that there are no problems with requiring equivalence as it is the responsibility of those proposing alternatives to demonstrate that what they are proposing has equivalent properties etc. The extent to which application of the sedimentation method has been used is unclear; calibration records of the distribution of droplet sizes have been accepted.
	C. The Gravimetric method is too complicated to calculate density of oil mist, an alternative method would be preferred. What, if any, alternative methods to the gravimetric method have been accepted for calculating density of oil mist? What was the basis for acceptance? A. Alternative methods have not been accepted so far. The gravimetric method has been used for all tests, and no application for an alternative in this respect was reported.
6.3	C. Original rationale behind twice the alarm set point range

	requirement? A. In order to ensure a high accuracy at 5% (2.5 mg/l) the measurement range shall be from 0 ~ 10% LEL. Accuracy of the measurements (scale), Generally, in the instrument and meter industry, accuracy ±10% means 10% of the full measuring range. But, there is no limitation of maximum measuring range（only minimum limitation in M67）, so if the alarm point is very low(for example, 1.0mg/l), but measuring range is very large(>5.0mg/l), the accuracy at alarm point is very low(±0.5 at 1.0mg/l, i.e. ±50%), and mis-alarm can easily to happen. If design accuracy is ±10% of the full measuring range, it is suggested that the maximum range is limited to twice the alarm set point. It is suggested that a requirement for accuracy at the concentration value corresponding to the alarm set point is established instead.
6.4	The set point of 5% LEL has been chosen as having a safe margin to the 100% LEL because the OMDs are not explosion-proof.
6.6	Measurement delay should be required to OMD; it is suggested that the measurement delay of the OMD should not be longer than 5 seconds.

6. Attachments, if any

None.

UR M68 "Dimensions of propulsion shafts and their permissible torsional vibration stresses"

Summary

In Rev.3 of this Resolution, the way to refer to instruments other than those specified by IACS was unified.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev.3 (Feb 2021)	12 February 2021	1 July 2022
Rev.2 (Apr 2015)	14 April 2015	1 January 2017
Rev.1 (Aug 2014)	12 August 2014	1 July 2015
Corr.2 (Nov 2012)	22 November 2012	-
Corr.1 (Mar 2012)	21 March 2012	-
New (Feb 2005)	20 February 2005	1 July 2006

- **Rev.3 (Feb 2021)**

1 Origin of Change:

☑ Other (Update to comply with the required format when industry standards are referred to)

2 Main Reason for Change:

There was a need to update this UR to comply with the following format when industry standards are referred to:

[Standard Designation], [version/revision, if applicable], [year of publication] (examples: API Spec 2F, 6th Edition, 1997; ISO 4624, 2002), where [version/revision, if applicable] and/or [year of publication] are decided by IACS and
are not necessarily to be the current/latest version.

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None

4 History of Decisions Made:

None

5 Other Resolutions Changes:

None

6 Any hinderance to MASS, including any other new technologies:

None

7 Dates:

Original Proposal: 28 October 2019 (Ref: PM18939_IMd)
Panel Approval: 9 November 2020 (Ref: PM20906_IMf)
GPG Approval: 12 February 2021 (Ref: 20206dIGb)

- **Rev.2 (Feb 2015)**

.1 Origin for Change:

☑ Suggestion by an IACS member

.2 Main Reason for Change:

To develop the approval requirements for the use of alloy steel which has a minimum specified tensile strength greater than 800 N/mm^2 for intermediate shaft material.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

The Machinery Panel commented on revisions by correspondence and at regularly scheduled meetings.

.5 Other Resolutions Changes

None

.6 Dates:

Original proposal: 25 July 2011 *Made by:* Machinery Panel
Panel Approval: 6 March 2015
GPG Approval:

- **Rev.1 (Aug 2014)**

.1 Origin for Change:

☑ Proposal by IACS Machinery Panel

.2 Main Reason for Change:

Outcome of the consequence assessment for Corr. 1 carried out under PM12913. Details provided in Part B.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

This task was initiated based on PM11925 ("To revise UR M68.7-3 due to failure in the formula for stress concentration"), where the members unanimously agreed that formulae in the previous revision were wrong. UR M68.7 was updated accordingly.

GPG requested the Machinery Panel to assess possible impact on the products already approved in accordance with the former formulae in M68.7.

The consequence assessment and proposed changes to Footnotes 6) and 7) have been unanimously agreed.

.5 Other Resolutions Changes

None

.6 Dates:

Original proposal: 14 August 2012 Made by: Machinery Panel
Panel Approval: 22 November 2013 (PM12913_IMi)
GPG Approval: 12 August 2014 (Ref: 12144_IGf)

- **Corr.2 (Nov 2012)**

.1 Origin for Change:

☑ Suggestion by Machinery Panel Chairman

.2 Main Reason for Change:

An error in M68.6 Table of k and ck factors for different design features was discovered and corrected as follows:

The column "longitudinal slot" under the heading "thrust shafts external to engines" moved under the heading "intermediate shafts with".

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

The proposed correction has been unanimously agreed.

.5 Other Resolutions Changes

None

.6 Dates:

Original proposal: 06 June 2012 *Made by:* Machinery Panel
Panel Approval: 06 June 2012
GPG Approval: 22 November 2012 (Ref. 12022_IGh)

- **Corr.1 (Mar 2012)**

.1 Origin for Change:

☑ Suggestion by an IACS member

.2 Main Reason for Change:

An error in a formula has been discovered which require correction.

Technical Background for UR M68 New, Feb 2005

WP/MCH Task 41
Technical Justification for revision of M33 M37 M38 M39 M48 and new UR M68

CIMAC established a working group (WG14) for the purpose of getting a unified practice among Classification Societies on the topic of shafting and permissible torsional vibrations.

This WG14 concluded the work by the end of 2002, however, with a more restricted scope than the original. The original scope included issues for both 4-stroke and 2-stroke plants, but it soon became clear that due to the limited time (all to be within 2002) only 2-stroke plants with fixed pitch propellers could be handled.

It was the intention of WG14 that the agreements of 2002 should be reflected in the rules of the participating societies.
During the IACS MCH meeting in London 2003, it was agreed that actions should be taken versus very old URs, meaning a) confirm b) revise or c) delete. Among other, the above mentioned URs were chosen because:

- All 5 UR are interconnected and partly repeat each other
- Reservations were made
- Several societies practiced considerable deviations from the UR
- WG14 had concluded on something different (for 2-stroke)
- Design features for controllable pitch propellers lacking

After revising the technical contents of the 5 URs, it was intended to merge them into one UR.
The 4-stroke issues of WG14 (that were not in the agreement of 2002) had little or no relevance for the revision of these URs which only dealt with shafts. Of that reason the revision should include all relevant kinds of shafts.

The draft UR replaces M33, M37, M38, M39 and M48.

Note: This UR applies to ships constructed for construction from 1 July 2006.

Submitted by WP/MCH Chairman
21 Dec 2004

Technical Background for UR M68 Corr.1, Mar 2012

1. Scope and objectives

It has been discovered that an error in the formula for stress concentration in slots commonly applied for OD shafts. The formula as stated in IACS UR68.7-3 should be updated accordingly.

The consequence is improved estimation of stress concentration in slots.

2. Engineering background for technical basis and rationale

The original formula, that was based on/verified by FEM parameter studies is as follows:

$$\alpha_t = 2{,}3 + 0{,}4\,\frac{l-e}{\sqrt{tr}}$$

With intention of simplifying the equation, by only using parameters usually applied in shafting the following substitutions were made:

$e = 2r \;\; \Rightarrow r = e/2$

$$t = \frac{d-di}{2}$$

leading to the following equation:

$$\alpha_t = 2{,}3 + 0{,}4\,\frac{l-e}{\sqrt{\left[\frac{d-di}{2} \times \frac{e}{2}\right]}}$$

$$\alpha_t = 2{,}3 + 0{,}8\,\frac{l-e}{d \times \sqrt{\left[\left(1-\frac{di}{d}\right) \times \frac{e}{d}\right]}}$$

however, by error it was applied 0,4 x $\sqrt{2}$, rather than 0,4 x 2.

Consequently the following formula has been stated and applied in the requirements:

$$\alpha_t = 2{,}3 + 0{,}57\,\frac{l-e}{d \times \sqrt{\left[\left(1-\frac{di}{d}\right) \times \frac{e}{d}\right]}}$$

leading to:

$$scf = \alpha_{t(hole)} + 0{,}57\,\frac{l-e}{d \times \sqrt{\left[\left(1-\frac{di}{d}\right) \times \frac{e}{d}\right]}}$$

The correct formulae should be

$$scf = \alpha_{t(hole)} + 0{,}8\,\frac{l-e}{d \times \sqrt{\left[\left(1-\frac{di}{d}\right) \times \frac{e}{d}\right]}}$$

3. Source/derivation of the proposed IACS Resolution

None

4. Summary of Changes intended for the revised Resolution:

Replace the original formulae with the amended formulae.

5. Points of discussions or possible discussions

Technical Background for UR M68 (Rev.1, Aug 2014)

1. Scope and objectives

Assess the possible impact on products already approved in accordance with the formula in UR M68.7

2. Engineering background for technical basis and rationale

It has proven difficult to do a detailed study of the consequences.
The following scope has been done:

- General consideration of increased notch factor and possible counter actions.
- Evaluation of slot design on delivered shafts
- Parameter study to evaluate the tabulated default notch factors applied in simplified method.

General consideration of increased notch factor and possible counter actions.

An increased stress concentration factor will increase the local stresses and hence reduce the permissible nominal stress level.
For an existing shaft where the stress concentration has proven to be higher than initially expected the fatigue lifetime will be reduced. It will have to be evaluated for each separate case if the expected lifetime still is within acceptable limits, as the lifetime also is influenced by the materials notch sensitivity and highly dependent on the occurring vibratory stresses (system dependent)

The high stress level occurs in the end of the slot and will result in fatigue cracks. To enable an early detection of cracks it could be recommended to have focus on the slot during shaft survey and to request crack detecting NDT in the slot end.

Evaluation of slot design on delivered shafts

A random selection of relative new shaft designs has been evaluated. (Characteristics as shown in table below).

l/d	e/d	di/d	alfat	scf_old	scf_new	scf increase	old C_K	new C_K	C_K increase
0,76	0,10	0,39	2,16	3,71	4,33	16,81 %	0,39	0,33	-14,39 %
0,99	0,13	0,17	2,17	3,66	4,26	16,45 %	0,40	0,34	-14,13 %
0,84	0,09	0,43	2,17	4,02	4,77	18,62 %	0,36	0,30	-15,69 %
0,84	0,10	0,40	2,17	3,85	4,52	17,62 %	0,38	0,32	-14,98 %
0,84	0,10	0,40	2,17	3,85	4,52	17,62 %	0,38	0,32	-14,98 %
0,77	0,10	0,39	2,17	3,71	4,33	16,76 %	0,39	0,34	-14,36 %
0,84	0,09	0,36	2,16	3,91	4,62	18,05 %	0,37	0,31	-15,29 %
0,84	0,10	0,38	2,17	3,82	4,49	17,49 %	0,38	0,32	-14,89 %
0,70	0,12	0,39	2,18	3,39	3,88	14,40 %	0,43	0,37	-12,59 %
0,81	0,14	0,34	2,19	3,46	3,97	14,78 %	0,42	0,36	-12,88 %

Although the stress concentration is increased by 14-19% the shafts are still above the tabulated default C_K value of 0,3.

For two cases revised permissible stresses have been compared against torsional vibration level. Results proved to be acceptable.

<u>Parameter study to evaluate the tabulated default notch factors applied in simplified method.</u>

A parameter study has been done to evaluate the tabulated default values applied for shafts with slot in M68.6.

Based on the investigation and the received comments from the members the following is proposed:

- The default value for C_k =0,3 is kept unchanged
- slot geometry under footnote 6) is modified as follows;:
    - di/d<0,7 (previous: 0,8)
    - l/d<0,8 (previous: 0,8)
    - e/d>0,15 (previous 0,1)
- Default value for k = 1,2 is kept unchanged.
- Text under footnote 7) is modified to read:

  7) C_K = 0.3 is an approximation within the limitations in 6). More accurate estimate of the stress concentration factor (scf) may be determined from M68.7.3 or by direct application of FE calculations. In which case: C_K = 1.45/scf

  Note that the scf is defined as the ratio between the maximum local principal stress and √3 times the nominal torsional stress (determined for the bored shaft without slots).

Technical Background for UR M68 (Rev.2, Apr 2015)

1. Scope and objectives

To develop requirements related to the approval of alloy steel which has a minimum specified tensile strength greater than 800 N/mm^2 intended for use as intermediate shaft material.

2. Engineering background for technical basis and rationale

Since it is generally believed that the fatigue strength of notched steel decreases as tensile strength increases when the tensile strength of said steel exceeds 800 N/mm^2, both UR M68.3 and UR M68.4 specify 800 N/mm^2 the upper limit for the minimum specified tensile strength of alloy steels used to make intermediate shafts.

Due to recent advances made in material technology, however, it has been discovered that there are cases when the minimum specified tensile strength of alloy steel used for intermediate shafts exceeds 800 N/mm^2, the fatigue strength of the steel exhibits equivalent to or greater than the fatigue strengths of alloy steels used for intermediate shafts that have a minimum tensile strength of exactly 800 N/mm^2.

Therefore, if it can be verified that alloy steel used for intermediate shafts exhibits similar fatigue life as conventional steel, even when minimum specified tensile strength of the alloy steel exceeds 800 N/mm^2, it is generally believed that the current specified calculation formulas may be still used.

To confirm the above, torsional fatigue tests were carried out by one member using a material which has a minimum specified tensile strength of 950 N/mm^2.

3. Source / derivation of the proposed IACS Resolution

None.

4. Summary of Changes intended for the revised Resolution:

Approval requirements related to the use of alloy steel which has a minimum specified tensile strength greater than 800 N/mm^2 as intermediate shaft materials was added as Appendix I.

5. Points of discussions or possible discussions

<u>Appendix I</u>
<u>1. Application</u>
The panel decided that the upper limits of minimum specified tensile strength should be specified. The limit was set as 950 N/mm^2 since this is the value which had been tested by one member.

<u>2.1 Test conditions</u>
Test conditions are primarily based upon ISO 1352. However, ISO 1352 is a little too open because it includes a number of options; Therefore, the test conditions

only reference specific requirements in ISO 1352. More details regarding this are specified in the UR itself based upon the tests carried out by one member.

3. Cleanliness requirements

Cleanliness requirements are specified according to a member society's comments. A summary is given as follows:

We limit the validity of the standard formula to 800 MPa tensile, because we consider that if the material contains inclusions / defects, the fatigue strength at such high levels may be dominated by crack growth. In such case, the fatigue strength is not likely to follow proportionally to the tensile strength at these strength levels.
Therefore we say that only if clean steel forgings are used, the formula can be used for higher strength than 800.
For the present steel, I agree that the tests documents that the formula can be used up to 950 MPa. But where is this particular steel, compared to the "worst" steel that can be delivered with this specification, in terms of cleanliness? The maximum "S" level specified, for example (Smax = 0.030) is not compliant to what we usually consider as a clean steel specification.
The UR should state the "S" content of this particular steel, and should also document its content of non-metallic inclusions by a cleanliness test, before their request can be accepted.

Although the panel agrees to introduce cleanliness requirements, there are no specific national or international standards for such materials. Therefore, the panel agreed to do the following:

- Require the cleanliness test in accordance with ISO 4967 method A. The degree of cleanliness is specified in Table 2 based upon a member society's practices.
- Require that specific steel composition be approved by the Society.

Technical Background

New Unified Requirement M69 (June 2008) for "Qualitative Failure Analysis for Propulsion and Steering on Passenger Ships"

IACS Machinery Panel Task PM5911 – NTSB Report MAR/01-01 Recommendation to IACS

Background:
A Project Team was established with a specific aim:
To evaluate whether the NTSB recommendation is justified and whether IACS needs to develop a UR for qualitative failure analysis for propulsion systems on new passenger ships. Depending on the results of evaluation:

a. Draft a letter to NTSB providing technical justification for why IACS considers a qualitative failure analysis is not necessary **or**
b. Develop a UR for qualitative failure analysis for propulsion systems on new passenger ships.

Narrative:
1. After evaluating the documentation relating to the incident, the Project Team decided that the best way of handling the issue was to develop a Unified Requirement specifically dealing with the NTSB's concerns

2. Since the NTSB report was issued, it was noted that the IMO had agreed revisions to SOLAS Chapter II-2, Regulation 21 which included safe return to port requirements for passenger ships having a length of 120 m or having three or more main vertical zones.

3. The task was to respond to a request for a "requirement for systems designers, manufacturers, and/or shipyards to perform and submit qualitative failure analysis to ensure the fail-safe operation of propulsion systems on new passenger ships".

4. The NTSB advised that requirements should "not focus solely on redundant propulsion systems". The NTSB in their findings "did not recommend that redundant propulsion systems be required on new passenger ships, nor that qualitative failure analysis should be limited to redundant propulsion systems". The "requirement would be applicable to all new passenger vessels regardless of the propulsion system used".

5. The NTSB further advised that as for the "meaning of the phrase ensure fail-safe operation of propulsion systems, the critical term was identified as fail-safe". The NTSB "recognised that individual components may fail - however the failure or malfunction of an individual component should not propagate through the entire system, resulting in a complete loss of propulsive power".

6. The NTSB also advised that "they believe that a qualitative failure analysis can be used to identify potential failures that could lead to a complete loss of propulsion. This information could help the designer determine what modifications could increase the reliability of the system. Although redundancy is one method that designers can use to achieve high reliability, improving the robustness of non-redundant components might also be an effective way to achieve this objective".

7. The **Objectives** stated in the draft UR are the keystone of the requirements and the extent of analysis required for different ships and propulsion arrangements needed to identified for ships needing to comply with the safe return to port and those that do not (outside the scope of SOLAS requirements).

8. During the development process it was agreed to include steering arrangements as well as propulsion noting the interdependence for safe manoeuvring of the ship.

9. It was agreed that it would not be effective to carry out failure analysis at component level if all the equipment in a compartment affected by fire or flooding was not available. In effect, where a ship is designed in accordance with the SOLAS safe return to port concept, the arrangements would be such that there would be at least two independent means for propulsion and steering. In such arrangements, it would only be necessary to carry out an analysis of the effects of failure in all the equipment due to fire or flooding in any space or compartment - i.e., all equipment within a space or compartment affected by fire or flooding would be lost. This is reflected Objective 1 in the revised document. Where the ship is not designed in accordance with the safe return to port concept, it would be necessary to carry out an analysis at component level as reflected in Objective 2. This was accepted as a realistic approach.

10. By taking the analysis to a high level for ships designed in accordance with the safe return to port concept, more components will be analysed at the same time and to repeat the analysis for single components would not add value when the result has to prove the availability of propulsion and steering.

11. For ships which are not designed with the safe return to port concept, single component analysis has been added for single systems.

12. The most severe common cause failures - fire and flooding have been identified for analysis which address the NTSB reported failure mode. It was noted that the Ecstasy did not have the analysis required by the final sentence in the **Systems to be considered** section of the proposed UR.

13. Under the headings **Systems to be considered**, the list was based on input from the Project Team and Machinery Panel Members and is considered sufficient to cover the systems that could affect the availability of propulsion and steering arrangements.

14. Under the headings **Failure Criteria** and **Verifications of Solutions**, these are considered to represent the current “state of the art” and which again have had extensive input from Machinery panel Members.

Submitted by Machinery Panel Chairman
10 June 2008

Permanent Secretariat note, June 2008:
New UR M69 was approved by GPG on 23 June 2008 (ref. 1125_IGs) with an implementation date of 1 January 2010.

Technical Background (TB) document for UR M69 (Rev.1 Feb 2021)

UR M71 "Type Testing of Reciprocating Internal Combustion Engines"

Summary

This UR provides requirements for type testing of reciprocating internal combustion engines. Revision 1 is associated with UR M87, 'Certification Scheme for Reciprocating Internal Combustion Engines,' is restructured accordingly, and provides clarification of the requirements.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev.1 (Apr 2025)	20 April 2025	01 January 2027
Corr.1 (June 2016)	3 June 2016	-
New (Feb 2015)	27 February 2015	1 July 2016

- **Rev.1 (Apr 2025)**

1 Origin of Change:

☒ Request by non-IACS entity (CIMAC)

2 Main Reason for Change:

CIMAC WG2 believes that the existing UR M51 and UR M71 need to be revised and updated in line with technological developments and with consideration of operational aspects.
The Machinery Panel has decided to assess these proposals and improve URs related to internal combustion (I.C.) engines.

3 Surveyability review of UR and Auditability review of PR

Draft document Rev.1 UR M71 has been reviewed by Survey Panel.

4 Human Element issues assessment

Not applicable, based on the scheduled date for creating a task for the revision.

5 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

☒ CIMAC WG2

6 History of Decisions Made:

CIMAC proposed revisions to the existing UR M51 and UR M71, which include the following**:**

- Revision of UR M51: This will cover only the factory acceptance tests of internal combustion (I.C.) engines.
- Revision of UR M71: This will focus solely on the type approval tests of I.C. engines.
- Development of a new UR M87: Titled "Certification Scheme for Type Approval of I.C. Engines," this UR will provide requirements regarding the type approval scheme for I.C. engines.
- Development of a new UR M88: Titled "Shipboard Trials of I.C. Engines," this UR will outline the requirements for testing I.C. engines installed on board ships.

The Machinery Panel reviewed CIMAC's proposals during its 30th meeting in 2019 and determined that a dedicated project team (PT) was necessary to consider these proposals.

At its first workshop in 2020, the Project Team on Marine (PTPM19102) made decisions regarding the principles for developing or amending IACS URs related to I.C. engines. The development of these URs was primarily based on the knowledge and experience of IACS members, while also considering CIMAC's proposals.

As a result, five URs, including UR M71, were drafted during the second workshop of the project team in 2021 and submitted to the Machinery Panel for review.
UR M71 was updated and restructured to align with other URs concerning engine certification. From 2021 to 2023, UR M71 underwent discussions and revisions based on feedback from the Machinery Panel.

7 Other Resolutions Changes

The following other URs have been amended in parallel:
- M87 Certification Scheme for Reciprocating Internal Combustion Engines (new)
- M44 Documents for Approval of Reciprocating Internal Combustion Engines (revision)
- M51 Factory Acceptance Test of Reciprocating Internal Combustion Engines (revision)
- M88 Shipboard Trials of Reciprocating Internal Combustion Engines (new)

8 Any hinderance to MASS, including any other new technologies:

None.

GPG Approval	: 20 April 2025	(Ref: 24205aIGc)

- **Corr.1 (June 2016)**

.1 Origin for Change:

☑ Suggestion by a Machinery Panel Member

.2 Main Reason for Change:

While reviewing UR M44 (Rev.8) and M44 (Rev.9) at Machinery Panel, it was found necessary to publish a corrigendum in order to clarify that UR M71 applies for type approval process of IC Engines.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

UR M71 (New) specified "an application for certification" in the notes for implementation status, while UR M44 (Rev.8) and M44 (Rev.9) referring to M71, uses "certification" as wording relating to production of individual diesel engines. To avoid future troubles caused by understandings diverse among Societies/licensors/licensees/shipowners, it was concluded necessary to publish a corrigendum in order to clarify that UR M71 applies for type approval process of IC Engines.

.5 Other Resolutions Changes

None

.6 Dates:

Original Proposal: 02 November 2015 Made by Machinery Panel
Panel Approval: 15 April 2016 (Ref: PM9906a)
GPG Approval: 3 June 2016 (Ref: 16088_IGc)

New (Feb 2015)

.1 Origin for Change:

☑ IACS WP/MCH Task 50

.2 Main Reason for Change:

To update the content of UR M5, M14, M18, M23, M50, M51 and any other related URs to make them aligned with modern manufacturing technologies and current quality control procedures, including resolution of Reservations put forward.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

Four meetings in the PT were held during the period 2008 and 2009 as part of the top-level project PT 5906 to rationalize all i.c. engine related UR's.
A decision was taken to combine the existing UR's M21, M32 and M50 detailing the requirements for Type Testing and also at the same time to consider objections from the Industry to IACS on some of the current requirements.

The draft submitted to the Machinery Panel was agreed at the last PT meeting.

The Machinery Panel has added definition for low-, medium-, and high-speed diesel engines, removed the requirement to strip down high-speed engines and made editorial changes to enhance readability.

.5 Other Resolutions Changes

UR M21, M32 and UR M50 are to be deleted and replaced by this UR.

.6 Dates:

Original Proposal: 02 April 2010 (Made by: IACS Machinery Panel PT50)
Panel Approval: 08 January 2015 (By: IACS Machinery Panel)
GPG Approval: 27 February 2015 (Ref: 7569_IGw)

Part B. Technical Background

List of Technical Background (TB) documents for UR M71:

Annex 1. **TB for Original UR M71 (Feb 2015)**

See separate TB document in Annex 1.

Annex 2. **TB for Revision 1 of UR M71 (Apr 2025)**

See separate TB document in Annex 2.

Note: There is no separate Technical Background (TB) document available for Corr.1 (June 2016).

Technical Background (TB) document for Original UR M71 (Feb 2015)

1. Scope and objectives

Existing UR's M21, M32 and M50 to be reviewed taking into account operational feedb ack. The opportunity to combine M21, M32 and M50 into a new UR covering all engines was to be taken.

2. Engineering background for technical basis and rationale

Experience gained through the implementation of existing UR M 21, M32 and UR M 50.

2a. Specification of the data utilized in the development/revision of the proposed IACS Resolution, if any

3. Source/derivation of the proposed IACS Resolution

Feedback from Class Societies on existing UR M 21 and UR M 50, and industry via CIMAC WG2.

4. Summary of Changes intended for the revised Resolution:

M71.1

Standardizes the definition of Engine Approval and where Type testing is placed in the overall process. Engine components which are considered to be of interest and are required to be demonstrated by the test as being in compliance with applicable criteria and/or standards have been described.
The maximum validity time for the Type Approval certificate has been based upon the IMO MCS Circular 1221. This standardizes the time period, but individual Societies can make this time period shorter.
Define low-, medium-, and high speed diesel engines.

M71.3

The engine type has been defined in a way that is as meaningful as possible without leading to excessive testing requirements.

The extension of a type test certificate to a different torque rating is now based upon engine parameters that are more meaningful to the running performance of the components under examination. Requests for extension will be required to be substantiated with a declaration of satisfactory service history of the engine type; this information is considered as equivalent to Stage A of the type test.

M71.5

The testing is split into three recognizable modules:

Stage A. It has been recognized that many hours of tests are undertaken in-house (internal) prior to the official type test and the information from these are to be taken into account *provided detailed records* are maintained. These are further detailed in

M71.7 and the purpose is to reduce the number of running hours undertaken during the official tests.

Stage B. Detailed in M71.8

Stage C. Detailed in M71.9

M71.6

It was recognized that some designs of cylinder heads would not enable pressure measurements to be taken. For the purpose of type testing heads are to be suitably modified to enable these pressure measurements to be taken such that confidence in the results and design intent is achieved.

M71.7

The 100hr full load test has been moved to the stage A test to reduce the length of time Societies are required to be in attendance. This is on the basis that full records are kept by the manufacturer's test house and are available to Classification societies at any time upon request.

M71.8

The time to be run at any load point is a function of attaining steady state conditions and the length of time required for collection of data and for the attending surveyor to make a visual inspection. A recommendation time of 0.5 hours has been made.

5. Points of discussions or possible discussions

M71.3, Notes 2)

Discussion over an increase of the mean effective pressure proposed by CIMAC WG2 took place within the Panel.

> *Providing maximum power is not increased by more than 10%, an increase of maximum approved power may be permitted without a new type test provided engineering analysis and evidence of successful service experience in similar field applications (even if the application is not classified) or documentation of internal testing are submitted if the increase from the type tested engine is within:*
> - *10% of the maximum combustion pressure, or*
> - *15% of the mean effective pressure, or*
> - *10% of the rpm*

On the one hand, an increase in MEP by 15% was supported by six members as the increase in MEP by 15% is only applicable on condition that the RPM is reduced, given that the increase in MEP is also subject to the limitation to the power increase of 10% and the additional requirements, such as engineering analysis and service experience or internal testing, are also taken into account.

On the other hand, five members were of the view that the MEP should remain at 10% because MEP has a close relationship with engine component through-life loading and the engine stress level is proportional to MEP even with a slight decrease in the RPM. It is difficult to ensure the stress level of critical engine components, such as crankshaft and connecting rod, is still within the designed safety margin.

M71.8

Discussion centered on the test's load points after receiving representation from WG2. The consensus of the PT was that a Type Test should be exhaustive and any relaxation to test points should be considered in the acceptance test of individual engines.

6. Attachments if any

None

Technical Background (TB) document for Rev.1 1 UR M71 (Apr 2025)

1. Scope and objectives

This UR is associated with IACS UR M87 and contains the requirements for type testing of engines and subsystems.
The existing UR M71 has been reviewed and focuses on topics related to type testing.

Content related to type approval has been moved to the new UR M87, titled 'Certification Scheme for Reciprocating Internal Combustion Engines.

2. Engineering background for technical basis and rationale

CIMAC WG2 believes that the existing UR M51 and UR M71 need to be revised and updated in line with technological developments and with consideration of operational aspects.
CIMAC submitted proposed documents to the Machinery Panel (MP) for review, including the revised M51 and M71, as well as two new URs.

The Project Team PM19102 was tasked with organizing URs related to I.C. engine approval and inspection, considering CIMAC's proposals and operational aspects.
Some amendments were made based on experience gained through the implementation of the existing URs M44, M71, and M51.
The structure of the new UR M71 is also aligned with M87, M44, and M51, as applicable.

2a. Specification of the data utilized in the development/revision of the proposed IACS Resolution, if any

None

3. Source/derivation of the proposed IACS Resolution

Feedback from CIMAC WG2 and classification societies.

4. Summary of Changes intended for the revised Resolution:

The applicability date is set based on CIMAC's suggestion, as a sufficient transition period is required, especially considering the renewal of an expired type approval certificate shortly after the implementation of the new revision of UR M71

M71.1
General type approval topics are moved to M87.

M71.4
New paragraph "Definitions". Reference made to general definitions in M87. Only Definitions used in M71 are included here.

M71.5
Type approval requirements, including the definition of an engine type, have been moved to M87.
The paragraph has been revised to address the validity of the type test, specifying the circumstances under which a new type test is required. The main principles regarding cylinder arrangement and increases in engine rating are retained. Possible functional tests following a design update are also specified.

M71.5.3
The Machinery panel agreed to retain "or" instead of "and" as was suggested.

M71.5.3.2
Include “the latest approved” in the paragraph.

M71.5.5.1
To improve the intent of design update by adding the word “substantial”.

M71.8
The structure of Stage A tests is harmonized with Stage B: safety, functional, and load tests. The endurance test and load cycle tests for high-speed engines have been moved to this paragraph.

M71.8.1
The paragraph has been restructured based on CIMAC’s proposal for the sake of clarity in implementation and reading.

M71.8.6.2
Replace 'as applicable' with 'if deemed necessary by the engine designer' to harmonize the applicability of the load cycle tests that need to be included in the manufacturer’s test procedures.

M71.9
The original test requirements have been structured to safety, functional and load tests as well as inspection items of fire protection measures. The safety precautions are integrated in the safety tests.

M71.9.3.2
Test criteria for operation with damaged turbocharger are clarified. Test is required for 2- and 4-stroke engines, but for single main propulsion engine application only. Achievable output is specified for fixed pitch propeller application and controllable pitch propeller application

M71.9.4
Integration test is generalized with respect to sub-system systematic.

M71.9.5
Load test requirements have been converted into a table.

M71.9.5.3
Testing of sub-systems is added. A complete additional load test shall be avoided if the use of the sub-system is optional. Testing of Gas as fuel is not part of this paragraph. It is defined in M78.

M71.10.5
Components of relevant sub-system are to be inspected.

5. Points of discussions or possible discussions

M71.8.7
Current M71: Propulsion engines for high-speed vessels that may be used for frequent load changes from idle to full are normally to be tested with at least 500 cycles.

CIMAC proposal: High speed propulsion engines that may be used for frequent load

changes from idle to full are normally to be tested with at least 500 cycles.
An engine manufacturer also complaint that the wording in 8.7 is vague enough and is open to interpretation. After comparing the current M71.8.7, the Panel accept CIMAC's proposals even the wording is not prescriptive enough either.
The reasons are,
- what we should care about is the engine running condition, "frequent load changes from idle to full" is not limited to high speed vessels.
- "frequent load changes from idle to full" is normally for high speed engine and the expenses of such load cycle test for high speed engine can be accepted.
Consequently, the test is proposed to be limited to high speed propulsion engines.

M71.5.3.2, the Machinery panel agreed with CIMAC's suggestion to include "the latest approved" in the paragraph.

M71.5.5.1, the Machinery panel agreed with CIMAC's suggestion to improve the intent of design update by adding the word "substantial".

M71.8.6.2, the Machinery Panel agreed with CIMAC's suggestion to replace 'as applicable' with 'if deemed necessary by the engine designer' to harmonize the applicability of the load cycle tests that need to be included in the manufacturer's test procedures.

M71.9.2.2 CIMAC proposes, any other shut down function should be read as other shut down function not already demonstrated in the Type approval test of the engine control system.

The Machinery Panel doesn't agree because the type approval test for the control system is separate from testing the engine. Here, we're talking about the integration test of the control system.
Also, safety tests are crucial for the safety of everyone at the test bed. If the designer thinks it's necessary to shut down the engine in case of a failure, we need to show that it works properly.
According to the requirements, we're only looking at lub. oil pressure and thrust bearing temperature. The designer should limit the number of additional shutdowns needed to keep the engine available.

M71.9.3.2: CIMAC proposes to change the topic 'failure of engine' to a list of items such as fuel pump, lubrication pump, damaged piston, cylinder liner, exhaust valves, etc., instead of 'damaged turbocharger.'
This suggestion was discussed within the Machinery Panel, which determined that the test requirements for turbocharger failure, including function and maximum output tests, should be retained.
As the cylinder cut-out function (stable running) is tested in conjunction with the integration test of the control system, maximum output during cylinder cut-out should not be tested to avoid damage to the new engine. Other failures are addressed by the mandatory FMEA, subject to design approval, and it was concluded that further tests are not considered necessary.

M71.10.5: CIMAC proposes that the components of relevant sub-systems be inspected as agreed upon with the Society or stipulated by the engine designer when approved by the Society, which may require some dismantling, the suggestion agreed by the Machinery Panel.

The document has been reviewed by SuP without comment.

6. Attachments if any

UR M72 “Certification of Engine Components”

Summary

This revision of the UR provides clarifications regarding the NDE requirements of Engine Components.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev.3 (April 2023)	28 April 2023	1 July 2024
Rev.2 (Jan 2019)	07 January 2019	1 January 2020
Rev.1 (Mar 2016)	04 March 2016	1 July 2017
Corr.1 (Aug 2015)	20 August 2015	-
New (Feb 2015)	27 February 2015	1 July 2016

- **Rev 3 (Apr 2023)**

1 Origin for Change:

☑ Suggestion by IACS member

2 Main Reason for Change:

Task PM22913 was initiated to deal with queries from an engine manufacturer, submitted by CIMAC to the Panel, regarding waiving the NDE testing of cylinder heads due to special shaper of cylinder heads.

During the discussion on the above issue, further amendments to the text of UR M72 Note 2 were proposed by several members to clarify and improve the requirements.

3 List of non-IACS Member Classification Societies contributing through the TC Forum and/or participating in IACS Working Group:

None

4 History of Decisions Made:

A qualified majority agreed to edit the note 2 of UR M72.
The revisions to UR M72 resulting from PM22913 were agreed by a qualified majority.
The changes agreed under tasks PM22913 were combined into revision 3 of this UR.

5 Other Resolutions Changes

None

6 Dates:

Original Proposal:	17 July 2022	(by Machinery Panel)
Panel Approval:	04 April 2023	(Ref: PM22913_IMd)
GPG Approval:	28 April 2023	(Ref: 23047_IGc)

- **Rev 2 (Jan 2019)**

1 Origin for Change:

☑ Suggestion by IACS member

2 Main Reason for Change:

Task PM16910 was initiated to deal with queries from an engine manufacturer, submitted by a panel member, regarding the testing of cylinder blocks. Strict application of the UR M72 requirements would suggest that the requirements for engines that have a cylinder block type arrangement only apply to crosshead engines so therefore there are no test requirements for trunk-piston engines with a cylinder block type arrangement. (e.g. 4-stroke engines where the cylinders are not integral with the crank case).

During the discussion on the issue above, further amendments to the text or UR M72 were proposed by several members in order to clarify and improve the requirements.

In connection with UR M72, a further external query on the interpretation of the contents of UR M72 raised by an engine manufacturer was also being dealt with under task PM16907. This query regarded the application of the M72 requirements mechanical and chemical composition testing for high pressure fuel system components and a request for clarification of the Society Certificate definition in paragraph 1.2. The outcome from task PM16907 was a response to the manufacturer, it was agreed that any necessary revisions to UR M72 would be combined with the changes decided in PM16910.

3 List of non-IACS Member Classification Societies contributing through the TC Forum and/or participating in IACS Working Group:

None

4 History of Decisions Made:

A qualified majority agreed to extend the scope of PM16910 to include wider editorial modifications to UR M72.

The revisions to UR M72 resulting from PM16907 and PM16910 were agreed by a qualified majority.

The changes agreed under tasks PM16907 and PM16910 were combined into revision 2 of this UR.

5 Other Resolutions Changes

None

6 Dates:

Original Proposal: March 2016 by Machinery Panel
Panel Approval: 11 December2018 (Ref: PM16910_IMm)
GPG Approval: 07 January 2019 (Ref: 18212_IGb)

- **Rev 1 (Mar 2016)**

1 Origin for Change:

☑ Suggestion by IACS member

2 Main Reason for Change:

UR M72 requires hydraulic testing for high pressure fuel injection systems and common servo oil systems in the case of engines having cylinder bore exceeding 300mm.
However, for engines having cylinder bore not exceeding 300mm, the hydraulic testing requirements are not sufficiently clear especially for high pressure fuel injection pipes including common fuel rail and high-pressure common servo oil systems.
Machinery panel was agreed to revise UR M72 to clarify the scope of hydraulic testing.

3 List of non-IACS Member Classification Societies contributing through the TC Forum and/or participating in IACS Working Group:

None

4 History of Decisions Made:

The majority agreed that hydraulic testing is to be certified for all parts of the high-pressure piping system for components for engines of cylinder bore >300mm and that Test Reports are required for components for engines of cylinder bore ≦300mm.

5 Other Resolutions Changes

None

6 Dates:

Original Proposal: November 2015 by Machinery Panel
Panel Approval: 3 February 2016 (Ref: PM15906)
GPG Approval: 4 March 2016 (Ref: 16028_IGb)

- **Corr.1 (Aug 2015)**

1 Origin for Change:

☑ Request by non-IACS entity (Doosan Engines)

2 Main Reason for Change:

IACS Machinery Panel considered an external query questioning on the definitions of "Cylinder jacket" in UR M6 and "Cylinder liner, steel parts". Machinery Panel has worked on UR M72 to add a note as a follow-up action of the external query from Doosan Engines. The background is that UR M72 (new Feb 2015), which will replace both UR M6 and M18, requires pressure test for Cylinder block (for crosshead engines) and Engine block (for >400 kW/Cyl), but does not use the term "cylinder jacket" which may result in confusion whether the upper/lower jackets (new design) are to be pressure tested. In this respect, Machinery Panel decided to add a note in UR M72 to complement it.

3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

4 History of Decisions Made:

It was unanimously agreed within Machinery Panel to amend UR M72 as a 'Corrigendum' as this is just a clarification to the existing requirements (not a new technical requirement) and hence not considered as a 'Revision'. The implementation date of this corrigendum will be the same as that of the original version, i.e. 1 July 2016.

5 Other Resolutions Changes

None

6 Dates:

Panel Approval: 31 July 2015 (Ref: PM15904)
GPG Approval: 20 August 2015 (Ref: 15099_IGe)

- **New (Feb 2015)**

1 Origin for Change:

☑ Suggestion by IACS members
☑ Based on IACS Requirement *(M6, M18, M19, M58)*

2 Main Reason for Change:

For the test, inspection and certification of engine parts, perceived discrepancies existed among the existing unified requirements, modern manufacturing technology and current quality control procedures, and actual practices of IACS members. Alternative certification schemes will also be considered by PT. It is required to develop a new UR, which addresses engine parts certification, tests and inspection, to make them aligned.

3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

4 History of Decisions Made:

All URs related engine and engine parts inspection, such as M5, M6, M18, M19, M23 and so on, were reviewed during first two PT meeting. The initial draft was developed after the second PT meeting, which considered the existing requirements of engine parts inspections and PT members' proposals. The draft UR was worked out during the last two PT meetings. Many hours were spent in the process of determining which engine components should be included in the UR, relevant examinations/inspections that need to be carried out, type of certificates that should be required, and how the examination and certificate requirements of the engine components shall apply to engines of different type/bore size/power.

At the last PT meeting, the draft UR was completed except for the ">x kW" break-off points for engines.

The engine size break-points have been finalised by the panel.

At the 16th meeting it was agreed to move the definitions of Type of Certificates from UR Z-ACS to M72.

One society advised that all pumps, pipes and valves for the hydraulic oil and the flammable oil systems in the machinery space are generally required to be hydraulically tested depending on the design pressure not the physical size of the equipment or part.

Considering the danger of fire, hydraulic testing for the following parts and systems is to be carried out regardless of the size of the engine:

- -High pressure fuel injection pump body,
- -High pressure fuel injection valves that are not autofretted,
- -High pressure fuel injection pipes including common fuel rail,
- -High pressure common servo oil system,
- -Accumulator of common rail fuel or servo oil system,
- -Piping, pumps, actuators, etc. for hydraulic drive of valves, if applicable.

A majority of the Panel members voted to keep the present limitation of hydraulic testing to engines with cylinder bores exceeding 300mm.

5 Other Resolutions Changes

UR M6, M18, M19 and M58 to be deleted and replaced by this UR.

6 Dates:

Original Proposal: 02 April 2010 (Made by: IACS Machinery Panel PT)
Panel Approval: 08 January 2015 (By: IACS Machinery Panel)
GPG Approval: 27 February 2015 (Ref: 7569_IGw)

Part B. Technical Background

List of Technical Background (TB) documents:

Annex 1. **TB for New (Feb 2015)**

See separate TB document in Annex 1.

Annex 2. **TB for Rev.2 (Jan 2019)**

See separate TB document in Annex 2.

Annex 3. **TB for Rev.3 (Apr 2023)**

See separate TB document in Annex 3.

Note: *There are no Technical Background (TB) documents available for Corr.1 (Aug 2015) and Rev.1 (Mar 2016).*

Technical Background (TB) document for UR M72 (New Feb 2015)

1. Scope and objectives

Within the scope given in the Form A for MCH panel task PM5906, the existing UR's M5, M14, M18, M23 were identified as those dealing with testing of engine parts and materials.

The objective was to make them aligned with modern manufacturing technology and current quality control procedures considering that, with only minor deviations, all engine parts are manufactured with automated machines under strict quality control, thus granting full interchangeability of parts, and manual adjustment of parts is not normally applied.

Some additional UR's were also identified (M6, M19, M58) as dealing with testing of engine parts and materials, and have been reviewed as well, since the opportunity to combine them into a new UR covering all engine parts and testing activities was to be taken.

2. Engineering background for technical basis and rationale

Modern production technology which improves the accuracy and repeatability in component manufacturing. Improved quality control measures.
Experience gained through the implementation of existing URs and perceived need to solve the Reservation put forward.

3. Source/derivation of the proposed IACS Resolution

Reconsideration of previous URs and feed back from Class Societies on existing URs.

4. Engineering background of changes and additions.

A draft for an M72 was developed based upon proposals from different Societies, starting from general principles (suitably equipped plant, applied quality control system, conformity of production, documentation, class requirements) and going into details of a table listing tests and documentation required for engine parts.

For the definitions of type of documentation required and symbols, reference was made to the UI dealing with Alternative Certification Scheme (UI-ACS)

In the work to decide which engine components should be included in Table M72.2 of the UR, relevant examinations/inspections that need to be carried out, the kinds of certificates that should be required, and how the examination and certificate requirements of the engine components shall apply to engines of different type/bore size/power, factors as engine component criticality, manufacturer's quality control and practical issues as it has been recognized that not all parts can be tested under survey.

The work also focused on the possibility to delegate to the manufacturer most of the tests (and thus only requiring a Work's certificate), similar to that established for an Alternative Certification Scheme based on the general principle that a quality control system is to be in force.

The figure identifying the threshold size for each component can be either the bore diameter, the power (eventually per cylinder) or the type of engine (crosshead vs. trunk piston).

Significant modifications in respect of previously applicable URs are:

- Deletion of the definition of "mass production" and inspection procedures
- Addition of material test report for main, crosshead, and crankpin bearing
- Addition of Ultrasonic tests for bolts
- Deletion of material and NDT requirements for Crosshead and relevant bolts
- Deletion of material and NDT requirements for Steel gear wheels for camshaft drives
- Deletion of pressure test of piston crown
- Deletion of pressure test for injection valves and pipes that are auto fretted
- Deletion of pressure test for cooling space of exhaust pipes
- Addition of pressure test of air side of Charge air coolers
- Test requirements for turbochargers are moved into UR M-TC

5. Points of discussions or possible discussions

The need/possibility to require a Society Certificate, when the documentation requirement for all the tests to be carried out is a Work's certificate (except for a visual inspection); it was decided that the Work's certificates documentation review is an actual operation which, together with a visual inspection can allow the issuance of a Society certificate for the relevant component.

Therefore, for nearly all the material properties (chemical and mechanical properties), NDT, pressure tests and dimensional inspection, only Work's certificates are required (with the only exception of crankshafts and conrods).

One Society advised all pumps, pipes and valves for the hydraulic oil and the flammable oil systems in the machinery space are generally required to be hydraulically tested depending on the design pressure not the physical size of the equipment or part.

Considering the danger of fire, hydraulic testing for the following parts and systems is to be carried out regardless of the size of the engine:

- High pressure fuel injection pump body,
- High pressure fuel injection valves that are not autofretted,
- High pressure fuel injection pipes including common fuel rail,
- High pressure common servo oil system,
- Accumulator of common rail fuel or servo oil system,
- Piping, pumps, actuators, etc. for hydraulic drive of valves, if applicable.

A majority of the Panel members disagreed with the proposal so the present limitation of hydraulic testing for engines with cylinder bores exceeding 300mm remained.

During the course of review of the UR by the Panel several editorial changes and

corrections were made for requirements clarification for users.
One Society proposed required testing of the following items applicable to all main diesel engines that are essential for machinery propulsion:

- Engine driven pumps (oil, water, fuel, bilge)
- Coolers, both sides

The proposed additional testing requirements are based in part on the fact other similar equipment installed in the machinery space are generally required to have hydraulic testing based on the design pressure not the physical size of the equipment they are installed in.

A majority of the members disagreed with the proposal so the present limitation of hydraulic testing for engines with power output exceeding 800 kW per cylinder remained.

For repair of engines with bores less than 300 mm, UR accepts material certification of connecting rods based on manufacturer's Work's Certificate, rather than Society Certificate, in line with the practice of one Society.
An attempt to apply the document when amending M44 revealed that the X used in table M72.2 was not understood and it was agreed to add the explanation of the meaning of X.

None

Technical Background (TB) document for UR M72(Rev.2 Jan 2019)

1. Scope and objectives

Queries raised by manufacturers initiated two parallel tasks (PM16907 and PM16910). Task PM16907 resulted in a formal response being sent to the manufacturer. The points addressed in this response required some revision of UR M72 to clarify the certificate definitions and the requirements applying to high pressure fuel systems.

The query that initiated PM16910 relates to the testing requirements for cylinder blocks and whether these should apply to trunk piston type engines. This task's primary objective was to clarify this aspect of the Table. During initial reviews a range of further editorial amendments were identified by several members to clarify and improve the content of the UR. A qualified majority agreed to extend the scope of PM16910 to include wider changes to the UR to clarify a number of other minor issues.

2. Engineering background for technical basis and rationale

The principal technical change considered under PM16910 relates to the test requirements for cylinder blocks. It was agreed that the terminology in UR M72 should be understood in accordance with ISO 7967-1:2005 where the following definitions apply:

Engine block: crankcase with an integral cylinder or cylinder jacket (or casing)
Cylinder block: two or more cylinders, integral or bolted together

This means that the cylinder block test requirements should be applied to all engines that have this type of arrangement (irrespective of the engine type). Further interpreting UR M72 it was considered that the testing and certification requirements should be applied where the engine power is greater than 400kW/cylinder (to align with the requirements for engine blocks).

Further changes were discussed and agreed on the basis of the improvements made to the clarity of the current technical requirements.

3. Source/derivation of the proposed IACS Resolution

Amendments to the UR were developed under tasks PM16907 and PM16910.

4. Summary of Changes intended for the revised Resolution:

Changes to UR M72 identified as a result of PM16907 were as follows:

- The definition of society certificate was modified to clarify which component is to be tested.

- Minor modification to wording of Works Certificate definition to aid clarity.

- The requirements for mechanical and chemical testing for "High pressure fuel injection pipes including common fuel rail" and "High pressure common servo oil system" were identified, clarifying that "W(C+M) applies when D≤300mm.

- The requirements for mechanical and chemical testing for "high pressure fuel injection pump body" were introduced and made applicable both to D≤300mm and D>300mm.

- New footnote added to clarify that the requirements or UR M72 will be superseded if there are any applicable requirements provided in another UR.

Changes to UR M72 related to PM16910 as follows:

- Paragraph 1.4 amended in order to add the wording "batch" to clarify the definition of the Test Report.

- Paragraph 1.7 amended to open the requirement beyond the apparent assumption that the manufacture of the component is started and completed at a single site and make it more applicable to current manufacturing approaches.

- Cylinder blocks - The applicability of the testing requirements was amended to align with the requirements for engine blocks (<400kW/cyl).

- Forged main journals with flange – visual inspection expanded to include reference to fillets after it was noted that journals with flange might have a fillet radius (transition fillet radius) that should be subject to visual inspection.

- Piston rod – "if applicable" deleted as not considered necessary.

- Piston rod & Cross head – addition text in the non-destructive testing column deleted as it is potentially confusing. It was suggested that the current requirement appears to mandate two stages of CD and it is not immediately apparent why CD would need to be completed before final machining or why UT is not required after final machining.

- Various other minor typographical corrections made throughout.

- The rows of the table relating to "Semi-built crankshaft", "Crank throw" and "Forged main journal and journals with flange" were consolidated into a single row in the table as they all have the same test requirements.

5. Points of discussions or possible discussions

The changes to UR M72 were agreed by a qualified majority the following points of discussion were made:

PM16907 – the queries from the manufacturer relating to the technical requirements of the UR resulted in the following responses, these were adapted/incorporated into the revision of UR M72:

- With regards to high pressure injection systems and common servo oil systems, IACS originally intended to require "W" only for engines with bore exceeding 300mm and 'TR' for engines with bore not exceeding 300mm.
  Following this principle, IACS found it necessary to amend the requirements of hydraulic testing for those systems in Table M72.2 after adoption of UR M72.
  In particular, the hydraulic testing for "High pressure Fuel injection pipes

including common fuel rail" you have questioned are required for both D>300mm ("W") and D<300mm ("TR"). Please see UR M72 Rev.1 which was adopted on February 2016.

- Required documentation level was discussed for a long time, and then "W" or "TR" was put in the appropriate place for all components listed in Table M72.2.

- While it is not clearly specified in UR M72, it is necessary for piping to comply with relevant IACS UR such as UR P2.

- The expression "the certified product itself" is neither "a 3.2 certificate of the raw material" nor "type approved product". The expression "the certified product itself" means the product itself entitled to the certificate as a result of tests and inspections carried out.

Queries relating to the certificate types were replied to with the following agreed response, these points were incorporated into the revision of UR M72:

- The intention of sentence "the test was witnessed by the Society Surveyor" is to clarify that certificates issued by manufacturers are considered equivalent to a Society Certificate provided that Class surveyor endorsed it, even if certificates itself are not issued by Classification Society.

- In DNV-GL, ACS is MSA. In other Societies, please see page 11, APPENDIX 1 GLOSSARY, IACS UR M44.

- The expression "accredited third party" means "a completely independent person with stamp authority from the Classification Society, or a laboratory accepted by the Classification Society and authorized by the Authorities of the country where the laboratory is located to carry out the specific tests". In this case, the work's certificate is considered equivalent to a Society Certificate.

PM16910 – Changes made as described in section 4 above were agreed by a qualified majority, the following changes were proposed but did not receive majority support:

- Deletion of paragraph 1.5 was proposed as it was considered potentially superfluous to requirements and could be removed with no negative effect on the remaining UR but this did not receive sufficient support from the panel. All other changes were agreed (or amendments made that were then agreed) by the panel.

- Following a request by a Member Society, Members were requested to express their intention or not to add mechanical and chemical testing requirements for High pressure fuel injection valve (item 28 in Table M72.2). The qualified majority decided not to add these requirements for the reason that these valves are to be periodically maintained (with completely dismantled and assembled including an injection test at the last stage of maintenance) and Members are not aware of valve failures that may be attributed to a lack of mechanical and chemical testing.

- One Member Society proposed to modify paragraph 1.4 as follow in order to better clarify that the intent of the proposed update is to tie the Test Report to the components being certified or the related batch:

> "1.4 Test Report (TR)
> This is a document signed by the manufacturer stating:
> - conformity with requirements.
> - that the tests and inspections have been carried out on samples from the current production batch relating to the component(s) being certified."

The proposal was not supported by the qualified majority.

Technical Background (TB) document for UR M72 (Rev.3 April 2023)

1. Scope and objectives

Queries raised by manufacturers initiated on tasks (PM22913).
Task PM22913 resulted in a formal response being sent to the manufacturer. The points addressed in this response required some revision of UR M72 to clarify the required NDE test when isn't applicable due to shape of components.

The query that initiated PM22913 relates to the testing requirements for cylinder Heads and blocks of Engines.

This task's primary objective was to clarify this aspect of the note 2 of UR M72. During initial reviews a range of further editorial amendments were identified by several members to clarify and improve the content of the UR note 2. A qualified majority agreed to extend the scope of PM22913 to include changes to the UR to clarify a footnote 2 issues.

2. Engineering background for technical basis and rationale

The principal technical change considered under PM22913 relates to the NDE test requirements for cylinder heads & blocks. It was agreed that the terminology in UR M72 note 2 should be understood in accordance with ISO 12680-1 where the following definitions apply:

Ultrasonic examination Part1 for steel casting for general purposes & EN 12680-2 Founding – Ultrasonic examination Part 2 for steel casting for highly stressed components.

Further changes were discussed and agreed on the basis of the improvements made to the clarity of the current technical requirements.

3. Source/derivation of the proposed IACS Resolution

Amendments to the UR were developed under tasks PM22913.

4. Summary of Changes intended for the revised Resolution:

Changes to UR M72 identified as a result of PM22913 were as follows:

Non-destructive examination means e.g., ultrasonic testing, crack detection by MPI or DP. When certain NDE method on the finished component is impractical (for example UT for items 12/13), the NDE method can be performed at earlier appropriate stages in the production of the component, see M72.1.2.

UR M73 "Turbochargers"

Summary

In Rev.2 of this UR, clarifications have been provided as regards the expression "totally new design", the type testing load cycles and the containment test.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev.2 (May 2023)	25 May 2023	1 July 2024
Rev.1 (Mar 2022)	23 March 2022	1 January 2023
Corr.1 (June 2016)	03 June 2016	-
New (Feb 2015)	27 February 2015	1 July 2016

- **Rev.2 (May 2023)**

1 Origin of Change:

Suggestion by IACS member

2 Main Reason for Change:

2.1 To review the UR M73 based on industry comments seeking clarification on the expression "totally new design" specified in M73.3 and whether the 500 load cycles test is limited to turbochargers for high-speed engines;
2.2 to clarify the containment test temperature; and
2.3 to consider a proposal made in the past by the industry on containment safety critical cases.

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None

4 History of Decisions Made:

The revised UR was developed and agreed by correspondence and meeting within the panel.

5 Other Resolutions Changes:

None

6 Any hinderance to MASS, including any other new technologies:

None

7 Dates:

Original Proposal	: 03 October 2018	(Made by: Machinery Panel)
Panel Approval	: 24 April 2023	(Ref: PM13914aIMza & PM13914c)
GPG Approval	: 25 May 2023	(Ref: 19027_IGc)

- **Rev.1 (Mar 2022)**

1 Origin for Change:

Suggestion by a Machinery Panel Member

2 Main Reason for Change:

Need for uniform policy for legacy Turbochargers designed prior to entry into force of UR M73; in particular to Note 2 of UR M73 for the "date of application for certification".

3 List of non-IACS Member Classification Societies contributing through the TC Forum and/or participating in IACS Working Group:

None

4 History of Decisions Made:

With regard to the expression "new turbocharger type", the question is whether a turbocharger unit covered by a Type Approval (TA) certificate which is issued (or extended) on or after the effective date (1 July 2016) of the UR would need to be in full compliance with the requirements of the current (latest) edition of UR. Thus it was considered necessary to update the Application Note(s) of the UR.

5 Other Resolutions Changes:

Consideration for a possible combination with the work of PM13914a.

6 Any hinderance to MASS, including any other new technologies:

None

7 Dates:

Original Proposal	: 23 April 2021	Made by Machinery Panel
Panel Approval	: 13 December 2021	(Ref: PM13914bIMf)
GPG Approval	: 23 March 2022	(Ref: 22027_IGb)

- **Corr.1 (June 2016)**

1 Origin for Change:

Suggestion by a Machinery Panel Member

2 Main Reason for Change:

While reviewing UR M44 (Rev.8) and M44 (Rev.9) at Machinery Panel, it was found necessary to publish a corrigendum for further clarification on the application of UR M73.

3 List of non-IACS Member Classification Societies contributing through the TC Forum and/or participating in IACS Working Group:

None

4 History of Decisions Made:

UR M73 contains not only the requirements to be applied for individual turbo chargers (i.e., M73.4) but also the requirements to be applied for new turbocharger types (i.e., paragraphs other than M73.4). Thus, it was concluded necessary to publish a corrigendum in order to clarify the above.

Additionally, consideration was given to the term "a generic range" in paragraphs 2.3 and 3.2.2 coming with no clear definition. Therefore, a footnote providing the definition of "a generic range" was inserted at the bottom of a page containing paragraph 3.2.2 so as to give clearer understanding.

5 Other Resolutions Changes

None

6 Dates:

Original Proposal	: 02 November 2015	Made by Machinery Panel
Panel Approval	: 15 April 2016	(Ref: PM9906a)
GPG Approval	: 03 June 2016	(Ref: 16088_IGc)

- **New (Feb 2015)**

1 Origin for Change:

IACS WP/MCH Task 50

2 Main Reason for Change:

The existing M23 had been reviewed by PT PM5906, and perceived discrepancies were identified between the existing requirements and today's design and safety philosophy. It was agreed to develop a complete revision of UR for turbochargers, which addressed the technical requirements for turbochargers and their matching with engines.

3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

4 History of Decisions Made:

The existing M23 was reviewed after the Kick-off PT meeting, and the team agreed to develop a complete revision of UR for turbochargers, which addresses the requirements for turbocharger design approval, type test, monitoring and alarm, certification and matching with engines.

The draft was agreed at the last PT meeting.

Based upon feedback on Turbo Charger failure where the housing did not manage to contain the rotating parts due to the way the turbine disintegrated the containment test was altered.

5 Other Resolutions Changes:

UR M23 to be deleted and replaced by this UR.

6 Dates:

Original Proposal	: 01 July 2010	(Machinery Panel PM5906)
Panel Approval	: 08 January 2015	(Machinery Panel)
GPG Approval	: 27 February 2015	(Ref: 7569_IGw)

Part B. Technical Background

List of Technical Background (TB) documents for UR M73:

Annex 1. **TB for New (Feb 2015)**

See separate TB document in Annex 1.

Annex 2. **TB for Rev.1 (Mar 2022)**

See separate TB document in Annex 2

Annex 3. **TB for Rev.2 (May 2023)**

See separate TB document in Annex 3

Note: There is no separate Technical Background (TB) document available for Corr.1 (June 2016).

Technical Background (TB) document for Original UR M73 (Feb 2015)

1. Scope and objectives

Perceived discrepancies between the existing M23 "Mass production of engines: mass produced exhaust driven turboblowers" and today's design and safety philosophy required a complete revision of the UR for turbochargers. The new M-73 reflects changes in turbocharger design approaches and manufacturing processes based on modern technologies. The requirements are applicable for turbochargers regarding design approval, type testing and certification. The requirements focus on safety of personnel (containment in the event of disc burst), reliable lifetime performance, monitoring and proper matching with the engines.

2. Engineering background

Turbochargers are categorized in three groups depending on served power by cylinder groups with:

Category A ≤ 1000 kW
Category B >1000 kW and ≤ 2500 kW
Category C > 2500 kW

Documentation, type testing, certification and alarm and monitoring depend on this grouping. For all turbochargers a new introduced containment requirement becomes mandatory. Turbochargers shall fulfil containment in the event of a rotor burst. This means that at a rotor burst no part may penetrate the casing of the turbocharger or escape through the air intake.

3. Source /derivation of the proposed IACS Resolution

Even careful design and testing cannot completely exclude the event of a rotor burst or parts of it. By implementation of containment requirements in their rules some Societies have already addressed this. Based on their own design approach, containment tests or an analysis of sufficient containment integrity of the casing have been carried out by major turbocharger manufacturers.

4. Summary of Changes intended for the revised Resolution

M73.2 The documentation to be submitted depends on the categorization.
For turbochargers in Category A ≤ 1000 kW only the documentation for the containment and its integrity in case of a rotor burst must be submitted.

For categories B and C a more comprehensive documentation including alarm levels and type test reports shall be submitted.

For category C turbochargers, among others, additional material specifications, possible welding details and the summary of lifespan calculation shall be submitted.

M73.3 Here design requirements and corresponding type testing are specified. Focus is especially on the integrity of the containment and the component lifespan. For a generic range of turbochargers this shall be analyzed.

M73.4 Certification shall be based on the adoption and application of a quality system which shall ensure that the designer's specifications are met and that manufacturing is in accordance with the approved drawings. For category C turbochargers this shall be verified by means of periodic product audits by the society.

M73.5 For all turbochargers of category B and C in this part for the parameters to be monitored the alarm and display requirements are given.

5. Points of discussions or possible discussions

None

6. Attachments if any

None

Technical Background (TB) document for M73 Rev.1 (Mar 2022)

1. Scope and objectives

With regard to the expression "new turbocharger type" the discussion is on whether a turbocharger unit covered by a Type Approval (TA) certificate which is issued (or extended) on or after the effective date (1 July 2016) of the UR would need to be in full compliance with the requirements of the current (latest) edition of UR.

2. Engineering background for technical basis and rationale

Example case of possible scenario: TA certification: Last TA cert no. 3 for turbo model XY having validity dates 15 Sep 2018 - 14 Sep 2023 replaced expired TA cert no.2 for same model XY that had validity dates 15 Sep 2013 – 14 Sep 2018 and original application for certification date of 10 Aug 2013.

Compliance to UR M73: Turbochargers covered in last TA cert no. 3 for turbo model XY having validity dates 15 Sep 2018 - 14 Sep 2023 may not have been built in full compliance with the current(latest) UR M73 being in effect on or after 1 July 2016.

3. Source /derivation of the proposed IACS Resolution

There is a need for uniform approach between members, as opinions were divided. Some societies were of the view that the requirements of UR M73 are to be implemented for legacy turbochargers on/after 1 July 2016, while other societies' position was that legacy T/Cs are not required to comply with UR M73 at the time of their type approval certificates renewal.

4. Summary of Changes intended for the revised Resolution

After agreement to additions of the following types of Notes to the uniform application statement of this UR, Machinery Panel has agreed to the following:

(A) the need to replace the wording "becomes invalid" and "the issuance of a new certificate" with "reaches its expiry date" and "the issuance of a renewal certificate", respectively,

(B) deletion (and transfer to the TB file) of the last sentence of Note 2 based upon the understanding that it is clear that the "date of application" related to the existing (expired) type approval certificates cannot be used as the new "date of application" for renewal of type approval certificates.

(C) deletion (and transfer to the TB file) of the last sentence of the 1st Paragraph of Note 3 covered by the preceding sentence stating "[...] reaches its expiry date" and,

> *Note 2: The "date of application for certification" is the date of whatever document the Classification Society requires/accepts as an application or request for certification of a new turbocharger type or of a turbocharger type that has undergone substantive modifications in respect of the one previously type approved, or for renewal of an expired type approval certificate. On or after [date] the "date of application" of an expired type approval certificate*

may not be carried over/re-considered for the issuance of a new certificate and/or the validity of an existing certificate may not be extended for turbochargers that are not built in compliance with this UR revision.

Note 3: The requirements of UR M73 Rev.1, except for M73.4, are to be uniformly implemented by IACS Societies to turbochargers with the date of application for certification on or after [date]. Turbochargers with an existing type approval on [date] are not required to be re-type approved in accordance with this UR until the current Type Approval becomes invalid. For the purpose of certification of these turbochargers, the current type approval and related submitted documentation will be accepted in place of that required by this UR revision until the current type approval expires or the turbocharger type has undergone substantive modifications.

The requirements of M73.4 Rev.1 are to be uniformly implemented by IACS Societies to turbochargers with the date of application for certification of an individual turbocharger on or after [date].

5. Points of discussions or possible discussions

With regard to Note 2, for the purpose of certification of these turbochargers, the current type approval and related submitted documentation will be accepted in place of that required by this UR revision until the current type approval expires or the turbocharger type has undergone substantive modifications.

With regard to Note 3, on or after 1 January 2023 the “date of application” of an expired type approval certificate may not be carried-over/re-considered for the issuance of a renewal certificate and/or the validity of an existing certificate may not be extended for turbochargers that are not built in compliance with this UR revision.

6. Attachments if any

None

Technical Background (TB) document for UR M73 Rev.2 (May 2023)

1. Scope and objectives

The scope is the revision of the UR M73 to clarify the following points:

1) The expression "totally new design" in the context of a new reference containment test is required.

2) Whether 500 load cycles tests are required only for high-speed engines or also for low and medium speed engines, taking into account the provisions of UR M71 "Type Testing of I.C. Engines".

3) The temperature at which the containment test is conducted.

4) Designs with cases more critical that those defined in the UR with respect to containment safety.

2. Engineering background for technical basis and rationale

1) Various examples were proposed by the members regarding design changes that should be considered as "totally new design". Among them, what the members commonly considered as "totally new designs" were described as examples in this UR.

2) Some members considered that the 500 load cycles test was related to the item of the type test of the high-speed engines specified in the UR M 71.5.6 (Corr.1) and that it was not necessary to conduct this test for turbochargers intended for low and medium speed engines. However, the majority view was that 500 load cycles tests could not be omitted even for low and medium speed engines, and it was decided to state this clearly in this UR. (See paragraph 5)

3) In addition to the above 1), focus was given to the temperature and speed at which containment tests are to be carried out, and it was considered necessary to discuss the relationship between test speed, material temperature and mechanical properties, and the implications this may have for the containment test. (i.e., turbocharger operation resulting in lower casing temperatures may cause the material to have a more brittle behaviour which may, consequentially, provide a more onerous condition than would be the case at the maximum temperature. On the other hand, the materials conventionally used for turbocharger casings exhibit a characteristic whereby the Ultimate Tensile Strength (UTS) reduces as the temperature increases, albeit that the relationship is non-linear. In addition, as the casing temperature increases with engine power/turbocharger speed and that the centrifugal force of fragments which detach from the rotor increases with the square of turbocharger speed, it is considered that the most onerous test condition exists at maximum temperature and rotor speed.)

   After reviewing these matters with the industry, it was recognized that providing evidence for all cases in the speed range and temperature range would impose an undue burden on the manufacturer of the turbocharger that is not proportionate to the risk. Therefore, it was considered reasonable for manufacturers to review potential for more critical cases and, if such cases were identified, to require manufacturers to provide evidence of containment safety.

2a. Specification of the data utilised in the development/revision of the proposed IACS Resolution, if any

N/A

3. Source/derivation of the proposed IACS Resolution

N/A

4. Summary of Changes intended for the revised Resolution

1) List examples of design changes considered as "totally new design".
2) Clarify that 500 load cycles tests are required not only for high-speed engines but for low and medium speed engines.
3) Clarify the containment test temperature.
4) Specify that manufacturers are to determine whether test conditions more critical than those defined in M73 exist with respect to containment safety.

5. Points of discussions or possible discussions

Regarding 500 load cycles tests, a member understanded that the turbochargers for high-speed engines installed in high-speed vessels such as patrol vessels and fishing vessels should undergo the 500 load cycles test because those vessels perform quick and repeated start-stop operations, but it is not necessary to conduct the test for turbochargers for low and medium-speed engines typically installed in merchant vessels because those vessels don't perform such operations. However, majority disagreed with the above view.

Regarding the test temperature, a member pointed out that, unlike the speed, it is difficult to cause a burst at the intended temperature. However, there was a dissenting opinion that the test could actually be conducted, and this was not reflected in this UR.

6. Attachments if any

None

UR M74 “Ballast Water Management Systems”

Summary

In Rev.3 of this Resolution, a new section gathering ventilation requirements from UR F45 and UR M74 previous revision is added.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev.3 (Mar 2025)	03 March 2025	1 January 2027
Rev.2 (June 2021)	01 June 2021	1 July 2022
Rev.1 (Dec 2014)	19 May 2016	1 January 2017
New (Sept 2015)	17 September 2015	1 January 2017

- **Rev.3 (Mar 2025)**

1 Origin of Change:

☑ Other (request from GPG)

2 Main Reason for Change:

To merge the requirements for ventilation and vent pipes specified in UR F45 and in UR M74(Rev.2) to a new section in UR M74 for ships installed with BWTS, and to consider further amendments to UR M74.

3 Surveyability review of UR and Auditability review of PR

Draft rev.3 has been reviewed by SuP for surveyability items.

4 Human Element issues assessment

Not applicable

5 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None.

6 History of Decisions Made:

1. New section for ventilation requirements:

   Members agreed to merge the requirements for ventilation and vent pipes specified in UR F45 and in UR M74(Rev.2) in a new section 4 in UR M74 as per form A (agreed by members following PM21913_IMg). This section includes section 6 of UR F45 and also requirements 3.3.1.5, 3.3.2.3, 3.3.2.6, 3.3.2.7 and 3.3.2.8 of UR M74 rev.2.

The definition of BWMR from UR F45 is also added in M74.2.7 (PM21913_IMd), "BWMR" being used in the requirements transferred in UR M74.

Additionally, the following requirements' modifications have been made:

1.1. Change in paragraph 4.1.1 of UR M74 Rev3:
- Following a member's question to know whether BWMS category 6 could be provided with a de-gas arrangement, it was decided to apply the requirements of paragraph 4.1.1 to BWMS with hydrogen de-gas arrangement without mentioning their category (PM21913_IMk).
- The requirements concerning ventilation for hydrogen de-gas arrangement from §4.2.5 are now included in §4.1.1, considering that BWMS with de-gas arrangement can be installed in E/R (unlike BWMS using ozone) and that §4.2 is not applicable to E/R pursuant to new §4.2.6.
- Requirements for fans with spark arrester is replaced by requirement to have the ventilation installed with a flame arrester or a flame screen. Position of the flame screen or flame arrester has also been specified (PM21913_IMk, PM21913_IMr).

1.2. Change in §4.2.3 of UR M74 Rev3:
The wording: " dangerous gases that could be generated during the electrolysis process" is replaced by "dangerous gases that could leak into the BWMR during the electrolysis process" (PM21913_IMn), considering that dangerous gas will not be discharge directly into the BWMR.

1.3. Change in §4.2.5 of UR M74 Rev3:
- The requirements for hydrogen de-gas arrangements have been transferred to §4.1.1 (see above) (PM21913_IMn).
- Reference to primary and secondary ventilation is deleted as it is not defined and was unclear to machinery panel members (PM21913_IMk).

1.4. New §4.2.6:
This new paragraph was introduced after members agreed that both §4.2 and §4.3 are not applicable to the case where the BWMS is installed in the engine room (PM21913_IMn).

2. Modifications of sketches in Annex II:

   The meaning of "VOS", of the red and white circles with their different patterns for the spectacle flanges and of the yellow symbols inside the tank, in the sketches in annex II for BWMS technology group 3b (In-line de-oxygenation – injection of inert gas from either an oil fired inert gas generator or inert gas from treatment of the flue gas from main or auxiliary boilers) and 3c (In-tank de-oxygenation with IGG) were confusing and not well understood. The sketches are now completed and clarified (PM21913bIMc).

3. Requirements for hypochlorite:

Paragraphs 2.4 defining “dangerous liquid” is completed to emphasize that hypochlorite solution of 0.1% is not considered as a dangerous liquid.
The Panel majority was of the view that IACS is not in the position to give a definite limit for lower and higher concentration of dangerous or non-dangerous sodium hypochlorite liquid. This will be under the responsibility of manufacturer/supplier of hypochlorite solutions or certification holder of BWTS. There was however a majority support in the Panel for identifying hypochlorite solutions of concentration 0.1 % as non-dangerous. (PM21913cIMf).

4. Additional sketches for isolation means:

   For each means of appropriate isolation of paragraphs 3.2.3.1.1, 3.2.3.1.2 and 3.2.3.1.3, a new sketch corresponding to the alternative to the positive means, described in the note of each paragraph (“As an alternative to positive means of closure, an additional valve having such means of closure may be provided between the non-return valve and the liquid seal”) has been added for clear understanding (PM21913dIMc).

5. Reference to UR E22 in paragraph 3.1.4

   The sentence referring to UR E22 has been adapted following Cyber Panel recommendations (PM21912_IMt).

6. Arrangement of one single UV BWMS on board of tankers

   A single BWMS in category 1 is not acceptable when the system requires treatment for both ballasting and de-ballasting operation. This requirement was not clearly stated in the main text of UR M74, and it is now added in §3.2.2 (PM21913dIMd).
   Table 1 in UR M74 rev.2 did not allow a single BWMS category 1 installed outside the cargo area. Note (3) of table 1 in annex I is also changed to precise that a single BWMS in category 1 is not acceptable when the system require treatment for both ballasting and de-ballasting operation (PM21913dIMd).
   (Existing note (3) of table 1 in annex I concerning In-tank technologies is not kept as Annex I does not cover in-tank technologies).

7. Installation of BWMS in cargo compressor room and cargo pumps room

   Note 1 of paragraph 3.2.1.2 is deleted as it was unclear and considered as covered by paragraph 3.2.1 and 3.1.6 (PM21913dIMc).

8. Location of isolation means

   The wording “on the open deck in the cargo area” of paragraph 3.2.3.2 was deemed unclear as the isolation means could be accepted in enclosed space such as the cargo pump room, and not only on the weather deck in the cargo area. The requirement is therefore modified to allow installation of isolation means in an enclosed space in the cargo area for active substance, N2 gas, inert gas, neutralizer liquid, fresh water, compressed air or sea water piping up to 2 inches (PM21913dIMh and PM21913_IMw).

9. Alternative isolation arrangement - Note 2 of paragraph 3.2.3.1

   For clarity reason, note 2 of paragraph 3.2.3.1 has been modified (PM21913dIMc). Following a member's comment asking for the specific reasons of a waiver for piping up to 2 inches for only active substance piping and neutralizer piping, it was also extended to N2 gas, inert gas, fresh water, compressed air and sea water piping (still up to 2 inches) (PM21913dIMi).

10. Modifications of sketches for full flow treated ballast

    The sketches in annex I for BWMS technologies for which the only acceptable isolation means is a spool piece (case 1.2, 1.3a, 1.4 and 1.7) have been modified in order to show clearly the spool piece during ballasting operation (spool piece connected) (PM21913dIMh).

11. Other modifications

- Table 2 is removed from the UR and included in the technical background (PM21913_IMj) despite comments raised concerning the difficulties to maintain the table once it is in the TB. Nevertheless, members disagreed to delete completely the table as it does serve as valuable information to the various types (PM21913_IMi) although it may be problematic for new technologies going forward and for maintenance for each new revision of the UR.
- The paragraph 3.3.3.2 has been changed, replacing the wording "not containing dangerous liquid" and "not containing dangerous gas" by "containing non-dangerous liquid" and "containing non-dangerous gas" respectively. The examples given are indeed non dangerous liquid or gas so the new wording is more appropriate and not misleading (PM21913_IMh).
- Paragraph 3.1.4 has been updated following Cyber Panel recommendations (PM21913_PCa) as UR E22, which is referred to, has been revised from rev.2 to Rev.3.
- The note concerning the implementation date of the UR (note 5 of Rev.3) has been changed to be clearer concerning UR application for new ships on one hand and existing ships on the other hands (PM21913eIMj).

7 Other Resolutions Changes:

UR F45 "Installation of BWMS on-board ships" is changed by removing paragraph 6 of the UR related to ventilation and which have been transferred to UR M74.

8 Any hinderance to MASS, including any other new technologies:

None.

9 Dates:

Original Proposal	: 14 June 2021	(Ref: 17162_IGw)
Panel Approval	: 06 September 2024	(Ref: PM21913_IMx)
GPG Approval	: 03 March 2025	(Ref: 17162_IGze)

- **Rev.2 (June 2021)**

1 Origin of Change:

☑ Request by non-IACS entity (INTERCARGO)

2 Main Reason for Change:

- To address the following priority work:
    - 1.1. Align the requirements of IACS UR M74 with IEC 60092-502, SOLAS, IMO IBC and IGC Codes and UI SC 274;
    - 1.2. Separate clearly in the revised text of UR M74 the requirements which are exclusively applicable to tankers from the requirements applicable to any other type of ship;
    - 1.3. Extend the sketches of UR M74 to the most complete range of BWMS (including UV and electrolysis systems representing more than 90% of the BWMS's market);
    - 1.4. Align the requirements of UR M74 with UR P2;
    - 1.5. Analyse the applicability, the scope and the objective of the risk assessment specified in UR M74 § 3.4.4 to ensure that the operational limitations and need for mitigation measures are anticipated upstream from manufacturer's side and capitalized in a generic design appraisal process of manufacturer's package before shipyard's submission of the installation drawings for each installation on board a specific ship;
    - 1.6. Beyond the Statutory Type Approval Certification issued by the Administration for the compliance with IMO G8 Guideline, analyse the applicability, the scope and the objective of the Type Approval Certification process (or equivalent) to ensure that the type of BWMS complies with the Classification Rules and to ensure a consistent implementation for each installation on board (for new building and retrofit installation) as well as for the replacement of components during the lifecycle of the ship.
    - 1.a. Revise UR M74 with regards to the above objectives 1.1. to 1.4.
    - 1.b. Include all the potential benefits for the design review process by Classification Societies with regards to the above objectives 1.5. and 1.6. in the revised text of UR M74 or propose follow-up actions to the Machinery Panel.
- To address risks associated with various types of BWTS.
- To address the other priority work as follows:
    - 2.1. to analyse the concerns raised by INTERCARGO related to "retrofit problems" with regards to the following:

a. power consumption, mechanical reliability, replacement of components and consumables;

b. INTERCARGO's clarification expressed in MEPC 71/4/19 and MEPC 71/INF.20;

- 2.2. to include the concerns raised by INTERCARGO with regards to the above objective 2.1. in the revised text of UR M74 or propose follow-up actions to the Machinery Panel.

- 3. to analyse the additional concerns which extend beyond the objective 2., to include these additional considerations in the revised text of UR M74.

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None

4 History of Decisions Made:

- By 16208_IGa (2016-11-4) followed by IGb (2016-11-13), Machinery Panel was tasked to revise the UR M74 with the view of addressing the concerns raised by INTERCARGO related to the "retrofitting problems" on existing ships.

- Machinery Panel's reference PM11902bIMc dated 2017-01-16 where the creation of a Project Team to address the task PM11902b was agreed.

- Machinery Panel's reference PM11902bIMd dated 2017-03-14 deciding to conglobate the two tasks PM11902a and PM11902b in one task renumbered "PM11902b" for the works of the Project Team PT PM42/2017.

- By 16208IGe (2017-05-16) Machinery Panel was tasked to review the documents MEPC 71/INF.20 (*Information on the technical and operational challenges of retrofitting ballast water treatment systems on existing bulk carriers*) and MEPC 71/4/19 (*Challenges faced by bulk carrier owners and operators*) prepared by INTERCARGO for the 71th session of the IMO MEPC.

- By 17162IGa (2017-11-01), the first stage of PT PM 42/2017 discussion was provided to Safety Panel for their use under the task reference PS17030a (SP14017p): discuss fire safety protection issues associated with various types of BWTS considering the work of Machinery Panel's PM42/2017.

- Discussion was commenced to review the outcome of the PT PM 42/2017 in December 2019, and Rev.2 of this Resolution was agreed in February 2021.

- Furthermore, the following discussion was carried out:

    - After review of one of the F series URs developed by Safety Panel on BWMS, it was agreed to delete the proposed paragraph in UR M74.3.3.1.5 which was intended to require "interlock".

- After review of the definitions of the cargo area for oil tankers and for chemical tankers, it was agreed that only the definition for oil tankers should be changed.

5 Other Resolutions Changes:

None

6 Any hinderance to MASS, including any other new technologies:

None

7 Dates:

Original Proposal:	04 November 2016 (Ref: 16208_IGa_IMd)
Panel Approval:	10 May 2021 (Ref: PM11902dIMd)
GPG Approval:	01 June 2021 (Ref: 16208_IGp)

- **Rev.1 (May 2016)**

1 Origin for Change:

☑ Suggestion by IACS member

2 Main Reason for Change:

To address GPG's comments on the UR M74 (New Sept 2015) as well as additional issues raised by Machinery Panel members.

3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

4 History of Decisions Made:

The amendment to paragraph 3.1.7.1 proposed by GPG was generally agreed by the Panel subject to the deletion of "and PSC purpose" considering that the sampling point for PSC purpose is specified in paragraph 5.2 of Res. MEPC.173(58).

Regarding the proposed text as new paragraph 3.1.7.2, the Panel agreed with the philosophy but considers that 'correct operation' is undefined and the term 'system' could be referring to the whole system, or just the sampling system.

A Panel member proposed to revise the para 3.2.3.3 of the UR to add a non-return valve to the double block and bleed arrangement for the following reasons:

- the revised FSS Code requires the two means to prevent the backflow.
- the automatic double block and bleed valves are less safe than the other arrangements mentioned in 3.2.3.1 and 3.2.3.2 in the UR.

This proposal was supported by the majority thus agreed by the Machinery Panel.

The Machinery Panel, at its 21st meeting, agreed to revise the wording in para 3.1.3 of the UR to introduce the requirement on minimum treatment rate while operates the BWMS.

The Panel also agreed to update the definition of hazardous area in para 2.3 of the UR to align it with the IGC Code.
Noting the original version (New, Sept 2015) of UR M74 is not yet in force, GPG approved that the same uniform implementation date (1 January 2017) should be applied to the revision 1.

Considering that the existing uniform implementation statement in New (Sept 2015) can be also interpreted as the date of application to survey installations for BWMS onboard, GPG agreed to update the statement to clarify that the UR is to apply when a request to approve plans is made on or after 1 January 2017.

5 Other Resolutions Changes

None

6 Dates:

Panel Approval: 27 January 2016 (Ref: PM11902)
GPG Approval: 19 May 2016 (Ref: 11164_IGq)

- **New (Sept 2015)**

1 Origin for Change:

☑ Other (triggered by the Panel at the 12th meeting)

2 Main Reason for Change:

Despite the fact that the BWM Convention (2004) is expected to enter into force soon, the current UR set does not cover the issues raised with respect to the installation of the Ballast Water Management Systems (BWMS). For this reason, the Panel has decided to develop a relevant UR to assist shipyards, ship owners and makers of BWMS in view of smooth implementation of the Convention.

3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

4 History of Decisions Made:

Form A agreed by GPG under 11164_IGd dated 27 December 2011.

5 Other Resolutions Changes

None

6 Dates:

Original Proposal: 14 October 2011 (Ref: 11164_PMa)
Panel Approval: 1 June 2015 (Ref: PM11902)
GPG Approval: 17 September 2015 (Ref: 11164_IGm)

Note: *There is no Technical Background (TB) document available for Rev.1 (May 2016).*

Technical Background document for UR M74 (New, Sept 2015)

1. Scope and objectives

The BWM Convention (2004)[1] will enter into force soon. However, there is no unified requirement with respect to the installation of the Ballast Water Management Systems (BWMS). For this reason, the Machinery Panel has decided to develop a relevant UR 'Installation of ballast water management system' through PT11902. The benefit of undertaking the task is to provide specified requirements for shipyards, ship owners and makers of BWMS, which will in turn assist in smooth implementation of the Convention.

2. Engineering background for technical basis and rationale

This UR has been developed based on the results of the risk assessment and each PT member's experience/knowledge as there is no relevant rule except for BWM Convention 2004. The specific procedures for developing the UR are as follows:

1. To investigate BWMS approved by IMO so far;
2. To categorize types of BWMS;
3. To assess the risk of each type of BWMS (i.e. Piping Leaks, Explosion, etc.)
4. To categorize places where BWMS are installed (i.e. Dangerous area and safe area);
5. To develop the frame of UR (i.e. 1. Application, 2. Definition, etc.); and
6. To develop a draft UR based on identified risks and places where BWMS are installed, taking into account the following observations:
    a. class involvement may potentially be relevant for the consideration of other aspects (extending beyond the actual management performance of the system)
    b. broader aspects in relation with the integration of a ballast management system with other shipboard systems;

3. Source / derivation of the proposed IACS Resolution

1. BWM Convention (2004)
2. BWM.2/Circ.30: List of ballast water management systems that make use of Active Substances which received Basic and Final Approvals (2010)
3. IEC 60092-502: 1999 'Electrical installations in ships – Tankers'
4. IEC 60079: Electrical apparatus for explosive gas atmospheres
5. ABS GUIDE FOR BALLAST WATER TREATMENT Section.4/3.3 Ventilation System
6. IACS Recommendation No.9 Guidelines for installation of cargo oil discharge monitoring and control system on board oil tanker (Sept. 2005 Deleted)
7. MSC 292(87): ADOPTION OF AMENDMENTS TO THE INTERNATIONAL CODE FOR FIRE SAFETY SYSTEMS (2010)
8. MSC.1/Circ.1370: GUIDELINES FOR THE DESIGN, CONSTRUCTION AND TESTING OF FIXED HYDROCARBON GAS DETECTION SYSTEMS (2010)
9. SOLAS Reg.II-2/9

---
1 BWM Convention (2004): International Convention for the Control and Management of Ship's Ballast Water and Sediments adopted 13 Feb. 2004

4. Summary of Changes intended for the revised Resolution

None

5. Points of discussions or possible discussions

(1) Means of protection from the overflow

PT Members unanimously agreed to the following requirement 3.1.3 in the draft for the prevention of sustained flow including an audible and visible alarm with the values in the square brackets based on each member's experience.

『3.1.3 Means are to be provided to protect BWMS from the sustained flow which exceeds the [110]% of TRC for [60] seconds. An audible and visible alarm is to be activated when the flow exceeds [105]% of TRC.』

However, some members in the Machinery Panel pointed out that the wording 3.1.3 in the draft does not in line with the G8 and G9 of BWM Convention because the threshold level for alarming is subject to Flag Administration TA. Therefore, the following revised wording is inserted in the final draft.

『3.1.3 The BWMS is to be operated at a flow rate which does not exceed the Treatment Rated Capacity (hereinafter referred to as 'TRC') specified in the Type Approval Certificate (TAC) of flag administration.』

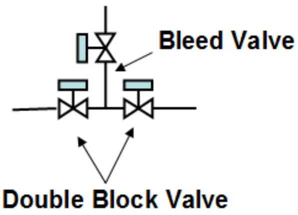
(2) How to arrange BWMS in tankers

The requirement 3.2.2 in the draft was a highly controversial topic.

In case of tankers carrying flammable liquids having a flashpoint not exceeding 60 ^{o}C or products listed in IBC Code Ch.17, two sets of an independent BWMS are required in principle – i.e. one for ballast tanks in hazardous areas and the other for ballast tanks in non-hazardous areas. However, it was generally agreed that two sets of an independent BWMS in one vessel could be a burden for ship owners. For these reasons, all members of PT11902 tried to find a solution and found out 'an appropriate isolation arrangement' to install 'one' BWMS in tankers. Subsequently, the following two isolation methods were proposed in the draft as appropriate isolation.

i) Two(2) screw down check valves in series

ii) Automatic double block and bleed valves



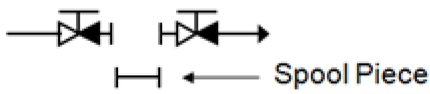
However, some members in the Machinery Panel raised reservations about the safety level of appropriate isolation arrangement, especially ‘Automatic double block and bleed valves’.

For this reason, industry hearing was carried out to reflect the opinion of shipyards and ship owners on this matter. Industries have had a general consensus on our intention and agreed with the concept of ‘Two (2) screw down check valves in series’.

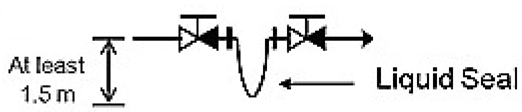
But they also have some doubts on the safety of ‘Automatic double block and bleed valves’, especially in case of the failure of valves, just like the members of IACS Machinery Panel pointed out. And, therefore, they have the less positive view on this arrangement, ‘Automatic double block and bleed valves’, expecting little profit in spite of lots of effort.

In consideration of the opinions by panel members and industries, it was decided to withdraw the proposal ‘Automatic double block and bleed valves’ and only consider two of the methods as appropriate isolation. However, GPG agreed to retain it. “Automatic double block and bleed valves” as an acceptable arrangement in 3.2.3. Means of appropriate isolation are therefore as follows:

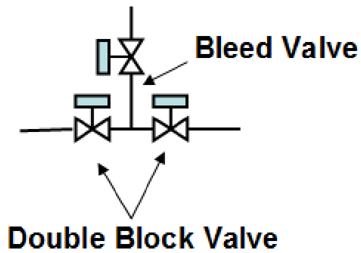
.1 Two screw down check valves in series with a spool piece, or



.2 Two screw down check valves in series with a liquid seal at least 1.5 m in depth, or



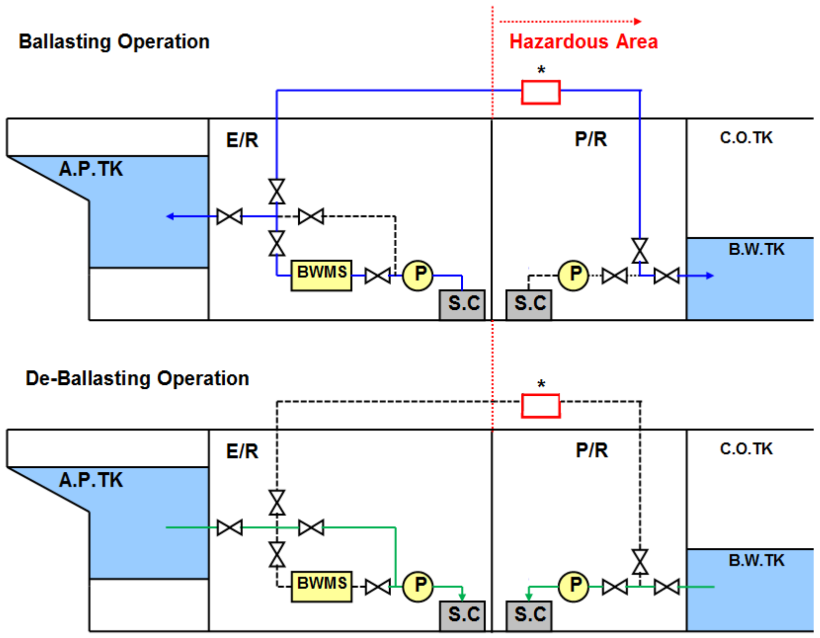
.3 Automatic double block and bleed valves



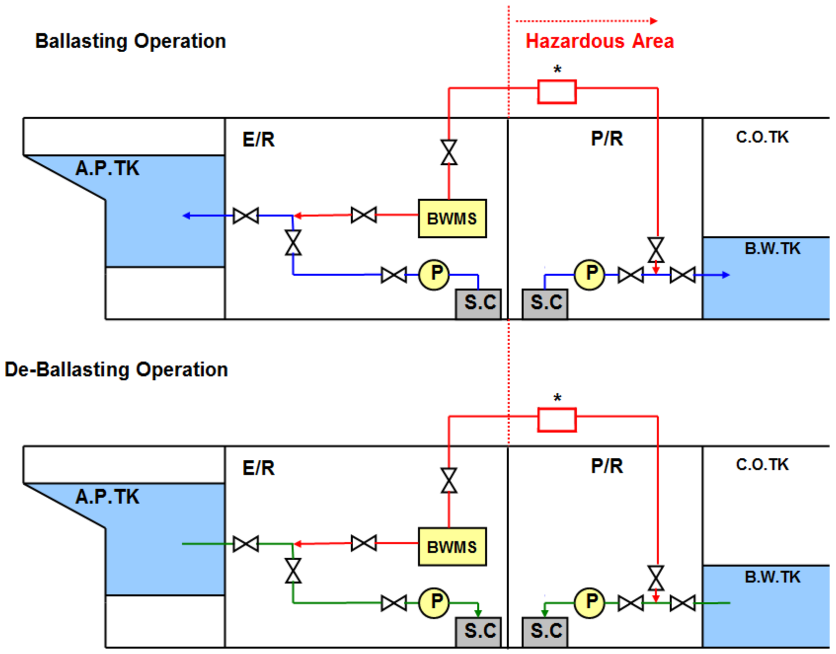
Examples of appropriate isolation arrangements are shown in Annex I. Isolation arrangements are to be fitted on the exposed deck in the hazardous area. Also, ballast water originating from a hazardous area is not to discharge into a non-hazardous area, except as given by 3.1.7.

Annex I:

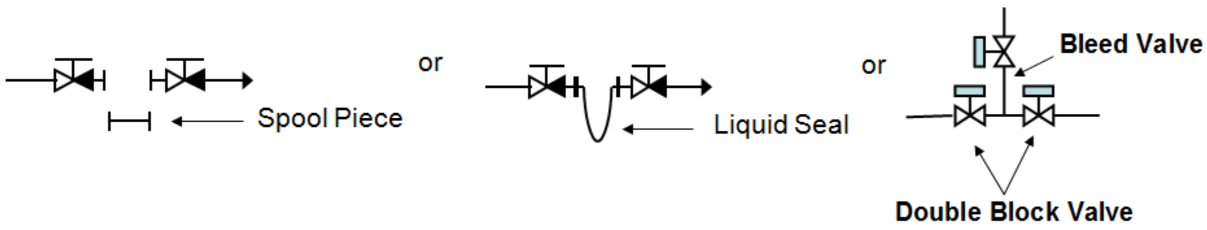
- BWMS which does not require after-treatment



- BWMS which requires after-treatment [Injection Type]



* : Appropriate Isolation Means: Two (2) screw down check valves in series with a spool piece or a liquid seal, or automatic double block and bleed valves



(3) Ventilation

The below table in the draft was developed based on the ABS GUIDE FOR BALLAST WATER TREATMENT, 'Section.4 / 3.3 Ventilation System'.

		BWMS in an enclosed space with access to hazardous area, Zone 1[1]	BWMS in an enclosed space with access to hazardous area, Zone 2[1]	
			Option 1	Option 2
Over-press. protection[2]	Overpressure ventilation	O	O	
	Overpressure loss alarm	O	O	
	Automatic power disconnection	O	O	
Air lock protection[3]	Air lock access	O		O
Mechanical ventilation[4]	At least 6 air change/hr			O
	Ventilation failure alarm			O

1. Refer to IEC60092-502 Clause 3.15.
2. Refer to IEC60092-502 Clause 8.4.
3. Refer to IEC60092-502 Clause 8.3.
4. The access is fitted with two doors forming an air-lock, both gas-tight, self-closing and without holding back arrangements.

However, the above table is simplified as the following wording, '3.3 Ventilation', in the final draft because some members gave comments that it is so complicated.

『3.3 Ventilation

3.3.1 BWMS not in hazardous areas

.1 A BWMS that does not generate dangerous gas is to be located in an adequately ventilated area.

.2 A BWMS that generates dangerous gas is to be located in the space fitted with a mechanical ventilation system providing at least six (6) air changes per hour or as specified by the BWMS manufacturer, whichever is greater.

3.3.2 BWMS in hazardous areas

A BWMS, regardless of generating dangerous gas, is to be located in the space fitted with mechanical ventilation complying with relevant requirements, i.e. IEC60092-502, IBC code, IGC code, etc.』

(4) Special Requirements

During the 20th machinery panel meeting dated from 16th to 19th Sept. 2014, Panel discussed how to deal with oily bilge water from the space where BWMS was located. Some members thought that the oily bilge water could be neglected due to the small amount, it can be treated as the same to the space for hydraulic machinery. Some members thought that even if there was a little leakage oily water, it can be accumulated by appropriate tray. After discussion, most of members thought it was unnecessary to address some requirements for oily bilge water from the space whether BWMS was located.

(5) Application of PV valves to de-oxidation type of BWMS

Paragraph 3.1.8 was proposed to allow the application of PV valves to de-oxidation type of BWMS, which requires an effective means to segregate ballast tanks from open air during the ballast water treatment process.

> 3.1.8 Pressure-vacuum valves (PV valves) may be accepted for closing devices of air pipes where the ballast water tanks are required to be closed due to the method of the BWMS, e.g. De-oxidation type of BWMS.

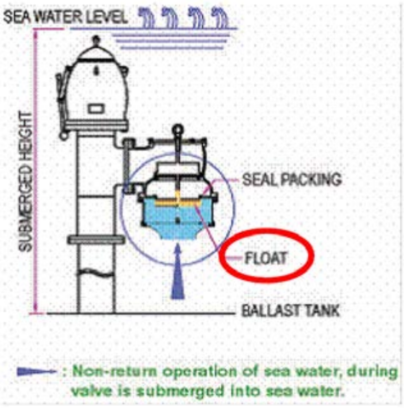
Several members argued that PV valves might be accepted only on tankers in accordance with Reg.20(4) of the ICLL Convention. In the prolonged discussion, however, considering the characteristics of de-oxidation type of BWMS, the Panel agreed to adopt PV valves as a practical means of segregation from open air.

In this case, ballast tanks should also be fulfilled the requirements of Reg. 20 of ICLL Convention. Following arrangements were suggested as satisfying such requirements;

i) A possible solution proposed is to combine a closable air pipe head at convention height above the deck and a PV valve at a height above the deck, both depending on location onboard. In other words, it proposes to fit a closable air pipe head at the height above the deck (760 mm / 450 mm) according to Reg. 20 of ICLL Convention and additionally to fit a PV valve at the height above the deck (4500 mm / 2300 mm) as a means of segregating the ballast tank from the air in order to comply with current ICLL Regulations and at the same time to adopt a PV valve as a practical means of segregation for the de-oxidation type of BWMS.

ii) If PV valves are applied, water on deck may flood easily into ballast tanks through the vacuum side of PV valves since the vacuum side of PV valves can be simply opened by the water ingress pressure. Therefore, the vacuum side of PV valves should be considered as open-end. One possible solution discussed was to assemble an automatic closing device to the vacuum side so that it can prevent water ingress through vacuum side of PV valves. Alternatively, PV valves equipped with a floater inside the chamber to prevent the flooding into the tank may be utilised to prevent penetration of sea water (See the figure below).

10. Optional arrangement 2.
for water ballast tanks



Finally, Machinery Panel decided to remove paragraph 3.1.8 from the UR and to insert the above into the Technical Background under the points of discussions.

6. Attachments if any

None

Technical Background document for UR M74 (Rev.2 June 2021)

1 Scope and objectives

1. Investigate all the BWMS on the market (Attachment 1) and provide a complete categorization of the available technologies (Table 1 and Annex II of UR M74 Rev.2).

2. Identify the specific hazards associated with the various BWMS technologies and provide the necessary requirements in Rev.2 when this was not covered in the Rev.1 (Attachment2, Table 2).

3. Separate from the UR M74 all the requirements related to fire safety that will be addressed by the Safety Panel PT PS17030a (Attachment 2, Table 2).

4. Apply the above principles set in 4. to the full range of in-line BWMS technologies identified in 1. and extend the Annex I accordingly (Rev.2 Annex I).

5. Align the requirements with the other IACS UR and UI, IMO regulations and IEC standards.

6. Revamp the vague expressions of the Rev.1 that could be subject to non-harmonized interpretations.

7. Provide the necessary requirements to ensure that the Rules from the Classification Societies will be fully implemented.

8. Clarify the applicability and scope of the risk assessment specified in UR M74 § 3.4.4

9. Beyond the statutory Type Approval Certification issued by the Administrations or their RO in the scope of the IMO Convention (G8 Guideline and BWMS Code), clarify the applicability and scope of the Type Approval Certification conducted for BWMS in the scope of Classification Rules and certification of components in the scope of Classification Rules

10. Address the concerns raised by INTERCARGO related to "retrofit problems".

2 Engineering background for technical basis and rationale

See Attachment 3.

3 Source / derivation of the proposed IACS Resolution

The Rev.2 is based on deep and thorough consideration of the following IMO, IACS and IEC requirements:

1. 2004 BWM Convention, IMO BWM/CONF/36 entered into force on 08 September 2017

2. 2008 G2 Guideline: IMO MEPC Res. 173(58) - Guidelines for ballast water sampling

→ Reference made in §3.2. 4 of the Rev.2 for the sampling lines (§3.1.7 in Rev.1)

3. 2008 G8 Guideline: IMO MEPC Res. 174(58) - Guidelines for the approval of BWMS

4. 2016 G8 Guideline: IMO MEPC 279(70) - Guidelines for the approval of BWMS that applies:

   a. when approving BWMS as soon as possible, but not later than 28 October 2018; and,

   b. for any BWMS installed on ships on or after 28 October 2020.

   c. BWMS installed on board ships prior to 28 October 2020 should be approved taking into account either the 2008 G8 Guideline, or preferably the 2016 G8 Guidelines.

→ Reference made for the implementation date of the Rev.2 at Note (3) of the front page.

Rev.2 of this UR is to be uniformly implemented by IACS Societies for BWMS:

i) For existing ships, where an application for approval for the plans of BWMS is made on or after 1 January 2022; or

ii) For new ships contracted for construction on or after 1 January 2022.

5. 2008 G9 Guideline: IMO MEPC Res. 169(57) - Procedure for approval of BWMS that make use of active substances

6. IMO (GESAMP) MEPC Reports for the Basic and Final approval in accordance with the G9 Guideline which provide for the concerned BWMS the necessary information for the assessment related to the presence of dangerous liquids or dangerous gas, the chemical reactions in presence, the necessary safety measures to be considered, etc.

→ Reference made for the safety assessment addressed by Note (1) of Table 1, Note (2) of §3.3.2, Note of §3.3.3.5 and Note of §3.3.4 of the Rev.2

7. IMO BWM.2/Circ. 7: Interim Survey Guidelines for the purpose of the International Convention for the Control and Management of Ship's Ballast Water and Sediments under the Harmonized System of Survey and Certification (Res. A.948(23)) implemented in 2017's HSSC Code Res. A.1120(30).

8. IMO BWM.2/Circ. 20: Guidance to ensure safe handling and storage of chemicals and preparations used to treat ballast water and the development of safety procedures for risks to the ship and crew resulting from the treatment process

9. IMO BWM.2/Circ.34/Rev.6: List of ballast water management systems that make use of active substances which received Basic and Final Approvals (2017)

10. IMO's document in Attachment 1, Table 3: List of BWMS which received Type Approval Certification by their respective Administrations (resolutions MEPC.175(58) and MEPC.228(65))

11. SOLAS Ch. II-2 Reg. 3/6: Definition of "cargo area" for oil tankers

→ Reference made in §2.2 of the Rev.2 and corrected in §3.2 of the Rev.2

12. IBC Code Ch. 1.3.6: Definition of "cargo area" for chemical tankers

→ Reference made in §2.2 of the Rev.2 and corrected in §3.2 of the Rev.2

13.IGC Code Ch. 1.2.7: Definition of "cargo area" for gas carriers

→ Reference made in §2.2 of the Rev.2 and corrected in §3.2 of the Rev.2

14. Note: On gas carriers, there is no ballast tank falling under the definition of "cargo area".

15. IMO Res. A.673(16) as amended by MSC Res. 236(82) Ch. 1.3.1(or OSV Chemical Code Res. A.1122(30) Ch 1.2.7): Definition of "cargo area" for OSV transporting and handling limited amount of noxious and hazardous substances in bulk

→ Reference made in §2.2 of the Rev.2 and corrected in §3.2 of the Rev.2

16. FSS Code Ch. 15 as amended by IMO MSC Res. 367(93): Inert gas systems

→ Reference made in §3.1.7 of the Rev.2 to select the applicable requirements for BWMS categories 3a, 3b, 3c and 8

→ Reference used in §2.2.3.1.3 of FSS Code Ch 15 for modifying "screw-down non-return valve" of the Rev.1 to "non-return valve with positive means of closure" + "Note: As an alternative of the means of closure, an additional valve having such means of closure may be provided between the non-return valve and…" in §3.2.3 of the Rev.2

→ Reference used in §2.3.1.1.2 of FSS Code Ch 15 to prohibit the installation of BWMS categories 3b and 3c in cargo area in §3.2.1.1 of the Rev.2

17. FSS Code Ch. 16, IMO MSC Res. 292(86): Fixed hydrocarbon gas detection systems

→ Reference used in § 3.2.4 of the Rev.2 (previously §3.1.7 in Rev.1).

18. IMO MSC.1 Circ. 1370: Guidelines for the design, construction and testing of fixed hydrocarbon gas detection systems

19. IACS UR P2 Rev.2 (November 2001): Rules for pipes

→ Reference made to UR P2 Table 1 in §3.3.2.1 of Rev.2 for the selection of the applicable Class of piping conveying dangerous gas (example O2 by-product, CH4 by product, O3 active substance, H2 by-product) or dangerous liquids (example sulfuric acid active substance): Class I without special safeguards or Class II with special safeguard

→ Reference made to Note 1) of Table 1 of UR P2 in Note 1) of §3.3.2.1 of Rev.2 to specify the acceptable "special safeguards" in case of Class II piping conveying dangerous gas (ex. O2, O3, H2): only pipe duct or double walled pipe can reduce a gas leakage and limit its consequences

→ Reference made to Note 1) of UR P2 Table 1 in Note 2) of §3.3.2.1 of Rev.2 to specify the acceptable "special safeguards" in case of Class II piping conveying dangerous liquids (ex. Sulfuric acid): additional safeguard may be considered such as shielding, screening, etc.

20. IACS UR P4 Rev.4 (December 2008): Production and application of platic pipes on ships

→ Reference made in Note 3) §3.3.2.1 of Rev.2

21. IACS UR F20 Rev.7 (May 2015): Inert gas systems

→ Reference made in §3.1.3.1.7 of Rev.2

→ Reference used in Note of §3.2.1.1 of Rev.2 to make the difference in between BWMS using an Inert Gas Generator (categories 3b or 3c) and BWMS using a Nitrogen Generator (categories 3a and 8).

→ Reference made to the foot note *) "safe location" of UR F20 in Footnote *) of Rev.2

22. IACS UR F44 Rev.2 (October 2010): Fore peak ballast systems on oil tankers

→ Reference made in Note §3.2.2 of Rev.2 to use the same BWMS for both Fore Peak Tank (that could be located outside the cargo area) and the other ballast water tanks within the cargo area when they are all supplied by the same ballasting system in accordance with the UR F44.

23. IACS UI SC274 (December 2015): Hazardous area classification in respect of selection of electrical equipment, cables and wiring and positioning of openings and air intakes

→ Reference made in §3.2.1 of Rev.2.

24. IEC 60092-502 (1999) §3.15: Definition of "hazardous area"

→ Reference made in §2.5 of the Rev.2 to tackle the inconsistencies of Rev.1.

25.IEC 60092-502 (1999) § 4.2.2.7: 3m zone 1 beyond gas or vapour outlet

→ Reference made in Footnote *) of the Rev.2 (outlet of the H2 degas device)

26. IEC 60092-502 (1999) §4.2.2.9: 1.5m zone 1 beyond openings into cofferdams or other zone 1 spaces

→ Reference made in § 3.1.5 of the Rev.2 (outlet of the P/V protecting devices installed on ballast water tanks)

27. IEC 60092-502 (1999) §4.2.2.9: 1.5m zone 2 beyond zone 1 as specified in 4.2.2

→ Reference made in Footnote *) and 3.1.5 of the Rev.2

28.IEC 60079-29 which includes not only Part 29-1: Gas detectors - Performance requirements of detectors for flammable gases; but also

a. Part 29-2: Gas detectors - Selection, installation, use and maintenance of detectors for flammable gases and oxygen; and

b. Part 29-3: Gas detectors - Guidance on functional safety of fixed gas detection systems; and

c. Part 29-4: Gas detectors - Performance requirements of open path detectors for flammable gases; and

→ Reference made to IEC 60079-29 in §3.3.1.1 of Rev.2 instead of 60079-29-1 (Rev.1) to include also the 60079-29-2 and 60079-29-3 and 60079-29-4

4 Summary of Changes intended for the revised Resolution

Comprehensive revision as highlighted in the underlined version of Rev.2.

5 Points of discussions or possible discussions

See Attachment 3.

6 Attachments if any

- **Attachment 1:** IMO's list of the 83 BWMS which have received Type Approval Certification by their respective Administrations (updated in December 2019).

- **Attachment 2:** BWMS Technologies – Identification of the specific hazards

  - Table 1: Proposal from PT PM 42/2017: issues addressed by the Machinery Panel through the UR M74 Rev.2

  - Table 2: Proposal from PT PM 42/2017: Fire safety protection issues to be addressed by the Safety Panel PT through PS17030a (SP14017p)

- **Attachment 3:** Detailed Engineering Background and Points of Discussion

****

Table 1: List of ballast water management systems that make use of Active Substances which received Basic Approval from IMO[1]

	Name of the system and proposing country	Name of manufacturer	Date of Basic Approval
1	Peraclean® Ocean (subsequently changed to SEDNA® Ballast Water Management System (Using Peraclean® Ocean)), Germany	Degussa GmbH, Germany	24 March 2006 (MEPC 54)
2	Electro-Clean (electrolytic disinfection) system (subsequently changed to Electro-Cleen™), Republic of Korea	Techcross Ltd. and Korea Ocean Research and Development Institute (KORDI)	24 March 2006 (MEPC 54)
3	Special Pipe Ballast Water Management System (combined with Ozone treatment), Japan (subsequently changed to FineBallast OZ (the Special Pipe Hybrid Ballast Water Management System combined with Ozone treatment version))	Japan Association of Marine Safety (JAMS)	13 October 2006 (MEPC 55)
4	EctoSys™ electrochemical system, Sweden (subsequently changed to the RWO ballast water management system)	Permascand AB, Sweden, subsequently acquired by RWO GmbH, Germany	13 October 2006 (MEPC 55)
5	PureBallast System, Sweden	Alfa Laval/Wallenius Water AB	13 July 2007 (MEPC 56)
6	NK Ballast Water Treatment System, Republic of Korea (subsequently changed to NK-O3 BlueBallast System (Ozone))	NK Company Ltd., Republic of Korea	13 July 2007 (MEPC 56)
7	Hitachi Ballast Water Purification System (ClearBallast), Japan	Hitachi, Ltd./Hitachi Plant technologies, Ltd.	4 April 2008 (MEPC 57)
8	Resource Ballast Technologies System, South Africa	Resource Ballast Technologies (Pty) Ltd.	4 April 2008 (MEPC 57)
9	GloEn-Patrol™ Ballast Water Management System, Republic of Korea	Panasia Co., Ltd.	4 April 2008 (MEPC 57)
10	OceanSaver® Ballast Water Management System, Norway	MetaFil AS (subsequently changed to OceanSaver AS)	4 April 2008 (MEPC 57)
11	TG Ballastcleaner and TG Environmentalguard System (subsequently changed to JFE Ballast Water Management System), Japan	The Toagosei Group (TG Corporation, Toagosei Co., Ltd. and Tsurumi Soda Co., Ltd.)	10 October 2008 (MEPC 58)
12	Greenship Sedinox Ballast Water Management System, the Netherlands	Greenship Ltd	10 October 2008 (MEPC 58)
13	Ecochlor® Ballast Water Treatment System, Germany	Ecochlor, Inc, Acton, the United States	10 October 2008 (MEPC 58)
14	Blue Ocean Shield Ballast Water Management System, China	China Ocean Shipping (Group) Company (COSCO)	17 July 2009 (MEPC 59)

[1] More comprehensive information regarding the systems approved until May 2019 is available in document BWM.2/Circ.34/Rev.8.

Table 1 (continued)

	Name of the system and proposing country	Name of manufacturer	Date of Basic Approval
15	Hyundai Heavy Industries Co., Ltd. (HHI) Ballast Water Management System (EcoBallast), Republic of Korea	Hyundai Heavy Industries Co., Ltd., Republic of Korea	17 July 2009 (MEPC 59)
16	AquaTriComb™ Ballast Water Treatment System, Germany	Aquaworx ATC GmbH	17 July 2009 (MEPC 59)
17	SiCURE™ Ballast Water Management System, Germany	Siemens Water Technologies	26 March 2010 (MEPC 60)
18	Sunrui Ballast Water Management System (subsequently changed to BalClor Ballast Water Management System), China	Qingdao Sunrui Corrosion and Fouling Control Company	26 March 2010 (MEPC 60)
19	DESMI Ocean Guard Ballast Water Management System, Denmark	DESMI Ocean Guard A/S	26 March 2010 (MEPC 60)
20	Blue Ocean Guardian (BOG) Ballast Water Management System, (subsequently changed to "ARA Ballast" Ballast Water Management System), Republic of Korea	21st Century Shipbuilding Co., Ltd.	26 March 2010 (MEPC 60)
21	Hyundai Heavy Industries Co., Ltd. (HHI) Ballast Water Management System (HiBallast), Republic of Korea	Hyundai Heavy Industries Co., Ltd., Republic of Korea	26 March 2010 (MEPC 60)
22	Kwang San Co., Ltd. (KS) Ballast Water Management System "En-Ballast", Republic of Korea	Kwang San Co., Ltd.	26 March 2010 (MEPC 60)
23	OceanGuard™ Ballast Water Management System, Norway	Qingdao Headway Technology Co., Ltd.	26 March 2010 (MEPC 60)
24	Severn Trent DeNora BalPure® Ballast Water Management System (subsequently changed to BalPure® BP-500), Germany	Severn Trent De Nora (STDN), LLC	26 March 2010 (MEPC 60)
25	Techwin Eco Co., Ltd. (TWECO) Ballast Water Management System (Purimar), Republic of Korea	Techwin Eco Co., Ltd. Purchased by Samsung	1 October 2010 (MEPC 61)
26	AquaStar Ballast Water Management System, Republic of Korea (subsequently changed to AquaStar™ BWMS and MACGREGOR WATER BALLAST TREATMENT SYSTEM)	AQUA Eng. Co., Ltd.	1 October 2010 (MEPC 61)
27	Kuraray Ballast Water Management System, (subsequently changed to MICROFADE™ Ballast Water Management System), Japan	Kuraray Co., Ltd.	1 October 2010 (MEPC 61)
28	ERMA FIRST Ballast Water Management System (subsequently changed to ERMA FIRST BWTS), Greece	ERMA FIRST ESK Engineering Solutions S.A.	15 July 2011 (MEPC 62)
29	BlueSeas Ballast Water Management System, Singapore	Envirotech and Consultancy Pte. Ltd.	15 July 2011 (MEPC 62)
30	SKY-SYSTEM® with Peraclean® Ocean Ballast Water Management System, Japan	Katayama Chemical, Inc.	15 July 2011 (MEPC 62)

Table 1 (continued)

	Name of the system and proposing country	Name of manufacturer	Date of Basic Approval
31	JFE BallastAce that makes use of NeoChlor Marine® Ballast Water Management System, Japan	JFE Engineering Corporation	15 July 2011 (MEPC 62)
32	BallastMaster Ballast Water Management System, Germany	GEA Westfalia Separator Systems GmbH	15 July 2011 (MEPC 62)
33	BlueWorld Ballast Water Management System, Singapore	Envirotech and Consultancy Pte. Ltd.	15 July 2011 (MEPC 62)
34	Neo-Purimar™ Ballast Water Management System, Republic of Korea	Samsung Heavy Industries Co., Ltd.	15 July 2011 (MEPC 62)
35	"Smart Ballast" Ballast Water Management System, Republic of Korea	STX Metal Co., Ltd.	2 March 2012 (MEPC 63)
36	DMU ·OH Ballast Water Management System, China	Dalian Maritime University	2 March 2012 (MEPC 63)
37	EcoGuardian™ Ballast Water Management System, Republic of Korea	Hanla IMS Co., Ltd.	2 March 2012 (MEPC 63)
38	KTM-Ballast Water Management System, Republic of Korea (subsequently changed to MARINOMATE™ Ballast Water Management System)	Korea Top Marine (KT Marine) Co., Ltd.	5 October 2012 (MEPC 64)
39	Hamworthy Aquarius™-EC BWMS, the Netherlands (subsequently changed to Aquarius™-EC BWMS)	Hamworthy Water Systems Ltd.	5 October 2012 (MEPC 64)
40	OceanDoctor Ballast Water Management System, China	Jiujiang Precision Measuring Technology Research Institute	5 October 2012 (MEPC 64)
41	HS-BALLAST Ballast Water Management System, Republic of Korea	HWASEUNG R&A Co., Ltd.	5 October 2012 (MEPC 64)
42	GloEn-Saver™ Ballast Water Management System, Republic of Korea	PANASIA Co., Ltd.	5 October 2012 (MEPC 64)
43	Van Oord Ballast Water Management System, the Netherlands	Van Oord B.V.	17 May 2013 (MEPC 65)
44	REDOX AS Ballast Water Management System, Norway	REDOX Maritime Technologies AS	17 May 2013 (MEPC 65)
45	BlueZone™ Ballast Water Management System, Republic of Korea	SUNBO INDUSTRIES Co., Ltd., DSEC Co., Ltd., and the Korean Institute of Machinery & Material (KIMM)	17 May 2013 (MEPC 65)
46	ECOLCELL BTs Ballast Water Management System, Italy	Azienda Chimica Genovese (ACG)	4 April 2014 (MEPC 66)
47	Ecomarine-EC Ballast Water Management System, Japan	Ecomarine Technology Research Association	4 April 2014 (MEPC 66)
48	ATPS-BLUE$_{sys}$ Ballast Water Management System, Japan	Panasonic Environmental Systems & Engineering Co., Ltd.	4 April 2014 (MEPC 66)
49	KURITA™ Ballast Water Management System, Japan	Kurita Water Industries Ltd.	4 April 2014 (MEPC 66)
50	ElysisGuard ballast water management system, Singapore	KALF Engineering Pte. Ltd.	17 October 2014 (MEPC 67)

Table 1 (continued)

	Name of the system and proposing country	Name of manufacturer	Date of Basic Approval
51	NK-CI BlueBallast System, Republic of Korea	NK Company Ltd.	15 May 2015 (MEPC 68)
52	ECS-HYCHLOR™ System, Republic of Korea	TECHCROSS Inc.	15 May 2015 (MEPC 68)
53	ECS-HYCHEM™ System, Republic of Korea	TECHCROSS Inc.	15 May 2015 (MEPC 68)
54	ECS-HYBRID™ System, Republic of Korea	TECHCROSS Inc.	15 May 2015 (MEPC 68)
55	VARUNA Ballast Water Treatment System, Singapore	Kadalneer Technologies Pte. Ltd.	15 May 2015 (MEPC 68)
56	ClearBal BWMS, Denmark	University of Strathclyde	28 October 2016 (MEPC 70)
57	MICROFADE II BWMS, Netherlands	Kashiwa Co., Ltd. and Kuraray Co., Ltd	7 July 2017 (MEPC 71)
58	Envirocleanse inTank™ BWTS, Norway	Envirocleanse, LLC	7 July 2017 (MEPC 71)
59	BIOBALLAST 1000	Biomarine S.r.l.	26 October 2018 (MEPC 73)
60	CleanBallast® – Ocean Barrier System	Veolia Water Technologies Deutschland GmbH	17 May 2019 (MEPC 74)
61	FlowSafe, Cyprus	Flowater Technologies Ltd.	17 May 2019 (MEPC 74)

Table 2: List of ballast water management systems that make use of Active Substances which received Final Approval from IMO[2]

	Name of the system and proposing country	Name of manufacturer	Date of Final Approval
1	PureBallast System, Norway	Alfa Laval/Wallenius Water AB	13 July 2007 (MEPC 56)
2	SEDNA® Ballast Water Management System (Using Peraclean® Ocean), Germany	Degussa GmbH, Germany	4 April 2008 (MEPC 57)
3	Electro-Cleen™ System, Republic of Korea	Techcross Ltd. and Korea Ocean Research and Development Institute (KORDI)	10 October 2008 (MEPC 58)
4	OceanSaver® Ballast Water Management System, Norway	OceanSaver AS	10 October 2008 (MEPC 58)
5	RWO Ballast Water Management System (CleanBallast), Germany	RWO GmbH Marine Water Technology, Germany	17 July 2009 (MEPC 59)
6	NK-O3 BlueBallast System (Ozone), Republic of Korea	NK Company Ltd., Republic of Korea	17 July 2009 (MEPC 59)
7	Hitachi Ballast Water Purification System (ClearBallast), Japan	Hitachi, Ltd. /Hitachi Plant technologies, Ltd.	17 July 2009 (MEPC 59)
8	Greenship Sedinox Ballast Water Management System, the Netherlands	Greenship Ltd	17 July 2009 (MEPC 59)
9	GloEn-Patrol™ Ballast Water Management System, Republic of Korea	Panasia Co., Ltd.	26 March 2010 (MEPC 60)
10	Resource Ballast Technologies System, South Africa	Resource Ballast Technologies (Pty) Ltd.	26 March 2010 (MEPC 60)
11	JFE BallastAce® Ballast Water Management System, Japan	JFE Engineering Corporation	26 March 2010 (MEPC 60)
12	Hyundai Heavy Industries Co., Ltd. (HHI) Ballast Water Management System (EcoBallast), Republic of Korea	Hyundai Heavy Industries Co., Ltd., Republic of Korea	26 March 2010 (MEPC 60)
13	Special Pipe Hybrid Ballast Water Management System combined with Ozone treatment version (SP-Hybrid BWMS Ozone version), Japan	Mitsui Engineering & Shipbuilding Co., Ltd.	1 October 2010 (MEPC 61)
14	"ARA Ballast" Ballast Water Management System, Republic of Korea	21st Century Shipbuilding Co., Ltd.	1 October 2010 (MEPC 61)
15	BalClor Ballast Water Management System, China	Qingdao Sunrui Corrosion and Fouling Control Company	1 October 2010 (MEPC 61)
16	OceanGuard™ Ballast Water Management System, Norway	Qingdao Headway Technology Co., Ltd.	1 October 2010 (MEPC 61)
17	Ecochlor® Ballast Water Management System, Germany	Ecochlor Inc, Acton, the United States	1 October 2010 (MEPC 61)

[2] More comprehensive information regarding the systems approved until May 2019 is available in document BWM.2/Circ.34/Rev.8.

Table 2 (continued)

	Name of the system and proposing country	Name of manufacturer	Date of Final Approval
18	Severn Trent De Nora BalPure® Ballast Water Management System (subsequently changed to BalPure® BP-500), Germany	Severn Trent De Nora (STDN), LLC	1 October 2010 (MEPC 61)
19	HiBallast Ballast Water Management System, Republic of Korea	Hyundai Heavy Industries Co., Ltd.	15 July 2011 (MEPC 62)
20	Purimar Ballast Water Management System, Republic of Korea Final Approval extended for use in fresh water	Samsung Heavy Industries Co., Ltd.	15 July 2011 (MEPC 62) 17 May 2019 (MEPC 74)
21	SiCURE™ Ballast Water Management System, Germany	Siemens Water Technologies	2 March 2012 (MEPC 63)
22	ERMA FIRST Ballast Water Management System (subsequently changed to ERMA FIRST BWTS), Greece	ERMA FIRST E.S.K. Engineering Solutions S.A.	2 March 2012 (MEPC 63)
23	MICROFADE™ Ballast Water Management System, Japan	Kuraray Co., Ltd.	2 March 2012 (MEPC 63)
24	AquaStar™ Ballast Water Management, Republic of Korea (subsequently changed to AquaStar™ BWMS and MACGREGOR WATER BALLAST TREATMENT SYSTEM)	AQUA Eng. Co.	2 March 2012 (MEPC 63)
25	Neo-Purimar™ Ballast Water Management System, Republic of Korea	Samsung Heavy Industries Co., Ltd. (SHI)	2 March 2012 (MEPC 63)
26	DESMI Ocean Guard BWMS, Denmark	DESMI Ocean Guard A/S	5 October 2012 (MEPC 64)
27	JFE BallastAce that makes use of NEO-CHLOR MARINE™, Japan	JFE Engineering Corporation	5 October 2012 (MEPC 64)
28	Smart Ballast BWMS, Republic of Korea	STX Metal Co., Ltd.	5 October 2012 (MEPC 64)
29	AQUARIUS® EC Ballast Water Management System, the Netherlands	Wärtsilä Water Systems Limited	17 May 2013 (MEPC 65)
30	EcoGuardian™ Ballast Water Management System, Republic of Korea	Hanla IMS Co., Ltd.	17 May 2013 (MEPC 65)
31	OceanDoctor BWMS, China	Jiujiang Precision Measuring Technology Research Institute and Institute of Marine Materials Science and Engineering of Shanghai Maritime University	17 May 2013 (MEPC 65)
32	Ballast Water Management System with PERACLEAN® OCEAN (SKY-SYSTEM), Japan	Nippon Yuka Kogyo Co., and Katayama Chemical, Inc.	4 April 2014 (MEPC 66)
33	Evonik Ballast Water Treatment System with PERACLEAN® OCEAN, Germany	Evonik Industries AG	4 April 2014 (MEPC 66)

Table 2 (continued)

	Name of the system and proposing country	Name of manufacturer	Date of Final Approval
34	MARINOMATE™ Ballast Water Management System, Republic of Korea	KT Marine Co. Ltd.	17 October 2014 (MEPC 67)
35	BlueZone™ Ballast Water Management System, Republic of Korea	SUNBO Industries Co. Ltd.	17 October 2014 (MEPC 67)
36	KURITA Ballast Water Management System, Japan	Kurita Water Industries Ltd.	17 October 2014 (MEPC 67)
37	Ecomarine-EC Ballast Water Management System, Japan	Ecomarine Technology Research Association	15 May 2015 (MEPC 68)
38	ECS-HYCHLOR™ System, Republic of Korea	TECHCROSS Inc.	22 April 2016 (MEPC 69)
39	NK-Cl BlueBallast System, Republic of Korea	NK Company Ltd.	22 April 2016 (MEPC 69)
40	ATPS-BLUE$_{sys}$ Ballast Water Management System, Japan	Panasonic Environmental Systems & Engineering Co., Ltd.	22 April 2016 (MEPC 69)
41	ECS-HYCHEM™ System, Republic of Korea	TECHCROSS Inc.	28 October 2016 (MEPC 70)
42	ECS-HYBRID™ System, Republic of Korea	TECHCROSS Inc.	7 July 2017 (MEPC 71)
43	Envirocleanse inTank™ BWTS (Electrochlorination Variation), Norway	Envirocleanse, LLC.	26 October 2018 (MEPC 73)
44	Envirocleanse inTank™ BWTS (Bulk Chemical Variation), Norway	Envirocleanse, LLC	17 May 2019 (MEPC 74)
45	MICROFADE II, Japan	Kuraray Co., Ltd.	17 May 2019 (MEPC 74)

Table 3: List of type approvals for ballast water management systems that are in accordance with the 2016 Guidelines (G8) or the BWMS Code (resolution MEPC.279(70) or MEPC.300(72))*

	Approval Date	Name of the Administration	Name of the ballast water management system	Copy of Type Approval Certificate	Active Substance employed	MEPC report granting Final Approval
1	2 February 2018	Norwegian Maritime Authority	PureBallast 3.2 and PureBallast 3.2 Compact Flex ballast water management system	Provided (MEPC 72/INF.19)	No Active Substances used according to the communication received from the Administration of Singapore (please refer to MEPC 72/INF.19)	Not applicable
2	21 September 2018	Danish Environmental Protection Agency and Danish Maritime Authority	CompactClean ballast water management system	Provided (MEPC 74/INF.32	No Active Substances used according to the communication received from the Administration of Denmark (please refer to MEPC 74/INF.32)	Not applicable
3	14 December 2018	Norwegian Maritime Authority	OceanGuard® Ballast Water Management System	Provided (MEPC 74/INF.9)	Yes, please refer to MEPC 61/2/21, annex 5	Please see MEPC 61/24, paragraph 2.7
4	19 December 2018	Norwegian Maritime Authority	HiBallast™ Ballast Water Management System	Provided (MEPC 74/INF.8	Yes, please refer to MEPC 62/2/18, annex 5	MEPC 62/24, paragraph 2.5
5	20 December 2018	Norwegian Maritime Authority	Envirocleanse inTank™ Electro-chlorination Ballast Water Treatment System	Provided (MEPC 74/INF.6)	Yes, please refer to MEPC 73/4/1, annex 5	Please see MEPC 73/19, paragraph 4.4
6	6 April 2018 (revised 20 December 2018)	Norwegian Maritime Authority	BalClor® Ballast Water Management System	Provided (MEPC 74/INF.7)	Yes, please refer to MEPC 61/2/15, annex 9	MEPC 61/24, Paragraph 2.7.3

* Table 3 above was compiled based on information provided to IMO by the respective Administrations taking into account resolution MEPC.228(65) on *Information reporting on type approved ballast water management systems*

Table 4: List of type approvals for ballast water management systems that are in accordance with Guidelines (G8) (resolutions MEPC.125(53) and MEPC.174(58))*

	Approval Date	Name of the Administration	Name of the ballast water management system	Copy of Type Approval Certificate	Active Substance employed	MEPC report granting Final Approval
1	June 2008	Det Norske Veritas, on behalf of the Norwegian Administration	PureBallast System	Provided (MEPC 61/INF.3)	Yes, please refer to MEPC 56/2/2, annex 5	MEPC 56/23, paragraph 2.8
2	10 June 2008	Federal Maritime and Hydrographic Agency, Germany	SEDNA® Ballast Water Management System (Using Peraclean® Ocean)	Provided (MEPC 58/INF.17)	Yes, please refer to MEPC 57/2/10, annex 7	MEPC 57/21, paragraph 2.16
3	2 September 2008	Office of the Maritime Administration, Marshall Islands	NEI Treatment System VOS-2500-101	Available at request	No Active Substances used according to the communication received from the Administration of Marshall Islands (Letter of 10 December 2008)	Not applicable
4	31 December 2008	Ministry of Land, Transport and Maritime Affairs, Republic of Korea	Electro-Clean™ System	Provided (MEPC 59/INF.6)	Yes, please refer to MEPC 58/2/7, annex 7	MEPC 58/23, paragraph 2.8
5	17 April 2009	Det Norske Veritas, on behalf of the Norwegian Maritime Directorate	OceanSaver® Ballast Water Management System	Provided (MEPC 59/INF.17 and MEPC 62/INF.15)	Yes, please refer to MEPC 58/2/8, annex 4	MEPC 58/23, paragraph 2.10
6	29 April 2009	Lloyd's Register, as delegated by the Administration of the United Kingdom	Hyde GUARDIAN™ ballast water management system	Provided (MEPC 59/INF.20)	No Active Substances used according to the communication received from the Administration of United Kingdom (please refer to MEPC 59/INF.20)	Not applicable

* Table 4 above was compiled based on information provided by the respective Administrations taking into account resolution MEPC.228(65) on *Information reporting on type approved ballast water management systems*. Systems listed in this table may have also received type approval based on the 2016 Guidelines (G8) or the BWMS Code (resolution MEPC.279(70) or MEPC.300(72)). Please refer to Table 3 for a list of ballast water management systems that have received type approvals under the 2016 Guidelines (G8) or the BWMS Code.

Table 4 (continued)

	Approval Date	Name of the Administration	Name of the ballast water management system	Copy of Type Approval Certificate	Active Substance employed	MEPC report granting Final Approval
7	12 November 2009	Det Norske Veritas, on behalf of the Norwegian Maritime Directorate	OptiMarin Ballast System (OBS)	Provided (MEPC 61/INF.4)	No Active Substances used according to the communication received from the Administration of Norway (please refer to MEPC 61/INF.4)	Not applicable
8	24 November 2009	Ministry of Land, Transport and Maritime Affairs, Republic of Korea	NK-O3 BlueBallast System (Ozone)	Provided (MEPC 60/INF.14)	Yes, please refer to MEPC 59/2/16, annex 6	MEPC 59/24, paragraph 2.8.
9	4 December 2009	Ministry of Land, Transport and Maritime Affairs, Republic of Korea	GloEn-Patrol™ Ballast Water Management System	Provided (MEPC 61/2/19)	Yes, please refer to MEPC 60/2/11, annex 4	MEPC 60/22, paragraph 2.7
10	19 January 2010	Merchant Shipping Directorate of Malta	NEI Treatment System VOS-2500-101	Provided (BWM.2/Circ.25)	Please refer to circular BWM.2/Circ.25	Not applicable
11	5 March 2010	Ministry of Land, Infrastructure, Transport and Tourism of Japan	Hitachi Ballast Water Management System (ClearBallast)	Provided (MEPC 61/INF.21)	Yes, please refer to MEPC 59/2/19, annex 4	MEPC 59/24, paragraph 2.8
12	26 May 2010 and 25 March 2011	Inspection and Measurement Division, Maritime Bureau, Ministry of Land, Infrastructure, Transport and Tourism of Japan	JFE BallastAce® Ballast Water Management System	Provided (MEPC 62/INF.25)	Yes, please refer to MEPC 60/2/12, annex 5	MEPC 60/22, paragraph 2.7
13	1 September 2010	Federal Maritime and Hydrographic Agency, Germany	CleanBallast® 500-1 ballast water management system (formerly named RWO Ballast Water Management System (CleanBallast))	Provided (MEPC 67/INF.29)	Yes, please refer to MEPC 59/2/16, annex 5	MEPC 59/24, paragraph 2.8
14	28 January 2011	China Maritime Safety Administration	BalClor™ Ballast Water Management System	Provided (MEPC 62/INF.29)	Yes, please refer to MEPC 61/2/15, annex 9	MEPC 61/24, Paragraph 2.7.3

Table 4 (continued)

	Approval Date	Name of the Administration	Name of the ballast water management system	Copy of Type Approval Certificate	Active Substance employed	MEPC report granting Final Approval
15	19 April 2011 Renewal 18 January 2013	The South African Department of Transport The South African Department of Transport	Resource Ballast Technologies System	Provided (MEPC 62/INF.18) Provided (MEPC 65/INF.26)	Yes, please refer to MEPC 60/2/11, annex 7	MEPC 60/22, paragraph 2.7
16	16 February 2011	China Maritime Safety Administration	Blue Ocean Shield Ballast Water Management System	Provided (MEPC 62/INF.28)	No Active Substances used according to the communication received from the Administration of China (please refer to MEPC 62/INF.28)	Not applicable
17	10 March 2011	Det Norske Veritas, on behalf of the Norwegian Maritime Directorate	PureBallst 2.0 and PureBallast 2.0 Ex	Provided (MEPC 62/INF.14)	No Active Substances used according to the communication received from the Administration of Norway (please refer to MEPC 62/INF.14)	Not applicable
18	16 March 2011	The Ministry of Land, Transport and Maritime Affairs, Republic of Korea	EcoBallast Ballast Water Management System (Hyundai Heavy Industries Co., Ltd.)	Provided (MEPC 63/INF.5)	Yes, please refer to MEPC 59/2/16, annex 8	MEPC 60/22, paragraph 2.13
19	28 March 2011	China Maritime Safety Administration	BSKY™ Ballast Water Management System	Provided (MEPC 62/INF.30)	No Active Substances used according to the communication received from the Administration of China (please refer to MEPC 62/INF.30)	Not applicable
20	29 April 2011	Federal Maritime and Hydrographic Agency, Germany	Ocean Protection System® OPS-250	Provided (MEPC 67/INF.27)	No Active Substances used according to the communication received from the Administration of Germany (please refer to MEPC 67/INF.27)	Not applicable
21	6 June 2011	Inspection and Measurement Division, Maritime Bureau, Ministry of Land, Infrastructure, Transport and Tourism of Japan	FineBallast® OZ (the Special Pipe Hybrid Ballast Water Management System combined with Ozone treatment version)	Provided (MEPC 63/INF.12)	Yes, please refer to MEPC 61/2/15, annex 6	MEPC 61/24, paragraph 2.7

Table 4 (continued)

	Approval Date	Name of the Administration	Name of the ballast water management system	Copy of Type Approval Certificate	Active Substance employed	MEPC report granting Final Approval
22	27 July 2011	Federal Maritime and Hydrographic Agency, Germany	BalPure® BP-500	Provided (MEPC 64/INF.20)	Yes, please refer to MEPC 61/2/21, annex 7	MEPC 61/24, paragraph 2.7
23	6 August 2011	Office of the Maritime Administrator, Republic of the Marshal Islands	NEI Treatment System VOS-500 to VOS-6000	Available at request	No Active Substances used according to the communication received from the Administration of Marshall Islands (Letter of 9 August 2011)	Not applicable
24	31 October 2011	The Ministry of Land, Transport and Maritime Affairs, Republic of Korea	Purimar™ System	Provided (MEPC 63/INF.6)	Yes, please refer to MEPC 62/2/18, annex 6	MEPC 62/24, paragraph 2.5
25	7 November 2011	Det Norske Veritas, on behalf of the Norwegian Maritime Directorate	OceanGuard™ Ballast Water Management System	Provided (MEPC 65/INF.2)	Yes, please refer to MEPC 61/2/21, annex 5	MEPC 61/24, paragraph 2.7
26	4 November 2011	Federal Maritime and Hydrographic Agency, Germany	Ecochlor® Ballast Water Treatment System, Series 75	Provided (MEPC 67/INF.26)	Yes, please refer to MEPC 61/2/21, annex 6	MEPC 61/24, paragraph 2.7
27	11 November 2011	The Ministry of Land, Transport and Maritime Affairs, Republic of Korea	HiBallast™ Ballast Water Management System	Provided (MEPC 63/INF.4)	Yes, please refer to MEPC 62/2/18, annex 5	MEPC 62/24, paragraph 2.5
28	22 December 2011	Det Norske Veritas, on behalf of the Norwegian Maritime Directorate	OceanSaver® Ballast Water Management System	Provided (MEPC 64/INF.4)	Yes, please refer to MEPC 58/2/8, annex 4	MEPC 58/23, paragraph 2.10

Table 4 (continued)

	Approval Date	Name of the Administration	Name of the ballast water management system	Copy of Type Approval Certificate	Active Substance employed	MEPC report granting Final Approval
29	10 May 2012 Amended (1st) 15 January 2015 Amended (2nd) 19 October 2018	Hellenic Republic, Ministry of Development, Competitiveness and Shipping, General Secretariat of Shipping, Merchant Ships Inspection General Directorate, Design and Construction Directorate	ERMA FIRST BWTS ERMA FIRST BWTS	Provided (MEPC 64/INF.26) Amended (MEPC 68/INF.19) Amended (MEPC 74/INF.4)	Yes, please refer to MEPC 63/2/11, annex 5	MEPC 63/23, paragraph 2.7
30	30 May 2012	Inspection and Measurement Division, Maritime Bureau, Ministry of Land, Infrastructure, Transport and Tourism of Japan	MICROFADE™ Ballast Water Management System	Provided (MEPC 64/INF.17)	Yes, please refer to MEPC 63/2/11, annex 6	MEPC 63/23, paragraph 2.7
31	12 June 2012	China Maritime Safety Administration	Cyeco™ Ballast Water Management System	Provided (MEPC 64/INF.12)	No Active Substances used according to the communication received from the Administration of China (please refer to MEPC 64/INF.12)	Not applicable
32	15 June 2012	The Ministry of Land, Transport and Maritime Affairs, Republic of Korea	AquaStar™ Ballast Water Management System (subsequently changed to AquaStar™ BWMS and MACGREGOR WATER BALLAST TREATMENT SYSTEM)	Provided (MEPC 64/INF.18)	Yes, please refer to MEPC 63/2/11, annex 7	MEPC 63/23, paragraph 2.7
33	12 July 2012	The Ministry of Land, Transport and Maritime Affairs, Republic of Korea	ARA PLASMA BWTS Ballast Water Management System	Provided (MEPC 64/INF.33)	Yes, please refer to MEPC 61/2/15, annex 8	MEPC 61/24, paragraph 2.7
34	27 August 2012	Federal Maritime and Hydrographic Agency, Germany	BallastMaster ultraV 250 ballast water management system (formerly named AquaTriComb BW 250)	Provided (MEPC 67/INF.28)	No Active Substances used according to the communication received from the Administration of Germany (please refer to MEPC 67/INF.28)	Not applicable

Table 4 (continued)

	Approval Date	Name of the Administration	Name of the ballast water management system	Copy of Type Approval Certificate	Active Substance employed	MEPC report granting Final Approval
35	20 September 2012	The Norwegian Maritime Authority	CrystalBallast® Ballast Water Management System	Provided (MEPC 65/INF.13)	No Active Substances used according to the communication received from the Administration of Norway (please refer to MEPC 65/INF.13)	Not applicable
36	7 November 2012	The Danish Maritime Authority and the Danish Nature Agency	DESMI Ocean Guard OxyClean Ballast Water Management System	Provided (MEPC 65/INF.5)	Yes, please refer to MEPC 64/2/6, annex 4	MEPC 64/23, paragraph 2.6
37	12 December 2012	The Norwegian Maritime Authority	MMC Ballast Water Management System	Provided (MEPC 66/INF.9)	No Active Substances used according to the communication received from the Administration of Norway (please refer to MEPC 66/INF.9)	Not applicable
38	20 December 2012	The Netherlands Ministry of Infrastructure and the Environment	Wärtsilä AQUARIUS® UV ballast water management system	Provided (MEPC 65/INF.11)	No Active Substances used according to the communication received from the Administration of the Netherlands (please refer to MEPC 65/INF.11)	Not applicable
39	5 February 2013	China Maritime Safety Administration	BALWAT Ballast Water Management System	Provided (MEPC 66/INF.15)	No Active Substances used according to the communication received from the Administration of China (please refer to MEPC 66/INF.15)	Not applicable
40	5 June 2013	French Ministry of Ecology Sustainable Development and Energy	BIO-SEA® Ballast Water Treatment System	Provided (MEPC 66/INF.10)	No Active Substances used according to the communication received from the Administration of France (please refer to MEPC 66/INF.10)	Not applicable
41	26 June 2013	Inspection and Measurement Division, Maritime Bureau, Ministry of Land, Infrastructure, Transport and Tourism of Japan	JFE BallastAce	Provided (MEPC 66/INF.30	Yes, please refer to MEPC 64/2/7, annex 5	MEPC 64/23, paragraph 2.6

Table 4 (continued)

	Approval Date	Name of the Administration	Name of the ballast water management system	Copy of Type Approval Certificate	Active Substance employed	MEPC report granting Final Approval
42	22 August 2013	China Maritime Safety Administration	HY™-BWMS	Provided (MEPC 66/INF.14)	No Active Substances used according to the communication received from the Administration of China (please refer to MEPC 66/INF.14)	Not applicable
43	10 October 2013	China Maritime Safety Administration	NiBallast™ Ballast Water Management System	Provided (MEPC 66/INF.12)	No Active Substances used according to the communication received from the Administration of China (please refer to MEPC 66/INF.12)	Not applicable
44	4 November 2013	China Maritime Safety Administration	Cyeco™ Ballast Water Management System	Provided (MEPC 66/INF.16)	No Active Substances used according to the communication received from the Administration of China (please refer to MEPC 66/INF.16)	Not applicable
45	5 November 2013	Inspection and Measurement Division, Maritime Bureau, Ministry of Land, Infrastructure, Transport and Tourism of Japan	FineBallast MF	Provided (MEPC 66/INF.28)	No Active Substances used according to the communication received from the Administration of Japan (please refer to MEPC 66/INF.28)	Not applicable
46	14 November 2013	The Norwegian Maritime Authority	KBAL Ballast Water Management System	Provided (MEPC 65/INF.12)	No Active Substances used according to the communication received from the Administration of Norway (please refer to MEPC 65/INF.12)	Not applicable
47	2 December 2013	China Maritime Safety Administration	Seascape Ballast Water Management System	Provided (MEPC 66/INF.13)	No Active Substances used according to the communication received from the Administration of China (please refer to MEPC 66/INF.13)	Not applicable
48	20 December 2013	The Norwegian Maritime Authority	Trojan Marinex™ Ballast Water Management System	Provided (MEPC 67/INF.6)	No Active Substances used according to the communication received from the Administration of Norway (please refer to MEPC 67/INF.6)	Not applicable

Table 4 (continued)

	Approval Date	Name of the Administration	Name of the ballast water management system	Copy of Type Approval Certificate	Active Substance employed	MEPC report granting Final Approval
50	24 February 2014	Federal Maritime and Hydrographic Agency (BSH)	SeaCURE BWMS SC-1500/1	Provided (MEPC 69/INF.13	No Active Substances used according to the communication received from the Administration of Germany (please refer to MEPC 69/INF.13)	MEPC 63/23, paragraph 2.7
51	27 March 2014	Inspection and Measurement Division, Maritime Bureau, Ministry of Land, Infrastructure, Transport and Tourism of Japan	Miura BWMS ballast water management system	Provided (MEPC 67/INF.20)	No Active Substances used according to the communication received from the Administration of Japan (please refer to MEPC 67/INF.20)	Not applicable
52	30 April 2014	Federal Maritime and Hydrographic Agency, Germany	Cathelco Ballast Water Management System – A2	Provided (MEPC 67/INF.30)	No Active Substances used according to the communication received from the Administration of Germany (please refer to MEPC 67/INF.30)	Not applicable
53	18 June 2014	Inspection and Measurement Division, Maritime Bureau, Ministry of Land, Infrastructure, Transport and Tourism of Japan	ECOMARINE ballast water management system	Provided (MEPC 67/INF.21)	No Active Substances used according to the communication received from the Administration of Japan (please refer to MEPC 67/INF.21)	Not applicable
54	30 June 2014	The Norwegian Maritime Authority	Alfa Laval PureBallast 3.0 Ballast Water Management System	Provided (MEPC 67/INF.5)	No Active Substances used according to the communication received from the Administration of Norway (please refer to MEPC 67/INF.5)	Not applicable
55	11 July 2014	China Maritime Safety Administration	PACT marine™ Ballast Water Management System	Provided (MEPC 68/INF.5)	No Active Substances used according to the communication received from the Administration of China (please refer to MEPC 68/INF.5)	Not applicable
56	5 September 2014	The Danish Maritime Authority and The Danish Nature Agency	RayClean™ BWTS	Provided (MEPC 68/INF.10)	No Active Substances used according to the communication received from the Administration of Denmark (please refer to MEPC 68/INF.10)	Not applicable

Table 4 (continued)

	Approval Date	Name of the Administration	Name of the ballast water management system	Copy of Type Approval Certificate	Active Substance employed	MEPC report granting Final Approval
57	21 October 2014	Inspection and Measurement Division, Maritime Bureau, Ministry of Land, Infrastructure, Transport and Tourism of Japan	SKY-SYSTEM®	Provided (MEPC 68/INF.28)	Yes, please refer to MEPC 66/2/7, annex 4 and Corr.1	MEPC 66/21, paragraph 2.5
58	17 November 2014	China Maritime Safety Administration	OceanDoctor® Ballast Water Management System	Provided (MEPC 68/INF.4)	Yes, please refer to MEPC 65/2/19, annex 7	MEPC 65/22 paragraph 2.8
59	5 January 2015	The Danish Maritime Authority and The Danish Nature Agency	Bawat™ BWMS	Provided (MEPC 68/INF.9)	No Active Substances used according to the communication received from the Administration of Denmark (please refer to MEPC 68/INF.9)	Not applicable
60	27 January 2015	China Maritime Safety Administration	AHEAD®-BWMS ballast water management system	Provided (MEPC 69/INF.2)	No Active Substances used according to the communication received from the Administration of China (please refer to MEPC 68/INF.2)	Not applicable
61	6 February 2015	United Kingdom, Maritime & Coastguard Agency	Coldharbour GLD™ Ballast Water Management System, incorporating types SeaGuardian™ IGG500 to IGG6000	Provided (MEPC 68/INF.27)	No Active Substances used according to the communication received from the Administration of the United Kingdom (please refer to MEPC 68/INF.27)	Not applicable
62	28 February 2015	China Maritime Safety Administration	YP-BWMS ballast water management system	Provided (MEPC 69/INF.5)	No Active Substances used according to the communication received from the Administration of China (please refer to MEPC 69/INF.5)	Not applicable
63	8 May 2015	Ministry of Oceans and Fisheries of Republic of Korea	EcoGuardian™ Ballast Water Management System	Provided (MEPC 69/INF.31	No Active Substances used according to the communication received from the Administration of the Republic of Korea (please refer to MEPC 69/INF.31)	MEPC 65/22, paragraph 2.8

Table 4 (continued)

	Approval Date	Name of the Administration	Name of the ballast water management system	Copy of Type Approval Certificate	Active Substance employed	MEPC report granting Final Approval
64	8 September 2015	Ministry of Oceans and Fisheries of the Republic of Korea	BlueZone™ Ballast Water Management System	Provided (MEPC 69/INF.32	No Active Substances used according to the communication received from the Administration of the Republic of Korea (please refer to MEPC 69/INF.32)	MEPC 67/20, paragraph 2.6
65	12 September 2015	China Maritime Safety Administration	NiBallast™ Ballast Water Management System	Provided (MEPC 69/INF.3)	No Active Substances used according to the communication received from the Administration of China (please refer to MEPC 69/INF.3)	Not applicable
66	19 November 2015	Netherlands Shipping Inspectorate, Ministry of Infrastructure and the Environment	Van Oord Ballast Water Management System	Provided (MEPC 69/INF.15)	No Active Substances used according to the communication received from the Administration of Norway (please refer to MEPC 69/INF.15)	Please see MEPC 65/22, paragraph 2.5
67	21 December 2015	China Maritime Safety Administration	Seascape® Ballast Water Management System	Provided (MEPC 69/INF.4)	No Active Substances used according to the communication received from the Administration of China (please refer to MEPC 69/INF.4)	Not applicable
68	23 December 2015	French Ministry of Ecology Sustainable Development and Energy	BIO-SEA® Ballast Water Treatment System (BWTS); Models BIO-SEA ®30-55, BIO-SEA ®30-87, BIO-SEA ®60-55, BIO-SEA ®60-87 and BIO-SEA ®90-87	Provided (MEPC 70/INF.24)	No Active Substances used according to the communication received from the Administration of France (please refer to MEPC 70/INF.24)	Not applicable
69	11 January 2016	China Maritime Safety Administration	LeesGreen® Ballast Water Management System	Provided (MEPC 70/INF.5)	No Active Substances used according to the communication received from the Administration of China (please refer to MEPC 70/INF.5)	Not applicable

Table 4 (continued)

	Approval Date	Name of the Administration	Name of the ballast water management system	Copy of Type Approval Certificate	Active Substance employed	MEPC report granting Final Approval
70	15 April 2016	China Maritime Safety Administration	PACT Marine™ Ballast Water Management System	Provided (MEPC 70/INF.4)	No Active Substances used according to the communication received from the Administration of China (please refer to MEPC 70/INF.4)	Not applicable
71	27 July 2016	Singapore	Semb-Eco LUV 500 ballast water management system	Provided (MEPC 70/INF.22)	No Active Substances used according to the communication received from the Administration of Singapore (please refer to MEPC 70/INF.22)	Not applicable
72	12 January 2017	Singapore	Semb-Eco LUV 500 & Semb-Eco LUV 1500 ballast water management system	Provided (MEPC 71/INF.12)	No Active Substances used according to the communication received from the Administration of Singapore (please refer to MEPC 71/INF.12)	Not applicable
73	13 January 2017	Inspection and Measurement Division, Maritime Bureau, Ministry of Land, Infrastructure, Transport and Tourism of Japan	KURITA BWMS	Provided (MEPC 71/INF.26)	Yes, please refer to MEPC 67/2/4, annex 6	Please see MEPC 67/20, paragraph 2.6
74	19 March 2017	Netherlands Shipping Inspectorate, Ministry of Infrastructure and the Environment	Damen InvaSave 300	Provided (MEPC 71/INF.4)	No Active Substances used according to the communication received from the Administration of the Netherlands (please refer to MEPC 71/INF.4)	Not applicable
75	30 March 2017	Inspection and Measurement Division, Maritime Bureau, Ministry of Land, Infrastructure, Transport and Tourism of Japan	ATPS-BLUE$_{sys}$	Provided (MEPC 71/INF.27	Yes, please refer to MEPC 69/4/5, annex 6	Please see MEPC 69/21, paragraph 4.6

Table 4 (continued)

	Approval Date	Name of the Administration	Name of the ballast water management system	Copy of Type Approval Certificate	Active Substance employed	MEPC report granting Final Approval
76	13 November 2017	Singapore	Semb-Eco LUV 250, Semb-Eco LUV 500, Semb-Eco LUV 750, Semb-Eco LUV 1000 and Semb-Eco LUV 1500 ballast water management system	Provided (MEPC 72/INF.2)	No Active Substances used according to the communication received from the Administration of Singapore (please refer to MEPC 72/INF.2)	Not applicable
77	2 February 2018	Norwegian Maritime Authority	PureBallast 3.2 and PureBallast 3.2 Compact Flex ballast water management system	Provided (MEPC 72/INF.19)	No Active Substances used according to the communication received from the Administration of Singapore (please refer to MEPC 72/INF.19)	Not applicable
78	6 April 2018 (revised 20 December 2018)	Norwegian Maritime Authority	BalClor® Ballast Water Management System	Provided (MEPC 74/INF.7)	Yes, please refer to MEPC 61/2/15, annex 9	MEPC 61/24, Paragraph 2.7.3
79	12 April 2018	French Ministry of Ecology, Sustainable Development and Energy	BIO-SEA® B ballast water management system (BWMS); Models BIO SEA B01-0055 to BIO-SEA B14 2000	Provided (MEPC 73/INF.7)	No Active Substances used according to the communication received from the Administration of France (please refer to MEPC 73/INF.7)	Not applicable
80	21 September 2018	Danish Environmental Protection Agency and Danish Maritime Authority	CompactClean ballast water management system	Provided (MEPC 74/INF.32	No Active Substances used according to the communication received from the Administration of Denmark (please refer to MEPC 74/INF.32)	Not applicable
81	14 December 2018	Norwegian Maritime Authority	OceanGuard® Ballast Water Management System	Provided (MEPC 74/INF.9)	Yes, please refer to MEPC 61/2/21, annex 5	Please see MEPC 61/24, paragraph 2.7
82	19 December 2018	Norwegian Maritime Authority	HiBallast™ Ballast Water Management System	Provided (MEPC 74/INF.8	Yes, please refer to MEPC 62/2/18, annex 5	MEPC 62/24, paragraph 2.5

83	20 December 2018	Norwegian Maritime Authority	Envirocleanse inTank™ Electro-chlorination Ballast Water Treatment System	Provided (MEPC 74/INF.6)	Yes, please refer to MEPC 73/4/1, annex 5	Please see MEPC 73/19, paragraph 4.4

Note: all lists above updated in December 2019.

Table 1, Proposal from PT PM 42/2017: issues addressed by the Machinery Panel through the UR M74 Rev. 2

BWMS's Technology category →			1	2	3a	3b	3c	4	5	6	7a	7b	8
Identification of specific hazards ↓	**←Reference in UR M74 Rev. 2**	**←Reference in UR M74 Rev. 1**	In-line UV including UV + Advanced Oxidation Technology (AOT) or UV + TiO2 or UV + Plasma	In-line Flocculation (ex. Clearballast™)	In-line membrane separation and de-oxygenation (injection of N2 from a N2 Generator) ex. Ni-Ballast™	In-line de-oxygenation (injection of Inert Gas from Inert Gas Generator) ex. VOS™	In-tank de-oxygenation with Inert Gas Generator ex. GLD™	In-line full flow electrolysis (ex. Electroclean™)	In-line side stream electrolysis (ex. HiBallast™)	In-line (stored) chemical injection (ex. JFE BallastAce® with NeoChlor Marine® or TG Ballast Cleaner®)	In-line side-stream ozone injection without gas/liquid separation tank and without Discharge treatment tank (ex. NK-O3 BlueBallast)	In-line side-stream ozone injection with gas/liquid separation tank and Discharge water treatment tank (ex. FineBallast®OZ)	In-tank pasteurization and de-oxygenation with N2 Generator ex. BAWAT™
Risk of fire & explosion**: location of BWMS in hazardous areas of tankers outside the cargo pump room with certified safe type of electrical equipment**	3.2.1.1 Annex I, Table 1	Not covered	Acceptable			Not acceptable, refer to IMO MSC Res. 367(93), FSS Code Ch 15 §2.3.1.2		Acceptable			Not acceptable		Acceptable
Potential reactivity or increased hazardous environment with high concentration of cargo vapors: **location of BWMS in cargo pump room**	3.2.1.2 Annex I, Table 1	Not covered	Acceptable					Not acceptable unless it is demonstrated by the BWMS manufacturer that the risk can be disregarded			Not acceptable		Acceptable
Contamination from BWMS room to other enclosed spaces: **O2 and O3 piping and vent pipe routing through other enclosed spaces**	3.3.2.5 3.3.2.6 3.3.2.7	Not covered	-	-	-	-	-	-	-	-	X	X	-
O2 leakage inside BWMS room: O2 detection	3.3.1.2	Not covered	-	-	[LA] with min 2 sensors as per IMO MSC Res. 369(93), FSS Code Ch 15 § 2.2.4.5.4			-	-	-	[LA], [HA], [HHA+shutdown] with min 2 sensors		[LA] with min 2 sensors
O3 leakage from O3 generator inside BWMS room: O3 detection, [HA], [HHA+shutdown]	3.3.1.3	Not covered	-	-	-	-	-	-	-	-	[HA], [HHA+shutdown] with 2 sensors		-
O3 leakage from O3 double walled piping or pipe ducts: (O3 detection [HA], [HHA+shutdown]) or (monitored under-pressurization with alarm and shutdown]	3.3.1.4	Not covered	-	-	-	-	-	-	-	-	X	X	-

Notes:

"X" in the cell indicates that the hazard is relevant.

"-" in the cell indicates that the hazard is not relevant.

(1) To be investigated on a case by case basis based on the result of the IMO (GESAMP) MEPC report for Basic and Final approval in accordance with the G9 Guideline.

Table 2, Proposal from PT PM 42/2017: Fire safety protection issues to be addressed by the Safety Panel PT through PS17030a (SP14017p)

BWMS's Technology category →			1	2	3a	3b	3c	4	5	6	7a	7b	8
Identification of specific hazards ↓	←Reference in UR M74 Rev. 2	←Reference in UR M74 Rev. 1	In-line UV including UV + Advanced Oxidation Technology (AOT) or UV + TiO2 or UV + Plasma	In-line Flocculation (ex. Clearballast™)	In-line membrane separation and de-oxygenation (injection of N2 from a N2 Generator) ex. Ni-Ballast™	In-line de-oxygenation (injection of Inert Gas from Inert Gas Generator) ex. VOS™	In-tank de-oxygenation with Inert Gas Generator ex. GLD™	In-line full flow electrolysis (ex. Electroclean™)	In-line side stream electrolysis (ex. HiBallast™)	In-line (stored) chemical injection (ex. JFE BallastAce® with NeoChlor Marine® or TG Ballast Cleaner®)	In-line side-stream ozone injection without gas/liquid separation tank and without Discharge treatment tank (ex. NK-O3 BlueBallast)	In-line side-stream ozone injection with gas/liquid separation tank and Discharge water treatment tank (ex. FineBallast®OZ)	In-tank pasteurization and de-oxygenation with N2 Generator ex. BAWAT™
Fire growth potential: acceptable spaces outside cargo area for the location of the BWMS (accommodation spaces, service spaces, control stations, machinery spaces of category A, other machinery spaces, Ro-Ro spaces, etc)	Removed	3.4.3.2 3.1.8	Not assessed by PT PM 42/2017			Same as for Inert Gas Generator (machinery space of category A)		Not assessed by PT PM 42/2017					
Containment of fire: fire categorization of the BWMS room and fire integrity of the boundaries with adjacent spaces	Removed	3.4.3.1											
Prevention against fire: Fire detection	Not covered												
Fire fighting: fixed fire fighting system in the BWMS room	Not covered												
Fire fighting: portable fire fighting equipment in the BWMS room	Not covered												
Contamination from BWMS room to other enclosed spaces: direct access to other enclosed spaces	Not covered												
Contamination from BWMS room to other enclosed spaces: gas-tight and self-closing door	Not covered			(1)	X	X	X	(1)	(1)	(1)	X	X	X
Contamination from BWMS room to other spaces: Independent ventilation + outlet arranged at a safe location on the open deck (refer to the definitions	Removed	3.1.6.2 3.1.8		(1)	X	Same as for Inert Gas Generator		X	X	X	X	X	X

proposed UR M74 2.7)						(machinery space of category A)							
Ventilation of the BWMS room: minimum air changes per hour, mechanical extraction type, etc.	Removed	3.3.1.1 3.3.1.2 3.3.2		Min. 6	Min. 6 (extraction type)	Min. 6 (positive pressure type)		Min. 6	Min. 6	Min. 6	Min. 20 + alarm + shutdown		Min. 6 (extraction type)
Chemical reactivity: potential reactivity with the performance of the type of the foam in case the BWMS is located in a space protected by a fixed foam fire extinguishing system	Not covered			(1)				(1)	(1)	(1)			
Chemical or physical reactivity with water: potential reactivity with water spraying system (example exothermic reactivity from Sulfuric acid tank of Ecochlor)	Not covered									(1)			
Compressed air storage inside BWMS room: impact on the calculation of the minimum capacity of the gas fire extinguishing medium	Not covered										In case the BWMS is located in a space protected by a fixed gas fire extinguishing system		
Compressed O2 storage inside BWMS room: impact on the calculation of the minimum capacity of the gas fire extinguishing medium	Not covered												
O3 leakage inside the BWMS room: air breathing apparatus	Removed	3.1.8									X	X	
Chemical leakage inside the BWMS room : Emergency eye wash, shower	Not covered									(1)			

	Not assessed by PT PM 42/2017		Preliminary assessment has been conducted by PT PM 42/2017 but a further assessment by the Safety Panel PT (PS17030a) is required.

<u>Notes:</u>
"X" in the cell indicates that the hazard is relevant.
"-" in the cell indicates that the hazard is not relevant.
(1) To be investigated on a case by case basis based on the result of the IMO (GESAMP) MEPC report for Basic and Final approval in accordance with the G9 Guideline.

Removed	This hazard has been identified and assessed by the PT PM 42/2017 with the following recommendation: to be further assessed by the Safety Panel PT (PS17030a). Consequently, PT PM 42/2017 proposed to delete the requirement related to this issue from the UR M74 Rev. 2: ~~*3.1.6 Where the operating principle of the BWMS involves the generation of a dangerous gas, the following requirements are to be satisfied:*~~ ~~*3.1.6.2 The ventilation line of a space where dangerous gas could be present is to be led to a safe area on open deck.*~~ ~~*3.1.8 For the spaces, including hazardous areas, where toxicity, asphyxiation, corrosivity or reactivity is present, these hazards are to be taken into account and additional precautions for the ventilation of the spaces and protection of the crew are to be considered.*~~ ~~*3.3 Ventilation*~~ ~~*3.3.1 BWMS not in hazardous areas:*~~

	~~.1 A BWMS that does not generate dangerous gas is to be located in an adequately ventilated area.~~ *~~.2 A BWMS that generates dangerous gas is to be located in a space fitted with a mechanical ventilation system providing at least 6 air changes per hour or as specified by the BWMS manufacturer, whichever is greater.~~* *~~3.3.2 A BWMS, regardless of whether or not it generates dangerous gas, is to be located in a space fitted with mechanical ventilation complying with relevant requirements, e.g. IEC60092-502, IBC Code, IGC Code, etc.~~* *~~3.4.3 Where the BWMS is installed in an independent compartment, the compartment is to be:~~* *~~.1 Provided with fire integrity equivalent to other machinery spaces.~~* *~~.2 Positioned outside of any combustible, corrosive, toxic, or hazardous areas unless otherwise specifically approved.~~*

Detailed Engineering Background and Points of Discussion

1. Categorization of the BWMS technologies and identification of the specific hazards associated with the various technologies:

This Rev.2 has been developed based on PT's members experience, information available from their respective Classification Societies, benchmarking of the available Classification Rules for the installation of BWMS (but not limited to the Classification Rules of the Societies of the PT members) and an exhaustive review of the 83 BWMS listed in IMO's document in Attachment 1 according to the latest list dated May 2018 published in IMO website.
https://wwwcdn.imo.org/localresources/en/OurWork/Environment/Documents/Table%20of%20BA%20FA%20TA%20updated%20January%202020.pdf

The various technologies and their categorization resulting from this exhaustive review are illustrated in the Table 1 and Annex II of UR M74 Rev.2.

BWMS's Technology category (informative Annex II should be referred to)		1	2	3a	3b	3c	4	5	6	7a	7b	8
	Characteristics ↓	In-line UV or UV + Advanced Oxidation Technology (AOT) or UV + TiO2 or UV + Plasma	In-line Flocculation	In-line membrane separation and de-oxygenation (injection of N2 from a N2 Generator)	In-line de-oxygenation (injection of Inert Gas from Inert Gas Generator)	In-tank de-oxygenation with Inert Gas Generator	In-line full flow electrolysis	In-line side stream electrolysis	In-line (stored) chemical injection	In-line side-stream ozone injection without gas/liquid separation tank and without Discharge treatment tank	In-line side-stream ozone injection with gas/liquid separation tank and Discharge water treatment tank	In-tank pasteurization and de-oxygenation with N2 generator
Des-infection when ballasting	Making use of active substance		X			In-tank technology: No treatment when ballasting or de-ballasting	X	X	X	X	X	In-tank technology: No treatment when ballasting or de-ballasting
	Full flow of ballast water is passing through the BWMS	X	X	X	X		X				X	
	Only a small part of ballast water is passing through the BWMS to generate the active substance							X				
After-treatment when de-ballasting	Full flow of ballast water is passing through the BWMS	X									X	
	Injection of neutralizer						X	X	X	X	X	
	Not required by the Type Approval Certificate issued by the Administration		X	X								
Examples of dangerous gas as defined in UR M74 §2.3			(1)	O2 N2	CO2 CO		H2 Cl2	H2 Cl2	(1)	O2 O3 N2		O2 N2

Note:
(1) To be investigated on a case by case basis based on the result of the IMO (GESAMP) MEPC report for Basic and Final approval in accordance with the G9 Guideline.
(2) In-line side stream electrolysis may also be applied in-tank in circulation mode (no treatment when ballasting or de-ballasting).

Taking into consideration future developments of BWMS technologies, some additional technologies may be considered in this Table 1 by identifying their characteristics in the same manner as for the above BWMS categories 1, 2, 3a, 3b, 3c, 4, 5, 6, 7a, 7b and 8.

The PT conducted a risk analysis for all these BWMS to identify all the potential hazards to be considered with regards to their respective categories.

The PT has been informed that another PT reporting to the Safety Panel will be tasked through PS17030a (SP14017p) with the following objectives:

i. *To assess fire safety protection issues associated with the various types of BWMS taking into account safety hazards identified by the Machinery Panel (under M42/2017).*
ii. *To consider whether location restrictions are needed for certain types of BWMS (wrt to e.g., ro-ro spaces, engine rooms etc.).*
iii. *To develop the appropriate interpretations/understanding for issues raised.*

At the end of that technical approach, the PT concluded that:

i. There is an extensive diversity of BWMS technologies and the existing Rev.1 is not addressing this complete range of technologies.
ii. The existing Rev.1 is not fully covering the potential issues related to the BWMS; and
iii. The existing Rev.1 contains requirements that will be subject to a separate task PS17030a from a different working group (Safety Panel, SP14017p)
iv. The BWMS technologies are originated from the water treatment facilities at shore but remains new and only partially explored by the marine industry.
v. Not all BWMS have been subject to a risk analysis by the Classification Societies, only some of them.
vi. In their MEPC (GESAMP) Reports for the Basic and Final approval in accordance with the G9 Guideline for BWMS that makes use of active substances, the IMO provides the necessary information for the assessment related to the presence of dangerous liquids or dangerous gas, the chemical reactions in presence, the necessary safety measures to be considered, etc.

To tackle the concerns from this conclusion, the PT considered that it will be necessary to:

i. insert the Table 1 of the Attachment 2 in §2.1 of the Rev.2;
ii. make reference to these categories in the wording of the requirements of the Rev.2 to clarify for which BWMS's technology the requirement is applicable;
iii. insert a Table 2 in §3.1 of the Rev.2 to clarify the applicability of the requirements with regards to the technologies;
iv. revise the concerned requirements of Rev.1, as necessary;
v. add the missing requirements in Rev.2 where they are not covered by the existing Rev.1;
vi. make reference in the Rev.2 to the IMO (GESAMP) MEPC report for the Basic and Final approval in accordance with the G9 Guideline for the assessment of the potential dangerous gas and dangerous liquids that could be expected to be stored or handled by the BWMS and the necessary mitigation measures to be considered for the safety of the ship and its crew;
vii. remove from the UR M74 the issues that will be addressed by the Safety Panel PT through the task PS17030a (SP14017p)

The result of this work is illustrated in:
i. Table 2 of the Attachment 2: Proposal from PT PM 42/2017: issues addressed by the Machinery Panel through the UR M74 Rev.2; and
ii. Table 3 of the Attachment 2: Proposal from PT PM 42/2017: Fire safety protection issues to be addressed by the Safety Panel PT through PS17030a (SP14017p)

2. Re-alignment of the definitions and requirements with the IMO, IACS and IEC requirements

The PT identified in the Rev.1 some confusing misalignments with the IMO, IACS and IEC requirements:

i. When compared to the definition given in the IGC Code Ch. 1.2.24 adopted through IMO Resolution MSC 370(93), there is a mistake in the definition of "hazardous areas" given in §2.3: "electrical" is missing in "…installation and use of <u>electrical</u> equipment."
ii. The definition of the "hazardous areas" given in §2.3 has been extracted from the IGC Code Ch. 1.2.24 adopted through IMO Resolution MSC 370(93) but is not aligned with the definition of the "hazardous areas" applicable for oil or chemical tankers.
iii. Considering that the definition of "hazardous areas" given in the IGC Code is related to the hazards generated by the liquefied gas cargoes (i.e. large quantities of gas), is it relevantly applicable for BWMS which are dealing with limited quantities of active substances?
iv. The difference made in between the "dangerous gas" defined in §2.2 with the definition of "hazardous areas" given in §2.3 is not sufficiently clear and could lead to confusion in its interpretation.
v. In §3.1.5 of Rev.1 (renumbered §3.1.6 in the Rev.2), when we apply the definition of "hazardous areas" given in §2.3, we will request certified electrical equipment (understand implicitly certified in accordance with IEC 60079 - Electrical apparatus for explosive gas atmospheres) in case the atmosphere is not flammable/explosive but presents some other hazards like toxicity, corrosivity and reactivity. This would not be logical and would not address the concern.
vi. In §3.1.4, §3.1.6.2, §3.1.6.3, §3.4.2.3, reference is made to "safe area on open deck", does it mean "non-hazardous in the sense of IEC 60092-502" or "non-hazardous in the sense of §2.3" or "non-hazardous in the sense of the definition given in the IGC Code" or "at a sufficient distance from any source of ignition"?
vii. In §3.1.7, reference is made to "safe area" but the requirement excludes the liquefied gas carriers: why having extracted in §2.3 the definition of the hazardous areas from the IGC Code?
viii. In §3.2.2, reference is made to "non-hazardous area", is it the same meaning as "safe area" described previously?
ix. In §3.2.3, it is said: "isolation arrangements are to be fitted on the exposed deck in the hazardous area". There are hazardous areas on the open deck in way of the battery room and paint rooms access doors and ventilation openings and also on the forward poop deck in case of stern cargo loading/unloading manifold arranged in accordance with IACS UR F16: is it an acceptable location for the means of appropriate isolation?
x. For gas carriers carrying flammable liquids having a flash point not exceeding 60°C, the segregated ballast water tanks could be hazardous area but their ballast pump is located in the Engine Room (non-hazardous). The reason is that there is no ballast tank within the cargo area for liquefied gas carriers.
   But in such case, the application of §3.2.2 to the liquefied gas carriers will be conflicting with the IGC Code.
xi. Some chemical carriers can carry toxic cargoes that are not flammable. In such case, there is no hazardous area in the sense of the IEC 60092-502 referred to in the IBC Code but the segregated ballast water tanks remains within the cargo area. These tankers would be excluded from the application of §3.2.2 which is not in compliance with IBC Code Ch. 3.5.1.

The PT identified that the above conflicts have been created by a confusion in between the concept of "hazardous area" given in the IEC 60092-502 and only aimed at placing requirements on the type of electrical equipment installed in these hazardous area and the concept of "cargo area" given in the IMO and IACS requirements which is aimed at segregating the piping systems. To tackle with those conflicts, the PT introduced the following definition:

『 2.2 Cargo area of tankers is defined in SOLAS Ch. II-2 Reg. 3/6, IBC Code Ch. 1.3.6, IGC Code Ch. 1.2.7 and LHNS Guidelines Res. A.673(16) as amended by MSC Res. 236(82) Ch. 1.3.1 (or OSV Chemical Code Res. A.1122(30) Ch 1.2.7) as applicable.』

Upon further review of the definitions of the cargo area for oil tankers and for chemical tankers following GPG Members comments, the below discussion was carried out by the Panel.

i. The qualified majority has not been achieved on the view that the requirement related to the cargo area in this UR should be applied to NLS tankers regardless of the application of the IBC Code, taking into account that the IBC Code may or may not apply to NLS tankers (not carrying liquid products listed in Chapter 17 of the Code). However, from a practical viewpoint, while the IBC Code is not necessarily applied to NLS tankers, category Z substances listed in Chapter 18 of the IBC Code are normally carried by oil tankers and therefore there was no need to explicitly cover NLS tankers in this UR.
ii. The extension of the definition of the cargo area for oil tankers was considered, with a view to covering also tankers carrying "other liquid products having a similar fire hazard" stated in SOLAS regulation II-2/1.6.1. The qualified majority has been achieved on the following modification:

> for ~~oil~~ tankers to which regulation 1.6.1 of SOLAS Chapter II-2 as amended by IMO resolutions up to MSC.421(98) (hereinafter the same) applies, regulation 3.6 of SOLAS Chapter II-2 ~~as amended by IMO resolutions up to MSC.421(98)~~

By referring to the "cargo area", the PT re-aligned the piping segregation with the IMO and IACS requirements listed in Section 3 as quoted below. For Paragraph 3.2.2, addition of the second sentence to accept alternative arrangements was discussed by the Panel, but the qualified majority agreed on deleting it given the possible lack of uniform implementation of the Rev.2.

『 3.2.2 ~~For tankers carrying flammable liquids having a flashpoint not exceeding 60 °C or products listed in the IBC Code having a flashpoint not exceeding 60 °C or cargoes heated to temperature above their flashpoint and cargoes heated to temperature within 15 °C of their flashpoint.~~
In general, two independent BWMS ~~may~~ should be required i.e. one for ballast tanks ~~in hazardous areas~~ located within the cargo area and the other one for ballast tanks ~~in non-hazardous areas~~ located outside cargo area. Specific arrangements where only one single In-line BWMS (categories 1, 2, 3a, 3b, 4, 5, 6, 7a and 7b) could be accepted are given in Annex I.
』

『 3.2.4. ~~3.1.7 Ballast piping, including~~ Sampling lines which are connected to the ballast water piping system serving the tanks in the cargo ~~hazardous~~ area and provided for the purpose of the following:
- for any BWMS: ballast water sampling required by the G2 Guideline of the BWM Convention (2004); or
- for BWMS technologies categories 4, 5, 6, 7a and 7b: total residual oxidant (TRO) analysis in closed loop system ~~from ballast tanks considered as hazardous areas, is~~ are not to be led into ~~an~~ a non-hazardous enclosed space outside the cargo area ~~regarded as a safe area, without any appropriate measures, except ships carrying liquefied gases in bulk~~. However, the ~~a~~ sampling ~~point~~ lines ~~for checking the performance of BWMS, for ballast water containing dangerous gas~~, may lead into a non-hazardous enclosed space outside the cargo area ~~be located in a safe area~~ provided the following requirements are fulfilled:
.1 The sampling facility (for BWMS monitoring/control) is to be located within a gas tight enclosure (hereinafter, referred to as a 'cabinet'), and the following i) through ~~(iii)~~ iv) are to be complied.
i) In the cabinet, a stop valve is to be installed on ~~in~~ each sampling line ~~sample pipe~~.

ii) Gas detection equipment is to be installed in the cabinet and the valves specified in i) above are to be automatically closed upon activation of the gas detection equipment.

iii) Audible and visual alarm signals are to be activated both locally and at the BWMS control station when the concentration of explosive gases reaches a pre-set value, which should not be higher than 30% of the lower flammable limit (LFL) ~~of the concerned product~~. Upon an activation of the alarm, all electrical power to the cabinet is to be automatically disconnected.

iv) The cabinet is to be vented to a safe location in non-hazardous area on open deck and the vent is to be fitted with a flame arrester.

.2 The standard internal diameter of sampling pipes is to be the minimum necessary in order to achieve the functional requirements of the sampling system.

.3 The cabinet ~~measuring system~~ is to be installed as close ~~to the bulkhead~~ as possible to the bulkhead facing the cargo area, and ~~length of~~ the sampling lines located outside the cargo area are to be routed on their shortest ways ~~measuring pipe in any safe area is to be as short as possible~~.

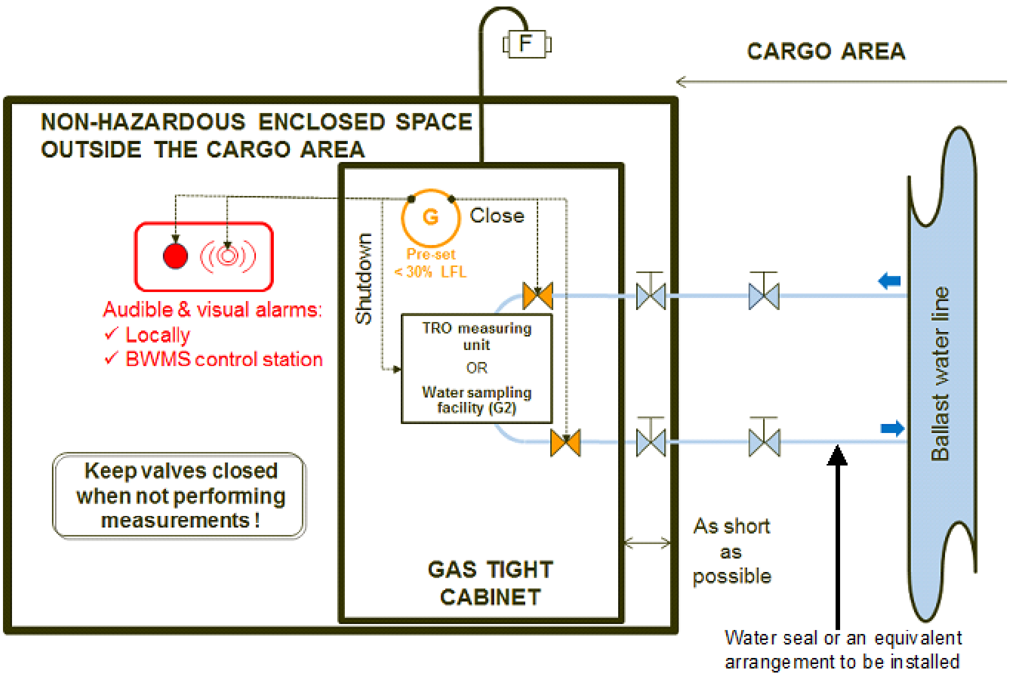
.4 Stop valves are to be located in the non-hazardous enclosed space outside the cargo area ~~safe area~~, in both the suction and return lines ~~pipes~~ close to the ~~bulkhead~~ penetrations through the bulkhead facing the cargo area. A warning plate stating "Keep valve closed when not performing measurements" is to be posted near the valves. Furthermore, in order to prevent backflow, a water seal or equivalent arrangement is to be installed on the hazardous area side of the return pipe.

.5 A ~~safety~~ stop valve is to be installed on the cargo ~~hazardous~~ area ~~side of~~ for each sampling line ~~pipe~~.

.6 The samples which are extracted from the ballast water piping system serving the tanks within the cargo area are not to be discharged to a tank located outside the cargo area and not to discharge to a piping line supplying the spaces located outside the cargo area.⟧

In order to avoid the confusion in between:

the requirement given in §3.2.4 (originally §3.1.7 in the Rev.1) which is applicable to the water sampling lines of tankers subject to §3.2 (aligned with the FSS Code Ch. 16) vs. the requirement given in §3.2.3 (aligned with FSS Code Ch. 15) which is applicable to the main ballast lines and active substances or neutralizer injection lines, the following sketch has been added in §3.2.4: ⟧



The PT re-aligned below the definition of the “hazardous area” with the definition given in the IEC 60092-502 as referred to in §3.1.5 of the Rev.1 (renumbered §3.1.6 in the Rev.2) where a further modification and retention of the sentence decided by the Panel are highlighted in red:

〚2.5 ~~2.3~~ Hazardous area is defined in IEC 60092-502:1999 and means an area in which an explosive gas atmosphere is or may be expected to be present, in quantities such as to require special precautions for the construction, installation and use of electrical ~~equipment~~ apparatus. When a gas atmosphere is present, the following hazards may also be present: toxicity, asphyxiation, corrosivity and reactivity.〛

The PT introduced the definition of the « non-hazardous areas”:

〚2.6 Non-hazardous area means an area which is not a hazardous area as defined in above 2.5.〛

The PT completed the definition of the « dangerous gas » which is now clearly differentiated from the definition of « hazardous area » where further editorial modifications and retention of the sentence decided by the Panel are highlighted in red:

〚2.3 ~~2.2~~ Dangerous gas means any gas which may develop an ~~explosive and/or toxic~~ atmosphere being hazardous to the crew and/or the ship due to ~~the presence of~~ flammableility, explosiveility, toxicity, asphyxiation, corrosiveility and reactivity hazards ~~may be present with~~ and for which due consideration of the hazards ~~for~~ is required, e.g. hydrogen (H_2), hydrocarbon gas, oxygen (O2), carbon dioxide (CO2), carbon monoxide (CO), ozone (O_3), chlorine (Cl_2) and chlorine dioxide (ClO_2), etc.〛

The PT introduced the definition of the “safe location” for the location of the outlets of the vent pipes releasing either inert gas or nitrogen enriched air or oxygen-enriched air with reference to the note *) “safe location” of UR F20 and extended that approach for hydrogen-enriched air:

〚Footnote *):
Safe location needs to address the specific types of discharges separately.
Signboards or similar warnings at the discharge areas are to be provided.:

Safe location*(1): inert gas or nitrogen product enriched air from:
- in-line (categories 3a and 3b) and in-tank (categories 3c and 8) de-oxygenation BWMS: the protection devices installed on the ballast tanks, nitrogen or inert gas generators, nitrogen buffer tank (if any); or
- in-line ozone injection BWMS (categories 7a and 7b): the oxygen generator;
safe locations on the open deck are:
- not within 3 m of areas traversed by personnel; and
- not within 6 m of air intakes for machinery (engines and boilers) and all ventilation inlets/outlets.

Safe location*(2): oxygen-enriched air from:
- in-line and in-tank de-oxygenation BWMS (categories 3a and 8): the nitrogen generator; or
- in-line ozone injection BWMS (categories 7a and 7b): the protection devices or vents from oxygen generator, compressed oxygen vessel, the ozone generator and ozone destructor devices;
safe locations on the open deck are:
- outside of hazardous area;
- not within 3 m of any source of ignition and from deck machinery, which may include anchor windlass and chain locker openings, and equipment which may constitute an ignition hazard;
- not within 3 m of areas traversed by personnel; and
- not within 6 m of air intakes for machinery (engines and boilers) and all ventilation inlets.

Safe location*(3): hydrogen by-product enriched gas from:
- in-line full flow electrolysis BWMS (category 4), in-line side-stream electrolysis BWMS (category 5) and in-line injection BWMS using chemical which is stored onboard (category 6): the hydrogen de-gas arrangement (when provided);

safe locations on the open deck are:
- not within 5 m of any source of ignition and from deck machinery, which may include anchor windlass and chain locker openings, and equipment which may constitute an ignition hazard;
- not within 3 m of areas traversed by personnel; and
- not within 5 m of air intakes from non-hazardous enclosed spaces.
The areas on open deck, or semi-enclosed spaces on open deck, within 3 m of the outlets are to be categorized hazardous zone 1 plus an additional 1,5 m surrounding the 3 m hazardous zone 1 is to be categorized hazardous zone 2.
Electrical apparatus located in the above hazardous areas zone 1 and zone 2 is to be suitable for at least IIC T1.

Safe location*(4): For in-line ozone injection BWMS (categories 7a and 7b), vent outlet from O3 destructor device (ODS) can be considered as oxygen-enriched air ~~as per paragraph .2~~ provided that:
- the ODS are duplicated; and
- the manufacturer justified that the quantity of consumable (activated carbon) used by the ODS is sufficient for the considered life cycle of the BWMS; and
- ozone detection is arranged in the vicinity of the discharge outlet from the vent outlet of the ODS to alarm the crew in case the ODS is not working.

If one of the above 3 conditions is not fulfilled, the safe location from ODS on open deck are:
- outside of hazardous area;
- not within 3 m of any source of ignition;
- not within 6 m of areas traversed by personnel; and
- not within 6 m of air intakes for machinery (engines and boilers) and all ventilation inlets.⟧

3. Revamping of the Annex I in Rev.2

The PT noted the following issues and inconsistencies in the existing Annex I of Rev.1:

i. There is no indication on the colour code to explain the difference in between the blue/red/green/black dotted lines (refer to PM11902cIMb regarding the questions for clarification on M74 3.2.3 and Annex).
ii. The valves indicated in the Annex I are not addressed in the UR but provide confusion to the reader (refer to PM11902cIMb regarding the questions for clarification on M74 3.2.3 and Annex).
iii. The ballast discharging lines are oriented to the sea chest which could be confusing.
iv. The Annex I in Rev.1 is actually allowing only limited BWMS technologies:
    a. BWMS which does not require after treatment: cases 1.2 and 1.3a
    b. BWMS which requires after treatment: cases 1.3b and 1.6

To tackle with the above issues, the PT decided to completely revamp the Annex I and adopted the following driving principles:

1. With due consideration of the definition of "cargo area" given in SOLAS Convention, IBC and IGC Codes and LHNS Guidelines (or OSV Chemical Code):
   → The segregated ballast water tanks sited immediately adjacent to integral cargo tanks are to be considered within the cargo area: §3.2 and Annex I apply
   → When the cargo tanks are not integral tanks but independent tanks arranged in a cargo hold (ex. Asphalt carrier or gas carriers Type A, Type B and Type C) or separated with insulation spaces and/or inter-membrane spaces (ex. Membrane LNG carriers), the segregated ballast water tanks are not to be considered within the cargo area: §3.2 and Annex I do not apply.

2. FSS Code Ch. 15 §2.3.1.1.2 *The inert gas generators shall be located outside the cargo tank area.*
   → Cases 2.3b is not allowed, refer to §3.2.1.1 in Rev.2.

3. Considering the O2 generator, O2 storage tank and O3 generator that significantly promote the potential of fire and explosion, the PT unanimously agreed to extend the same to BWMS categories 7a and 7b.
   → Cases 2.7a and 2.7b are not allowed, refer to §3.2.1.1 in Rev.2.

4. IBC Code Ch. 3.5 Bilge and ballast arrangements
   3.5.1 Pumps, ballast lines, vent lines and other similar equipment serving permanent ballast tanks shall be independent of similar equipment serving cargo tanks and of cargo tanks themselves. ***Discharge arrangements for permanent ballast tanks sited immediately adjacent to cargo tanks shall be outside machinery spaces and accommodation spaces. Filling arrangements may be in the machinery spaces provided that such arrangements ensure filling from tank deck level and non-return valves are fitted.***

→ The sea chests and ballast pumps in the ER can be used for filling the ballast tanks located within the cargo area (cases 1.2, 1.3a, 1.4, 1.5, 1.7a, 1.8a) but cannot be used for discharging the ballast tanks located within the cargo area (case 1.1 is not allowed).
→ The sea chests and ballast pumps in the CPR cannot be used for filling or discharging the Aft Peak Tank.

5. IMO MSC Circ. 406 Rev.1, interpretation of IBC Ch. 3.5.1 *Discharge arrangement of permanent ballast tanks sited immediately adjacent to cargo tanks*
   An eductor situated in the cargo area using water power from the machinery spaces is acceptable for discharging purposes provided a non-return valve and means of separation are fitted in the supply line and the supply line is above deck level. A non-return valve and means of separation should be located outside the machinery space (see figure 4).

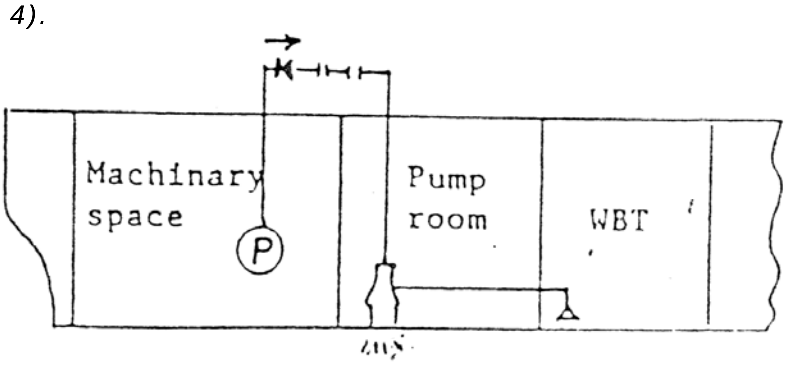


Figure 4 - Discharge arrangement of permanent ballast tanks sited immediately adjacent to cargo tanks (Paragraph 3.5.1)

→ When full flow of ballast water is pumped from the ER and discharged to the cargo area, a spool piece (i.e. non-permanent connection) is required: difference is to be made in between the means of disconnection proposed in §3.2.3.1 vs. the other means of appropriate isolation proposed in §3.2.3.2 and §3.2.3.3.
→ For cases 1.2, 1.3a, 1.4, 1.7b, 2.1, 2.2, 2.3a and 2.4: only the means of disconnection §3.2.3.1 are to be used.

The result of this technical approach is summarized in the below table:

The cases 2.1, 2.2, 2.3a and 2.4 are those for which additional consideration should be provided to:

i. Prevent against any discharge arrangement from the segregated water ballast tanks within the cargo area that would be arranged in the machinery spaces;

ii. Prevent the discharge of segregated water ballast tanks within the cargo area to the Aft Peak Tank;
iii. Prevent the use of the sea chests and pumps in the CPR for ballasting or de-ballasting the Aft Peak Tank;
iv. Ensure that no any remaining water or vapours originated from the cargo area could be expected inside the BWMS before connecting the BWMS to the machinery spaces.

For those cases 2.1, 2.2, 2.3a and 2.4, refer to the discussion in Section **6 "Annex I: operating limitations for cases 2.1, 2.2, 2.3a and 2.4"** , the note (3) in Rev.2 Annex I Table 1 and to the operating limitations applicable to cases 2.1, 2.2, 2.3a and 2.4.

	BWMS's Technology category →	**1**	**2**	**3a**	**3b**	**4**	**5**	**6**	**7a**	**7b**

	~~BWMS is located in the cargo area~~	~~Case 2.1 (2), (3)~~	~~Case 2.2 (2), (3)~~	~~Case 2.3a (2), (3)~~	~~Not Accept able~~	~~Case 2.4 (2), (3)~~	~~Case 2.5~~	~~Case 2.6~~	~~Not Acceptable~~	

*Notes:

(1) To be investigated on a case by case basis based on the result of the IMO (GESAMP) MEPC report for Basic and Final approval in accordance with the G9 Guideline.

(2) Only « Means of dis-connection » as described in 3.2.3.1 are to be applied. Other means of appropriate isolation 3.2.3.2. or 3.2.3.3 are not acceptable.

~~(3) Warning notice with operating instructions and means of mechanical or electronic interlocking are to be applied~~

(43) In-line side stream electrolysis may also be applied in-tank in circulation mode (no treatment when ballasting or deballasting)

4. Footnote *) 4. (Rev.2) discharge from Ozone Destructor Device (ODS)

Ozone (O3) is a highly toxic gas (irritant and poisoning when inhaled), highly oxidant (corrosive), not flammable but promoting the combustion process so that spontaneous explosive reaction can be expected.
Ozone Destructor device (ODS) is fitted at the venting discharge from the Ozone generator. Through the ODS, the Ozone is catalysed back into Oxygen tanks to a catalytic process using activated carbon. For the BWMS categories 7a investigated, the PT members wandered whether we could expect Oxygen-enriched air only or also a probability of Ozone-enriched air at the outlet of the vent pipe from the ODS with due consideration of the potential failure modes. For the BWMS category 7a used for this investigation, the ODS is duplicated and contains a consumable (activated carbon) in sufficient quantity for all the life-cycle of the ship but there was no Ozone detector at the outlet of the ODS.
The PT discussed extensively on the reliability of the ODS and its potential failure modes. The PT recognized that the ODS is a passive device but identified that in case of mechanical damage of the ODS during the operations or maintenance of the ship, one or both ODS can de damaged and that, for safety reasons, the crew needs to be informed of such failure for renewing that damaged part. This investigation resulted into PT's decision that it is not necessary to introduce specific requirements related to the discharge of Ozone-enriched air but the following

requirements have to be considered in order to disregard the risk of ozone at the outlet of the vent pipe from the ODS:

『Safe location*(4): For in-line ozone injection BWMS (categories 7a and 7b), vent outlet from O3 destructor device (ODS) can be considered as oxygen-enriched air as per paragraph .2 provided that:
- the ODS are duplicated; and
- the manufacturer justified that the quantity of consumable (activated carbon) used by the ODS is sufficient for the considered life cycle of the BWMS; and
- ozone detection is arranged in the vicinity of the discharge outlet from the vent outlet of the ODS to alarm the crew in case the ODS is not working.

If one of the above 3 conditions is not fulfilled, the safe location from ODS on open deck are:
- outside of hazardous area;
- not within 3 m of any source of ignition;
- not within 6 m of areas traversed by personnel; and
- not within 6 m of air intakes for machinery (engines and boilers) and all ventilation inlets.
』

5. §3.1.2 (Rev.1) reference to the TAC issued by the Flag Administration, modified in Rev.2

The group identified that through the 46 CFR 162.060-20 (b) (4), the USCG (who are not a ratifying Party to the IMO Convention) request a manual operation for the activation of the by-pass. This requirement is not applicable for the BWMS certified in accordance with the IMO G8 Guidelines only. In addition, 46 CFR 162.060-20 (b) indicates at (5) *Means that compensate for a momentary loss of power during operation of the BWMS so that unintentional discharges do not occur*. The PT discussed on potential interpretation of the combination of these two requirements leading to a "fail-close" operation mode of the by-pass which could be somehow conflicting with the principle of prioritizing the safety of the ship and its crew against the protection of the environment.
The PT noted that both IMO G8 Guidelines and USCG refer to the Operation Maintenance and Safety Manual (OMSM) to address the emergency procedures to be applied for securing the ship and noted that the manual is named "Operation and Technical Manual" in 2008 G8 Guideline but renamed OMSM in 2016 G8 Guideline. In practice, the manuals prepared by the BWMS's manufacturers are now commonly named OMSM even if they are approved in accordance with the 2008 G8 Guideline. The emergency procedures provided by the BWMS manufacturers in their OMSM could be summarized by "Emergency situation" → "BWMS shutdown" → "Alarm" → "By-pass open".
In order to address the applicable emergency procedures approved by the Administration during their review of the OMSM, the PT agreed for the addition of the following requirement in §3.1.3 of the Rev.2:

『The arrangement of the bypasses or overrides of the BWMS is to be consistent with the approved Operation Maintenance and Safety Manual by the Flag Administration's Type Approval.
』
And in a new §3.1.9:

『3.1.9 When it is required to have an automatic shutdown of the BWMS for safety reasons, this must be initiated by a safety system independent of the BWM control system. 』

In addition, it was noted that the operating limitations specified in the TAC issued by the Flag Administrations are not limited to the maximum Treatment Rated Capacity (TRC) only. Other operational limitations need to be considered such as minimum water salinity for electrolysis BWMS, after treatment (additional disinfection or neutralization) before discharging, etc. To address all the potential requirements specified in the TAC issued by the Flag Administrations, it was agreed to provide the following revision in §3.1.3 of Rev.2:

『The BWMS is to be operated ~~at a flow rate within the Treatment Rated Capacity (TRC) range~~ in accordance with the requirements specified in the Type Approval Certificate (TAC) issued by the Flag Administration. BWMS should be operated within its Treatment Rated Capacity (TRC) as per the TAC. This may require limiting of ship's ballast pump flowrates.』

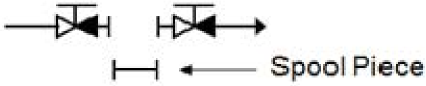
and

『In case the maximum capacity of the ballast pump(s) exceeds the maximum treatment rated Capacity (TRC) of the BWMS specified in the TAC issued by the Flag Administration, there should be a limitation on the BWMP giving a maximum allowable flow rate for operating the ballast pump(s) that shall not exceed the maximum TRC of the BWMS. 』

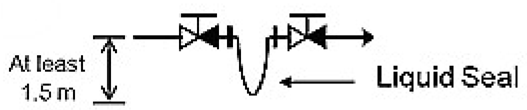
6. §3.2.3 (Rev.1) means of appropriate isolation: screw-down valve, modified in Rev.2

The PT noted that this requirement for "screw-down" was limiting the type of the valves to globe valves or gate valves only which is not a practical solution for the industry. In case of big diameters (example for the main ballast lines), the shipyards usually propose butterfly valves and in case of small diameters (example for the generation and injection of the active substances or neutralizer), shipyards could also propose ball valves. It is recognized that screw-down valves provide the highest level of protection against liquid leakages but are required when the consequence of a liquid leakage will be critical for the stability of the ship (example for flooding concerns through the bilge lines or through the valve on the collision bulkhead) but for some diameter ranges, screw-down valves are not easily available on the market and it is not possible to install an actuator with an hydraulic remote control for the screw-down valves (it needs the installation of an explosion proof electrical motor for each valve).
In practice, the use of butterfly valves or ball valves is commonly accepted by the Classification Societies when the flooding through a valve leakage is not a concern for the stability of the ship in cases of cargo ships (See MSC.1/Circ.1567 and SOLAS regulation II-1/12.6.1 as amended by Resolution MSC.421(98)). In this regard, it is to be noted that the means of appropriate isolation are required to be installed on the exposed deck and consequently not relevant for the concern of flooding a watertight compartment located below the free-board deck. In this regard, the request for "screw-down" type at §3.2.3 was considered excessive by the PT.
It was also noted that the purpose of the positive means of closure of the valves referred to in §3.2.3 is not primarily the protection against liquid leakages; this protection against liquid leakages is already achieved by the non-return swing check flap integrated to the non-return valve or by addition of a swing check valve. Through the reference to the non-return devices required for the inert gas systems in FSS Code Ch 15/2.2.3.1 (refer to HF for Rev.1), the PT identified that the primary purpose of the means of appropriate isolation is to prevent the return of dangerous vapours originated from the cargo area to the gas safe spaces when the pipes are empty. Therefore, it was agreed to align that §3.2.3 with FSS Code Ch. 15/2.2.3.1 through the following revision:

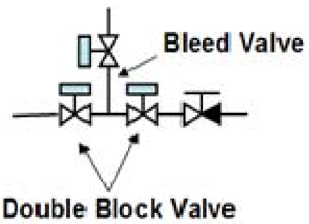
『.1 Two ~~screw down check~~ non-return valves with positive means of closing in series with a spool piece (also mentioned "means of disconnection" in Annex I), or
Note: As an alternative to positive means of closure, an additional valve having such means of closure may be provided between the non-return valve and the spool piece.



.2 Two ~~screw down check~~ non-return valves with positive means of closing in series with a liquid seal at least 1.5 m in depth, or
Note: As an alternative to positive means of closure, an additional valve having such means of closure may be provided between the non-return valve and the liquid seal.



.3 Automatic double block and bleed valves and a non-return valve with positive means of closing.
Note: As an alternative to positive means of closure, an additional valve having such means of closure may be provided after the non-return valve.



』

This modification remains in accordance with the SOLAS, IBC and IGC requirements which are not specifying "screw-down" type (see also IMO MSC Circ. 406 Rev.1 Figure 4 where "screw-down" is not mentioned).

An additional consideration has been raised for adding a remote control valve in the engine room to maintain the fire integrity of the bulkhead facing the cargo area. However, after further discussion, this consideration has been abandoned by the PT considering that this could be discussed with the PT Safety Panel PS17030a in charge of the fire protection issues related to the BWMS.

7. §3.4.2.2 (Rev.1) strength and construction of chemical tanks, modified and renumbered §3.3.3.2 in Rev.2

The PT acknowledged that the wording given in the Rev.1 was too vague and could be interpreted either with zeal (in practice, what kind of evidence involving the Classification Rules could be provided to justify that the tank has sufficient strength if the tank was not subject to a design review as applicable to a pressure vessel?) or with laxity (no reference to any Rules or standard means no straight forward action).
The PT also acknowledged that the existing requirement in Rev.1 was not making any difference in between a compressed O2 storage tank (which is more dangerous than a compressed air tank subject to the pressure vessels requirements from the Classification Societies) and a N2 buffer tank with low design pressure.
The PT also acknowledged that existing requirement in Rev.1 was not making any difference in between a sulphuric acid storage tank (which is highly dangerous due to the exothermic reaction of the acid sulphuric when in contact with water) and a neutralizer storage tank that would not contain dangerous liquids.
After extensive discussions, the PT agreed to modify the requirement by making the difference in between:
- independent tank permanently fixed on-board vs. portable tanks; and
- dangerous gas vs. non-dangerous gas (some gases ex. nitrogen are chemical substances but are not dangerous in the sense of the definition given in §2.3 of the Rev.2); and
- dangerous liquid vs. non dangerous liquid (some chemicals ex. the neutralizers are chemical substances but are not dangerous in the sense of the definition given in §2.4 of the Rev.2):

『.2 Chemical substances (even if they are not defined as dangerous liquid in the sense of 2.4) and gas storage tanks are to ~~have sufficient strength and be constructed such that maintenance and inspection can be easily performed~~ be designed, constructed, inspected, certified and maintained in accordance with:

- for independent tanks permanently fixed onboard containing dangerous liquids (eg. sulfuric acid H2SO4) or dangerous gas (eg. oxygen O2): the Classification Rules as applicable to pressure vessels
- for independent tanks permanently fixed onboard not containing dangerous liquid (eg. sodium sulphite, sodium biosulphite or sodium thiosulfphate neutralizers) and not containing dangerous gas (eg. nitrogen N2): the Classification Rules or other industry standard recognized by the Classification Society

for portable tanks: the IMDG Code or other industry standard recognized by the Classification Society. 』

8. §4 (Rev.1) Automation, deleted in Rev.2

The PT identified that the existing §4 in Rev.1 was redundant and source of confusion with the following statutory requirements:
- 2008 G8 Guideline IMO MEPC Res. 174(58) §4 Technical specifications §4.5.3 and §4.5.4
- 2016 G8 Guideline IMO MEPC Res. 279(70) §4 Technical specifications §4.9.3

and §7 Installation requirements following Type Approval process §7.2 and PART 5 – Self Monitoring §5.3.5.
On the other hand, the PT did not identified the added value of that §4 compared to the statutory requirements of the IMO G8 Guidelines.
In order to avoid any conflict or misunderstanding with the Statutory requirements of the IMO G8 Guidelines, it was decided to delete that §4.

9. Risk assessment §3.3.4

The PT has conducted a survey with the following questions:

1. Refer to §3.3.4: what is your understanding and definition of an acceptable "Risk assessment" for BWMS? The majority replied that referring to acceptable standards (ex. ISO 31010) or Classification Rules (ex. BV's NI525 Risk Based Qualification of new technology methodological guidelines) or IACS (ex. Recommendation Rec. 146) plus that a reference to the methodology (ex. FMEA, FEMCA, HAZID, HAZOP, etc) were necessary.
2. With reference to §3.3.4: in which case should we request a "Risk assessment"? The majority replied:
- For BWMS category 4: in all cases
- For BWMS category 5: in all cases
- For BWMS category 6: when the MSDS indicates that the chemical substance stored on-board is either flammable, toxic, corrosive or reactive;
- For BWMS categories 7a and 7b: in all cases.
3. What is the expected outcome of requesting a risk assessment? The majority replied:
- Ensure that the package supplied by BWMS's manufacturer is intrinsically safe; and
- Provide mitigation measures to the hazards created by the BWMS which have been identified during the Classification's TAC process but that need to be considered during the installation on-board.
4. Do you agree that if a risk assessment is to be carried out for BWMS, it should be conducted in a generic manner during the Classification's TAC process and not in a systematic manner during the installation on-board a specific ship? The majority replied "YES"
5. Do you request a 3rd Party attending the risk assessment (for example attendance during HAZID or HAZOP meetings)? The majority replied "NO"
6. When the "Risk assessment" report is submitted to the Classification, is it required to be approved by the Classification Society? The majority replied "YES"
7. For which BWMS category (1, 2, 3a, 3b, 3c, 4, 5, 6, 7a, 7b, 8). The majority replied 4, 5, 6, 7a and 7b.
- Would you systematically request a risk assessment? The majority replied "NO"
- Would you request a risk assessment on a case by case basis: The majority replied "NO"
- Would you exempt from requesting a risk assessment? The majority replied "NO"

The result of the discussions has been implemented in the following revision of §3.3.4:

『3.3.4 A risk assessment ~~may~~ is to be conducted ~~to ensure that risks, including but not limited to those arising from the use of dangerous gas affecting persons on board, the environment, the structural strength or the integrity of the ship are addressed.~~ in a generic manner during the TAC process mentioned in 3.1.4 and submitted to the Classification Society for approval for the following BWMS categories:
- BWMS category 4: in all cases;
- BWMS category 5: in all cases;
- BWMS category 6: when one of the MSDS indicates that the chemical substance stored on-board is either flammable, toxic, corrosive or reactive;
- BWMS category 7a and 7b: in all cases.
Note: The IMO reports issued during the basic and final approval procedures of the BWMS that make use of active substances (G9 Guideline) could be used as a reference for this assessment.

.1 The recommended risk assessment techniques for BWMS and other guidances are listed below but not limited to:
- FMEA, FMECA, HAZID, HAZOP, etc.
- ISO 31010 – Risk Assessment Techniques
- IACS Recommendation Rec. 146
- Rules of the Classification Society for risk assessment techniques

.2 The risk assessment should ensure that the package supplied by the BWMS's manufacturer is intrinsically safe and/or provides mitigation measures to the hazards created by the BWMS which have been identified during the TAC process mentioned in 3.1.4 but that need to be implemented during the installation on-board. 』

By the Panel, the term "*TAC process*" was modified to "design review" according to improvement of §3.1.4 (See Section 11 below).

10. BWMS certification by Classification

The PT has conducted a survey with the following questions:

1. Do you want Type Approval from Classification to be made mandatory for all BWMS? The majority replied "YES"
2. Do you think that the BWMS package should be inspected by Classification at manufactory? The majority replied "YES"
3. How do you identify the BWMS's components that are required to be inspected and certified by the Classification at manufactory (product certification) like pressure vessels, piping class I or Class II, self-draining, filters, switchboards, etc? The majority replied during the Type Approval or generic Design Approval process of manufacturer's package but this is too late if this is conducted for the installation on-board a specific ship.

The result of the discussions has been implemented by inserting the following §3.1.4 after §3.1.3:

『3.1.3 The BWMS is to be operated ~~at a flow rate within the Treatment Rated Capacity (TRC) range~~ in accordance with the requirements specified in the Type Approval Certificate (TAC) issued by the Flag Administration.
The arrangement of the bypasses or overrides of the BWMS is to be consistent with the approved Operation Maintenance and Safety Manual by the Flag Administration's Type Approval.
In case the maximum capacity of the ballast pump(s) exceeds the maximum treatment rated Capacity (TRC) of the BWMS specified in the TAC issued by the Flag Administration there should be a limitation on the BWMP giving a maximum allowable flow rate for operating the ballast pump(s) that shall not exceed the maximum TRC of the BWMS.

3.1.4 BWMS should be subject to Type Approval process from the Classification society to verify the compliance of the BWMS's manufacturer package with the Classification Rules.
In general, monitoring functions of BWMS belongs to system category I under the application of the UR E22 Rev.2. However in case a by-pass valve is integrated in the valve remote control system, the by-pass valve belongs to the system category II Ballast transfer remote control system.
The BWMS's components are required to be inspected and certified by the Classification Society at the manufactory (Society Certificate (SC) as defined in UR M72) including pressure vessels, piping class I or II, filters, switchboards, etc.』

By the Panel, the following changes were made:

At the end of the first paragraph of §3.1.3, the following sentence was added: BWMS should be operated within its Treatment Rated Capacity (TRC) as per the TAC. This may require limiting of ship's ballast pump flowrates.

In the first paragraph of §3.1.4, the term "*Type Approval*" was modified to "design review" subject to addition of the following sentence at the end of said paragraph: Manufacturers of the BWMS may apply for this design review at the type approval process.

11. Cavitation

In order to address the systems using the cavitation for the ballast water treatment, the following requirement has been added at §3.1.8:

『3.1.8 When cavitation is the BWMS treatment process (for example by use of pressure vacuum reactor working in combination with a vertical ballast water drop line) or part of the BWMS treatment process (for example by use of "smart pipe" or "special pipe" in BWMS category 7b or by use of "venturi pipe" in BWMS technology 3b) or by use other means, the design and the wall thickness or grade of materials or inside coating or surface treatment of the part of the piping where the cavitation is taking place is to be specifically considered』

On Member deemed that §3.1.8 should be applied to the category 7a due to usage of venturi pipe. PT clarified that §3.1.8 should apply to the "special pipes" provided intentionally for creating cavitation as a treatment process but §3.1.8 should not address ejectors used for injecting an active substance to the ballast water.

12. Other modifications

The following notable modifications were made to improve the Rev.2:

In the first paragraph of §3.1.2, the following sentence was added as the first sentence: The BWMS is to be provided with by-pass or override arrangement to effectively isolate it from any essential ship system to which it is connected.

In the first paragraph of §3.1.5, a clarification was made that vacuum or overpressure in the ballast piping should also be covered.

In §3.1.7.2, compliance with F20.4.6 is also additionally required and a clarification was made that the terms "cargo tanks" and "cargo piping" (for the application of F20.4.6) should be understood as "ballast tanks" and "ballast piping" respectively and, for de-oxygenation BWMS (categories 3a, 3b, 3c and 8), the requirements in 3.1.7.1 prevail notwithstanding F20.4.

In §3.2, the term "cargo tank area" not defined in the FSS Code Chapter 15 was deleted.

In Note 2 of §3.2.3.1, a requirement, which may be applied the discretion of the Classification Society and for active substance piping and neutralizer piping (both up to 2 inches) only, was added for exceptional cases.

In §3.2.3.2, the location of the means of appropriate isolation was clarified.

In §3.3.1.2, it was clarified that automatic shutdown should be required when the oxygen level raises above 25 % and that audible and visual alarms independent from those specified in the preceding paragraph should be activated prior to this shut-down.

In §3.3.1.5, it was clarified that ventilation fans should be certified explosion proof and have spark arrestors in the location with H2 in dangerous concentrations.

****

Technical Background (TB) document for UR M74 (Rev.3 March 2025)

1. Scope and objectives

To merge the requirements for ventilation and vent pipes specified in UR F45 and in UR M74(Rev.2) in a new section in UR M74.
To consider further amendments to UR M74 based upon Machinery Panel Members' proposals or questions from their clients.

2. Engineering background for technical basis and rationale

The modification of UR M74 has been made by the Machinery Panel members starting with the integration of ventilation requirements from UR F45 in UR M74. Other modifications came from members' proposal and queries and were based on members' experience in BWMS installation on board of ships.

2a. Specification of the data utilised in the development/revision of the proposed IACS Resolution, if any

None.

3. Source/derivation of the proposed IACS Resolution

As soon as UR M74 Rev.2 and new UR F45 were published, Machinery Panel was tasked by GPG to merge the ventilation requirements between the two URs to avoid confusion as the topic is addressed in both UR.

4. Summary of Changes intended for the revised Resolution:

- A new section (paragraph 4) has been added and is dedicated to ventilation requirements gathering those of UR F45 and UR M74 (Rev.2).
- Sketches for BWMS technology group 3b and 3c have been completed for the purpose of clarification.
- The definition of dangerous liquid has been completed giving example and aiming at precising the status of hypochlorite solution.
- Additional sketches corresponding to the alternative to positive means of closure have been added in paragraphs 3.2.3.1.1, 3.2.3.1.2 and 3.2.3.1.3.
- Table 2 is removed from the UR and now included in the technical background.
- Several wording improvements have been made for a better understanding of the UR by the Machinery Panel members. These improvements also include changes in the reference format to IMO convention and documents.
- The paragraph 3.2 for the installation of BWMS on board of tankers has been modified:
    - Clarification concerning installation arrangement of a single UV system on board of tankers (§3.2.2 and table 1 of Annex I).
    - Deletion of note 1 of §3.2.1.2 concerning the installation of BWMS in cargo compressor room and cargo pump room.

   - o Clarification concerning the location of isolation means and requirement to allow their installation in enclosed space (§3.2.3.2).
   - o Waiver to allow alternative isolation arrangement (Note 2 of paragraph 3.2.3.1) for 2 inches active substance piping and neutralizer piping extended to other BWMS piping system (N2 gas, inert gas, compressed air, fresh water, sea water).
- Modification of sketches in annex I for ballasting operation with spool piece of case 1.2, 1.3a, 1.4 and 1.7.
- Note 5 for the implementation date of the UR has been clarified.

5. Points of discussions or possible discussions

1. Machinery Panel members agreed to keep table 2 “Applicability of the requirements for each BWMS technology” from UR M74 rev.2 in the technical background. Below table is updated with modifications brought in UR M74 rev.3.

BWMS's Technology category (informative Annex II should be referred to)→	**1**	**2**	**3a**	**3b**	**3c**	**4**	**5**	**6**	**7a**	**7b**	**8**
UR M74 requirement ↓	In-line UV or UV + Advanced Oxidation Technology (AOT) or UV + TiO_2 or UV + Plasma	In-line Flocculation	In-line membrane separation and de-oxygenation (injection of N_2 from a N_2 Generator)	In-line de-oxygenation (injection of Inert Gas from Inert Gas Generator)	In-tank de-oxygenation with Inert Gas Generator	In-line full flow electrolysis	In-line side stream electrolysis	In-line (stored) chemical injection	In-line side-stream ozone injection without gas/liquid separation tank and without Discharge treatment tank	In-line side-stream ozone injection with gas/liquid separation tank and Discharge water treatment tank	In-tank pasteurization and de-oxygenation with N_2 generator

4.2.3						x	x	x			
4.2.4									x	x	
4.2.5									x	x	
4.2.6		x	x	x	x	x	x	x	x	x	x
4.3.1	x	x	x	x	x	x	x	x	x	x	x
4.3.2		x	x	x	x	x	x	x	x	x	x
4.3.3		x	x	x	x	x	x	x	x	x	x

2. The applicability of the ventilation requirements to the case where a BWMS is installed in the engine room was discussed within the Panel. The ventilation requirements were considered to address the case where a dedicated space is used for the installation of a BWMS and the necessity to address also the case where a BWMS is installed in an engine room was raised. It was noted that the definition of BWMR is applicable to engine room but ventilation requirements for BWMR are not all applicable to the engine room.
   Members agreed that the BWMS, when allowed to be installed in the engine room, is to be in a well-ventilated area (during ballasting and de-ballasting operation as ballasting operation are done in ports where ventilation may not be at full power) and, in this case, the ventilation rate of the engine room is not to be increased.
   It was finally considered, after transferring ventilation for hydrogen de-gas arrangement requirements from paragraph 4.2.5 to 4.1.1, that paragraphs 4.2 and 4.3 are not applicable to the engine room and paragraph 4.2.6 was added.

   The following points were also brough up during the above discussion:
   - A member proposed to ask for a minimum of 6 air changes when a BWMS is installed in the engine room. This proposal was rejected considering that there is no such requirements in shipbuilding, that a minimum capacity of the ventilation is not enough to ensure that the BWMS is in a well-ventilated area in the engine room to prevent accumulation of vapours and gases and that, as there is an interlocking arrangement, it is not necessary to impose additional minimum ventilation rate.

- In order to clarify that the BWMR definition is also applicable to engine room, it has been proposed to complete the BWMR definition indicating that for the application of the UR and pursuant to the BWMR definition, the E/R is considered as a BWMR when the BWMS is installed in the E/R/ This proposal was rejected by members. On the same idea, it was considered to add a clause such as "where a BWMS is located in the engine room, the requirements of section 4.2 shall be met, as applicable", and rejected by members.

3. The proposal to have the BWMR with negative pressure was also discussed and rejected as a negative pressure was considered difficult to maintain in the engine room (during various modes of operations, a slight overpressure may be applied).

4. Removing Nitrogen as a dangerous gas was discussed by members. It was acknowledged that nitrogen is not toxic, but paragraph 2.3 lists "asphyxiation" as a hazard under the definition for dangerous gas. Considering also several requirements of the UR are linked with N2 and the potential lack of oxygen in the space, such as § 3.3.1.2, members decided to keep N2 as a dangerous gas for the application of the UR.

5. Also, as there is no similar requirement in the FSS code Ch.15, it was proposed to delete paragraph 4.2.2 about the location of the ventilation exhaust in the lower part of a BWMR containing a nitrogen generator. The machinery panel members preferred to retain the requirements as this requirement intends to prevent the risk of asphyxiation should nitrogen be present in the space or accumulation of oxygen in the space, and for ship designer to take into consideration the arrangement of the ventilation duct.

6. The 2nd paragraph of clause M74.3.3.1.5 of UR M74 Rev. 2 (4th paragraph of M74.4.1.1, rev.3) was requiring having spark arrestor for ventilation fan. Members believed that the requirement is intended to prevent the passage of flame into the ventilation systems through an outlet of the systems in a similar manner to SOLAS II-2/Reg.4.5.3.3. Also, the current clause can be read as if the spark arrestor shall be installed in a ventilation fan although explosion-proof ventilation fans are required. In addition, the term "spark arrestor" looks like the UR requires specific arrangements differing from "flame arrester" (especially the expression 'flame arrester' is stated on UR M74.3.2.4.1 iv)). Also, considering MSC/Circ.677 defines separately flame screen and flame arrestor, the expressions "flame arrester" or "flame screen" were changed to "flame arrester or flame screen".
   The paragraph has been further modified based on the understanding that fan would be "non-sparking type", and that motor would be motor "certified safe type" depending on their installation in hazardous area or ventilation duct of the de-gas arrangement or not. To further reduce the likelihood of flames entering the ventilation duct, a flame arrester or flame screen is required installed to prevent ignition. As a minimum the flame arrester or flame screen shall be located at the ventilation outlet, but the need for such also at the ventilation inlet should be considered subject to the risk assessment for the actual installation. An indication of the required certification level of the flame screen (group IIC, corresponding to hydrogen) was proposed, but not retained by members.

7. Considering that dangerous gas will not be discharged directly into the BWMR, members agreed to modify paragraph 4.2.3 so that the ventilation system for BWMR containing electrolysis systems shall be located to efficiently evacuate "dangerous gases that could leak into the BWMR" (and not "dangerous gas that could be generated during the electrolysis process").

8. Paragraphs 2.4 and 3.3.3.2 of the UR were discussed in the Panel in view of whether sodium hypochlorite is to be considered as a dangerous liquid. Paragraph 2.4 defines dangerous liquid as any liquid that is identified as hazardous in the Material Safety Data Sheet or other documentation relating to this liquid. Paragraph 3.3.3.2 clarifies that sulfuric acid (H2SO4) is an example of a dangerous liquid, while the same paragraph clarifies that sodium sulphite, sodium biosulphite or sodium thiosulfphate neutralizers are not considered dangerous liquids. However, it is not clear whether a hypochlorite solution is to be considered a dangerous liquid or not.
   Hypochlorite is the active substance generated by a BWMS using in-line full flow electrolysis or in-line side stream electrolysis. A hypochlorite solution (in the form of sodium hypochlorite) may also be used by a BWMS with in-line (stored) chemical injection. In in-line full flow electrolysis BWMS, the hypochlorite concentration is typically 10-12 ppm or less, while the side stream of in-line side stream electrolysis BWMS typically contains 1000-2000 ppm (0,1 -0,2 %) hypochlorite before the side stream is injected into the main ballast line (or in-tank in circulation mode). The sodium hypochlorite concentration is typically 12% when stored in a tank for a BWMS with stored chemical for injection in-line (or in-tank in circulation mode).
   As per the IBC Code, solutions containing 15% or less sodium hypochlorite are categorized as noxious liquid substances which, if discharged into the sea from tank cleaning or deballasting operations, are deemed to present a hazard to either marine resources or human health or cause harm to amenities or other legitimate uses of the sea and therefore justify a limitation on the quality and quantity of the discharge into the marine environment. GESAMP has defined the maximum allowable discharge concentration (MADC) for hypochlorite to be 0.1 mg/L. Otherwise, the IBC Code considers sodium hypochlorite (<15%) as a non-flammable product and references only two special requirements of the IBC Code; increased ventilation requirements (Paragraph 15.17) and high-level alarm (Paragraph 15.19.6).
   The Panel majority was of the view that IACS is not in the position to give a definite limit for lower and higher concentration of dangerous or non-dangerous sodium hypochlorite liquid. This will be under the responsibility of manufacturer/supplier of hypochlorite solutions or certification holder of BWTS. There was however a majority support in the Panel for identifying hypochlorite solutions of concentration 0.1 % as non-dangerous. Paragraph 2.4 is thus updated in this revision by using this as an example. This concentration is typically used by side-stream electrolysis. This means that piping conveying hypochlorite solutions of concentration 0.1 % does not need to meet the requirements in paragraph 3.3.2.
   There was also a general support in the Panel that hypochlorite solutions of higher concentration (typical 12% as normal commodity for a chemical injection system), although not considered as non-dangerous, may be considered as a less harmful/dangerous liquid.
   However, considering that IACS is not in the position to give a definite limit for lower and higher concentration of dangerous or non-dangerous liquid, the panel

concluded that it is not relevant to define any requirements to a "less harmful/dangerous liquid".

9. UR E22, which is referred to in §3.1.4 of UR M74, was revised from Rev.2 to Rev.3, and it was considered that it may be not enough to just change the reference from Rev.2 to Rev.3, and that the text of the § 3.1.4 related to UR E22 should be changed because the category of system under UR E22 Rev.3 should now be judged for each ship, and by system integrator (the category was judged by Classification society under UR E22 Rev.2). Therefore, Machinery Panel members agreed to ask to Cyber Panel members for their comments and advice to update UR M74.3.1.4 and modification to para 3.1.4 of UR M74 was proposed by Cyber Panel based on the following detailed explanation:

   As standalone Rule requirements, M74 is incomplete in that it refers to monitoring, control, alarm and safety functions in the text but only makes one reference to E22 in order to exclude monitoring systems from consideration: "*In general, monitoring functions of BWMS belongs to system category I under the application of the UR E22 Rev. 2. However, in case a by-pass valve is integrated in the valve remote control system, the by-pass valve belongs to the system category II Ballast transfer remote control system.*"
   E22 applies system categories to computer-based systems, so it cannot apply directly to mechanical components such as valves.

   Instead, the application of a system category must be to functions associated with the BWMS that are implemented in software on computer-based systems. Cyber Panel view is that higher system categories would likely apply to flammable gas alarms, pressure alarms, automatic shutdowns etc. referenced elsewhere in that document, where they are achieved by computer based system functions.

   Cyber Panel's understanding of the use of a bypass valve is that ballasting operations can continue under manual supervision without functional BWMS controls, subject to risk assessment by the owner. This is an emergency protection for the ship and personnel only. It does not provide a protection for the environment, as indicated in HSSC survey guidelines, (BI) 1.1.3.18, "Confirming that, if applicable, the suitable bypasses or overrides to protect the safety of the ship and personnel are installed and used in the event of an emergency and these shall be connected to the BWMS so that any bypass of the BWMS shall activate an alarm. The bypass event shall be recorded by the control and monitoring equipment and within the ballast water record book".
   It is concluded that use of a bypass is not expected to be typical, except perhaps for the operation of heavy lift vessels taking and releasing ballast at the same location.
   When it is used, the safety of the ship is being prioritised over the environmental protection objectives achieved by a functional BWMS.

   Cyber Panel has no objection to limiting the application of E22 regarding monitoring functions alone, provided it is then correctly applied to control, alarm and safety functions.

   Understanding that inadvertent opening of the bypass valve would be undesirable as it has potential environmental consequences, the following revised text was suggested:

Monitoring functions of BWMS typically belong to system category I under UR E22. In case a bypass valve is integrated in the valve remote control system, the Ballast transfer remote control system may belong under system category II.

This does not absolve makers of control, alarm and safety systems for BWMS from following the requirements of the appropriate system category which may be system category II or higher.

10. Table 1 of Annex 1, in rev. 2 of the UR, is stating that the installation a single UV system outside of the cargo area on board of tankers is not acceptable. It was commented that if a specific location for some systems is not accepted, this should be explicitly clarified in the main text as per the case of ozone and de-oxygenation systems in 3.2.1.1. It was also noted that the installation of a single BWMS is not acceptable for UV based systems (category 1) when treatment is required during both ballasting and de-ballasting operations. Therefore, members agreed to:
    - to clearly state, by completing paragraph 3.2.2 and also adding a note in table 1 of annex I, that, when treatment of ballast water is required during ballasting and de-ballasting operation, it is not acceptable to install a single BWMS outside the cargo area.
    - Delete category 1 in paragraph 3.2.2 in the list of references to specific arrangement with one single in-line BWMS given in annex I, as no example of acceptable arrangement with BWMS cat. 1 is given in Annex I.

11. The reference to the "cargo tank deck" in note 1 of paragraph 3.2.1.2 was deemed unclear as main deck level and cargo tank top level may not be the same, depending on the tankers type. It was also proposed to delete the requirement of this note to have the cargo pump room above the cargo tank deck as it was found not to reflect the designs of oil tankers and chemical tankers.
    According to Table 1 «Proposal from PT PM 42/2017: issues addressed by the Machinery Panel through the UR M74 Rev. 2» in the Technical Background for rev.2, Cat.4 to Cat.6 will be taken countermeasures for the installation BWMS in cargo pump room based on risk assessment. The existing Note 1) of 3.2.1.2 is understood to be additional requirements for Cat.4 with respect to the location of certain rooms such as cargo compressor rooms of liquefied gas carriers and inside cargo pump rooms of oil tankers or chemical tankers. However, by deleting only the expression «if that cargo pump room is located above the cargo tank deck», the Note will be then understood that it is only acceptable for Cat.4 BMWS to install in the rooms excluding Cat.5 and Cat.6.
    Finally, members agreed to delete the complete note which is deemed covered by paragraphs 3.2.1 and 3.1.6.

12. The wording "the open deck in the cargo area" in paragraph 3.2.3.2, for the location of appropriate isolation means between ballast piping serving the ballast tanks inside and outside of the cargo area, needed some clarification:
    - Whether the definition of "cargo area" includes enclosed spaces like cargo pump rooms, compressor rooms etc. or only exposed cargo deck areas.
    - Whether "open deck" means "exposed deck areas (not including enclosed spaces)" or "deck areas (including enclosed spaces)".

Members agreed that the means of isolation may be located in enclosed spaces in the cargo area (e.g. cargo pump room) and not only on weather deck in the cargo area. Considering it is difficult to describe all conditions in the UR under which the appropriate isolation means may be located in enclosed spaces in the cargo area (such as the location and the construction of the enclosed space, ventilation, type of BWMS etc.) and considering members preferred that the arrangement for the installation of the isolation means in enclosed spaces should be accepted under specific conditions instead of a wording letting to the review of the Classification Society the possibility to install the means of isolation in an enclosed space without limitations in the UR, members agreed that the means of isolation can be provided in an enclosed space in the cargo area for piping up to 2 inches for active substance, N2 gas, inert gas, neutralizer liquid, fresh water, compressed air or sea water in accordance with the provisions of note 2 of paragraph 3.2.3.1.

13. In note 2 of paragraph 3.2.3.1, the waiver for both active substance and neutralizer piping up to 2 inches in note 2 is extended also to other pipes such as N2 gas, inert gas, fresh water, compressed air and sea water.
No specific reasons were found for a waiver only to active substance and neutralizer piping, only that the reasoning behind allowing both active substance piping and neutralizing piping up to 2 inches is related to the fact that ballast water treatment systems of various designs would always need those piping to be provided in order to perform the treatment and other pipes not essential for the operation of the BWTS will therefore be arranged as per today’s practice, i.e. on open deck and not through the cargo pumproom bulkhead.

14. Additionally, the below matters were discussed, and members agreed on the following:
    - Paragraph 3.3.1.3 requires the installation of an ozone sensor. The sensor’s specification is according to the manufacturer’s specification and no type approval certificate is required.
    - Considering de-oxygenation with Inert gas generator BWMS (case 1.3b), providing inert gas to cargo area through a water seal, members shared the understanding that the water seal would not work as intended. Inert gas will by the flow of IG empty the water seal itself, resulting in the back flow prevention not working. Therefore, water seal would not be appropriate for piping transferring gases.
    - Members confirmed that when the cargo tanks are not integral tanks but independent tanks arranged in a cargo hold (ex. Asphalt carrier, chemical tankers with independent cargo tanks or gas carriers Type A, Type B and Type C) or separated with insulation spaces and/or inter-membrane spaces (ex. Membrane LNG carriers), the segregated ballast water tanks are not to be considered within the cargo area and therefore §3.2 and Annex I do not apply.
    - Paragraph 3.3.3.3 of UR M74 concerns integral tanks which are part of the hull construction and dedicated to the storage of chemical which are to be used in the ballast treatment process.
      The Machinery Panel members considered that requirements for corrosion additions to the tanks’ plate, survey interval, etc. may be needed. It was also noted that corrosion assessment is to be performed by the manufacturer during the type approval process of the BWMS (This assessment is to cover also piping, mixing tanks and storage tanks).
      Concerning the survey of these tanks, and considering that these tanks:

- are integral tanks, and
- are containing chemicals,

it was proposed that some of the survey requirements applicable to the tanks of chemical tankers, by analogy, could be also usefully applied to the tanks storing chemical used in the ballast treatment process.
Following modification was proposed:
"3.3.3.3 When the chemical substances are stored inside integral tanks, the ship's shell plating shall not form any boundary of the tank. The tank is to be surveyed in accordance with the requirements of cargo tanks of chemical tankers but no need to apply §4.2.3 and §4.2.4 in IACS UR Z10.3."
Survey Panel was consulted for comments.
Survey Panel noted the difficulty to develop survey requirements at this stage. Although integral tanks which contain chemicals for BWMS are understood, but design/location of the concerned tank and compositions of chemicals are also important factors among others to consider survey requirements. Regarding this difficulty, Survey Panel was of the view that development of survey requirement should be done in consultation with Hull Panel and Safety Panel.
Therefore the draft survey requirement received from Machinery Panel for Paragraph 3.3.3.3 of UR M74 was not agreeable to Survey Panel at this stage.
Members agreed to close the matter being understood that it may be reopen if the need arise in the future.

- The implementation date note of the UR was deemed unclear due to:
  - the lack of a few definitions such as existing ships and new ships,
  - the possible confusion between BWMS itself and the BWMS installation on board of ships.

  It was also considered that the implementation date note could consider different application cases such as new installation, modification, or replacement.
  During discussion, the following points were noted:
  - When contracting with a shipyard or a manufacturer, Classification societies are referring to their rules applicable at that moment. Generally, no references are made to IACS URs, and applicable rules depend on general classification conditions set in their rules. Each IACS members has the obligation to implement the URs in their rules.
  - The purpose of the implementation note of the UR is to set a uniform implementation date of the UR in Class Societies rules. Adding different application cases is therefore useful if it is considered to have different implementation date depending on each case (There would be no real added value to have different application cases with the same implementation date). Also, it is not feasible to have different implementation date for URs' individual paragraph in the rules.

  It was considered to have a note with a single date for implementation in the members' rules edition. The subject was shared with Safety Panel which agreed that rules are applied relating to the contract date and that it is therefore sufficient for the "typical" UR to specify an implementation date, i.e. the date from which the UR are to be applied by the rules. The simple wording would therefore be sufficient for newbuilding projects. However, the UR M74 and F45 also apply for retrofitting, replacement and major conversion (UR F45: "For existing ships, where the application for approval for the installation plans of BWMS is dated on or after …") which clarifies that the requirements also apply for existing ships. Without this sentence it would be up with the individual society whether or not the UR is applicable for retrofitting, replacement and major conversion. Therefore, the implementation instructions ensuring that the requirements in the UR are implemented also for existing ships undergoing retrofitting, replacement or retrofit of BWMS were modified rather than deleted for a better understanding and application, in order that the latest rules in force are applied and not the rules from the year the vessel was built for such retrofits.

UR M75 "Ventilation of emergency generator rooms"

Summary

In Rev.1 of this Resolution, changes have been made to achieve consistency with requirements from SOLAS Convention and the International Load Line Convention so that possible challenges during PSC inspections could be avoided.

Part A. Revision History

Version no.	**Approval date**	**Implementation date when applicable**
Rev.1 (Jan 2021)	20 January 2021	1 January 2022
New (Feb 2016)	2 February 2016	1 January 2017

- **Rev.1 (Jan 2021)**

1 Origin of Change:

☑ Suggestion by IACS member

2 Main Reason for Change:

In paragraph 1 of UR M75 (Feb 2020) titled "Introduction", following was stated:

Quote
Emergency generator rooms are provided with ventilation openings for the admission of combustion air to engines and the removal of heat. These openings are usually provided with louvers which can be closed (when fire breaks out in emergency generator rooms). The louvers may be hand-operated or power-operated. Alternatively, the louvers may be of fixed type with a closing door which may be hand-operated or automatic.
Unquote

Although, the above quoted text(in italics) was just a description of the arrangements commonly used for ventilation openings and closing devices in emergency generator rooms and had only informative value, it was observed that there was a possibility of the above text being understood as requiring the openings of emergency generator rooms to be fitted with closable louvers under all situations.

To elaborate on the above, the requirement for providing closing appliances for emergency generator room louvers is governed by Reg.9 of SOLAS Ch II-2, in particular notes of table 9.3. to 9.8 (i.e. based on the fact whether the emergency generator room is fitted with a fixed gas fire-extinguishing system) and in accordance to Reg. 19 of ICLL, Annex I;

In order to eliminate possible mis-understanding as described above and to clarify the applicability of the UR (i.e. when means of closure is fitted to the emergency generator room openings, provisions of UR M75 should apply), the UR has been amended.

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None

4 History of Decisions Made:

It's agreed by Machinery Panel Members that UR M75 is to be modified by:

- specifically stating that the emergency generator room air intake openings are required to be provided with closing appliances only under some certain circumstances as described in SOLAS and International Load Line Convention;

- removing the original content in '1. Introduction'.

5 Other Resolutions Changes:

None

6 Any hinderance to MASS, including any other new technologies:

None

7 Dates:

Original Proposal:	12 August 2019 (Made by Machinery Panel Member)
Panel Approval:	13 November 2020 (Ref: PM19937_IMk)
GPG Approval:	20 January 2021 (Ref: 20214_IGc)

- **New (Feb 2016)**

1 Origin of Change:

☑ Suggestion by IACS member

2 Main Reason for Change:

Reports of failures of emergency generators caused by inadvertent ventilation louver closing.

3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

4 History of Decisions Made:

The UR was developed by correspondence in the Panel and agreed at the 22nd Panel meeting.

5 Other Resolutions Changes:

None

6 Any hinderance to MASS, including any other new technologies:

None

7 Dates:

Original Proposal:	23 April 2013 (Made by Machinery Panel Member)
Panel Approval:	22nd Panel Meeting
GPG Approval:	2 February 2016 (Ref: 14075_IGe)

Part B. Technical Background

List of Technical Background (TB) documents for UR M75:

Annex 1. **TB for New (Feb 2016)**

See separate TB document in Annex 1.

Annex 2. **TB for Rev.1 (Jan 2021)**

See separate TB document in Annex 2.

◄▼►

Technical Background (TB) document for UR M75 (New Feb 2016)

1. Scope and objectives

- Prevent ventilation louvers of emergency generator rooms from inadvertently closing
- Clarify requirements for manual and automatic operation

2. Engineering background for technical basis and rationale

Based on an incident where a leaking non-return valve in the air supply to the louver operating system resulted in the closing of a ventilation louver with subsequent failure of the emergency generator after a short period, it was considered that louvers shall be of the fail-to-open type.

Ventilation louvers need to be open when the emergency generator is started and safeguards are to be provided to prevent their inadvertent closing.

Ventilation louvers may either be hand-operated or power-operated (hydraulic / pneumatic / electric) and are to be operable under a fire condition.

3. Source / derivation of the proposed IACS Resolution

None.

4. Summary of Changes intended for the revised Resolution:

N/A.

5. Points of discussions or possible discussions

None.

6. Attachments if any

N/A.

Technical Background (TB) document for UR M75 (Rev.1 Jan 2021)

1. Scope and objectives

1. Re-analyse UR M75 to identify the sentence which may lead to mis-understanding and confusion on the emergency generator room openings

2. Amend UR M75 to make it clear about the conditions under which means of closure should be fitted to the emergency generator room openings.

2. Engineering background for technical basis and rationale

1. Introduction of UR M75 reads as:

"

Emergency generator rooms are provided with ventilation openings for the admission of combustion air to engines and the removal of heat. These openings are usually provided with louvers which can be closed (when fire breaks out in emergency generator rooms). The louvers may be hand-operated or power-operated. Alternatively, the louvers may be of fixed type with a closing door which may be hand-operated or automatic.

"

But the sentence "These openings are usually provided with louvers which can be closed (when fire breaks out in emergency generator rooms)." has been understood as that the openings of emergency generator rooms are required to be fitted with closable louvers under all situations. This understanding is different from requirements from SOLAS and International Load Line Convention, which require closable louvers to be fitted to the emergency generator room openings only under some certain circumstances.

A member was of the opinion that section **1. Introduction** of existing UR M75 was just a description of the arrangements commonly used for ventilation openings and closing devices in emergency generator rooms. It had only informative value and was not a requirement. Accordingly, it was proposed to replace it by the application statement given in the first paragraph of section **2. Requirements**.

3. Source/derivation of the proposed IACS Resolution

None

4. Summary of Changes intended for the revised Resolution:

• The title of Section 2 is changed from 'Introduction' to 'Application'.

• The content of section 1 is changed to clarifying intention of UR applying on closing means for the emergency generator room air intake openings. And the closing means can be provided by closable louver or closing appliances.

• The first sentence of Section 2 is deleted due to overlapping with Section 1.

5. Points of discussions or possible discussions

At the late stage of discussion, Machinery Panel discussed whether there is a need to add a footnote to Paragraph 1 of this UR as follows:

*Footnote *1: This UR is not intended to apply to emergency generator rooms having air intake openings without means for closure such as those openings in accordance with Regulation 19(3) of the Protocol of 1988 relating to the International Convention on Load Lines, 1966, as amended by IMO resolutions up to MSC.375(93) and the notes of the following tables in Regulation 9 of SOLAS Chapter II-2, as amended by IMO resolutions up to MSC.421(98):*

1. Table 9.3 and 9.4 for ships carrying not more than 36 passengers;

2. Table 9.5 and 9.6 for cargo ships except tankers; or

3. Table 9.7 and 9.8 for tankers.

However, the qualified majority did not support the idea to add a footnote based upon the understanding that the text itself of Paragraph 1 is clear and that additional maintenance can be avoided if IMO instruments are not referred to in this UR.

6. Attachments if any

None

UR M76 "Location of fuel tanks in cargo area on oil and chemical tankers"

Summary:

This UR identifies acceptable locations and arrangements for fuel tanks on oil and chemical tankers.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev.1 (June 2018)	12 June 2018	1 July 2019
New (Apr 2016)	12 April 2016	1 July 2017

- **Rev.1 (June 2018)**

.1 Origin for Change:

☑ Suggestion by IACS member

.2 Main Reason for Change:

During the discussion at Machinery Panel to plan to amend mandatory IMO instruments such as SOLAS chapter II-2 based on the original UR M76, a need was found out to clarify types of liquid cargoes to which this UR applies to.

.3 List of non-IACS Member Classification Societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

It is agreed that this UR should be applied not only to low-flashpoint liquid cargoes (liquid cargoes having a flashpoint not exceeding 60°C) but also to toxic liquid cargoes for which toxic vapour detection is specified in column "k" of the table of chapter 17 of the IBC Code. It is also agreed that this UR is not intended to permit fuel tanks to be located adjacent to cargo tanks where prohibited by other regulations such as paragraph 15.12.3.1 of the IBC Code.

.5 Other Resolutions Changes

N/A

.6 Dates:

Original Proposal: 18 November 2016 Made by: Machinery Panel
Panel Approval: 09 May 2018 (Ref: PM16904a)
GPG Approval: 12 June 2018 (Ref: 18078_IGc)

- **New (Apr 2016)**

.1 Origin for Change:

☑ Suggestion by IACS member

.2 Main Reason for Change:

Due to Emission Control Areas requirements to use of marine fuels with a sulphur content not exceeding 0,1 % m/m (per MARPOL Annex VI) and minimum viscosity of 2 cSt (per UI SC255 and IMO MSC.1/Circ.1467), typically for marine gas oil MGO, the ultra low sulphur fuel tank capacity on-board standard designs is found inadequate and therefore owners and yards are seeking to expand such capacity by adding fuel tanks within the cargo area.

.3 List of non-IACS Member Classification Societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

- Form A approved under 12223_IGa/IAa
- Draft UI submitted to GPG under 12223_PMb on 21 August 2014
- Draft UI returned to Machinery Panel (12223_IGd dated 28 October 2014: considered to go beyond an interpretation)
- Panel decision to re-cast into UR
- Draft UR submitted to GPG under 12223_PMc on 27 April 2015
- Industry hearing initiated (12223_IAb dated 15 May 2015)
- Industry feedback returned to Machinery Panel (12223_IGg dated 20 July 2015)

.5 Other Resolutions Changes

N/A

.6 Dates:

Original Proposal: 5 March 2012 Made by: Machinery Panel
Panel Approval: 9 March 2016 (Ref: PM12907)
GPG Approval: 12 April 2016 (Ref: 12223_IGk)

Part B. Technical Background

Technical Background (TB) document for UR M76 (New Apr 2016)

1. Scope and objectives

The objective of this task is to identify acceptable locations and arrangements for fuel tanks on oil and chemical tankers and prepare a UR based on SOLAS Ch.II-2 Reg.4.5, also taking into account Reg.12A and 19 of MARPOL Annex I.

2. Engineering background for technical basis and rationale

Fuel tanks on standard tanker designs are located aft or forward of the cargo and slop tank boundaries.

SOLAS Chapter II-2, Regulation 4.5.1.1 specifies that fuel tanks are accepted used for separating machinery spaces from cargo and slop tanks, but is not especially clear as to whether such tanks can also be located within the cargo tank block as defined in the UR.

Fuel tanks within the cargo tank block would be subject to certain regulatory constraints. A fuel tank located within the cargo tank block would have to comply with MARPOL Annex I requirements for double hull and SOLAS requirements for access from open deck. It is also generally prohibited to route fuel oil transfer, sounding and air pipes through cargo tanks and ballast tanks. It is required that pumps serving tanks adjacent to cargo tanks and located within the cargo area (e.g. ballast tanks, pipe tunnels, stool spaces and cofferdams) shall be located within the cargo area. Further, it is prohibited to connect piping systems serving tanks within the cargo area so that they supply to machinery spaces. It is generally accepted to have fuel pumps located in the engine room to serve fuel tanks adjacent to cargo tanks, but this is based on the assumption that the probability of leaks is minimized.

Unless machinery space fuel systems are specially designed for handling low flashpoint fuels, leakages of low flashpoint cargo or chemical cargoes into machinery spaces may result in crew safety risks, explosion hazards and contamination of fuel. The risk of such leakages either through structural failures or piping systems must be limited. Fuel tanks located aft or forward of cargo tanks having only one boundary adjacent to cargo or slop tanks (i.e. vertical transverse bulkhead) are acceptable and have been proven reliable. The location of fuel tanks for example below cargo tanks or in stool tanks may represent an increased risk of contamination based on increased area exposure, constant and elevated static pressure from cargo (and P/V-valves), as well as experiences with cracks or leaks within said cargo tank structures.

It should also be noted that fuel tanks adjacent to cargo tanks are exempted from the requirements for gas detection and thus limiting the ability to detect leakages before transfer to the engine room (ref. IACS UI SC268).

3. Source / derivation of the proposed IACS Resolution

SOLAS Ch. II-2, Reg. 4.2.2.3.2
SOLAS Ch. II-2, Reg. 4.5.1.1

4. Summary of Changes intended for the revised Resolution:

New Resolution

5. Points of discussions or possible discussions

The following items were discussed by the Machinery Panel:

There was some discussion about the proper wording for 'open deck in the cargo area' as the terms 'cargo area' and 'cargo tank deck area' are used by other IMO instruments. It was clarified that the intention is to accept independent tanks located on open deck in the cargo area.

The proposal to add a new paragraph reading:
'Notwithstanding the above, fuel oil tanks may be situated in the entire cargo tank length provided that the minimum distances between the cargo tank boundaries and both the ship bottom and side-shell plating (in this case, 'w' should be measured excluding the breadth of the fuel oil tank) comply with the provisions of regulation 19.3 of MARPOL Annex I.' was rejected by the majority on the grounds that (i) it may give the impression that IACS promotes fuel tanks without double hull and/or within the protective area as required by MARPOL Annex I Reg.19.3, and (ii) it does not specify that the fuel tanks shall be segregated from the cargo tanks.

The original draft of a UI for SOLAS Ch.II-2 Reg.4.5 was not supported by GPG as it was felt that the text went beyond an interpretation of SOLAS. Upon further consideration the Panel agreed to re-draft the document as a Unified Requirement.

N/A

Technical Background (TB) document for UR M76 (Rev.1 June 2018)

1. Scope and objectives

The objective of this task is to clarify the requirements in the previous (original) version adopted in April 2016 by eliminating vague expressions found therein, in particular, regarding permissive fuel tank location, cargoes (oil and chemical) to be covered, duplication with IMO instruments such as "instead of cofferdams".

2. Engineering background for technical basis and rationale

a) Clarification of the vague expression "at the forward and aft ends" found in provisions specifying permissive fuel tank location so that fuel tanks within the cargo tank block at the forward and aft ends will not be accepted.

b) Clarification of the intention of the UR by eliminating duplication between the UR and IMO instruments which should not be reproduced in the UR i.e.:

- the wording "cofferdams" like pump rooms and ballast tanks as isolating spaces between cargo tanks and machinery spaces already covered by SOLAS or the IBC Code; and

- the sentence mentioning protective area of cargo tanks required by MARPOL Annex I and the IBC Code.

c) Clarification of "oil tankers" and "chemical tankers" to be covered by this UR i.e.:

- those carrying liquid cargoes having a flashpoint not exceeding 60°C; and

- those carrying "toxic" liquid cargoes for which toxic vapour detection is specified in column "k" of the table of chapter 17 of the IBC Code.

3. Source/derivation of the proposed IACS Resolution

None.

4. Summary of Changes intended for the revised Resolution:

Clarification of permissive fuel tank location with elimination of duplication between the UR and IMO instruments (SOLAS, IBC Code, MARPOL Annex I) and clarification of "oil tankers" and "chemical tankers" to be covered by this UR.

5. Points of discussions or possible discussions

None.

6. Attachments if any

None.

UR M77 "Storage and use of SCR reductants"

Summary

In Rev.4 of this Resolution, it is clarified the application of UR M77 in a viewpoint of quantity and object.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev.4 (Feb 2023)	10 February 2023	1 January 2024
Rev.3 (Sep 2021)	11 September 2021	1 July 2022
Rev.2 (Dec 2020)	11 December 2020	1 January 2022
Rev.1 (Aug 2019)	31 August 2019	1 January 2021
Original version	01 September 2016	1 January 2018

- **Rev.4 (Feb 2023)**

1 Origin of Change:

☑ Suggestion by IACS member

2 Main Reason for Change:

To consider the meaning of word 'bulk quantities' in UR M77.1 and clarify the application scope of UR M77.

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None

4 History of Decisions Made:

Revision 4 developed by correspondence.

5 Other Resolutions Changes:

None

6 Any hinderance to MASS, including any other new technologies:

None

GPG Approval:	31/08/2019 (Ref. 19029_IGf)

- **New (Sep 2016)**

1 Origin for Change:

☑ Suggestion by IACS member

2 Main Reason for Change:

Per 2.2.5 of the NOx Technical Code, NOx reducing devices such as Selective Catalytic Reduction (SCR) may be used so that marine diesel engines comply with MARPOL Annex VI/ Regulation 13. Although IMO has developed Guidelines with regard to particular requirements related to marine diesel engines fitted with Selective Catalytic Reduction (SCR) systems, it appears that Guidelines on the storage of the reductant have not been developed for selective catalytic reduction (SCR) converter systems.

3 List of non-IACS Member Classification Societies contributing through the TC Forum and/or participating in IACS Working Group:

None

4 History of Decisions Made:

Form A agreed within the 22nd Panel meeting.

Form A sent to GPG for record and monitoring purposes on 15 September 2015, under 15152_PMa.

The Machinery Panel commented on proposed draft UR by correspondence and during the 22nd and 23rd Panel meetings.

Draft UR agreed within the Panel and submitted to GPG under 15152_PMb on 21 July 2016

5 Other Resolutions Changes

N/A

6 Dates:

Original Proposal: 6 July 2015 made by Machinery Panel Member
Panel Approval: 21 July 2016 (Ref: PM13903)
GPG Approval: 01 September 2016 (Ref: 15152_IGc)

Annex 5. **TB for Rev.4 (Feb 2023)**

See separate TB document in Annex 5.

Technical Background (TB) document for UR M77 (New Sep 2016)

1. Scope and objectives

The objective of this task is to develop requirements for storage and use of reductants (such as Marine NOx reduction agent AUS 40 to ISO18611:2014) in selective catalytic converters. The UR would be of assistance to the Shipyards, designers, shipowners and makers of SCRs, who undertake to install such devices in accordance with 2.2.5 of the NOx Technical Code recognizing that NOx reducing devices, such as Selective Catalytic Reduction (SCR), may be used so that marine diesel engines comply with MARPOL Annex VI/ Regulation 13.

2. Engineering background for technical basis and rationale

The SCR units (one option of NOx reducing devices) are installed in the engine exhaust stream and fitted with a reaction chamber containing catalyst blocks together with an upstream dosing device that introduces a reducing agent into the exhaust stream. The reductant mixes within the exhaust gases and a chemical reaction on the surface of the catalyst reduces NOx entrained with the exhaust gas to nitrogen and water.

The SCR system can utilize either aqueous or anhydrous ammonia for the reduction reaction. Anhydrous ammonia is nearly 100% pure ammonia and often requires special permits for transportation and storage. The use of aqueous ammonia (28% or less) reduces transport and storage concerns. Modern exhaust emission abatement systems using SCR technologies use an ammonia reductant introduced as a urea/water solution (such as 40%/60%) sprayed into the exhaust stream to ensure mixing with the exhaust prior to the catalyst blocks.

Although IMO has developed Guidelines with regard to particular requirements related to certification of marine diesel engines fitted with Selective Catalytic Reduction (SCR) systems, it appears that IMO Guidelines on the storage of the reductant have not been developed so far (ISO has proceeded during the last years in the issuance of the standard 18611:2014 on Marine NOx reduction agent AUS 40 (aqueous urea solution) for selective catalytic reduction (SCR) converter systems).

3. Source / derivation of the proposed IACS Resolution

a) NOx Technical Code 2008 as amended;
b) Res. MEPC.198(62) & MEPC.217(63);
c) MEPC 66/INF.4;
d) CIMAC paper no. 220 Field experience of Marine SCR;
e) EPA/452/B-02-001 section 4, NOx Controls

4. Summary of Changes intended for the revised Resolution

N/A

5. Points of discussions or possible discussions

- The initial proposal to the Panel considered the cases of reductant i) using anhydrous ammonia (99.5% or greater concentration of ammonia by weight); ii) using aqueous ammonia (28% or less concentration of ammonia); and iii) using urea based ammonia (40%/60% urea/water solution). Considering that pure anhydrous ammonia is extremely toxic and difficult to safely store and that aqueous ammonia needs hydrolysis before use, the Panel unanimously agreed in its 22nd meeting that the UR should be limited to the development of guidelines or requirements for the storage and use of ISO18611:2014 Marine NOx reduction agent AUS 40, while the use of other reductants such anhydrous ammonia and aqueous ammonia is subject to special consideration.

- With regard to the urea based ammonia (such as 40%/60% urea/water solution), requirements on the location of the urea based ammonia storage tank, its associated piping systems, ventilation arrangements, level and temperature monitoring arrangements and means for the protection of the personnel are addressed in the UR.
- During the discussion within the Panel:
  -A proposal by a member to not limit the application of the UR to AUS 40 only, but to include also AUS 32 (not a marine specific standard) has been in principle agreed, therefore AUS 40 and its relevant ISO standard appear in the text following "e.g." or "such as".
  -A proposal by a member to replace "heated surfaces" in 2.1 by "surfaces whose temperature exceeds 100^{o}C" has not been followed.
  -Paragraph 2.10 on venting, purging and venting of the storage tank has been added at the request of a member (agreed by the Panel).
  -A suggestion made for the deletion of the sentence on Personnel Protective Equipment as falling in operational items covered by the onboard safety management system per the ISM Code was not followed.
  -With regard to a proposal to include specification for a temperature range of -10deg.C to +30deg.C for the storage of urea, it was preferred that reference is made in 2.3 to conditions specified in recognized standards (such as ISO 18611-3).
  -An extensive discussion was conducted on paragraph 2.4 for ventilation of the urea storage tank when installed in a closed compartment or within the engine room: i) For the case of location of the urea storage tank within the engine room the initial proposal reading "the storage tank area and the machinery spaces may be served by a common ventilation system" has been replaced by a paragraph clarifying when a separate ventilation system is not required; ii) For the case of installation of the urea storage tank in a closed compartment, the six (6) air changes suggested by a member have been agreed by the Panel. After exchanging views, it has been agreed to insert in the paragraph requirements on continuous operation of the ventilation system and associated alarms should the ventilation stops, together with warning notices to be posted outside the compartment and adjacent to each point of entry, requiring the use of ventilation.
  -With regard to the "risk based analysis" referred to in sections 3 and 4 for aqueous ammonia and anhydrous ammonia, the initially sentence read "risk based analysis and suitable standards acceptable to the class society". The Panel, based on a member's suggestion, agreed to delete the supplementary text on suitable standards.
- In light of the agreed text, the suggestion to change the title of the UR from "Storage and use of ammonia for SCR units" to "Storage and use of SCR reductants" has been adopted by the Panel.

6. Attachments if any

None

Technical Background (TB) document for UR M77 (Rev.1, Aug 2019)

1. Scope and objectives

The objective of this task was to amend the UR M77 (New, Sep. 2016) to clarify paragraphs UR M77.2.4, 77.2.6, 77.2.8 and 77.2.10 in order to have a uniform implementation between Members

2. Engineering background for technical basis and rationale

- Paragraph M77.2.4:
  An IACS Member proposed to clarify the meaning of wording "..the area is to be served by an effective mechanical supply and exhaust ventilation system.."

  In this regard it was observed that the quoted wording requires to install both an effective mechanical supply ventilation system and an effective mechanical exhaust ventilation system but this requirement was evaluated to be too strict compared with other similar requirements such as those for ventilation systems as stated in para. 12.1.4, of the IBC Code.
  The qualified majority finally agreed that an effective mechanical ventilation system of extraction type providing not less than 6 air changes per hour was considered to be appropriate for the purpose of this paragraph.

  An IACS Member, in order to solve their reservation against the requirement for alarm in case of loss of ventilation for urea storage tanks installed in a closed compartment, proposed to require only warning signs outside the entrances to the room instead of the audiovisual ventilation alarm.
  The rationale for this proposal was explained to be in the significant difference between the risk associated with a gas fuel leakage compared to the leakage of urea; ammonia decomposition is mainly temperature dependent and at room temperature urea is stable enough to be stored for long periods. Furthermore, ammonia gas has a very distinct and strong odour, detectable long before the concentration is harmful (detectable at 5-30ppm, lethal at approximately 100 times that level for 10 minute exposure), which means any personnel intending to enter the space will be warned of a leak and failed ventilation system well before the concentration is a health hazard
  The proposal was agreed by the qualified majority of Panel Members

  An IACS Member proposed to modify the wording "purged" with "ventilated" for the reason that considering that that urea is not flammable it is sufficient to empty and ventilating the tank before entry.
  This view was agreed by the qualified majority of Panel Members

- Paragraph M77.2.6:
  An IACS Member highlighted a discrepancy between par. 2.5 (which require tanks to be fitted with High and low level alarms together with high and low temperature alarms) and par. 2.6 4th bullet (which require integral tanks to be fitted only with high temperature alarm and low level alarm).
  Considering that paragraph 2.5 is applicable to all urea storage tanks and that the 4th bullet of paragraph 2.6 was evaluated to be redundant, the qualified majority decided to delete the 4th bullet of paragraph 2.6.

- Paragraph M77.2.8 renumbered as M77.2.9 in Rev.1:
  Under Task PM16912, the Panel decided that a clarification of the term "non-combustible" in UR M77.2.8 was necessary and for this purpose the Panel initially developed the following common understanding:

"Reductant tanks shall be of steel or equivalent with a melting point above 925 degrees C.
Pipes/piping systems should be steel or equivalent material with melting point above 925 degrees C, except downstream of the tank valve, provided this valve is metal seated and arranged as fail-to-closed or with quick closing from a safe position outside the space in the event of fire. In such case, TA plastic piping without fire endurance test is acceptable (0). "

An IACS Member, following a request for clarification from a ship designer, requested the Machinery Panel Members if they shared the understanding that:
1) it is not necessary to apply paragraph 2.8 to reductant pump filters for removing extraneous material for the reason that such filters are not directly exposed to flames and therefore paragraph 2.8 is not applicable to such components;
2) it is not necessary to apply paragraph 2.8 to the protective coating for corrosion inside surface of piping systems, storage tanks and spill trays for the reason that such protective coating material is not related to the reductant solution leakages caused by being exposed to flame

and proposed the following amendment:

"2.8 Reductant related piping systems, tanks, and other components which may come into contact with the reductant solution are to be of a suitable grade of non-combustible compatible material established to be suitable for the application, except for coating material and components which are not directly exposed to flames"

The proposal was not accepted by the qualified majority of Members who finally agreed with the following text reflecting, with some improvements, the common understanding:

"Reductant tanks are to be of steel or other equivalent material with a melting point above 925 degrees C.

Pipes/piping systems are to be of steel or other equivalent material with melting point above 925 degrees C, except downstream of the tank valve, provided this valve is metal seated and arranged as fail-to-closed or with quick closing from a safe position outside the space in the event of fire; in such case, type approved plastic piping may be accepted even if it has not passed a fire endurance test. Reductant tanks and pipes/piping systems are to be made with a material compatible with reductant or coated with appropriate anti-corrosion coating."

- Paragraph M77.2.9 renumbered as M77.2.10 in Rev.1:
  An IACS Member, in order to solve their reservation against the requirement to provide safety showers, proposed to delete the safety showers from the requirement for the reason that even if there are some risks connected to the handling of Urea Solutions, it appear that for short term exposure they are limited to skin and eye irritation in case of direct contact, and only long term exposure may cause other systemic effects; for this reason to require safety showers seems to be not justified.
  The proposal was accepted by the qualified majority.

- Paragraph M77.2.10 renumbered as M77.2.11 in Rev.1:
  An IACS Member, following a request for clarification from a shipyards, requested the Machinery Panel Members if they shared the understanding that a portable purge system to be brought from shore meets the requirements in para 2.10 of UR M77 for the reason that paragraph 2.10 is related to the safety of a person entering the tank for inspection at surveys; in this regard a permanently installed purge system is not considered necessary.
  This view was agreed by the qualified majority of the Machinery Panel Members who finally agreed with the following text:
  "2.10 Urea storage tanks are to be arranged so that they can be emptied of urea and ventilated by means of portable or permanent systems."

3. Source / derivation of the proposed IACS Resolution

None

4. Summary of Changes intended for the revised Resolution

- Paragraph M77.2.4:

  1) The wording "..the area is to be served by an effective mechanical supply and exhaust ventilation system providing.." was amended to read "the area is to be served by an effective mechanical ventilation system of extraction type providing"

  2) The second and the third sentence of para 2.4 were amended as follow:
     "The ventilation system is to be capable of being controlled from outside the compartment ~~and is to be maintained in operation continuously except when the storage tank is empty and has been thoroughly air purged. If the ventilation stops, an audible and visual alarm shall be provided outside the compartment adjacent to each point of entry and inside the compartment, together with a warning notice requiring the use of such ventilation~~. <u>A warning notice requiring the use of such ventilation before entering the compartment shall be provided outside the compartment adjacent to each point of entry</u>."

  3) The wording "air purged" was modified to read "ventilated"

- Paragraph M77.2.6:
  the 4th bullet of paragraph 2.6 has been deleted

- New Paragraph M77.2.7:
  The following new requirement has been introduced:
  <u>"The requirements specified in M77.2.4 also apply to closed compartments normally entered by persons:</u>

  - <u>when they are adjacent to the urea integral tanks and there are possible leak points (e.g. manhole, fittings) from these tanks; or</u>
  - <u>when the urea piping systems pass through these compartments, unless the piping system is made of steel or other equivalent material with melting point above 925 degrees C and with fully welded joints."</u>

- Paragraph M77.2.8 renumbered as M77.2.9 in Rev.1:
  The text was amended as follow:
  "2.~~8~~9 ~~Reductant related piping systems, tanks, and other components which may come into contact with the reductant solution are to be of a suitable grade of non-combustible compatible material established to be suitable for the application.~~ Reductant tanks are to be of steel or other equivalent material with a melting point above 925 degrees C.

  Pipes/piping systems are to be of steel or other equivalent material with melting point above 925 degrees C, except downstream of the tank valve, provided this valve is metal seated and arranged as fail-to-closed or with quick closing from a safe position outside the space in the event of fire; in such case, type approved plastic piping may be accepted even if it has not passed a fire endurance test. Reductant tanks and pipes/piping systems are to be made with a material compatible with reductant or coated with appropriate anti-corrosion coating."

- Paragraph M77.2.9 renumbered as M77.2.10 in Rev.1:
  The wording "and safety showers" has been deleted

- Paragraph M77.2.10 renumbered as M77.2.11 in Rev.1:
  The text was amended as follow:
  "2.1~~0~~1 Urea storage tanks are to be arranged so that they can be emptied of urea~~, purged and vented~~ and ventilated by means of portable or permanent systems."

5. Points of discussions or possible discussions

Text was agreed by correspondence and at the 29th Machinery Panel Meeting.

- A Member Society requested the Panel Members opinion whether the ventilation requirements specified in UR M77.2.4 applies also to the enclosed compartments adjacent to the urea tank and normally entered by persons which are designed and constructed as integral part of the hull in the case the urea piping systems pass through these compartments; in this regard it was proposed to add the following new paragraph M77.2.7 in order to include all cases where the ventilation requirements in para. 2.4 are to be applied (i.e. compartments adjacent to integral tanks and also all compartments passed through by urea piping):

  "The requirements specified in M77.2.4 also apply to closed compartments normally entered by persons:
    - when they are adjacent to the urea integral tanks and there are possible leak points (e.g. manhole, fittings) from these tanks; or
    - when the urea piping systems pass through these compartments, unless the piping system is made of steel or other equivalent material with melting point above 925 degrees C and with fully welded joints"

  The proposal was agreed by the qualified majority.

  To clarify the matter some Members Societies proposed to add a new bullet in paragraphs M77.2.6 with the following text proposals which however were not supported by the qualified majority:

  Proposal n.1:
  A Members Society observed that integral tanks may have possible leak points such as bolted hatch and measuring points required in M77.2.5 whether or not the

urea piping systems pass through these compartments and proposed the following modification:
"The requirements specified in M77.2.4 also apply to closed compartments adjacent to these tanks and normally entered by persons~~, when the urea piping systems pass through these compartments, unless the piping system is made of steel or other equivalent material with melting point above 925 degrees C and with fully welded joints~~."

Proposal n.2:
A Members Society commented that the requirements in M77.2.4 should also apply to all compartments passed through by urea piping, regardless of whether or not they are adjacent to the tank (except when this piping is made of steel or other equivalent material with melting point above 925 degrees C and with fully welded joints) and propose the following modification:
"The requirements specified in M77.2.4 also apply to closed compartments ~~adjacent to these tanks~~ containing urea piping and normally entered by persons, ~~when the urea piping systems pass through these compartments,~~ unless the piping system is made of steel or other equivalent material with melting point above 925 degrees C and with fully welded joints."

Proposal n.3:
A Members Society commented that the agreed text for the new bullet is stringent in a point of view requiring the ventilation regardless of existence of possible leak points and propose the following modification:
"The requirements specified in M77.2.4 also apply to closed compartments adjacent to these tanks and normally entered by persons, when the directly attached fittings or openings/accesses on the tank are located or the urea piping systems pass through these compartments, unless the piping system is made of steel or other equivalent material with melting point above 925 degrees C and with fully welded joints."

- One Members Society proposed to add the following sentence to paragraph 2.9 of the draft UR M77 (Rev.1, June 2019):
  "…tank material other than steel is subject to special consideration (see MSC.1/Circ.1527 and UI SC282 for consideration)."

  In this regard it was observed that the reference to MSC.1/Circ.1527 and UI SC282 may not be appropriate since both the documents provides interpretation for terms like "other approved material" or "other equivalent material" or "steel or equivalent" for specific SOLAS regulation (Reg.II-2/4.2.2.5,9.7.7.1) and circular (MSC.1/Circ.1321).
  The following alternative texts for the first sentence of paragraph 2.9 were proposed to Members for their consideration:

  Alternative 1:
  "Reductant tanks are to be of steel or other equivalent material with a melting point above 925 degrees C; materials other than steel for reductant tanks are subject to special consideration by the Classification Society."

  Alternative 2:
  "Reductant tanks are to be of steel or other equivalent material; evaluation of equivalency of materials other than steel for reductant tanks is to be based on the proposed materials having passed a standard fire test for "A" class divisions."

The proposed alternatives were however not supported by the qualified majority.

Technical Background (TB) document for UR M77 (Rev.2 Dec 2020)

1. Scope and objectives

UR M77(Rev.1) does not reflect the agreed format for referencing the ISO standards. Rev.2 has been developed to comply with the agreed format.

2. Engineering background for technical basis and rationale

Format for references to Industry standards

[Standard Designation], [version/revision, if applicable], [year of publication] (examples: API Spec 2F, 6th Edition, 1997; ISO 4624, 2002), where [version/revision, if applicable] and/or [year of publication] are decided by IACS and are not necessarily to be the current/latest version.

3. Source/derivation of the proposed IACS Resolution

None

4. Summary of Changes intended for the revised Resolution:

UR M77 has been updated to specify the revision/version of the ISO standards as follows:

ISO standards	**Replaced by**
ISO 18611-1	ISO 18611-1:2014
ISO 18611-3	ISO 18611-3:2014

5. Points of discussions or possible discussions

The changes are purely editorial with no impact on the Resolution since the UR M77 (New, Sep 2016) is assumed to be in line with the latest publications ISO 18611-1:2014 and ISO 18611-3:2014.

Technical Background (TB) document for UR M77 (Rev.3 Sep 2021)

1. Scope and objectives

This revision is to provide a waiver for FRP vessels, from the requirement M77.2.9 for urea storage tanks to be of steel or other equivalent material with a melting point above 925 degrees C, when these are built as integral tanks

2. Engineering background for technical basis and rationale

Yachts/Vessels less than 500GT often are made of FRP, while those above 500GT are typically made of steel. It is thought that UR M77.2.9 requirement for reductant tanks bans the installation of structural tanks made of FRP and forces to embed a steel tank in the FRP structure, which makes it impracticable for Yacht/Vessel Builders to accommodate and materialize.

It's believed that integral tanks made of FRP can be accepted on Yachts which themselves are made of FRP structure.

It is highlighted that the exemption provided for pleasure yacht/vessel by the paragraph 5.2.3 of MARPOL Annex VI Reg.13 is valid up to 1 January 2021, and there have been cases to install SCR. Timely development of exemption clause is necessary.

5.2 The standards set forth in paragraph 5.1.1 of this regulation shall not apply to:
"3. a marine diesel engine installed on a ship constructed prior to 1 January 2021 of less than 500 gross tonnage, with a length (L), as defined in regulation 1.19 of Annex I to the present Convention, of 24 metres or over when it has been specifically designed, and is used solely, for recreational purposes."

3. Source/derivation of the proposed IACS Resolution

According to paragraph 2.9 of UR M77, reductant tanks are to be of steel or other material with a melting point above 925 degrees C.

"2.9 Reductant tanks are to be of steel or other equivalent material with a melting point above 925 degrees C."

4. Summary of Changes intended for the revised Resolution:

In consideration of 2. Engineering background and rationale, it is suggested to put a Footnote to UR M77.2.9, providing an exemption for FRP vessels. The initial clause agreed by qualified majority is as follows:

"Footnote to 2.9: Material requirement to be of steel or other equivalent material with a melting point above 925 degrees C is not applicable for integral tanks on FRP vessels less than 500 GT, provided that the integral tanks are coated and/or insulated with a self-extinguishing material."

5. Points of discussions or possible discussions

The idea to develop an exemption clause for reductant tank made of FRP structure on FRP Yacht less than 500GT was agreed by qualified majority of the Machinery Panel members.

Concerning the idea of gross tonnage, one member suggests changing criterion from 500 GT to 400 GT, taking into account Regulation 5.1 of MARPOL Annex VI, which was not supported.

Among proposed Footnotes, the clause in above 4. Summary of change was finally proposed following the qualified majority, on the term "vessel" over "yacht" and on the need to specify a requirement for a self-extinguishing coating and/or insulation for integral tanks made of FRP.

A proposal to add an additional clause to exempt FRP vessels larger than 500GT on the basis of case by case acceptance which didn't achieve qualified majority support at the 2nd round of discussion was once more raised during 33rd Machinery Panel Meeting, and after deliberation it is decided to develop an alternative text in lieu of explicit expression of "case by case acceptance", without compromising the required clarity of IACS Procedures Volume 1, with a view to the universal implementation among all members in a uniform manner.

The footnote devised for the purpose is as follows:

* Footnote to 2.9: Material requirement "to be of steel or other equivalent material" in the first paragraph with a melting point above 925 degrees C is not applicable for integral tanks on FRP vessels such as those listed below, provided that the integral tanks are coated and/or insulated with a self-extinguishing material.

1) FRP vessels complying with Regulation 17 of SOLAS Chapter II-2 based upon its associated IMO guidelines (MSC.1/Circ.1574), and

2) FRP vessels exempted from the application of SOLAS e.g., yachts, fast patrol, navy vessels, etc., generally of less than 500 gross tonnage, subject to yacht codes or flag regulations.

6. Attachments if any

None

Technical Background (TB) document for UR M77 (Rev.4 Feb 2023)

1. Scope and objectives

This revision is to clarify application scope of UR M77, especially means of word stating 'bulk quantities' in UR M77.1.

2. Engineering background for technical basis and rationale

UR M77 has been published in September 2016. And the UR M77.1 informs that the UR applies to arrangements for the storage and use of SCR reductants, especially, where the SCR reductants are typically carried on board in bulk quantities.

It is needed to provide a specific criterion or meaning of the word 'bulk quantities' referred in UR M77.1 for the application of UR M77.

Furthermore, it also should take a consideration whether UR M77 is applied on small tanks such as daily tank and buffer tank which is not storage tank.

3. Source/derivation of the proposed IACS Resolution

None

4. Summary of Changes intended for the revised Resolution:

The last phrase of UR M77.1 'which are typically carried on board in bulk quantities' is deleted since the phrase is not to mean specific quantities but to have expressional meaning which loading, unloading and storage of SCR reductant can be freely placed on board regardless of quantity of SCR reductants.

5. Points of discussions or possible discussions

Regarding the small tanks such as daily tank and buffer tank, two kinds of volume 300 L and 500 L are proposed to leave to the discretion of individual Classification Societies. The former(300 L) is based on individual studies based on the following understanding from a member society.

> The requirements are mostly aimed at chemicals that are not used directly in cleaning the exhaust or controlling the pH of process water in operation. A 300 L threshold should cover all necessary designs where small amounts of chemical are used as secondary process chemicals

And the latter(500L) has been proposed by reference to the SOLAS conventions for oil tanks capacity such as SOLAS II-2/Reg.4.2.2.3.4 and Reg.4.2.3.2.

The members determine the 500 L as a threshold after considering the background of both proposals.

UR M78 "Reciprocating Internal Combustion Engines fuelled by Gases or Low-flashpoint Fuels"

Summary

In Rev. 3 of this UR M78 on "Internal Combustion Engine Fuelled by Gases or Low-flashpoint Fuels", the scope of application of UR M78 has been revised in accordance with agreed scope to cover additional gases or low-flashpoint fuels, and now covering methane, ethane, LPG and methyl/ethyl alcohol fuels. The UR has also been amended to clarify the content of the safety concept required to be submitted by the engine designer.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev.3 (Apr 2025)	20 April 2025	1 January 2027
Rev.2 (Jan 2024)	17 January 2024	1 January 2025
Rev.1 (Feb 2021)	12 February 2021	1 July 2022
New (July 2018)	17 July 2018	1 July 2019

- ### Rev.3 (Apr 2025)

1 Origin of Change:

X Suggestion by IACS member

2 Main Reason for Change:

UR M78 has originally been developed for Safety of Internal Combustion Engine Supplied with Low Pressure Gas. IACS Machinery Panel has the view that applicable requirements should be developed for all engine types and all alternative fuels being considered. Rev.2 expanded UR M78 scope to include all engine types and high-pressure natural gas fuel systems. Rev.3 further develops those requirements to include ethane, LPG and methyl/ethyl alcohol fuels, together with clarifying IACS' requirements for the engine safety concept.

3 Surveyability review of UR and Auditability review of PR

Draft revision 3 of UR M78 has been reviewed by SuP for surveyability items.

4 Human Element issues assessment

Not applicable

5 List of non-IACS Member classification societies contributing or participating in IACS Working Group:
None.

6 History of Decisions Made:

In November 2023 the Machinery Panel considered a request from a member to expand the scope of UR M78 to include fuels other than LNG.

A PT was established to develop draft text. first draft text was provided to the panel in September 2024.

After some discussion between the panel and the PT and a further draft was agreed.

This was discussed with industry (CIMAC) during a series of meetings in early 2024. further discussion in the panel followed and the text was finalised in November 2024.

7 Other Resolutions Changes:
UR M3, UR M53, UR M67, UR M82

8 Any hinderance to MASS, including any other new technologies:
None.

9 Dates:

Original Proposal	: 20 June 2019	(PM18914_IMg)
Panel Approval	: 25 November 2024	(Ref: 18914_IMzd)
GPG Approval	: 20 April 2025	(Ref: 24204_IGc)

- **Rev.2 (Jan 2024)**

1 Origin of Change:

X Suggestion by IACS member
☐ Based on IMO Regulation *(IGF & IGC Code)*

2 Main Reason for Change:

UR M78 has been developed for Safety of Internal Combustion Engine Supplied with Low Pressure Gas. IACS Machinery Panel has the view that applicable requirements should be approached by engine type, rather than gas supplying pressure to cover trunk piston type and crosshead type, premixed type, port injection and gas direct injection, of course taking gas supply pressure under consideration.

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None.

4 History of Decisions Made:

AS A FOLLOW-UP ACTION OF TASK PM6902(Safety of Internal Combustion Engines Supplied with Low Pressure Gas), THE MACHINERY PANEL DECIDED TO DEAL WITH THE FOLLOWING ACTIVITIES BUT NOT LIMITED TO:

- To start the development of a Revision (Rev.1) of the UR M78 on “Safety of Internal Combustion Engine Supplied with Low Pressure Gas” to extend the scope of application of the UR M78 to cover all types of engines (High pressure and low pressure, two stroke and four stroke, gas injection and pre-mixed gas type engines).

- To withdraw the UR M59 (1996) as evaluated to be no more suitable for ships to which the 2016 IGC Code applies and to review the existing requirements of the UR M59 with the view to be incorporated in the Revision 1 of UR M78.

- Propose a modification of the structure for the revised UR (for example: part with requirements applicable to all engines + part with specific requirements applicable to 2-stroke engines + part with specific requirements applicable to 4-stroke engines).

- To deal with, and possibly solve the issue raised by CIMAC regarding IGF Section 10.3.1.2 (i.e., CIMAC recommend that the term "piston in direct communication with the crankcase" is explained more detailed so that it will not lead to misinterpretations – Reference is made to PM18914_IMa dated 17/04/2018) and ensure that any work conducted by IACS is correctly focused on the issue raised.

- To consider, in the revision process, some additional comments received when the draft UR M 78(April 2018) was already agreed by the qualified majority.

- Both IGC and IGF Codes require that suitable pressure relief systems are fitted on engine components and systems (e.g. air inlet manifolds, scavenge spaces) that contain or are likely to contain ignitable gas and air mixture, unless these are designed to withstand the worst-case overpressure due to ignited gas leaks. For the protection of crankcases suitable IACS requirements are in place with URs M66 and M9, while for pressure relief systems on air inlet manifolds, scavenge spaces and exhaust gas manifolds UR M82 has been published.

- Consider the outcome of task PM18909 (addressing the issue of gas presence in the crankcase of 4-stroke low pressure dual fuel or gas engines and crankcase ventilation) for possible introduction of the relevant text in the revised UR M78, including acceptance criteria for M78.1.4.4.i).

- Consider the outcome of PM18914a regarding approval procedure for explosion relief devices for air inlet and exhaust manifolds.

- Current M78 refers to IGF and IGC Code in several paragraphs. The references to the Codes should be reviewed with regard to their applicability (especially M78.2.2.1.1 regarding general pipe design, materials, joining details, etc.).

- Define scope of testing and certification of engine components (in addition to M72).

5 Other Resolutions Changes:

None.

6 Any hinderance to MASS, including any other new technologies:

None.

7 Dates:

Original Proposal:	20 June 2019	(Ref: PM18914_IMg)
Panel Approval:	15 December 2023	(Ref: 18914_IMzg)
GPG Approval:	17 January 2024	(Ref: 23233_IGc)

- **Rev.1 (Feb 2021)**

No records are available.

- **New (July 2018)**

No records are available.

Annex 3. **TB for Rev.2 (Jan 2024)**

See separate TB document in Annex 3.

Annex 4. **TB for Rev.3 (Apr 2025)**

See separate TB document in Annex 4.

Technical Background (TB) document for UR M78 (New July 2018)

1. Scope and objectives

The existing UR M59 (Control and Safety Systems for Dual Fuel Diesel Engines) was issued in 1996 at a time when marine dual fuel engines were mainly of the 4-stroke type, operated according to the Diesel cycle and supplied with gas at high pressure (300 - 350 bar) and intended for offshore applications.

Since then, 4-stroke dual fuel engines supplied with low pressure gas (typically 5 – 6 bar) have been placed on the marine market and extensively used on LNG carriers and on various types of gas-fuelled ships. It was therefore proposed to develop a new UR to cover such engines.

While dual fuel engines supplied with high pressure gas are operated according to the standard Diesel cycle, DF and gas fuel only engines supplied with low pressure gas are operated according to the Otto cycle, which involves a compression of a gas/air mixture and need therefore to be covered by specific requirements.

The objective was to develop a document covering all types of diesel engines supplied with low pressure gaseous methane: dual fuel engines, gas fuel only engines and premixed engines (where gas is mixed with air before the turbo-charger). It should be noted that this UR does not reproduce any part of the IGC Code, IGF code or other IACS URs but only makes reference to the relevant parts thereof.

As agreed in the Machinery Panel, the UR addresses the engine itself, excluding arrangement and installation on board.

The final benefit of this new IACS UR is to provide a common approach for design and testing of the concerned engines, thus enabling a uniform application for all designers and manufacturers.

2. Engineering background for technical basis and rationale

2.1 Risk analysis
The UR requires a risk analysis to be conducted and gives provisions regarding the scope of the analysis and the different systems and equipment that need to be analysed.

2.2 General principles for the safety of the engines
Gas engines are to be capable of operating with the different qualities of gas that can be encountered.
Where there is a risk of explosion in certain systems or components of the engine, they are to be of reinforced design to withstand the explosion or fitted with explosion relief devices.

2.3 Gas piping
The gas piping on the engine is to be designed in accordance with the relevant provisions of the IGC Code and IGF Code, as applicable.
2.4 “Double wall” versus “alternative” gas piping arrangement

The gas piping system on the engine is to be designed according to the “double wall” arrangement or, where permitted by the IGF Code, to the “alternative” single wall arrangement, when the engine is installed in an ESD-protected machinery space.

2.5 Engine crankcase
The IGF Code does not require gas alarm or hot spot detection but a detailed evaluation regarding the hazard potential of fuel gas accumulation in the crankcase (see IGF reg. 10.3.1.2). This requirement has been considered as sufficient and introduced in paragraph 1.4 of the UR (Risk analysis).
The principle of a gas detection in the crankcase with an alarm before 100% LFL required by the IGC Code (reg. 16.7.3.3 and 13.6.17) has not been retained.

2.6 Gas ignition in the cylinder
For the gas ignition in the cylinder, reference is made to the relevant provisions of the IGC Code and IGF Code.

2.7 Control, monitoring, alarm, and safety systems
Alarms and safeties are to be provided in accordance with the Table except if the risk analysis proves otherwise.

2.8 Specific design requirements
Paragraph 3 of the UR provides specific requirements for DF engines, for GF engines and for pre-mixed engines. They are basically consistent with the requirements laid down in the IGC and IGF Codes.

2.9 Type testing
Specific requirements for gas engines have been introduced, such as verifying the permissible operating range for gas mode, the switch-over procedures between gas fuel and oil fuel modes (for DF engines).
For electrical prime movers, specific requirements have been introduced as the transient behaviour of gas engines in case of sudden load variations may differ from that of their counterpart supplied with FO.
Regarding the influence of the methane number or LHV of the fuel gas, it is not required to be verified during the Stage B type tests. It shall however be justified by the engine designer through internal tests or calculations and documented in the type approval test report.

2a. Specification of the data utilised in the development/revision of the proposed IACS Resolution, if any

None

3. Source/derivation of the proposed IACS Resolution

T The UR is consistent with:

- IGF Code
- Revised IGC Code
- Engine manufacturers’ practices (through CIMAC).

4. Summary of Changes intended for the revised Resolution:

None

5. Points of discussions or possible discussions

The main points of discussions are detailed below.

5.1 General comments
The following comments have been made by the PT Members:

- Member 1: We would suggest that the whole UR is checked for overlap with existing UR's. At one point we were trying to make this a standalone document but now seem to be just limiting to engine and just limiting to DF and GF requirements.

On that latter understanding all duplicated requirements could be deleted and just keep DF and GF specific requirements. Care needs to be exercised in trying to incorporate requirements from other IACS UR's that are still under development and may not be adopted in current form in the end.

- Member 2: Support XX above and would like to see that other URs related to engines are updated to also cover gas engines as found necessary.

After extensive discussions, it was decided not to reproduce any text from other Rules or Regulations (see 1. above). Accordingly, this new UR contains:

- Requirements specific to gas engines (e.g. risk analysis, safety of crankcase, etc.)

- Requirements which are relevant to subjects addressed by other IACS URs. Such requirements are in agreement with the concerned URs: UR M35 and UR M36 for alarms and safeties, UR M51 for factory acceptance test and shipboard trials of engines, UR M71 for type testing of engines, etc.

Requirements for the gas piping system were initially introduced, derived from IGC Code 5.11.2.2 (similar to IGF Code 7.3.2.1). They have finally been replaced by a reference to the IGC / IGF Codes. See 5.5 below.

5.2 Design of crankshaft
The UR states that the design of crankshafts is to comply with UR M53.
The following reservations have been made by the PT members:

- PT Member 1: In the case of a dual fuel engine utilizing existing diesel engine design this may not be a problem but for dedicated gas engine design may be over conservative. UR M53 contains a lot of outdated empirical data based on old diesel engine testing. UR M53 needs updating.

- PT Member 2: UR M53 is just updated. If an engine designer finds the UR M53 calculation method to be over conservative, he might demonstrate sufficient strength by one of the appendixes developed.

- PT Member 3: It is suggested to discuss this issue with CIMAC.

After UR M53 updating (Subject No.: PM11100) and as no comments have been made by CIMAC on this issue, it has been decided to keep the initial text.

5.3 Low load operation
During the discussions within the PT, a clause had been proposed, requiring the ability of the engine to operate at low loads on gas to be demonstrated during the type tests.

- PT Member 1: has proposed to delete this clause, arguing as follows:

What is meant by 'low loads'? The type test required operating points should define what operational running is to be demonstrated. GF engines are likely better at low load than DF engines. The whole issue of low load running is a big one. DF and gas engines are promoted as meeting Tier III NOx limits but operation of all of the DF engines below 10-15% load is limited. If they can't run in gas mode all of the time (Which with the exception of GF engines they won't) then operational and statutory issues arise.

- PT Member 2: has proposed to state that the lowest declared power shall be demonstrated during the type test, which has been finally introduced in the UR.

It has finally been decided not to introduce any requirement for minimum load testing as this is covered by UR M71.7.2, which is referred to in paragraph 4.1.6 of the UR (Stage A – internal tests).

5.4 Gas piping
The following clause was initially proposed:

In accordance with UR P2.2, gas piping is to be designed and constructed to:
- Class II requirements when it is of the double walled arrangement.
- Class I requirements otherwise

The following comments have been made by the PT members:

- PT Member 1: UR P2.2 is for general piping systems and does not apply to gas process piping where IGC Code would typically be applicable. Propose to delete or clarify this. What is exactly meant in terms of design approval, test and certification by this? We do not see that there should be a difference in Class approval of the gas pipes between single or double wall arrangements.

- PT Member 2: Propose to extend the scope of UR P2 to cover gas fuel piping systems. Whereas P2 does not explicitly covers gas fuel piping systems, "Flammable media with flash point below 60°C" and "liquefied gas" are covered by Table 1, which imposes Class I for the piping if arranged "without special safeguards", (according to Note 1 in the Table, the safeguard is intended "for reducing leakage possibility and limiting its consequences, e.g. pipes led in position where leakage of internal fluid will not cause a potential hazard or damage to surrounding areas, which may include the use of pipe ducts, shielding, screening, etc."). Class II is acceptable when the piping system is arranged "with special safeguards". There are specific requirements for Class I piping, concerning in particular:

- the non-destructive testing of welds and acceptance criteria,
- the connection of pipes.

- PT Member 3: Propose to delete reference to UR P2.2 as this does not apply for gas, as fuel, piping.

The final text does not to refer to UR P2.2. The extension of UR P2.2 to gas piping systems may however still be considered.

5.5 Use of "single wall" piping arrangement on the engine
The following clause was initially proposed:
Single wall gas piping may be accepted only for the following engines:

- engines of "pre-mixed" type (see 1.1.1)
- engines having a power per cylinder not exceeding 100 kW and supplied with gas at a pressure not exceeding 10 bar

The use of the single wall gas piping arrangement on the engine is subject to the requirements for ESD spaces in the Interim Guidelines or to the following alternative requirements:

1) A hood is to be provided in way of the engine, served by independent exhaust ventilation with high capacity, and fitted with means for gas detection.
2) The ignition hazards are to be assessed against the criteria set out in IEC standard 60079-10-1:2008 (or EN 60079-10-1:2009) and, where necessary, reduced in accordance with the guidance on design and control parameters given in the standard.

The following comments have been made by the PT members:

- PT Member 1: Propose to delete power limitation. This has been discussed in IGF Code but no agreement reached. Also propose to modify the above text as follows:

The use of the single wall gas piping arrangement on the engine, or an alternative arrangement considered equivalent, is subject to the specific requirements of the individual Society.

- PT Member 2: As the "double wall" piping arrangement is feasible and available for "large" engines, it should be made compulsory for such engines, as it prevents gas leakage from the engine and therefore increases the safety level of the installation. It is suggested to accept the "single wall" only for "small" engines and with sufficient safeguards, as proposed in the above text.

- PT Member 3: Propose to specify requirements to single walled and double walled piping separately without discussing ESD, hood or max cylinder output. This can be left to the IGF code and Societies Rules to state.

It has then been proposed to remove the reference to hood, ventilation, gas detection, assessment of the ignition hazard, and power limitation, being understood that each Society will have its own interpretations, which should anyhow comply with the relevant provisions of the IGC Code or IGF Code (as applicable).

The final text adopted by the Machinery panel just mentions that single wall arrangement is acceptable only for engines installed in ESD-protected machinery spaces of ships covered by the IGF Code.

5.6 Engine crankcase

The text initially proposed reads as follows:
An alarm is to be activated before the gas concentration in the crankcase reaches 100% LFL, with immediate shutdown of the engine and of the gas supply.
The following comments have been made by the PT members:

- PT Member 1: Suggest removing "with immediate shutdown of the engine and of the gas supply" as it may be taken to mean "automatic" shutdown of engine and gas supply.

- PT Member 2: We note this is the current text from the IGC Code being rewritten, however this is not to be an automatic shutdown. The usefulness of gas detection that is not automatic and set to alarm at 100% LFL is questionable. The CIMAC gas engine groups are going to look at the issue of crankcase gas concentration. Propose to delete this requirement from the UR since specific application to gas carriers can be applied by compliance with IGC Code if required. If it is to be retained then it should be clarified that gas detection in the crankcase vent pipe is acceptable since this is the only practical way of undertaking the measurement.

- PT Member 3: Propose to delete the requirement.

It has finally been decided to require, in accordance with IGF Code 10.3.1.2, an assessment of the hazard potential for crankcase fuel gas accumulation, for engines where the space below the piston is in direct communication with the crankcase. See 1.4.4 i) of the UR.

5.7 Gas specification for tests

The text initially proposed requires the type testing program to cover:
Various gas specifications as applicable to those specifications the approval is expected to consider.

Note: The permitted range of gas characteristics (methane number, LHV) may be simulated by introducing a certain amount of LPG or Nitrogen.

The following comments have been made by the PT members:

PT Member 1: We still think this is difficult to apply and verify. This would require gas analysis. The issue of testing gas and DF engines by IMO BLG with respect to NOx certification may help. As this is listed as "guidance" this will not be interpreted or applied consistently. The use of 'normally' as well creates opportunity for inconsistency. We would prefer to see agreed requirements.

PT Member 2: Propose to maintain the requirement to test the engine with different gas fuel specifications (compositions) corresponding to those permitted by the engine manufacturer.

PT Member 3: Agree that this is difficult to apply and verify. However, the ability to use different gases from different sources may become an important issue. If a specific gas shall be required, it should be sufficient to require a gas

with the lowest declared methane Number to be used.
The following text has finally been proposed:

The influence of the methane number and LHV of the fuel gas is not required to be verified during the Stage B type tests. It should however be justified by the engine designer through internal tests or calculations and documented in the type approval test report.

5.8 Specific tests for engines intended for high-speed vessels for tests
The text initially proposed requires the type testing program to cover:
Propulsion engines for high-speed vessels that may be used for frequent load changes from idle to full speed/power are to be tested with at least 500 cycles (idle – full load – idle) using the steepest load ramp that the control system (or operation manual if not automatically controlled) permits. The duration at each end shall be sufficient for reaching stable temperatures of the hot parts.

The following comments have been made by the PT members:

- PT member 1: How do we know if an engine will be used for high speed vessel applications? In a way this is acknowledging that the type test is not rigorous enough to cover certain applications. This perhaps could be better dealt with as main body requirements such as 'testing for engines driving propellers', 'testing for engines driving generators', 'testing for engines for high-speed vessels' where an applicant must demonstrate why the testing doesn't apply to his engine approval and type approval certificates could state 'not suitable for high-speed vessels'.

- PT member 2: Again, this should follow the UR for diesel covering the same.

Again, and argument to not specify general test requirements that are applicable for both diesel and gas engines in this UR.

It has been finally decided not to introduce the text in question. It should be noted that this text is included in UR M71.5.6.

5.9 Generating sets – load steps.

The initial text reads as follows:

Capability to take sudden load and loss of load in accordance with the provisions of UR M3.2.3

Where the electrical power system is fitted with a power management system the application of multiple load steps is permitted provided the total load is applied within 45 seconds. The maximum load steps are to be declared and demonstrated. For DF engines switchover to oil fuel during the test is acceptable.

The following comments have been made by the PT members:

- PT Member 1: UR M3.2.3 does not fully deal with this. Would agree that Fig 1 is very out of date (30 bar bmep engines have been around for 20 years). Would also agree that many load steps to full load are possible where matched to PMS system.

DF engines revert to oil mode if they can't handle the transient and therefore acceptance is on basis of oil engine compliance. This does not clarify the situation for pure gas engines, which can have better transient response than DF engines in gas mode. The CIMAC paper on transient response provides more detail on this.
Gas engines are usually accepted in accordance with ISO 8528 which includes a number of engine load acceptance grades. However much of this is dependent on agreement between supplier and purchaser. Have proposed text to allow multiple load steps in accordance with PMS and within a time frame. This needs further discussion. Load shedding can also be a big problem for pre-mixed engines.

- PT Member 2: Again, this is basically not a gas-specific issue. Also, diesel engines may have problems with 2 or 3 load steps, and in these cases the third part of M3.2.3 will allow if it is matched to PMS system. Propose to only refer to M3.2.3.

45 seconds as proposed above comes from requirements for emergency gensets and should not be mentioned here.

Taking into account the above comments, the text has been finalized as follows and agreed by the Machinery Panel:

Capability to take sudden load and loss of load in accordance with the provisions of UR M3.2.3

For GF and premixed engines, the influences of LHV, methane number and ambient conditions the dynamic load response test results are to be theoretically determined and specified in the test report. Referring to the limitations as specified in 2.1.2, the margin for satisfying dynamic load response is to be determined.

Note:
1. For DF engines, switchover to oil fuel during the test is acceptable.
2. Application of electrical load in more than 2 load steps can be permitted in the conditions stated in UR M3.2.3.

5.10 Gas Admission Valves

In order to address some Industry issues regarding the hazardous area classification for gas admission valves, the Panel decided to introduce the new Section 2.2.8 on "Gas Admission Valves", the initial text was as follow:

Gas admission valves shall be certified safe. However, if they are not certified for the zone they are intended for, it shall be documented that they are suitable for the applicable zone. Documentation and analysis is to be based on IEC 60079-10-1 and/or IEC 60092-502.

One Panel Member proposed to further modify the above text in order to:

- specify better which "zone" is to be applicable for the certification of the inside and the outside part of the valve; and

- specify that certification is not required for the outside of the valve in the case the valve is arranged without enclosure in accordance with the "ESD-protected machinery space” concept provided that the valve is de-energised upon gas detection in the space

After some rounds of discussion, the above proposal was finalized as follows and agreed by the Machinery Panel:

Gas admission valves shall be certified safe as follows:
1) The inside of the valve contains gas and shall therefore be certified for Zone 0.

2) When the valve is located within a pipe or duct in accordance with 2.2.2.1, the outside of the valve shall be certified for Zone 1.

3) When the valve is arranged without enclosure in accordance with the “ESD-protected machinery space” (see 2.2.2.2) concept, no certification is required for the outside of the valve, provided that the valve is de-energized upon gas detection in the space.

However, if they are not rated for the zone they are intended for, it shall be documented that they are suitable for that zone. Documentation and analysis is to be based on IEC 60079-10-1 or IEC 60092-502.

Technical Background (TB) document for UR M78 Rev.1 (Feb 2021)

1. Scope and objectives
The purpose of Revision 1 of this UR is to remove inconsistency between Paragraphs 4.1.4 & 4.2.1 (TA & FAT) and 4.3 (Shipboard Trials) and to specify references to IMO instruments in a consistent manner.

2. Engineering background for technical basis and rationale
A) Removal of inconsistency between Paragraphs 4.1.4 & 4.2.1 (TA & FAT) and Paragraph 4.3 (Shipboard Trials)

In this Revision, inconsistency on the exemption of 110% load tests on the gas mode of dual fuel engines, which was not allowed during Shipboard Trials (Paragraph 4.3) but during TA & FAT (Paragraphs 4.1.4 & 4.2.1) was removed.

B) Format for references to Industry standards
Format:
[Standard Designation], [version/revision, if applicable], [year of publication] (Examples: API Spec 2F, 6th Edition, 1997; ISO 4624, 2002), where [version/revision, if applicable] and/or [year of publication] are decided by IACS and are not necessarily to be the current/latest version.

C) Format for references to IMO instruments (where the number of amendments is small)
Format:
regulation/paragraph x.x.x of SOLAS/MARPOL/the XXX Code, as amended by resolutions MSC/MEPC.xx(xx), (...) and MSC/MEPC.xx(xx)

2a. Specification of the data utilised in the development/revision of the proposed IACS Resolution, if any
None

3. Source/derivation of the proposed IACS Resolution
None

4. Summary of Changes intended for the revised Resolution:
A) The exemption of 110% load tests
The exemption clauses related to 110% load testing on the gas mode of dual fuel engines which were specified in Paragraphs 4.1.4 and 4.2.1 have been moved to Paragraph 3.1.1 with required rewording.

B) Format for references to Industry standards
Paragraph 2.2.8 has been updated to specify the revision/version of the IEC standards.
as follows:

IEC Standards	Replaced by
IEC 60079-10-1	IEC 60079-10-1: 2015
IEC 60092-502	IEC 60092-502:1999

C) Format for references to IMO instruments

Paragraphs 1.2.11 and 1.2.13 which define the IGC Code and the IGF Code have been modified while the reference to the IGF Code could not be in line with the standard format as per the above 2.B), due to the fact that Resolution MSC.422(98) is the sole amendment to the IGF Code which had entered into force before approval of Rev.1 of this UR.

5. Points of discussions or possible discussions

It is necessary to continue to discuss the need on 110% load tests during TA, FAT and Shipboard Trials for gas engines and on the gas mode of dual fuel engines which are designed to develop its maximum continuous power up to 110 % since any consensus had not been achieved yet at the Working Group.

6. Attachments if any

None

Technical Background (TB) document for UR M78, Rev.2 (Jan 2024)

1. Scope and objectives

After the development of UR 78 for a 4-stroke engine supply with at relatively low pressure, it was inevitable to respond to the market for engines supply with gas at relatively high pressure.

In the IGC code, the safety of ships is classified according to the maximum working pressure for the safety of supply lines, storage, and transportation, and this has been applied as it is in the IGF code.

However, there was also an opinion that it would be unreasonable to discuss the safety of the engines or machinery itself from the perspective of low and high pressure, mainly related to the safety of storage tanks/containers or pipes.

While it is true that these 4-stroke engines are supplied with gas fuel at relatively low pressures, it is debatable whether they fall within the low-pressure category defined by the IGF and IGC Codes. Because there is no definition of the maximum working pressure, and the air supply pressure of the turbocharger increases today, in an environment where the gas supply pressure is bound to increase, generally classifying these four-stroke engines as low pressure is inevitably an expedient made by desperate measures.

Therefore, the working pressure of high or low pressure mainly acts on pipes or storage containers, and it is necessary to develop UR that acts on combustion engines for all operating principles, and we tried to clarify the gas fuel used in these engines.

In addition, the development of the IGF code was aimed at developing UR by recalling minimizing risk factors to ships, crew members and the environment, keeping in mind that the IGF Code took a Goal-based approach.

1.1 Project Process

PT read and discussed every paragraph of IGF codes, existing UR M78 and prepared a comparison table of IGC and IGF code and compared each other's, and discussed several issues, including why the safety concept and risk assessment, which are issues that can be problematic, such as matters to be verified in the IGF code, are information rather than review (approval items), and the definition of the safety concept and the definition of working pressure and working pressure in existing UR M78. Of course, discussed and thoroughly reviewed the MCR of the DF engine.

After this PT prepared an excel spread sheet of work item and discussed one by one.

2. Engineering background for technical basis and rationale

2.1 Title

Existing title was "Safety of Internal Combustion Engines Supplied with Low Pressure Gas".
There are two issues, one is using "Safety" and anther one is "Low pressure gas".

2.1.1 Safety

Safeguarding life, property and environment is an inherent objective of any IACS resolution and needs not be reflected in their titles. “Safety” has been deleted to align with titles of other IACS resolutions.

2.1.2 Natural gas

According to the preamble of IGF Code, the current version of this Code includes regulations to meet the functional requirements for “natural gas fuel”. Regulations for other low-flashpoint fuels will be added to this Code as, and when, they are developed by the Organization.

Further the IGF Code Part A-1, SPECIFIC REQUIREMENTS FOR SHIPS USING NATURAL GAS AS FUEL specify that,

Fuel in the context of the regulations in this part means natural gas, either in its liquefied or gaseous state.
However, the PT focused on the gaseous state, not liquified state or cryogenic gas, but extended this to cover similar fuels with main component methane such as bio-methane or synthetic methane. This direction was considered current industry trends.

Natural gas is stored and transported in the two forms. compressed and liquefied form. A special compression container or facility for liquefied gas is required for storage, but the density of compressed gas per volume is lower than that of the liquefied form. Therefore, compressed gas is not used unless the condition of the ship is prepared in advance.

Compressed natural gas (**CNG**) is a fuel gas mainly composed of methane (CH_4), compressed to less than 1% of the volume it occupies at standard atmospheric pressure. It is stored and distributed in hard containers at a pressure of 20–25 megapascals (2,900–3,600 psi), usually in cylindrical or spherical shapes.

Liquefied natural gas (**LNG**) is natural gas (predominantly methane, CH_4, with some mixture of ethane, C_2H_6) that has been cooled down to liquid form for ease and safety of non-pressurized storage or transport. It takes up about 1/600th the volume of natural gas in the gaseous state (at standard conditions for temperature and pressure).

Biogas is an environmentally friendly, renewable energy source produced by the breakdown of organic matter such as food scraps and animal waste. Biogas is a renewable fuel that's produced when organic matter, such as food or animal waste is broken down by microorganisms in the absence of oxygen. This process is called anaerobic digestion. For this to take place, the waste material needs to be enclosed in an environment where there is no oxygen.

Synthetic methane, or e-methane, is a so-called electro fuel. These 'e-fuels' are made from two raw materials: hydrogen that's produced from water via electrolysis (preferably using renewable energy), and CO_2 captured from the air around us or exhaust gases. In this UR Synthetic methane is used for simplification.

Ethane and others (including Natural gas plant liquids (NGPL): Natural gas includes ethane and certain substances from these processes, but they are not covered in this project.

This UR, has been revised to cover engines using natural gas whose main component is methane and gas containing biogas and syngas, which are mainly methane but not natural gas.

2.2 General principles for the combustion of the engines

Combustion engines basically burn according to two principles. One is to mix air and fuel in advance and burn in a relatively short time inside the combustion chamber, and the other is to inject fuel into a place where only air is compressed and burned. The former is called premixed combustion, where the combustion state is determined mainly by the flame propagation speed, while the latter is diffusion combustion, where the mixture state/speed of air and fuel determines the combustion state. On the market, the former is called combustion by gasoline or Otto principle, and the latter is called combustion by diesel principle.

Example – Pre-mixed combustion requires a slightly higher fuel supply pressure than supply air pressure, requiring a relatively low fuel supply pressure and more complete combustion.
As the situation develops, diffusion combustion requires high fuel supply pressure. The combustion is not perfect compared to the former, but their combustion conditions are completely different. It is academically or empirically confirmed that the compression pressure, maximum pressure, maximum temperature, and output power are completely different.

It becomes clear that the requirements for the engine do not change depending on the gas supply (working) pressure. Thus, this pressure change only relates to pipes, piping systems or storage devices.
It should be noted that land-based DF or gas engines may have gas and air mixed before the T/C. Such engines cannot be used in gas-safe machinery spaces on board vessels.

As for marine DF engines, pre-mixed combustion (Otto engine) was first applied to the 4-stroke trunk piston, and later, gas injection (Diesel principle) and premixed engines appeared in 2-stroke engines.

3. Source/derivation of the proposed IACS Resolution

The UR is consistent with:

- IGF Code 2016 as amended.
- Revised IGC Code 2014 as amended.
- Engine manufacturers' practices (through CIMAC).
- BS IEC 600092-502, 1999
- BS EN IEC 31010:2019, for Risk management – Risk assessment techniques
- BS ISO 5514: part2 :1988
- BS ISO 3046-2:1987:1987
- BS ISO 3036-1 2002

- ISO 8178 series (1 to 11) Reciprocating internal engines- Exhaust Emission measurement.

4. Summary of Changes intended for the revised Resolution:

Here is a summary of the work done in this revision.

- Amendments have been prepared to extend the scope of application of the UR M78 to cover all types of engines (2- and 4-stroke, gas injection and premixed gas combustion engines, trunk piston and crosshead, gas supplied with high and low pressure) from trunk piston engines with low pressure gas supply.

- In this revision the project team reviewed DF engines and GF engines using natural gas, but they also included biomethane and synthetic methane (whose main component is methane which is not natural gas). Ethane, which contains many components in natural gas, was excluded from the review.

- Although this revision extends the application to all DF and GF engines using natural gas, the structural modifications of the UR have been kept to a minimum.

- It is noteworthy that UR M59 (1996) has been withdrawn as part of this project, which was evaluated as no longer suitable for ships to which the 2016 IGC Code applies. Items necessary to maintain from UR M78 have been incorporated into UR M78.

- The PT rreviewed the issues raised by CIMAC regarding IGF Section 10.3.1.2 (where CIMAC recommended further clarification of the term "piston in direct communication with the crankcase" to avoid misleading references, see PM18914_IMa dated 17 April 2018). The PT further reviewed some additional comments including definition of "certified safe type" received from the Panel.

- The IGF and IGC code requirements for air inlet manifold, scavenging space and exhaust manifold pressure relief systems were reviewed and proposed.

- Design requirements were developed by reviewing the requirements for the design of pipes and pipe systems, including 78.2.2.1.1. in the IGF and IGC codes.

  The design of the piping system includes the material grade and connection of the pipe, and the design conditions including the grade of double pipe and single pipe are stipulated.

  In addition, the connection of the piping system includes the testing conditions of the expansion joint.
- The boundary line between low pressure and high pressure was defined based on the engineering unit of 1MP based on the maximum operating pressure, and this low and high pressure was used for designing pipes, piping systems, and other storage systems.

- Type testing, factory approval testing and on-board vessel testing were comprehensively reviewed and proposed by the stage and, as for the pending issue, the contents of the technical background about MCR are summarized as follows.

  In the DF engine type approval, factory approval, and onboard vessel testing, attention was paid to the fact that MCR verification for gas mode could be omitted, and the problems caused by this omission were reviewed and solutions were presented.

- Among the documents to be submitted for approval of the DF engine, it was confirmed that the documents on safety concept and risk assessment were not subject to approval by the responsible organization according to the IGF code but were merely for information.

- Required inspections and certificates of various components of the DF engine were generally reviewed, and requirements for these were presented in a table by component-by-item, and necessary explanations were provided.

- Although it was not included in the scope of work of this amendment, the matters to be amended in a short time for DF or GF engines for other low flash point fuels were reviewed and confirmed.

- The technical background and data related to the above work were prepared and presented, and the title change for the first stage work was reviewed and presented.

- Some of the reviews were done with the second stage fuel in mind, as well as other fuels with low-flash point (Ethane, LPG, Methyl/ethyl alcohol, Hydrogen and Ammonia).

The following summarizes and lists the items related to the revised work and presents the item in the order of revision.

1. Change of title to Reciprocating Internal Combustion Engines fuelled by Natural gas from Safety of Internal Combustion Engines Supplied with Low Pressure Gas

2. Scope of Engine – from Trunk Piston internal combustion engines supplied with low pressure natural gas as fuel to marine reciprocating internal combustion engines supplied with natural gas as fuel.

3. Applied gas extended to natural gas regardless of pressure from LNG supplied by low pressure, and biogas and e-gas whose main component is methane, although it is not natural gas.

4. Change of text structure for the 1.1.1 Types of engines, adding new paragraph and change of paragraph.

5. Deletion of paragraph regarding gas introduction to the engine related to pre-mixed engine, which will be duplicated and added to new text for definition of the pre-mixed engine.

6. Deletion of 1.1.2 application because of new paragraph introduction for the application and added a paragraph related to the application of the engine, in the 1.1.1 Types of engines.

7. Change of 1.2.1 Definition of Certified safe equipment, the change of definition related to this term started from the request of the Machinery Panel member however there is another request from machinery Panel member to retain original definition. However, after long discussion of the project team, found there is no different, meaning of the definition whether keep the original test or new test. And there is another opinion that definition is not necessary since

there is clear definition IGF code. Therefore, project ream decided to keep a new definition and put one note like IGF code.

8. Flexibility of Definition of Certified safe equipment, this new definition gives the flexibility of the definition of Certified safe equipment and a compromise of different opinion from the machinery panel.

9. Add a note related to certified safe equipment, this note already explained in item 7.

10. Deletion of definition of existing 1.2.4 Engine room, please refer to technical background.

11. Add a new definition for Explosion relief device, which can use for the protection of exhaust system and son on.

12. Change for definition of 1.2.5 Gas for this UR and note for bio-methane or synthetic methane.

13. Change of 1.2.6 Gas admission valve to give flexibility and rationalization.

14. Deletion of Gas Valve Unit to follow the machinery panel's opinion.

15. Definition of High-pressure gas in 11.2.10 by bar and maximum working pressure. The unit bar has been intentionally used because there are more gauges displayed in bar than MPa in the engine room.

16. Change of definition for 1.2.14 Low pressure gas, please refer to the technical background and item 15 definition of high-pressure gas.

17. Change of Definition for 1.2.18 pre-mixed engine, please refer to technical background.

18. Development for additional comment for 1.2.20 Safety Concept to include the result of the risk analysis to the safety concept.

19. Modification of 1.3.1 Documents and drawings to be submitted, specially to List of certified safe equipment and relevant certification from List of certified safe equipment and evidence of relevant certification.

20. Modification of 1.3.2 Documents and drawings to be submitted for the approval of DF engine. Specially to Schematic layout or other equivalent documents of pilot fuel system from Schematic layout or other equivalent documents of fuel oil system (main and pilot fuel systems).

21. Modification of 1.3.3 Documents and drawings to be submitted for the approval of GF engine. Specially to Schematic layout or other equivalent documents of the ignition system from Ignition system.

22. Modification of footnotes 1) to If required by UR M44, see also 2.2.5.1 from If required by UR M44, for clarification.

23. Change of foot note 3) to The documentation to contain specification of design pressure, working pressure, pipe dimensions and materials from The documentation to contain specification of pressures, pipe dimensions and materials for specification of documentation to be submitted.

24. Change of paragraph, second sentences in 1.4.1 the risk analysis is to address to a gas leakage downstream of the double block and bleed valves from a gas leakage downstream of the gas valve unit.

25. Added a paragraph (see also 2.1.2) to b) in 1.4.3. procedure for the risk analysis.

26. Change of paragraph to Gas admission valves from cylinder gas supply valve in 1.4.4. a) second paragraph.

27. Change of note, to gas supply system from Gas Valve Unit (GVU) due to deletion of definition on Gas Valve Unit (GVU) 1.2.10

28. Add a word "glow plug" to 1.4.4. b) failure of the ignition system (oil fuel pilot injection, sparking plugs, glow plugs)

29. Change of paragraph 1.4.4. d) to for engines where gas is supplied upstream of the turbocharger compressor, failure of a component likely to result in a source of ignition (hot spots) from for engines where gas is injected upstream of the turbocharger compressor, failure of a component likely to result in a source of ignition (hot spots)

30. Change of paragraph 1.4.4. g) to presence of gas in engine components (e.g. air inlet manifold or scavenge space and exhaust manifold) and in the external systems connected to the engines (e.g. exhaust duct, cooling water system, hydraulic oil system, etc.). from abnormal presence of gas in engine components (e.g. air inlet manifold and exhaust manifold of DF or GF engines) and in the external systems connected to the engines (e.g. exhaust duct).

31. Change of paragraph 1.4.4. i) to hazard potential for crankcase fuel gas accumulation, for trunk-piston engines, refer to IGF Code 10.3.1.2. and UR M 10 from hazard potential for crankcase fuel gas accumulation, for engines where the space below the piston is in direct communication with the crankcase, refer to IGF Code 10.3.1.2.

32. Adding a sentence as 1.4.4. j) risk of crankcase explosion in connection with active crankcase ventilation which produces a flow of external air into the crankcase, see UR M10.5 1)

33. Change of a word in 2.1.1 b) mitigate the consequences of a possible explosion to a level providing a tolerable degree of residual risk, due to the strength of the component(s) or the fitting of suitable explosion (from pressure) relief devices of an approved type.

34. Same as above, "pressure "changed to explosion.

35. Add a word “Explosion” before relief valve.

36. Add a paragraph end of 2.1.2 as follows; With reference to 2.1.2.b), the strength of the component(s) or the arrangement of explosion relief devices shall be documented (e.g. as part of the risk analysis) or otherwise demonstrated to be sufficient for a worst case explosion.

37. in the end of introduction paragraph of 2.2.1.1 added “as applicable “and added a few sentences as follows

Other connections as mentioned in IGF Code 7.3.6.4.4 may be accepted subject to type approval in accordance with the requirements of UR P2.7 and P2.11. All single walled or high-pressure gas pipes should be considered as Class I.

Low pressure double walled gas pipes should be considered as Class II.
All secondary enclosures for gas pipes should be considered as Class II.
Single walled gas vent pipes should be considered as Class I, except it is justified that the maximum built up pressure is less than 5 bar gauge, in which case it should be considered as Class II.

Gas vent pipes protected by a secondary enclosure should be considered as Class II.

38. 2.2.1.1 (cont): Added a “Table 1 for design condition for piping, piping system and components”.

	Design pressure	
Gas pipe, low pressure	see IGF 7.3.3.1	see IGC Code 5.4.1
Gas pipe, high pressure	see IGF 7.3.3.1	see IGC Code 5.4.1
outer pipe, low pressure	see IGF Code 9.8.1	see IGC Code 5.4.4
outer pipe, high pressure	see IGF Code 9.8.2	see IGC Code 5.4.4
Open ended gas pipes	see IGF Code 7.3.3.2	see IGC Code 5.4.1

39. 2.2.1.1 (cont.): Added a few sentences and notes for regarding “Flexible bellows” as follows;

Flexible bellows used in the fuel gas system on the engine shall be approved based on the requirements of IGF Code 16.7.2, and IGC Code 5.13.1.2, as applicable.

The number of cycles, pressure, temperature, axial movement, rotational movement and transverse movement which the bellow will encounter in actual service on the engine should be specified by the engine designer.

Note: IGF 16.7.2.4 (fatigue test due to ship deformations) is considered not relevant for bellows which are an integral part of the engine. The EJMA calculation or equivalent should be prepared instead.

Endurance against high cycle fatigue due to vibration loads shall be verified by testing or alternatively be documented by the Expansion Joint Manufacturers Association, Inc. (EJMA) calculation or equivalent (i.e. more than 10^7 cycles).

40. Added a phrase 2.2.2.2 a) as follows:

for engines supplied with low pressure gas and installed in ESD protected machinery spaces, as defined in IGF Code 5.4.1.2 and in compliance with other relevant parts of the IGF Code (e.g. 5.6);

41. Modification of 2.2.3 to add a phrase "Charge air system and exhaust gas system on the engine.

The charge air system and the exhaust gas system on the engine are to be designed in accordance with 2.1.2 above.

In case of a single engine installation, the engine is to be capable of operating at sufficient load to maintain power to essential consumers after opening of the explosion relief devices caused by an explosion event. Sufficient power for propulsion capability is to be maintained.

Note: Load reduction is to be considered on a case-by-case basis, depending on engine configuration (single or multiple) and relief mechanism (self-closing valve or rupture disk).

42. Modification of 2.2.4 Exhaust system on the engine as following sentences.

Continuous relief of exhaust gas (through open rupture disc) into the engine room or other enclosed spaces is not acceptable.

Suitable pressure relief system for air inlet manifolds, scavenge spaces and exhaust system should be provided unless designed to accommodate the worst-case overpressure due to ignited gas leaks or justified by the safety concept of the engine. A detailed evaluation regarding the hazard potential of overpressure in air inlet manifolds, scavenge spaces and exhaust system should be carried out and reflected in the safety concept of the engine.

Explosion relief devices for air inlet and exhaust manifold shall be type approved according to UR M82.

The necessary total relief area and the arrangement of the explosion relief devices shall be determined taking into account:

- The worst-case explosion pressure depending on initial pressure and gas concentration,
- the volume and geometry of the component, and
- the strength of the component.

The arrangement shall be determined in the risk analysis (see 1.4.4.g) and reflected in the safety concept.

43. Added a sentence at the end of paragraph 2.2.5.1.

For engines not covered by M9, the detailed evaluation as required in 1.4.4.i is to determine if crankcase explosion relief valves are necessary.

44. Added a paragraph regarding Crankcase ventilation as 2.2.5.3.

Ventilation of crankcase (either supply or extraction), if arranged, is to comply with UR M10.5.

Relevant evidence is to be documented in Safety Concept.

Each engine shall be fitted with independent venting systems for crankcases and sumps.

45. Added a phrase in 2.2.8 before Gas admission valves as followings.

Electrically operated gas admission valves shall be certified safe as follows:

46. Added a paragraph at the end of existing 2.2.8 as followings.

Gas admission valves operated by hydraulic oil system are to be provided with sealing arrangement to prevent gas from entering the hydraulic oil system.

47. Some modification and adding a few phrases on table 2 (of revision 2) - Monitoring and safety Functions for DF and GF engine as follows.

Parameter	Alarm	Automatic activation of the double block-and-bleed valves	Automatic switching over to oil fuel mode[1]	Engine shutdown
Abnormal pressures in the gas fuel supply line	X	X	X	X [5]
Gas fuel supply systems - malfunction	X	X	X	X [5]
Pilot fuel injection or spark ignition systems - malfunction	X	X [2]	X	X [2,5]
Exhaust gas temperature after each cylinder - high	X	X [2]	X	X [2,5]
Exhaust gas temperature after each cylinder, deviation from average – low [3]	X	X [2]	X	X [2,5]
Cylinder pressure or ignition - failure, including misfiring, knocking and unstable combustion	X	X [2,4]	X [4]	X [2,4,5]
Oil mist concentration in crankcase or bearing temperature [6] - high	X	X		X
Pressure in the crankcase – high [8]	X	X	X	
Engine stops - any cause	X	X		
Failure of the control-actuating medium of the block and bleed valves	X	X	X	
Failure of crankcase ventilation system, if applicable	X	X[7]	X[7]	

Footnotes:

1) DF engine only, when running in gas mode

2) For GF engines, the double block-and-bleed valves and the engine shutdown may not be activated in case of specific failures affecting only one cylinder, provided that the concerned cylinder can be individually shutoff and the safe operation of the engine in such conditions is demonstrated by the risk analysis.

3) Required only if necessary for the detection of misfiring

4) In the case where the failure can be corrected by an automatic mitigation action, only the alarm may be activated. If the failure persists after a given time, the safety actions are to be activated.

5) GF engine only

6) Where required by UR M10

7) Automatic safety actions to be activated as specified by the engine manufacturer, see UR M10

8) Only for trunk piston engines. This pressure sensor cannot replace or substitute a gas detector.

9) Only for trunk piston engines. For crosshead engines slow down shall apply (see UR M35 Tab.1)

48. Modification of chapter 3. Specific design Requirement as follows.
Basically, continued the existing concept which is accepted if the engine is designed for a lower power output in a gas mode than in diesel mode, however the engine designer stated and submitted MCR for gas mode.
The reason for the lower power output of the gas mode is not only the gas quality, but also the engine design, i.e. the premix type in general is less than the gas injection type.

49. Modification of the paragraph 3.1.1. General to clarify the MCR of the DF engine – MCR should be stated and submitted, please refer to TB.

50. Modification of 3.1.2 Starting, Changeover and stopping

51. Added a paragraph at the end of sentences as followings.
If the power level or other conditions do not allow safe and reliable gas operation, changeover to oil fuel mode shall be automatically performed.

52. Added 3.4 for Design requirement of Two stroke engines as follows.

Two-stroke engines

Scavenge air system
The risk analysis required in 1.4 is to cover the possible gas accumulation in a scavenge space.

Crankcase
The risk analysis required in 1.4 is to cover the possible failure of a piston rod stuffing box.

53. Modification of 4.1.2 Type of engine as follows for clarification.
Gas modification method (Cylinder injection after compression stroke, Cylinder individual injection before compression stroke or pre-mixed)

54. Change the word from supply to admission (~~supply~~)as gas admission valve operation (mechanical or electrically controlled)

55. Added a Note at the end of sentences 4.1.2 Type of engine as follows.

Note: Cylinder-individual injection before compression stroke may be port injection into the air inlet channel before the cylinder inlet valve, injection into the cylinder before or during compression stroke, or similar arrangements.

56. Added a phrase at the end of paragraph, 4.1.4 Test programme as following.

The type testing of the engine is to be carried out in accordance with UR M71.5, taking into account the additional requirements of this UR.

57. Moved and rearranged a paragraph, 4.1.4 testing programme for better understanding.
58. Added items in 4.1.5 for pilot fuel to be measured and recorded during testing.

59. Added a Note at the end of sentences for 4.1.5. Measurements and records as follow.

Note: The gas concentration in the crankcase should normally be measured inside the crankcase or at the crankcase outlet (crankcase vent pipe).

Gas concentration measurements may be carried out as part of Stage A if the method and the results are properly documented.

60. Added a paragraph at the end of sentences, 4.1.6 Stage A- internal tests as follows.

The influence of the methane number and LHV of the fuel gas on the engine's maximum continuous power available in gas mode is to be verified.

61. Added and modified 4.1.7 Stage B – witnessed tests as follows.

- all load points must be run in both gas and diesel modes that apply for the engine type as defined by the engine designer.

  The independent overspeed protection device has to be tested both in gas and diesel mode (UR M71.8.2).

- For engines with variable liquid / gas ratio, selected load tests are to be carried out at different ratios between the minimum and the maximum allowable values (most relevant and critical loads and ratios should be selected for the test).

- The maximum continuous power available in gas mode (see 3.1.1) is to be demonstrated.

- 110 % overload testing is not required in gas mode for DF engines, provided that changeover to oil fuel mode is automatically performed in case of overload.

- The load tests are to be carried out in diesel mode and in gas mode at the different percentages of the engine's MCR.

62. Added a paragraph for 4.1.7.2. Functional Tests in the middle of the sentences as follows.

For DF engines, verification of automatic changeover to diesel mode when the load demand exceeds the maximum continuous power available in gas mode (see 3.1.1 and 3.1.2)

63. 4.1.7.2 (cont): Modification of sentence as follows.

The efficiency of the ventilation arrangement or other approved principle of the double walled gas piping system is to be verified.

64. 4.1.7.2 (cont): Deletion of following sentence for feasibility and reality
~~Simulation of a gas leakage in way of a cylinder gas supply valve.~~

65. Modification of a paragraph as follows.

Failure of a ~~cylinder~~ gas admission ~~supply~~ valve

66. Added a paragraph regarding Engine type approval certificate as follows.

[4.1.9] Engine type approval certificate
For DF engines, the maximum continuous power available in gas mode should be specified on the type approval certificate in addition to the maximum continuous rating in diesel mode, if differing.

67. Modification of Factory acceptance test in 4.2.1 as follows.

For DF engines, the load tests referred to in UR M51.3.3 are to be carried out in diesel mode and in gas mode at the different percentages of the engine's MCR.

The maximum continuous power available in gas mode is to be demonstrated.

68. Modification of a paragraph in 4.2.5 as follows.

Failure of a cylinder gas admission supply valve

69. Added and modified shipboard trials in 4.3 as follow.

Shipboard trials are to be carried out in accordance with the provisions of UR M51.4, considering the additional requirements below.

For DF engines, the test loads required in UR M51.4.4 are to be carried out in all operating modes (gas mode, diesel mode, etc.), as applicable (see 3.1.1). The maximum continuous power available in gas mode is to be demonstrated.

Note:
If a test load is performed in all applicable operation modes without interruption (direct changeover at same power and speed), the duration as required in UR M51.4.4 may be considered as the total duration demonstrated in all fuel modes. However, demonstration at each mode shall not be less than one hour.

The starting maneuvers required in UR M51.4.2 are to be carried out in diesel mode and gas mode, if applicable.
For DF engines, automatic switching over to oil fuel mode is to be tested. Further, manual change over from diesel to gas mode and vice versa is to be tested.

A leak test is to be carried out for the gas piping system (IGF Code 16.7.3.3 after assembly on board.
The efficiency of the ventilation arrangement, or other approved principle, of the double walled gas piping system is to be verified.

70. Developed and added Chapter 5 Certification of Engine Components as follows.

71. Certification of Engine Components

The principals, definitions, and general requirements of UR M72 apply.

In addition to those components specified in UR M72, the engine components listed in Table 3 shall be documented as listed in the table.

TABLE 3: Required documentation for engine components

Part	Material properties	Non-destructive examination	Pressure testing	Visual inspection of welds	Component certificate
Gas pipe Low-pressure double walled	W(C+M)	W 2), 6)	W 4)	X	
Single walled Gas pipes	W(C+M)	W 1)	W 4)	X	SC
High-pressure gas pipes	W(C+M)	W 1)	W 4)	X	SC
Secondary enclosure for gas pipes	W(C+M)	W 2)	W 3)	X	
Gas pipe Low-pressure, Flanges*	W(C+M)	W 2), 6)		X	
Gas pipe High-pressure, Flanges*	W(C+M)	W 1)		X	SC
Gas pipe Low-pressure, Fittings and other components	W(C+M)		W 4)	X	
Gas pipe High-pressure, Fittings and other components	W(C+M)		W 4)	X	SC
Gas pipe Low-pressure Bodies of valves, 7)	W(C+M)		W 4)		
Gas pipe High-pressure Bodies of valves	W(C+M)		W 4)		SC
Gas venting pipes and flanges*, build up pressure less than 5.0bar	TR(C+M)	W 2)	W 4)	X	
Gas venting pipes and flanges*, build	TR(C+M)	W 2)	W 4)	X	

up pressure at 5.0bar or more with secondary enclosure					
Gas venting pipes and flanges*, build up pressure at 5.0bar or more	W(C+M)	W 1)	W 4)	X	SC
Gas venting pipes Secondary enclosure			W 5)	X	

Footnotes:

1) 100 % radiographic or ultrasonic inspection of all butt-welded joints (IGF Code 16.6.3.1)
2) 10 % radiographic or ultrasonic inspection of butt-welded joints (IGF Code 16.6.3.4)
3) Pressure test at 1.5 x design pressure to ensure gas tight integrity, not less than the expected maximum pressure at gas pipe rupture (as per IGF 16.7.3.4, and 9.8.4)
4) Pressure test at 1.5 x design pressure
5) Leak test.
6) If inside diameter > 75 mm or wall thickness > 10 mm: 100 % radiographic or ultrasonic inspection of all butt-welded joints (IGF Code 16.6.3.1)
7) If nominal diameter > 25 mm

(*) "Flanges" limited to the final connection to the engine.

5. Points of discussions or possible discussions

The main points of discussions are detailed below.

- CIMAC has reviewed the draft documents UR M78 Revision 2 with following notes;

i. 1.2.4: Explosion relief device means a device to protect personnel and components against a determined overpressure in the event of a gas explosion. The device may be a valve, a rupture disc or other, as applicable.

ii. 1.3.1 – No.4: Arrangement of explosion relief valves (crankcase1, charge air manifold, exhaust gas manifold and exhaust gas system) as applicable.

iii. 2.2.3: Charge air system and exhaust gas system on and after the engine
The charge air system and the exhaust gas system on and after the engine are to be designed in accordance with 2.1.2 above.

Two members expressed that adding personnel in paragraph 1.2.4 may not be appropriate.

A member expressed that adding the exhaust gas system in paragraph 1.3.1 may not be necessary as the exhaust gas system may fall into scope of yards.

However, manufacturers may include certain scheme in their safety concept document.

Finally the majority in MP agreed that CIMAC comments to be incorporated into draft of UR M78 Revision 2.

- SuP has reviewed draft UR M78 Revision 2 and found that majority of panel members have no comments on surveyable items.

5.1 Engine room

Engine room is a machinery space or enclosure containing gas fuelled engine(s).
The term engine room was not used in the M78, and it was agreed to delete it because the new definition might lead to confusion.

Different Opinion: However, Machinery Space, which has not been used in the current M78 but is used repeatedly in the IGC and IGF codes and is used interchangeably with this term, is actually several other machinery spaces, such as space for cargo gear or other equipment. The opinion that it could be a space that means a machine space came out at the end of the final meeting, but decision was made to delete it.

5.2 Venting pipe issue

Interim decision of PT is to keep as it is until IACS discuss with IMO and receive a waiver or unified interpretation.

5.3 maximum working pressure

Definition [1.2.10] High pressure gas means gas with a maximum working pressure greater than 10 bar gauge.
Working pressure will be decided based on scavenge pressure plus and regulated by pressure controller.
The design pressure of the pipe is determined by IGF code 9.8.2 based on maximum working pressure. Therefore, if there is no working pressure, there is no maximum operating pressure, and if so, the design pressure cannot be determined without maximum working pressure.

The maximum working pressure should take into account the safety relief valve setting and potential failure of the pressure control system, as applicable. Refer to UR P1.2.7.

This important information should be submitted and made known to those involved, but right now this information is not expressed correctly.

5.4 pre-mixed engine

[1.2.18] A pre-mixed engine is an engine in which fuel and air are mixed before combustion begins. i.e., in the cylinder, in the air intake space or through the common manifold including mixed before the turbocharger.

Previous - Pre-mixed engine means an engine where gas is supplied in a mixture with air through a common manifold for all cylinders, e.g. mixed before the turbocharger.

For the clarification of combustion principle of gas fuel, terms of pre-mixed and gas injection are necessary.

The reason is that there is an opinion that engines such as port-injection are not pre-mixed engines, but this is not true from the point of combustion theory.
Therefore, this will inform you that there are currently two opinions, and we will organize them at the next opportunity.

Because a pre-mixed combustion/engine is well defined in combustion theory to include cylinder injection, port inject and common manifold, and of course before or after turbocharger.

5.5 Documents and drawings to be submitted.

[1.3.1] Documents and drawings to be submitted for the approval of DF and GF engines.

Parts for gas admission system
The followings documents should be included- The documents to contain specification of design pressure, working pressure, pipe dimensions and materials.

5.6 Safety concept and Report of the risk assessments

As mentioned in interim report, this safety concept and risk assessment should be reviewed but these two important items are still for information document.

IGF code chapter 3 and 4, and first several sections of each chapter are related to these two issues, therefore the document should be prepared a document by engine designer and discussed with RO (responsible organization)

And understand that this safety concept definition does not make a clear connection with the goal and function requirement in chapter 3 of the IGF code, the risk assessment in the general requirements in chapter 4, and the functional requirements at the beginning of each chapter. Agree on the need for a clear redefinition. However, this issue hasn’t been agreed to deal in this PT and this issue is not prepared by PT. For to deal all the low-flash point fuel, this should be decided by machinery panel.

5.7 Pressure and pressure sensor in the crankcase

Please refer to item 47 in summary of changes above and below note 8.
Footnotes:

1) DF engine only, when running in gas mode

2) For GF engines, the double block-and-bleed valves and the engine shutdown may not be activated in case of specific failures affecting only one cylinder, provided

that the concerned cylinder can be individually shutoff and the safe operation of the engine in such conditions is demonstrated by the risk analysis.

3) Required only if necessary for the detection of misfiring

4) In the case where the failure can be corrected by an automatic mitigation action, only the alarm may be activated. If the failure persists after a given time, the safety actions are to be activated.

5) GF engine only

6) Where required by UR M10

7) Automatic safety actions to be activated as specified by the engine manufacturer, see UR M10

8) Only for trunk piston engines. This pressure sensor cannot replace or substitute a gas detector.

9) Only for trunk piston engines. For crosshead engines slow down shall apply (see UR M35 Tab.1)

Careful investigation for the related document (i.e., CIMAC Guideline 2013 July Guideline on the relevance of lubricant flash point in connection with crankcase explosions, UR M9, M10, M66 and M67) reached that ordinary pressure sensor can't replace the gas detector.

However, this pressure sensor is thought to be helpful in detecting the leakage of unburned fuel/burned gas between the piston and cylinder if this is well located, but there is a consensus that it cannot replace the gas detector and some member worried about to be used as substitute of detector.

6. Attachments if any
None

Technical Background (TB) document for UR M78 Rev.3 (Apr 2025)

1. Scope and objectives

Rev.3 of UR M78 further develops the requirements for IC engines using gases and low-flashpoint fuels in line with the Panel's Priority task for adding methanol as fuel. Furthermore, the UR also adds ethane and LPG as fuels since these have been in operation since around 2015, together with clarifying IACS' requirements for the engine safety concept.

2. Engineering background for technical basis and rationale

2.1 As a follow-up action (Safety of Internal Combustion Engines Supplied with Low Pressure Gas), the Machinery panel decided to deal with the following activities but not limited to:

- To start the development of a Revision (Rev.2) of the UR M78 on "Safety of Internal Combustion Engine Supplied with Low Pressure Gas" to extend the scope of application of the UR M78 to cover all types of engines (High pressure and low pressure, two stroke and four stroke, gas injection and pre-mixed gas type engines).
- To withdraw the UR M59 (1996) as evaluated to be no more suitable for ships to which the 2016 IGC Code applies and to review the existing requirements of the UR M59 with the view to be incorporated in the Revision 2 of UR M78.
- Propose a modification of the structure for the revised UR, for example: part with requirements applicable to all engines, part with specific requirements applicable to 2-stroke engines, part with specific requirements applicable to 4-stroke engines and part with specific requirement to different alternative fuels.
- To deal with, and possibly solve the issue raised by CIMAC regarding IGF Section 10.3.1.2 (i.e., CIMAC recommend that the term "piston in direct communication with the crankcase" is explained more detailed so that it will not lead to misinterpretations – Reference is made to PM18914_IMa dated 17/04/2018) and ensure that any work conducted by IACS is correctly focused on the issue raised.
- To consider, in the revision process, some additional comments received when the draft UR M78 (April 2018) was already agreed by the qualified majority.
- Both IGC and IGF Codes require that suitable pressure relief systems are fitted on engine components and systems (e.g. air inlet manifolds, scavenge spaces) that contain or are likely to contain ignitable gas and air mixture, unless these are designed to withstand the worst-case overpressure due to ignited gas leaks. For the protection of crankcases suitable IACS requirements are in place with URs M66 and M9, while for pressure relief systems on air inlet manifolds, scavenge spaces and exhaust gas manifolds UR M82 has been published.
- Consider the outcome of the task within the Panel (addressing the issue of gas presence in the crankcase of 4-stroke low pressure dual fuel or gas engines and crankcase ventilation) for possible introduction of the relevant text in the revised UR M78, including acceptance criteria for M78.1.4.4.i).
- Consider the outcome of the Panel's decision regarding approval procedure for explosion relief devices for air inlet and exhaust manifolds.
- Review the 110% overload test requirements.
- Current M78 refers to IGF and IGC Code in several paragraphs. The references to the Codes should be reviewed with regard to their applicability and gaps

between IGF Codes and IGC Codes including M78.2.2., including consideration of relevant fuel specific interim guidelines.
- Define scope of testing and certification of engine components (in addition to M72).
- Include acceptance criteria for hazard potential of natural gas (methane) and other fuels in crankcase (M78.1.4.4.i)
- Include requirements on crankcase ventilation, hazardous area, etc. to address the safety (flammability and toxicity) design approval aspects for safety technical documents including safety concept, and risk assessment for different fuels.
- Develop safety concept criteria to clarify scope for off-engine equipment as applicable to the engine type and fuel, e.g. exhaust system explosion relief, exhaust purging, fuel supply systems, ammonia fuel treatment systems, etc.

2.2 General

Industry experience with IC engines using gases and low-flashpoint fuels has expanded beyond the use of methane, with engines (generally dual fuel) burning ethane, LPG and methyl/ethyl alcohols entering the marine market from around 2015. Engines using hydrogen as fuel have also recently emerged and the development of ammonia engines moves ahead at an accelerated pace.

Whilst the fuel properties differ, the basic engine safety concepts and Class requirements (such as double barriers, ventilation, gas/leak detection, hazardous areas, type testing, etc.), established for the use of methane as fuel through class rules and the IGC and IGF Codes, are in many cases equally applicable to all gases or low-flashpoint fuels.

Accordingly, this revision broadens the scope and moves the UR language to a generic nature, with additional fuel specific requirements added where required.

2.3 Safety concept

The early DF engine approvals typically included a summary document clarifying the safety concepts applied by the engine designer.

With the first publication of UR M78, IACS introduced the requirement for the engine designer to include the safety concept within the list of required documentation to be submitted but did not elaborate on what was required to be included in the safety concept.

IGF Code 10.3.1.2 includes a single reference to the "safety concept of the engine", and which is to include a detailed evaluation regarding the hazard potential of fuel gas accumulation in the crankcase of trunk piston engines.

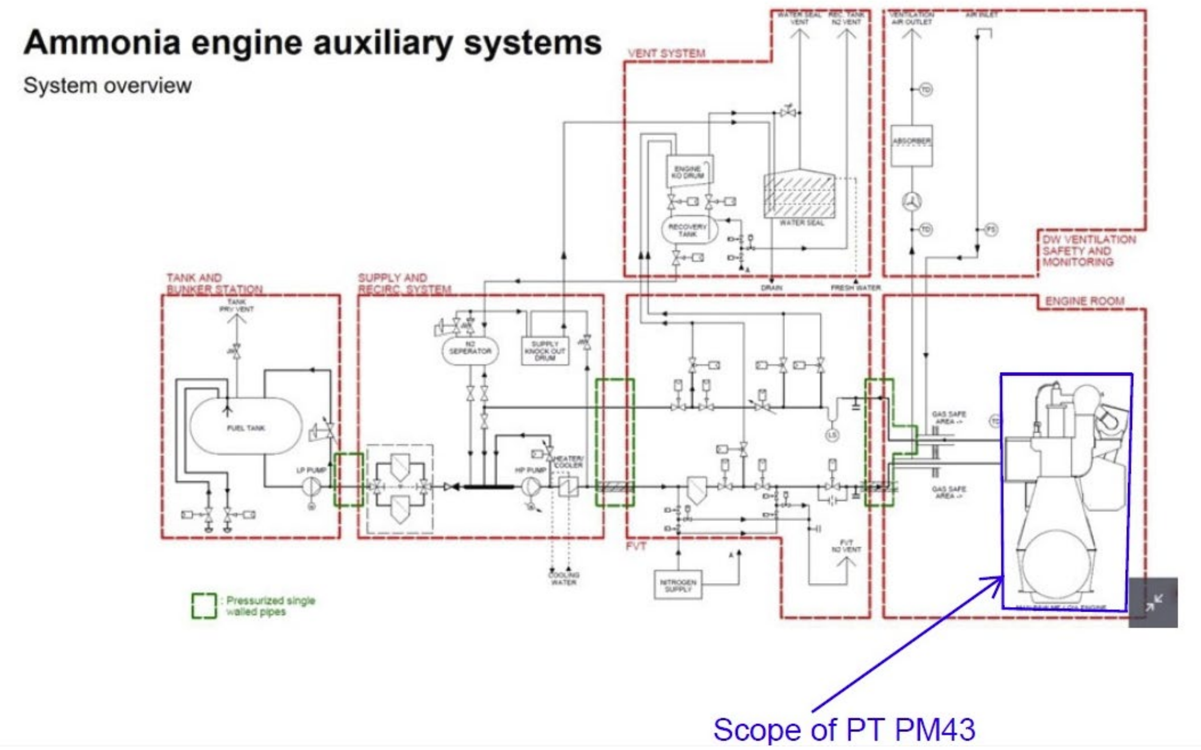
There remains a broad range of safety concept document types and content submitted by engine designers. Therefore, with this revision a new section is introduced to the UR to clarify IACS' expectations on what is to be addressed in the safety concept, and associated risk analyses.

This change supports harmonised application of IACS' requirements and common understandings on content of the engine safety concept.

2.4 Scope of UR M78

Due to the increased complexity of IC engines using gases or low-flashpoint fuels, and the formation of the new IACS Safe Decarbonisation Panel (SDP) and its focus on the new technologies and fuels being applied and considered by the marine industry, there emerged a need to clarify what is within the machinery panel responsibility, and specifically for the scope of UR M78.

Final scope of the Machinery Panel summarized with the agreed scope of UR M78 outlined below:



Source: MAN Energy Solutions

However, what may be within the scope of supply of the engine manufacturer, and what may be of major impact for the engine safety concept, is not always only limited to solely the engine itself (blue box above).

The Gas Valve Unit (GVU), Gas Valve Train (GVT), exhaust system explosion relief valves and purging requirements, and critically for the yet to be developed and approved ammonia engines, the fuel vent scrubbing systems, double wall piping absorber and ammonia levels in crankcases/under piston spaces are all critical parts of the engine designers FMEA and risk assessment and are therefore related to the type approval of the engine.

Accordingly, the scope of UR M78 has been further clarified with Machinery Panel and SDP, specifically with respect to the aforementioned safety concept, and included within Rev.3 of UR M78.

Approval of any specified off-engine equipment itself remains out of scope and subject to approval by SDP and/or Machinery Panel, as applicable.

Machinery Panel summarizes the agreed dialogue, with the approval of the engine safety concept to cover the off- and on-engine equipment, as applicable, and the following principles agreed for approval of associated UR's:

a. URs concerning the base engine, together with the scope of the safety concept beyond the base engine, should be developed by the Machinery Panel;
b. URs concerning off-engine equipment associated with alternative fuels, should be developed by the Safe Decarbonisation Panel; and
c. URs related to the use of alternative fuels are reviewed by each panel prior to approval by GPG.

2a. Specification of the data utilised in the development/revision of the proposed IACS Resolution, if any

N/A

3. Source/derivation of the proposed IACS Resolution

N/A

4. Summary of Changes intended for the revised Resolution:

4.1 Section 1- General

In-line with the agreed PT stage 2 work scope, the title of UR M78 has been revised to '*Reciprocating Internal Combustion Engines Fuelled by Gases or Low-flashpoint Fuels'*. This accommodates the extended range of fuels and aligns with the IGF Code terminology, with the exception of including 'other' to avoid the confusion that arises with the inclusion of ammonia and its often quoted 'flashpoint' of 132°C. UR M78 is intended to cover ammonia in the next revision.

The specific fuels covered by this revision of the UR have been listed and can be expanded as the further planned updates for ammonia and hydrogen are introduced with later revisions.

This Rev.3 also moves the UR language to a generic nature throughout, with additional fuel specific requirements added where required.

Consideration was given to the use of different language to 'gas' within the UR (since methanol and ethanol are liquid at ambient temperature and pressure), however in many cases the 'gas' terminology is now widely used within industry to refer to the 'alternative' (sometimes referred to as 'secondary') fuel whether that fuel is distributed in a gaseous or liquid state. This is clarified by clearly defining 'gas' with respect to application of UR M78 and introducing a definition for fuel oil, together with making editorial text changes throughout for consistency to the aligned definitions.

A number of editorial changes for consistency and clarity are also introduced throughout Rev.3.

Furthermore, a number of updates and changes to the proposed text have been applied based on industry feedback from CIMAC members.

4.2 Section 1.1.2 - Application

For clarity a new sub section title has been added titled 'Application' and with additional references added to IMO's interim guidelines MSC.1/Circ.1621 and MSC.1/Circ.1666 for methyl/ethyl alcohol and LPG fuels respectively.

The requirement to prohibit gases or low-flashpoint fuels in emergency generators has been rephrased. The understanding is that DF engines may be applied, for example as an emergency generator with auxiliary engine duties in harbour, provided that the engine is configured and operates solely in fuel oil mode for emergency generator mode.

The format of the application date given in the notes is amended in accordance with machinery panel decision to include dates for both application for type approval certification and new ship construction.

4.3 Section 1.2 - Definitions

A definition for fuel oil has been added to clarify that fuel oil is understood to be as defined by SOLAS II-2, Part B, regulation 4.2.1.1 and 4.2.1.2 for fuel oil with a flash point above 60°C and 43°C (emergency generator) respectively, where fuel oil is used for pilot fuel and fuel oil mode (sometimes called 'primary fuel' by engine OEMs) in DF engines.

The definition for 'gas' has been updated in-line with the comments in 4.1 above to clarify that for the purposes of the UR 'gas' means gaseous or liquid fuels, together with amendment of the note to provide clarification on the 'secondary' fuel.

A note has been added to the high pressure definition to allow high pressure requirements for methyl/ethyl alcohol fuels to be agreed by the Society in line with the footnotes to 7.3.6 and 7.3.12.6 of MSC.1/Circ.1621.

A definition for 'low-flashpoint fuel' has been added consistent with the IGF Code definition.

Additional text to clarify methane number definition has been added in the definition explanatory note.

Amendments have been applied to the 'pre-mixed' definition and requirements to clarify the understanding on 'pre-mixed' engines for application of UR M78. It was recognised that the UR needs to align with IACS UI GF5 and that this may need to be revisited for later revisions of the UR.

Other editorial amendments made to the definitions and moved what are effectively requirements from the safety concept definition to be given under the new safety concept section.

4.4 Section 1.3 – Documents and drawings to be submitted

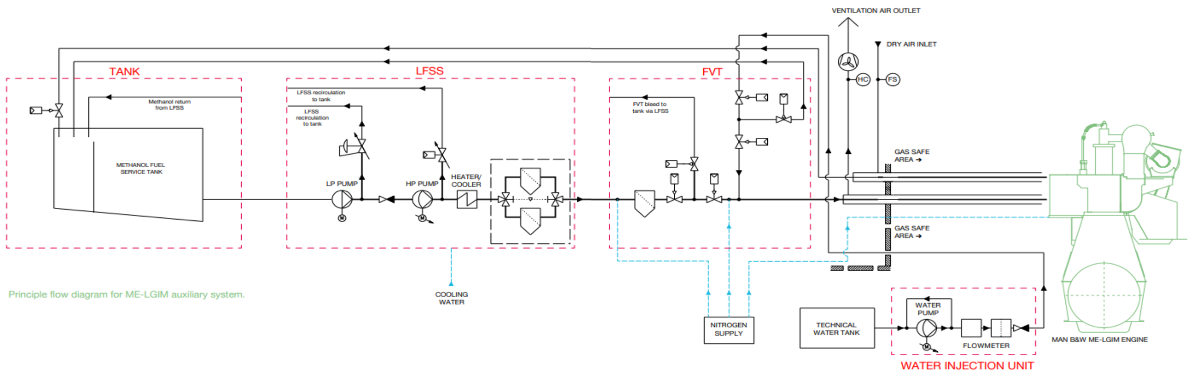
Based on industry feedback from CIMAC, the language for the required document submissions for the gas piping system and gas admission system drawings has been aligned with the format used in M44 to include “assembly and details”. Text also added to clarify that, where applicable, details of any fuel sealing systems are to be submitted.

With the expansion of the requirements that the safety concept is expected to cover with this Rev.3 of UR M78, the status of the submitted document has removed the ‘for information’ bracketed text, meaning the document is submitted for review/approval since it is crucial to the type approval of the engine.

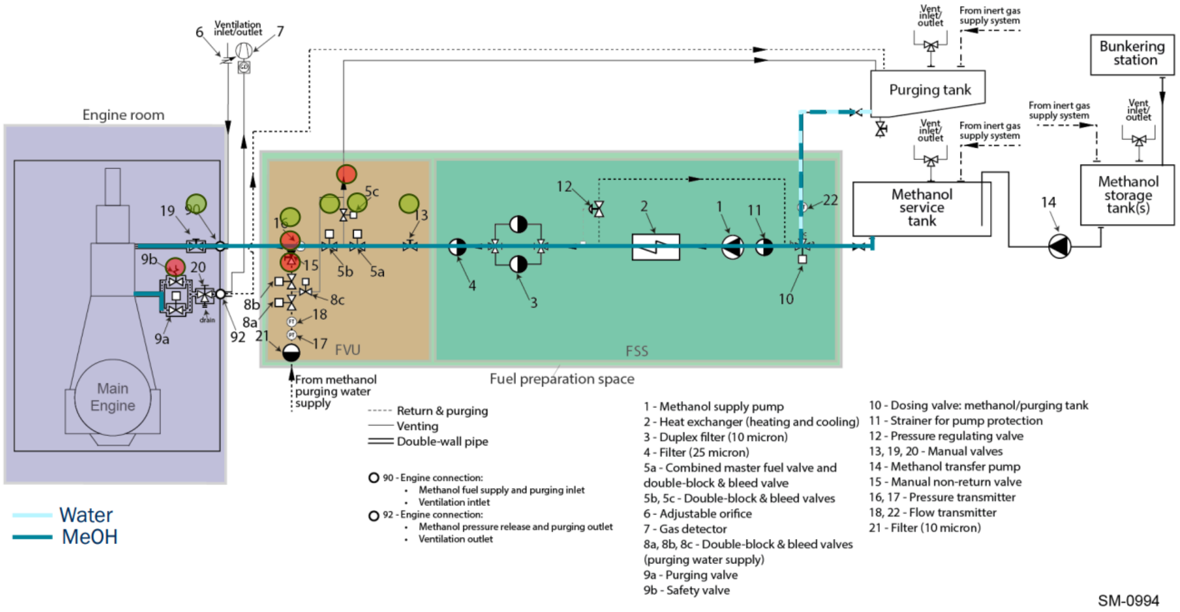
4.5 Section 1.4 Risk analysis

Updates made to clarify the applicable fuel safety valve requirements for methyl/ethyl alcohol fuel supply systems.

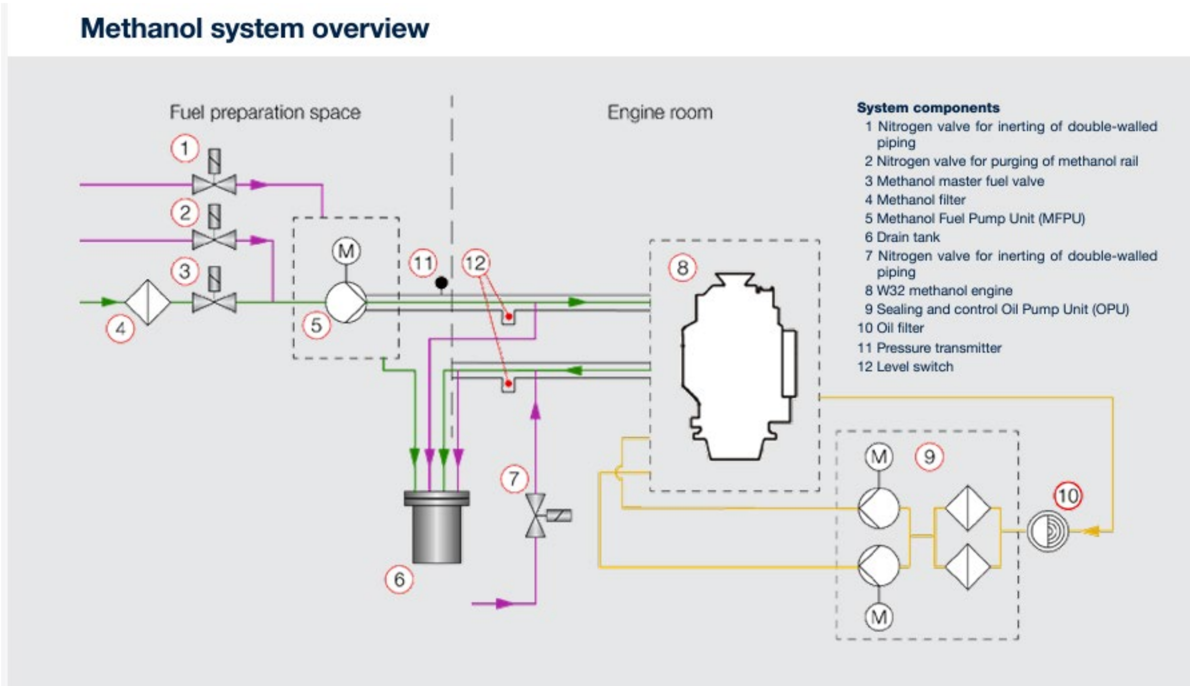
The PT discussed differences in requirements and language for DBB and MGV in the IGF Code and MSC.1/Circ.1621 for methyl/ethyl alcohol fuels. Rev.3 clarifies that functionality is to be considered by the risk analysis. The remote operated shut-off valve required by 9.6.5 of MSC.1/Circ.1621 is considered approximately equivalent to the IGF Code DBB for gas engines. The DBB and MGV functions are typically combined for methyl/ethyl alcohol applications and located outside the machinery space (engine room) containing the consumers – see MAN, WinGD and Wartsila examples below:



Source: MAN Energy Solutions



Source: WinGD



Source: Wartsila

The scope of the risk analysis is updated to include toxic releases due to the inclusion of methanol in Rev.3, and which also supports later proposed Rev.4 amendment for inclusion of ammonia. Minor updates also applied throughout Rev.3 to capture the risks of toxicity with the broadened scope of fuels.

For the purposes of risk analysis for toxicity, only methanol is specifically identified as the fuel of concern with this revision of UR M78.

4.6 Section 1.5 - Safety concept

The new safety concept section is added to clarify what is expected to be documented by the engine designer in the safety concept. This includes the non-exhaustive list that the safety concept is to describe:

- combustion control;
- operating modes;
- double barriers including ventilation air requirements;
- gas leakage detection;
- sealing systems;
- safety valve arrangements;
- fuel supply system purging and draining philosophy;
- crankcase venting arrangements;
- crankcase or piston underside space monitoring of gas accumulation;
- electrical equipment specifications including the necessity of using certified safe equipment;
- required monitoring, control and safety actions related to fuel supply systems, covering double block and bleed and master gas valve actions;
- fuel supply system specifications and engine control and safety system interaction;
- nitrogen purging and venting systems;
- fuel return/vent treatment equipment;
- off-engine exhaust system explosion relief devices;
- off-engine exhaust system fan purging; and
- auxiliary system specifications and monitoring.

This section is also updated in-line with sections 2.2 and 2.3 above and brings together the safety concept requirements identified throughout UR M78.

4.7 Section 2.1 – General principles

Minor editorial updates throughout with additional text to require the safety concept/risk analysis to consider discharges from explosion relief devices that may be toxic.

4.8 Sections 2.2.1 and 2.2.2 – Gas piping

Minor editorial updates throughout and additional references to the IMO interim guidelines for methyl/ethyl alcohol and LPG fuels included.

Application of previously agreed requirements for assigned piping classes and test pressures for the outer pipe or duct of double wall fuel piping systems was questioned during the development of Rev.3 - see 5.1 and 5.2 below – and has been amended in accordance with agreed machinery panel decision.

4.9 Section 2.2.4.2 – Inerting

Based on industry feedback from CIMAC, the requirement has been amended to require crankcase inerting provision only for crankcases with a volume that exceeds 0,6m^3.

4.10 Section 2.2.4.3 – Crankcase ventilation

Based on industry feedback from CIMAC, the requirement has been clarified to require the crankcase ventilation piping arrangements to be provided in the engine safety concept.

4.11 Section 2.2.6 – Control, monitoring, alarm and safety systems

The PT discussed the absence of ‘knocking’ terminology in the IGF Code and agreed to retain ‘misfiring’ and ‘knocking’ as examples of typical abnormal combustion operation, rather than the ‘poor combustion’ language of the IGF Code.

Additional clarification added to this section regarding the capability of engines to control transient combustion issues (such as misfiring and knocking) within the control system and to automatically activate the safety system only when the issue can no longer be corrected by the control system or if a failure has occurred.

Further clarification for continued operation in the event of a shut-off of gas mode for one cylinder has also been added.

Based on industry feedback from CIMAC, the note reference to Table 2 for DF engines has been deleted since not considered applicable and is covered by the notes to Table 2.

4.12 Table 2 – Monitoring and safety system functions for DF and GF engines

A new row has been added to the monitoring table for leak detection in the double wall (DW) piping annular space. It was recognised that the DW piping system is located on/off engine and frequently gas detection and ventilation fans are within scope of shipyard supply.

The language has been amended to capture both gas and liquid detection requirements and to refer to the applicable IGF Code, IGC Code, MSC.1/Circ.1621 and MSC.1/Circ.1666 requirements in the table footnotes.

Based on industry feedback from CIMAC, an additional footnote is added to clarify that for small engines common cylinder exhaust temperature/combustion monitoring may be applied, as permitted by 2.2.5 of UR M78 and UR M35.

4.13 Section 3.1 – DF engines

Edits applied to clarify the maximum continuous rating (MCR) and align with UR M44 terminology. Additional text also added to better clarify requirements on demonstrating the so-called ‘fuel sharing’ modes, with language edited throughout Rev.3 for consistency on the “variable liquid / variable gas ratio” terminology.

Additional text also added to clarify the principle of continued operation in ‘gas’ mode allowed in the event of loss of pilot injection on one cylinder, provided the individual cylinder is cut-off from ‘gas’ mode and the torsional vibrations are acceptable.

4.14 Section 4 Type testing, FAT and shipboard trials

It has been further clarified with Rev.3 which tests are to be carried out in both fuel oil and gas modes for DF engines. It is acceptable for DF engines to be provided with different ratings in fuel oil and gas modes. It is also acceptable for engines to (automatically) revert to fuel oil mode in the case of overload, or large transient loads are applied, or as proposed by CIMAC, the load demand leaves the gas mode operation range.

Testing at overload conditions (110%) for DF engines is not required to be demonstrated, unless the DF engines are designed to operate in overload conditions in gas mode.

Based on industry feedback from CIMAC, it has also been clarified that testing of the independent overspeed device need only be made in fuel oil mode.

Additional clarification made for allowance for testing control safety features using simulated sensor signals, i.e. simulated high temperature or pressure signals or simulating gas admission valve faults. Consideration needs to be given for specific designs, for example where simulation of gas admission faults is not possible. Based on IACS survey panel feedback, the notes have further clarified application of this to the integration testing.

Text has also been added to clarify that the category C surge margin turbocharger tests required by UR M51.3.4.2 are also to be demonstrated for gas mode, unless documented that a greater surge margin exists for gas mode than fuel oil mode.

Minor editorial and consistency amendments also applied throughout the section.

5. Points of discussions or possible discussions

Further consequential amendments to other associated URs (M3, M53, M67, M82) may be required, and will be dealt with through the usual machinery panel process.

Further to item 4.8 above, a number of items had been raised during the development of Rev.3 of the UR that required/require further consideration of IACS' panels. Specifically, these issues cover:

5.1 Fuel piping and double wall piping classes

It was noted that pipe classes according to UR P2 may give insufficient requirements for gas fuel piping in certain cases and excessive requirements in other cases, depending on application and size. In particular it was noted that classifying secondary pipe enclosures as Class II piping will effectively prohibit sleeve welding above certain pipe sizes. Therefore, some members suggested removing the references to piping classes from the UR.

Other members considered that the requirements are aligned with the IGF Code and UR P2, interpreting that this prohibits the use of slip-on welded sleeves but does permit a reduction of NDT to 10%.

Furthermore, it was suggested that specific P URs should be developed for all the alternative fuels being considered, and that may enable the requirements to be applied consistently to off-engine and on-engine piping systems.

CIMAC members also provided a number of comments to these (Rev.2) requirements, including:

- Noting that Class I was too onerous for vent piping;
- Applying a 5 bar criteria deviates from the usual LP/HP threshold; and
- The piping certification requirements are impractical for small mass produced engines.

After consideration within the Machinery Panel, it was agreed by PM18914_IMzzb to remove the references to UR P2 and piping classes.

Furthermore, it was noted that the footnotes to 7.3.6 and 7.3.12.6 of MSC.1/Circ.1621 for methyl/ethyl alcohol fuels do not define the applicability of the high pressure (10 bar) threshold to the requirements for piping stress analysis and expansion joints but defer this to the Administration. Accordingly, a footnote allowing this to be agreed with the Society and referring to the MSC.1/Circ.1621 footnotes was added to the definition of 'high pressure' to provide initial awareness. The development of further clarification, and/or an agreed high pressure threshold for methyl/ethyl alcohol or other specific fuels, will be considered further during the development of later revisions of UR M78.

5.2 Pressure testing of double wall piping systems

Following feedback from industry on the 1.5 x pressure test requirement for the double wall piping or duct, the PT proposed amendments to 2.2.2.1 and footnote 3) of table 3 which enables a reduced test pressure to be applied calculated in accordance with 9.8.1 or 9.8.2 of the IGF Code for ventilated open ended double wall piping systems.

For pressurized double wall piping systems, the test pressure remains at 1.5 x design pressure.

Machinery panel member experience on application of Rev.2 and the pressure test requirements was also sought and the proposed amendments agreed for Rev.3.

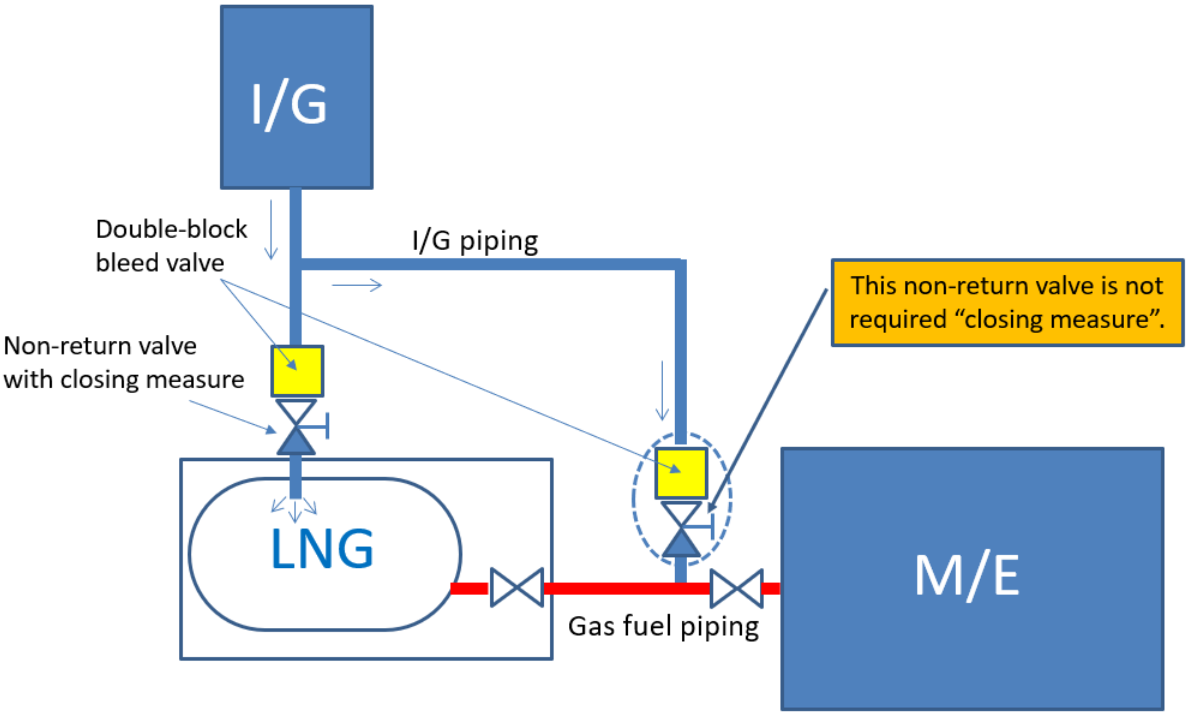
5.3 Inert gas connections to fuel supply lines

It was noted that differing understandings exist on the requirements for the safety function requirements for inert gas connections to fuel supply systems, specifically engine fuel supply line connections, which may be located on-engine and off-engine.

This issue had previously been considered by Machinery Panel decision, for application of 6.13.2 of the IGF Code for fuel containment systems and with respect to the requirements for the non-return valve, closable functionality, DBB and location of valves.

The Machinery Panel concluded at that time to close the task with the understanding as represented by the following diagram:

IGF Code 6.13.2



The PT discussed further and agreed that the IGF Code 6.13.2 requirement is applicable to inert gas supplies for fuel containment systems only and should not be interpreted as applicable to inert gas connections to engines, or other consumers such as boilers or gas turbines.

Accordingly, the PT concluded this item should be raised again for further discussion in the Machinery Panel to avoid confusion on the differences between application for inert gas systems for fuel containment and inert gas systems for consumers such as engines. The PT noted that this question is applicable to additional consumers (outside scope of UR M78) and to both on-engine and off-engine piping connections. Therefore, this item will be taken up for further consideration within the Machinery Panel.

UR M79 "Towing winch emergency release Systems"

Summary

This UR defines minimum safety standards for winch emergency release systems provided on towing winches that are used in the handling of ships within close quarters, ports or terminals.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev.1 (Feb 2020)	24 February 2020	1 July 2021
New (Oct 2018)	29 October 2018	1 January 2020

- **Rev.1 (Feb 2020)**

.1 Origin of Change:

☑ Suggestion by IACS Machinery Panel Member and Survey Panel

.2 Main Reason for Change:

The UR M79 (New, Oct 2018) has been revised in order to solve some requests for clarification raised by some winch manufacturers and shipyards via one member of the Machinery Panel and to solve an issue raised by the Survey Panel.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

The UR M79 (Rev. 1) has been developed by correspondence and agreed at the 30th Machinery Panel Meeting (17 to 20 September 2019).

GPG decided to modify para 1.1, adding "*including those ships normally not intended for towing operation in transverse direction.*" at the end of the existing text, to provide clarification on the applicability of the UR.

GPG also decided to modify the existing text defining the term "girting", such that the modified text states the purpose of the UR instead of defining the term "girting". The modified text was shifted under a new section "*2. Purpose*" as new paragraph 2.1. Existing paragraphs coming after new para 2.1 were renumbered.

.5 Other Resolutions Changes

None

6 Any hinderance to MASS, including any other new technologies:

None

.7 Dates:

Original Proposal:	15 April 2019 (Ref: PM19919_NKa)
Panel Approval:	19/11/2019 (Ref: PM19919_IMe)
GPG Approval:	24 February 2020 (Ref: 19235_IGh)

- **New (Oct 2018)**

.1 Origin of Change:

☑ Other (Questions from industry)

.2 Main Reason for Change:

MAIB Report No. 17/2008 into the loss of the tug, Flying Phantom, concluded that the emergency release of tension on the towing winch failed to prevent the tug being girted by the pull from the assisted vessel. It was also apparent that the winch had probably not payed out any towing line at all. They also observe that although the rules for tugs laid down by several Classification Societies specify a tow line emergency release system, there are varying requirements, and the towing winch is not generally regarded as equipment that should be the subject of Class surveys.

Examples of Classification Society requirements for emergency release systems include: 'able to operate at any angle of heel', or, the emergency release mechanism must be 'reliable'. There is no clear standard which specifies a time within which the emergency brake release must operate, or under what loading conditions, heel angles etc. Application of a recognized standard, in combination with a testing regime, would provide for a fully functional emergency release system when a girting event occurs.

.3 List of non-IACS Member classification societies contributing through the TC Forum and/or participating in IACS Working Group:

None

.4 History of Decisions Made:

Form A originally submitted to GPG on 4th April 2013 to complete task as a PT.
Lack of experienced individuals available to form a PT led to redrafting of Form A for work to be completed via correspondence, new Form A submitted to GPG on 7th February 2014. Form A approved by GPG on 7th August 2014.

.5 Other Resolutions Changes

None

.6 Dates:

Original Proposal:	13 July 2011 (Ref: PM11909_IMa)
Panel Approval:	22 June 2018 (Ref: PM11909_IMzi)
GPG Approval:	29 October 2018 (Ref: 11098_IGs)

Part B. Technical Background

Technical Background (TB) document for UR M79 (New Oct 2018)

1. Scope and objectives

The scope of the work item was to inform the Machinery Panel of the recommendation in MAIB Investigation Report 17/2008 to develop a UR regarding tug towing arrangement emergency release systems and to gauge member's opinions on the need for such development.

Having determined that members agreed with the need to progress, the main objective was to develop appropriate requirements and their associated rationale. As per the MAIB recommendation, the requirements have been proposed for the performance and operational requirements for a towline emergency release system taking into account the forces under which the system needs to operate and the speed of operation necessary to maintain the safety of the tug.

It was recognised that modern towing arrangement designs may mean that an emergency release is not necessary, the scope of the UR includes provision for these arrangements where it can be demonstrated that the stability of the vessel will not be jeopardised if the maximum design load is applied to the winch.

2. Engineering background for technical basis and rationale

The focus of this UR is the towing arrangement 'emergency release' system. This term has been selected based upon review of the following resources:

a) MAIB Investigation Report 17/2008
b) Consultation with industry bodies, and
c) Existing International standards.

Alternative references to 'quick release' or 'full release' were considered but from discussions with industry bodies, it is understood that a 'quick release' has a different function to an 'emergency release', where a quick release is a quick but controlled means of relieving tension that may be used frequently during normal operations. However, an emergency release is explicitly a safety function, letting go tension and starting to pay the line out within a designated time, and mandatorily functional under the dead ship condition. It is interesting to note that the paper DE 56/22/4 submitted by Norway refers to a 'quick emergency release'. Further, ISO 7365:2012 'Shipbuilding and marine structures — Deck machinery — Towing winches for deep sea use' refers to an 'Emergency Release'.

The requirements were developed primarily in response to MAIB Report No. 17/2008 into the loss of the tug, Flying Phantom, under an expectation by affected stakeholders that quick action would be taken to improve safety in such scenarios. Consequently, the primary area of focus was close quarters tug operations. It is also noted that MSC/Circ.884 – 'Guidelines for Safe Ocean Towing' refers to an emergency release so it was considered unnecessary to extend the scope of this UR to include other towage operations and winch types.

3.1 Performance requirements

As is alluded to in the MAIB report, speed of operation of the emergency release is a critical factor in respect of the requirements and the release time period was debated during development. Operation within a maximum of one second was considered because some modern winches are capable of this. However, feedback from industry bodies suggested that for other winches, especially those with more complex control arrangements, even two seconds may not be achievable. Consequently, in alignment with the proposals in DE 56/22/4, the limit was set to three seconds. It is noted that the time limit specified in ISO 7365 is 10s but this is for ocean towing tugs where the time available to react to a situation may be longer.

It is further noted that the document SSE5/10 containing in Annex 2 the IMO draft "Guidelines for Onboard Lifting Appliances and Anchor Handling Winches" states 3 seconds in 4.1.7.1 for anchor handling winches ("Within 3 seconds after activation of emergency release, the holding force caused by winch drive/brake-system should be reduced to equal maximum 20% of the BP of the vessel……"). The above is stated for ready reference only, as the UR does not apply to anchor handling winches.

It may be argued that these times are driven by the capabilities of the system rather than the need of the situation. However, it is considered difficult to derive a time limit based directly on the stability criterion of the tug because of the wide variance of tug and winch designs and the lack of information about the time taken for girting and the critical factors that affect that time.

Requirements are included to ensure that a residual load is applied to the winch drum once the brake is released to ensure that the drum doesn't freewheel and rotate faster than the line is being pulled from it, resulting in the line being wrapped back around the drum and jamming the system.

A minimum load for drum rotation is also set to ensure that the system will be able to operate and rotate the drum when not fully loaded. Two approaches are provided:

- The prescriptive approach provides for the value for the minimum load to be set at the lesser of 5 tonnes or 5% of the maximum design load with two layers of towline on the drum. This has been set following discussion with industry bodies. 10% was suggested by one party as the figure typically used but in discussions with tug owners, 5 tonnes is considered appropriate for larger tugs whilst 5% would account for smaller 'workboat' tugs.

- The alternative approach allows for a larger minimum load for rotation of 15% of the maximum design load, provided that this is less than 25% of the load that would result in listing sufficient for the immersion of the lowest unprotected opening. This is intended to provide a factor of safety to allow for friction and other losses in the system that may prevent the full load from the tow being exerted on the winch.

All emergency release systems are to be operable under dead ship conditions; consequently an alternative source of energy (e.g. a hydraulic accumulator) is required. The sizing of this accumulator is to be sufficient to allow three apply-release cycles. Where multiple winches are fitted on a tug it is permitted that they may share the alternative source of power on condition that only one winch is in operation at a time. In this case the alternative source of energy is to be sized according to the winch with the largest demand.

Where the drum release mechanism requires continuous application of power, a requirement is included in the UR for the alternative source of energy to be sufficient to hold the brake open for a minimum of five minutes. This is intended to allow time for the tug to release tension and manoeuvre sufficiently to take up a safe position and resume towage if possible. It is not intended for this requirement to be combined with the three operations requirement resulting in 15 minutes of holding capacity.

3.2 Operational requirements

The activation buttons are to be located on all working positions but the requirement permitting the bridge activation location is to ensure that an emergency release can be reset without need for a crewmember to access the working deck where the winch is operating.

A requirement has been included for prioritisation of the emergency release function over all other emergency stop functions on the tug. This to ensure that the emergency release will operate no matter what other emergency functions have been activated.

Hardwired control systems are preferred over electronic systems for the activation of the emergency release because this is a safety critical system, specifically required to work in a dead ship condition. Hardwired control systems are typically more reliable and generally more appropriate to operate on emergency (battery) power.

Provision is made for electronically controlled systems where they comply with the requirements of UR E22.

The requirement for the manufacturer to identify safety critical components of the winch emergency release system has been added to ensure that periodic survey of the equipment is focussed on the critical aspects – these may vary between different winch designs so it was considered inappropriate to include a prescriptive list of items in the UR.

Section 4 – Test requirements

In considering the design of towing winches and their emergency release arrangements it was recognised that the release mechanism needs to be capable of operating at loads up to the maximum design load and this needs to be verified.

A requirement has therefore been included to this effect. It is intended that verification would initially be undertaken by the winch design authority/manufacturer through testing to the extent that it is reasonably practicable. In this, it is recognised that there may be circumstances where testing of the complete winch system to achieve this may not be possible (e.g. due to health and safety requirements). Consequently, an allowance has been made that in such circumstances, a combination of methods may be used to verify that the winch emergency release is capable of operating at 100% of the maximum design load, (possibly by separate testing of certain components of the release system or through testing to validate a model).

It is noted that ISO 7365 allows for verification of the holding load based on theoretical calculation. It was considered inappropriate to provide for a more specific set of acceptance criteria due to the wide range of variables previously discussed.

For reference regarding alternative means of verification, please see the definitions below taken from the INCOSE systems engineering handbook:
Inspection: an examination of the item against applicable documentation to confirm compliance with requirements. Inspection is used to verify properties best determined by examination and observation (e.g., - paint colour, weight, etc.).

Analysis: use of analytical data or simulations under defined conditions to show theoretical compliance. Used where testing to realistic conditions cannot be achieved or is not cost-effective. Analysis (including simulation) may be used when such means establish that the appropriate requirement, specification, or derived requirement is met by the proposed solution.

Demonstration: a qualitative exhibition of functional performance, usually accomplished with no or minimal instrumentation. Demonstration (a set of test activities with system stimuli selected by the system developer) may be used to show that system or subsystem response to stimuli is suitable,. Demonstration may be appropriate when requirements or specifications are given in statistical terms (e.g., mean time to repair, average power consumption, etc.).

Test: an action by which the operability, supportability, or performance capability of an item is verified when subjected to controlled conditions that are real or simulated. These verifications often use special test equipment or instrumentation to obtain very accurate quantitative data for analysis.

3. Source / derivation of the proposed IACS Resolution

- Existing IACS members Rules
- Industry body codes of practise
- IS Code

4. Summary of Changes intended for the revised Resolution

None

5. Points of discussions or possible discussions

It was noted by one member that the use of the term ‘emergency release’ as opposed to ‘quick release’ could cause confusion as most towing winches have only one release mechanism. Although the distinction between "(operational) quick release" and "emergency (quick) release" can be understood theoretically, its practical value is questionable. In this respect it was considered that referenced IS Code requirement (Ch 2, para 2.4.3.4) for providing means for quick release (with proposed amendment by SDC 3) actually refers to "emergency (quick) release" within the context of the UR (the objective of the IS Code is safety and this is how it was perceived by the SDC working group). Once the update to the IS Code is complete it may be prudent to reference the incorporated SDC 3 amendments.

The methods of verification for the performance requirements were discussed, with potential for load testing OR a combination of load testing and other analysis added at the request of one member.

This UR was developed specifically for tugs (and towing winches) used for close quarters towing operations. In recognising that the vessel types, winch types and modes of operation (e.g. towing line lengths) used for ocean towage are usually different to those for close quarters work, it is suggested that further expansion on existing requirements for ocean towing either in the UR or another document could be proposed as follow-on work.

Consideration was given to cases where the tug/towing arrangement was such that girting was not possible, in such a case it may be possible to relax the emergency release arrangements. However for this to be done further discussion would be necessary if prescriptive criteria were to be included in the requirements. In light of the wide range of ship design and winch types and configurations, and the scenarios under which they might be used, the development of criteria to address all possible scenarios would involve significantly greater investigation and further development work.

The link between maintenance and efficiency of the equipment and the operation of the emergency release was discussed, initially requirements were included that required that the towing arrangement was maintained to ensure that as much of the towline force as possible was transferred to the winch. This was initially included following findings from the Flying Phantom incident which indicated that the excess friction added to the system where the towline was led around a sharp radius of a bow shackle attached to the gog line may have substantially reduced the load applied to the winch. This may have inhibited the operation of the emergency release, preventing the towline from being paid out sufficiently quickly to stop the tug from girting. However it was decided that this was an operational issue that is outside the remit of Class so was removed from the UR.

Technical Background (TB) document for UR M79 (Rev 1, Feb 2020)

1. Scope and objectives

To revise the UR M79 (New, Oct 2018) in order to solve some requests for clarification raised by some winch manufacturers and shipyards via one member of the Machinery Panel and to solve an issue raised by the Survey Panel.

2. Engineering background for technical basis and rationale

The Machinery Panel decided to revise the UR M79 (New, Oct 2018) after consideration of the following questions raised by some winch manufacturers and shipyards:

Question 1
Regarding paragraphs 3.1.4 and 3.1.6 (dead-ship condition requirement) of UR M79, it was found necessary to confirm whether the towline force can also be utilized to "allow the winch drum to rotate" as specified in paragraph 3.1.4.

In this regard it was confirmed that the existing phrase in the 1st sentence of paragraph 3.1.4 "The emergency release system is to allow the winch drum to rotate and the towline to pay out" is sufficient to be read that the towline force can also be utilized to "allow the winch drum to rotate" and therefore no amendment was considered necessary to improve clarity.

Question 2
Regarding the scope of application of dead-ship condition requirement (i.e. the definition of "Emergency release system", and paragraphs 3.1.6 and 3.1.7), it was found necessary to confirm whether ships not necessary to have capability as mentioned in SOLAS regulation II-1/26.4 (i.e. non-SOLAS ships) need do comply with these paragraphs.

In this regard it was confirmed that the requirements concerned apply also to non-SOLAS ships but the wording "dead-ship" was found inappropriate and therefore changed to "blackout" in paragraphs 3.1.6 and 3.1.7 as well as in the definition of emergency release system.

Question 3
Regarding the scope of application of UR M79 (i.e. paragraph 1.1) it was found necessary to confirm whether the requirements of UR M79 would need to be applied to ships designed not to carry out operation involving transverse towage and an IACS Member proposed to add the following sentence at the end of the paragraph:

"including those ships normally not intended for towing operation in transverse direction."

At the 30th Machinery Panel meeting (17 to 20 September 2019), Members confirmed that the ships concerned (normally not intended for towing operation in transverse direction) also need to comply with the requirements of UR M79 taking into account that risks of transverse towing of such ships in an abnormal condition cannot be eliminated.
The text proposed above was therefore not included in paragraph 1.1.

In addition to the above, it was pointed out by the Survey Panel that:

1) regarding paragraph 3.2.10 of the UR M79 (New), there are no indication/requirements about the responsibilities for the preparation and the review/acceptance (or approval) of the procedure required in this paragraph; in the Survey Panel's opinion, these issues need to be clarified, and this paragraph could be considered to be absorbed into paragraph 4.1.3.

   In this regard it was decided to move the existing paragraph 3.2.10 to section 4 as new paragraph 4.1.4 and to modify the requirement in order to specify that the Manufacturer need to document instructions for surveys of the emergency release system to be agreed by the Society and made available on board the ship on which the winch has been installed.

2) regarding paragraph 3.2.11 of the UR M79 (New), the Survey Panel recommended to move this paragraph into section 4 and to update the wording to include also 'Special Survey'.

3. Source / derivation of the proposed IACS Resolution

/

4. Summary of Changes intended for the revised Resolution

The following modifications have been introduced:

1) the wording "dead-ship" was modified to read "blackout" in paragraphs 3.1.6 and 3.1.7 as well as in the definition of emergency release system.

2) the text of paragraph 3.1.6 has been amended as follows to improve clarity:

   "3.1.6 ~~An alternative source of energy is to be provided such that normal operation of the emergency release system can be sustained under dead-ship conditions.~~ <u>Emergency release of the towline is to be possible in the event of a blackout. For this purpose, where additional sources of energy are required, such sources are to comply with 3.1.7.</u>"

3) the existing paragraph 3.2.10 has been moved to section 4 as new paragraph 4.1.4 reading as follow:

   <u>"4.1.4 Instructions for surveys of the emergency release system are to be documented by the manufacturer, agreed by the Society and made available on board the ship on which the winch has been installed."</u>

   In a similar manner, an indication "by the manufacturer" is added in paragraph 4.1.3 with also some minor editorial changes.

4) the existing paragraph 3.2.11 has been moved to section 4 as new paragraph 4.1.5 reading as follow:

“4.1.5 Where necessary for conducting the annual and special surveys of the winch, adequately sized strong points are to be provided on deck.”

During the revision process the following additional modifications have been agreed:

- Paragraph 3.2.1 was amended to reflect the Panel’s agreement that a position in close proximity to the winch should not be regarded as “safe location”, unless it is documented that the position is at least protected against towline break or winch failure; the amended text read as follow:

  “3.2.1 Emergency release operation must be possible from the bridge and from the winch control station on deck. The winch control station on deck is to be in a safe location. A position in close proximity to the winch is not regarded as “safe location”, unless it is documented that the position is at least protected against towline break or winch failure.”

- Paragraph 3.2.2 was amended to reflect the Panel’s agreement that installation of an emergency stop button for winch operation is not mandatory; the amended text read as follow:

  “3.2.2 The emergency release control is to be located ~~in~~ close ~~proximity~~ to ~~the~~ an emergency stop button for winch operation, if provided, and ~~both should~~ shall be clearly identifiable, clearly visible, easily accessible and positioned to allow safe operability.”

◄▲►

Technical Background (TB) document for UR M80 (New, May 2019)

1. Scope and objectives

The objective is the development of requirements for the AC Generating sets (i.e. prime movers, alternators and couplings) in addition to those required in UR M51, UR M3, UR E13 and UR M53.

2. Engineering background for technical basis and rationale

Following an external query associated with the transient voltage response limitation (when applying the two load steps to maximum power loading), it was recognised that there were neither specific IACS requirements for testing an Engine and an Alternator together nor which included the coupling, where installed.

After discussion and based on a qualified majority, it was concluded that new requirements for AC generating sets were to be developed covering torsional vibration, coupling selection criteria, power requirement, rating plate for generator sets and testing requirements associated with engine and alternator.

3. Source / derivation of the proposed IACS Resolution

- External query raised through IACS member.
- ISO 8528-1:2018 "Reciprocating internal combustion engine driven alternating current generating sets -- Part 1: Application, ratings and performance"
- ISO 8528-5:2018 "Reciprocating internal combustion engine driven alternating current generating sets -- Part 5: Generating sets"

4. Summary of Changes intended for the revised Resolution:

New requirements for AC generating sets have been developed to cover torsional vibration, coupling selection criteria, power requirement, rating plate for generator sets and testing requirements associated with engine and alternator; it was finally decided that these fit better in a new UR addressing AC generating sets than in a revised UR M3.

5. Points of discussions or possible discussions

The requirements for AC generating sets have been developed based on the international standards ISO 8528-1:2018 and ISO 8528-5:2018. During the discussion, the following items have been further considered.

1. Coupling
   - Members had different opinion for consideration issues for coupling selection. Several members had concerned the requirement in the clause 15.9 of ISO 8528-5:2018 is too heavy. In this reason, the provision has been developed by the vote.

2. Cyclic irregularity
   - The cyclic irregularity had been dropped by decision of qualified majority and replaced by frequency cyclic variations with the criterion according to IEC 60092-101:2018. Due to the lack of test method, however, the majority have agreed to delete a relevant provision for frequency cyclic variation.

3. Rating plate

- One member had proposed and been accepted that the generating sets which is the rated power with the prefix ESP as defined in ISO 8528-1:2018 shall be restricted to use on board. Because it means that the generating sets has a limited continuous power and no overload possibility.
- One member had proposed not to apply the performance class which is required in ISO 8528-5:2018 taken into account the consistency for requirements of the published UR E5 and E13. The required performance class in ISO 8528-5:2018 is stricter than the published resolution which had developed based on IEC standards. And the proposal have been accepted by the majority.
- One member had proposed to only require the rated power without the prefixes at rating plate. The proposal has not been accepted by the majority.

4. Coupling selection (paragraph 2.2 of the UR):

A) During the discussion regarding the coupling selection for the generating set it emerged that the selection shall take into account the stresses and torques imposed on it by the torsional vibration of the system which is influenced by but not limited to the following:
   a) operation up to Reciprocating Internal Combustion (RIC) engine fuel stop power as defined in ISO 15550:2016, paragraph 3.3.6;
   b) the inertia of the RIC engine and alternator;
   c) the short-circuit torque;
   d) misalignment;
   e) RIC engine misfiring, as defined in UR M53.2.2.2

   After consideration of this paragraph the qualified majority decided not to include in the UR the items listed from a) to e) (including the sentences in square brackets which were proposed by a Member).

B) One Member proposed to require the submission for approval to Class Societies of the torsional vibration calculations when the engine power is 110 kW or above. After discussion, the qualified majority of Panel Members agreed with the proposal.

C) One Member noted that a threshold for submission of torsional vibration calculations may be against the requirements in UR M53.2.2.2; alignment of UR M53 will be considered separately.

UR M81 "Safety measures against chemical treatment fluids used for exhaust gas cleaning systems and the residues which have hazardous properties"

Summary

The subject UR provides minimum technical requirements for exhaust gas cleaning systems using chemical treatment fluids and the residues which have hazardous properties.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
Rev.1 (July 2023)	28 July 2023	1 July 2024
New (Jan 2021)	21 January 2021	1 July 2022

- ### Rev.1 (June 2023)

1 Origin of Change:

☑ Suggestion by IACS member

2 Main Reason for Change:

Following recent reports of corrosion incidents in the EGCS discharge lines of washwater, particularly in distance pieces, IACS decided to amend UR M81 to add requirements for such discharge lines.

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None.

4 History of Decisions Made:

The revised UR was developed and agreed by correspondence within the panel.

5 Other Resolutions Changes:

None.

6 Any hinderance to MASS, including any other new technologies:

None.

7 Dates:

Original Proposal	: 1 February 2021	(Made by: Machinery Panel)
Panel Approval	: 20 June 2023	(Ref: PM20306aIMi)
GPG Approval	: 28 July 2023	(Ref: 18158aIGc)

- **New (Jan 2021)**

1 Origin of Change:

☑ Suggestion by IACS member

2 Main Reason for Change:

None.

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None.

4 History of Decisions Made:

According to an IACS member, there is a trend to fit on board an increasing number of exhaust gas cleaning systems (EGCS) to ensure compliance with the 2020 global sulphur cap, due to operators' concern on quality and/or cost of low-sulphur (0.5% m/m) fuel oil. Also, taking into account of it, the necessity of developing new UR for EGCS was proposed based on IACS UR M77 for SCR systems.

As a result of the discussion, the above proposal was unanimously agreed.

5 Other Resolutions Changes:

None.

6 Any hinderance to MASS, including any other new technologies:

None.

7 Dates:

Original Proposal:	15 December 2017	(Ref: PM17909_IMa)
Panel Approval:	10 December 2020	(Ref: PM17909_IMv)
GPG Approval:	21 January 2021	(Ref: 18158_IGb)

****

Part B. Technical Background

List of Technical Background (TB) documents for UR M81:

Annex 1. **TB for New (Jan 2021)**

See separate TB document in Annex 1.

Annex 2. **TB for Rev.1 (July 2023)**

See separate TB document in Annex 2.

Technical Background (TB) document for UR M81 (New Jan 2021)

1. Scope and objectives

The objective of this task is to develop requirements for storage and use of chemical treatment fluid such as the aqueous solution of sodium hydroxide (NaOH) or calcium hydroxide (Ca(OH)2) in exhaust gas cleaning systems (EGCS) in order to mitigate the hazards to personnel brought by the use of such systems.

2. Engineering background for technical basis and rationale

In IACS UR M77, the requirements for storage and use of reductants (such as Marine NOx reduction agent) in selective catalytic converters were developed. In recent years, the number of projects to fit EGCS on ship for compliance with the 2020 global sulphur CAP was increasing. In the EGCS, chemical treatment fluids such as the aqueous solutions of sodium hydroxide (NaOH) or calcium hydroxide (Ca(OH)2) were used rather than urea solutions. For this reason, taking into account of the characteristic of the EGCS, the need for a new UR regarding such chemical treatment fluids used in EGCS was recognized.

The chemical treatment fluids are considered to have hazardous property and be typically carried on board in bulk quantities like urea. So, the requirements in this UR were based on UR M77. On the other hand, further discussion was held and, as a result, additional requirements were specified as follows:

Kind of chemical treatment fluids:

In this UR "chemical treatment fluids" means the aqueous solutions of NaOH and Ca(OH)2 which are widely used in EGCS. Other aqueous solutions such as magnesium hydroxide (Mg(OH)2) were not considered common for marine use, so it was only specified that, if such fluids are used in EGCS, safety measures are to be taken according to the result of a risk assessment.

Temperature alarms for storage tanks:

In cases where heating and/or cooling system is provided depending on the operational area, high and/or low temperature alarm is required to prevent the fluid temperature from becoming too high or low. In addition, it is considered that the temperature monitoring can obtain the equivalent or more information as the high/low temperature alarms, so the temperature monitoring was specified together.

Strength of the storage tanks:

It is considered that the storage tanks are to have sufficient strength against a pressure of the fluids and the density of the aqueous solution is larger than that of water. Therefore, considering the cases of water/oil tanks' strength, the above pressure is to be corresponding to the maximum height of a fluid column in the overflow pipe, with an additional height to the top plate taking into consideration the specific density of the treatment fluid. The height of 2.5m above the top plate for the pressure test, proposed by a Member that opined this height was based upon the industry practice for testing independent fuel oil tanks, was changed to 2.4m, taking into account Hull Panel's comments.

Ventilation requirements for the compartment in which the storage tank is not installed:

Even a compartment doesn’t contain the storage tank, the ventilation requirements are to be applied to such spaces in cases where there are any possible leak points (e.g. manhole, fitting).

Prevention of the spread of any spillage from piping and connections:
Considering the hazardous properties of the chemical treatment fluids, it is specified that the piping systems are to comply with the requirements applicable to Class 1 piping systems and be joined by welding, and that detachable connection are to be screened and fitted with drip trays.

Tanks for residues:

The residues generated from the exhaust gas cleaning process is considered to be stored in a dedicated tank but it isn’t considered dangerous to be stored in the over flow tanks for chemical treatment fluids storage tank. For the capacity of such tanks it is to be decided in consideration of the number and kinds of installed exhaust gas cleaning systems as well as the maximum number of days between ports where residue can be discharged ashore referring to other requirements of MARPOL.

3. Source/derivation of the proposed IACS Resolution

IACS UR M77

4. Summary of Changes intended for the revised Resolution:

None

5. Points of discussions or possible discussions

Drip trays:

The aqueous solution of NaOH does not smell and appears/behaves like water, containment of leaks is thus vital for the safety of the crew, so closed drip trays (e.g. splash proof cabinets with integrated spill tray) are considered to be required for detachable connections of piping system containing the fluid. On the other hand, it is considered that an open drip tray is also acceptable provided that a screen is properly arranged and the spray is guided to the drip tray without scattering around.

Minimum sets of personnel protective equipment:

Although 3 sets is considered to be a safer number (in case one person using one set needs to be evacuated by two persons), the number of sets is based on ship’s operation and owner’s decisions. So, the minimum required number was specified as 2 sets.

Requirements for washwater:

Keeping in mind the recent damages on discharge piping of washwater, requirements for such piping should be further considered.

EGCS effluent line specified in UR P4:

UR P4(Rev.5) provides fire endurance requirements of plastic pipes used for EGCS effluent line. On the other hand, it was agreed that said line is not considered "chemical treatment fluid piping system" mentioned in this UR Mxx. Therefore, fire endurance requirements of plastic pipes used for "chemical treatment fluid piping system" should be further considered.

Requirements of IBC Code:

Chapter 17 of IBC Code as amended by IMO Resolution MSC.460(101) provides minimum requirements for ships carrying sodium hydroxide solution and calcium hydroxide slurry. Considering the toxicity of such chemicals, it should be further considered if said requirements are to be applied to storage tanks of chemical treatment fluid, especially requirements of tank vents, gauging, vapour detection, and specific and operational requirement (column g, j, k, and o).

Requirements for materials of pipes/piping systems

During the latest rounds of discussion, the requirement below was considered. The texts of the *underlined* two sets of square brackets were not accepted for the Original version of this UR, but this requirement should be reviewed during discussion of an amendment to UR M77 paragraph 2.9 in order to avoid leaving the requirement below outdated.

> 2.10 Storage tanks and pipes/piping systems for chemical treatment fluids [which transfer undiluted chemical treatment fluids] are to be of steel[or other equivalent]*[,]* material with a melting point above 925 degrees C*[, or other equivalent material acceptable to the Classification Society]*.

6. Attachments if any

None

Technical Background (TB) document for UR M81 (Rev.1 July 2023)

1. Scope and objectives

The scope is the revision of the UR M81 (New, Jan 2021) to develop the requirements for discharge lines.

2. Engineering background for technical basis and rationale

The EGCS discharge line is known to be affected by corrosion, and several cases of corrosion incidents have been reported to the member society. In particular, corrosion of the overboard distance pieces installed on the hull shell plating leads to flooding of the engine room, which has necessitated the establishment of requirements for the thickness and materials of such distance pieces.
First, the distance piece must be made of steel, not plastic (GRE, etc.). Since bare carbon steel is affected by corrosion, it was decided to require protection such as sleeves and coatings. Moreover, even if such protection is provided, it is recognized that the thickness of the pipe needs to be increased in case corrosion occurs, and some members have already implemented the requirement to use pipes with minimum thickness of 15 mm or pipes of sch.160 (the largest thickness of piping standards) in their class rules and, then, it is understood that this has become an accepted minimum limit in the industry. Similarly, for distance pieces made entirely of corrosion-resistant steel instead of sleeves and coatings, a minimum thickness of 12 mm is accepted.
In other words, if there is no pipe in the piping standards that have the minimum thickness of 12 mm/15 mm, it is necessary to use the tube with the maximum thickness.
Alternatively, to use the pipe of Sch.160.

2a. Specification of the data utilised in the development/revision of the proposed IACS Resolution, if any

None

3. Source/derivation of the proposed IACS Resolution

None

4. Summary of Changes intended for the revised Resolution:

M81.2.3: The closed compartment where a storage tank for chemical treatment fluids is installed shall have an independent ventilation system. This requirement has been amended to simplify.

M81.2.4: Among the requirements of M81.2.3, the requirements that should be applied in this clause are clarified. In addition, Wording is revised with reference to UR M77.2.4.

M81.3: The requirements for discharge lines are newly added.

5. Points of discussions or possible discussions

Warning Notice:

There was an opinion that the warning notice, requiring the use of such ventilation before entering the compartment, is not necessary for the engine room since the engine room is a well-ventilated space.

Relevant industry standards:

IACS is aware that there is a activity to establish standards for EGCS discharge line in an industry associations. After the publication of this standard, this UR may also be reviewed.

6. Attachments if any

Annex 1. **TB for New (Mar 2023)**

See separate TB document in Annex 1.

Technical Background (TB) document for UR M82 (New Mar 2023)

1. Scope and objectives

To specify type testing procedure for explosion relief devices (ERDs) for combustion air inlet manifold and exhaust gas manifold of internal combustion engines using gas as fuel.

2. Engineering background for technical basis and rationale

A failure or malfunction of any system or component involved in the gas operation of the engine may lead to a gas accumulation and a possible explosion in the combustion air inlet and exhaust gas manifold. M78.2.1.2 specify design requirements in this respect: Components containing or likely to contain gas are to be designed to mitigate the consequences of a possible explosion to a level providing a tolerable degree of residual risk, due to the strength of the component(s) or the fitting of suitable pressure relief devices of an approved type. The type testing procedure for the ERD is given by this UR. Suitability is assessed in terms of function and mechanical integrity of the ERD as well as the function of the flame arrestor.

The arrangement of the ERDs on the engines (required relief area, type, number and positions of the ERDs) based on the risk analysis required in M78.1.4 is part of the engine's approval and not subject of this UR.

3. Source/derivation of the proposed IACS Resolution

IACS UR M78 (July 2018), Safety of Internal Combustion Engines Supplied with Low Pressure Gas

IACS UR M66 (Jan 2008), Type Testing Procedure for Crankcase Explosion Relief Valves

4. Summary of Changes intended for the revised Resolution:

None

5. Points of discussions or possible discussions

ERD – explosion relief device

<u>1 Scope</u>
The general phrase "combustion air" covers all common phrases for 2- and 4-stroke engines, like scavenge air or charge air.

It was decided that extending the scope of this UR Mxx to ERDs installed downstream of the turbocharger would be considered after amendment of the UR78.

2 Definitions

This UR is a testing procedure for any kind of ERDs. No design requirements are specified. Functional requirements are:

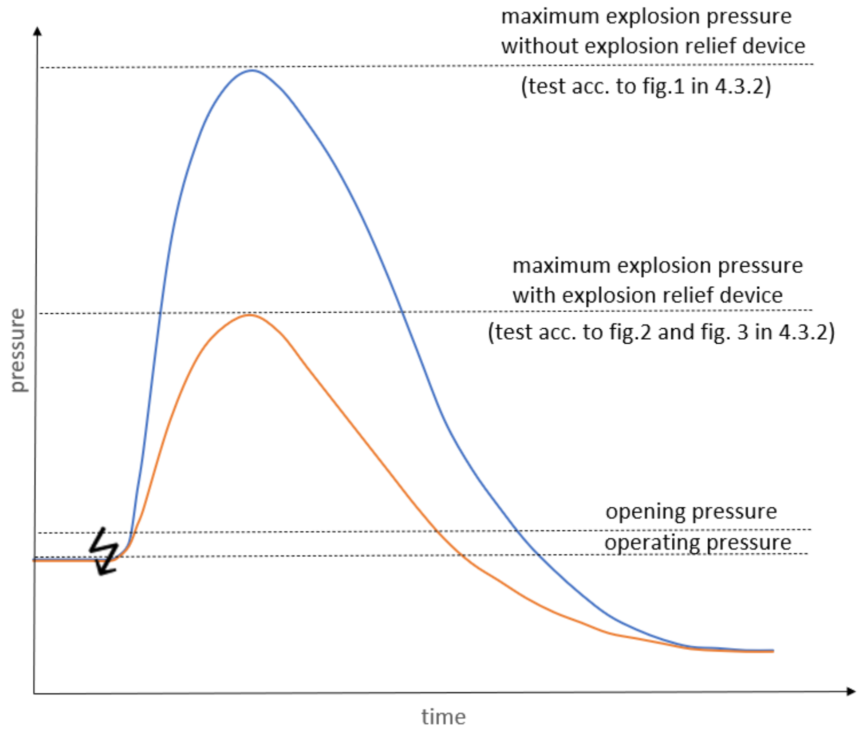
- pressure relief against a determined overpressure
- flame less pressure relief

Furthermore, the following topics are not subject of this UR:

- the arrangement and number of the ERDs on the engine
- used kind of the ERD (valve or rupture disc) for single or multi engine plants

3 Documents

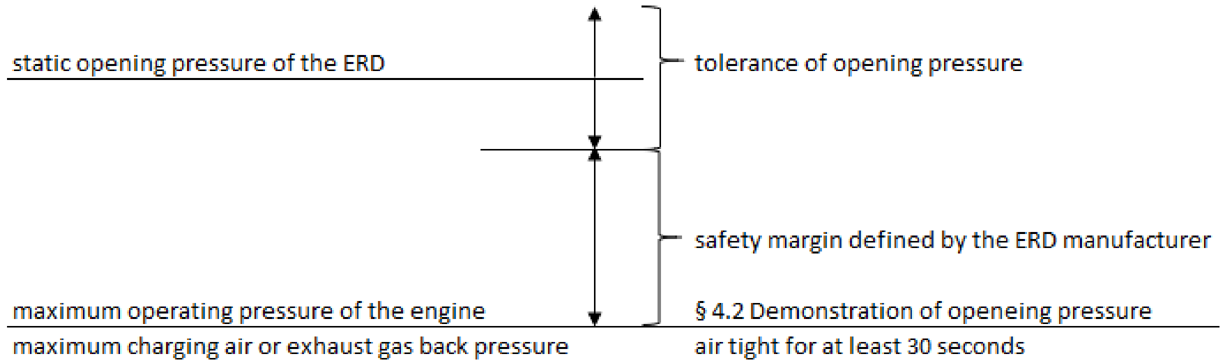
Definition of pressures



The "maximum explosion pressure with explosion relief device" is usually designated as "reduced maximum pressure ($p_{max\ red}$). "Reduced" means compared with the explosion pressure without explosion relief device

4.2 Demonstration of opening pressure

Definition of pressures



4.3.2 Test vessel
Pipe shape: The definition of the pipe shape, L/D ≥ 10 is in accordance with EN14994.

Relief area: A ratio between the relief area of the ERD and the test vessel volume is needed for realistic test conditions and comparison of different tests. The ratio of 700 cm^2/m^3 is in accordance with API 618, Reciprocating Compressors for Petroleum, Chemical, and Gas Industry Services. It is to be noted, this value is not a requirement for the arrangement and number of ERDs on the engine. This is basically different to the crankcase explosion relief valves with 155 cm^2/m^3 are given for testing in M66 and arrangement in M9.

Simulation of turbocharger: The air inlet and exhaust gas manifolds are not closed vessels. A rupture disc shall represent all openings, e.g. turbocharger and by-pass. This is a simplified model to simulate the leakage from the openings and the consequent reduction of the internal pressure of the manifolds, by rupturing the rupture disc during explosion tests (i.e. reference and ERD tests).

6. Assessment
The maximum explosion pressure of the ERD is to be observed at the arrangment calculation (numbers and locations of ERDs at the engine) later on.

UR M83 "Testing of the Control System of Controllable Pitch Propellers intended for Main Propulsion"

Summary

This UR provides requirements for the testing of the control system of controllable pitch propellers intended for main propulsion.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
NEW (October 2023)	30 October 2023	01 January 2025

- **New (October 2023)**

1 Origin of Change:

☑ Suggestion by IACS member further to questions raised by industry on UR M25 (Rev.4)

2 Main Reason for Change:

During the development of draft UR M25 Rev.4, it was pointed out that UR M25 scope was "Astern power for main propulsion" and did not refer to CPP. Accordingly, it was decided to develop a specific UR to cover the testing of CPP control systems.

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None.

4 History of Decisions Made:

The decision to issue this new UR was taken by the Panel in October 2020.

5 Other Resolutions Changes:

None.

6 Any hinderance to MASS, including any other new technologies:

None.

7 Dates:

Original Proposal	: October 2020	(Made by the MP member:PM18103a)
Panel Approval	: October 2023	(Ref: PM18103aIMk)
GPG Approval	: 30 October 2023	(Ref: 19026aIGb)

****

Part B. Technical Background

List of Technical Background (TB) documents for UR M83:

Annex 1. **TB for New (October 2023)**

See separate TB document in Annex 1.

Technical Background (TB) document for UR M83 (New October 2023)

1. Scope and objectives

To specify the requirements for the testing of the control system of controllable pitch propellers intended for main propulsion.

2. Engineering background for technical basis and rationale

The technical background for this UR has been derived from the engineering knowledge gained by members on CPP control systems.

2a. Specification of the data utilised in the development/revision of the proposed IACS Resolution, if any

None.

3. Source/derivation of the proposed IACS Resolution

- UR M25 (Rev.4): Astern power for main propulsion
- UR Z18 (Rev.9): Survey of Machinery, § 4 (Machinery Verification Runs)

4. Summary of Changes intended for the revised Resolution:

None (new version).

5. Points of discussions or possible discussions

Some members were of the opinion that the UR should cover astern orders only. During the ensuing discussion, it was reminded that the origin of task PM18103a was the failure of CPP control system of cargo ship Saffier, for which MAIB Report recommended "*to […] introduce a unified requirement for controllable pitch propeller systems to be subjected to a full range of tests in both ahead and astern directions during commissioning trials of new and existing systems*". It was finally agreed that the UR should cover both astern and ahead orders.

One member argued that it was not necessary to carry out the tests from all control positions as there are no differences in the power or functions of the propulsion system even if the control changes. This was found acceptable by the Panel, and it was decided to reflect it by introducing the following text in the UR:
"*Tests that are no affected by the control position may be carried out from one control position only.*"

One member suggested that a test of the fail-to-safe characteristics of the propeller pitch control system should be carried out to demonstrate that failures in the pitch command or feedback signals are alarmed and do not cause any change of thrust. This was agreed upon by the Panel.

As regards the “emergency operating conditions” referred to in with respect to paragraph § 3.1 of the UR, it should be noted that the emergency control from the bridge is not required, but may be arranged in addition to, and independent of, the normal control by the propulsion remote control system. However, the emergency operating condition test to be carried out at “local emergency control station” and from bridge emergency control when additionally arranged.

One member raised comments about the clarification of method and purpose for the recording of parameter “propelling thrust variation” in Para.3 on the basis of existing text with no criteria and no test procedure related to “Significantly altered” in Para.4. In addition, same member raised a view about the "Tests are to be demonstrated that the propelling thrust is not significantly altered when transferring control from one location to another one." in Para.4 that the significant alteration should be acceptable when transferring the control location from remote location (e.g. navigation bridge) to engine room with respect to prioritizing the safety of the ship over the safety of the engine considering emergency situations (e.g. risk of collision or running aground) when such transferring.

Draft UR document reviewed by SuP with a comment from one of their member as;
“The surveyor may accept the test plan to be implemented under the condition of no propeller-running-test considering the scope of modification or extent of repair/re-adjustment of a control system for existing ships”.
Accordingly, MP members confirmed and agreed to adopt and reflect the SuP member comment on cluse 3.3 of UR.

6. Attachments if any

None.

UR M84 "Capacity and availability of compressed air for essential services"

Summary

This UR provides requirements for the capacity and availability of compressed air required by systems, machinery and equipment providing essential services. The UR was considered necessary in order to ensure that sufficient compressed air capacity, in addition to the required starting air capacity, is ensured at all times where compressed air is essential for normal operation of the propulsion system.

Part A. Revision History

Version no.	Approval date	Implementation date when applicable
New (February 2024)	22 February 2024	01 July 2025

- **New (February 2024)**

1 Origin of Change:

☑ Suggestion by IACS member

2 Main Reason for Change:

None.

3 List of non-IACS Member classification societies contributing or participating in IACS Working Group:

None.

4 History of Decisions Made:

New work item was proposed during the 37th Machinery Panel meeting and subsequently agreed as a new task by Machinery Panel members. Form A submitted to GPG on 16 June 2023 and subsequently approved. The final draft was sent to GPG on December 2023 together with the HF and TB and the Human Element Checklist.

5 Other Resolutions Changes:

UR M61.1.5 (to be considered)

6 Any hinderance to MASS, including any other new technologies:

None.

7 Dates:

Original Proposal	: 20 March 2023	(Made by: PM23200_IMa)
Panel Approval	: 04 December 2023	(Ref: PM23200_IMi)
GPG Approval	: 22 February 2024	(Ref: 23100_IGe)

Part B. Technical Background

List of Technical Background (TB) documents for UR M84:

Annex 1. **TB for New (February 2024)**

See separate TB document in Annex 1.

Technical Background (TB) document for UR M84 (New)

1. Scope and objectives

The need for a new UR is considered necessary in order to ensure that sufficient LP air capacity, in addition to the required starting air capacity, is ensured at all times where LP air is essential for normal operation of the propulsion system.

2. Engineering background for technical basis and rationale

Service feedback indicates that the onboard demand for LP compressed air has increased significantly in recent years, primarily due to the demand from SCR systems when fitted to engines but also, for certain dual fuel engine types, the demand from ventilation of the annular spaces of double wall piping for gas fuel lines.

Feedback has identified arrangements in which the increased LP air demand is supplied via single dedicated LP compressor (albeit with back-up connection to starting air reservoir) for which the maximum capacity of the LP air compressor is only marginally greater than the total LP air demand in normal operation.

Such arrangements mean that the LP compressor operates with a very high duty cycle (perhaps even continuously) and in the event of failure or during routine maintenance requires the LP air demand to be supplied by the starting air system in order to maintain propulsion. The starting air system may or may not be sized for the continuous supply of LP air in such circumstances.

2a. Specification of the data utilised in the development/revision of the proposed IACS Resolution, if any

None.

3. Source/derivation of the proposed IACS Resolution

Derivation of the UR is based on practical knowledge of IACS members and service feedback.

4. Summary of Changes intended for the revised Resolution:

None.

5. Points of discussions or possible discussions

Comment that clarification is needed with regards to ’low-pressure service air’ and the ‘sufficiency/capacity’ requirement. Comment that although ‘low-pressure service air ‘has been revised to ‘low-pressure compressed air’ this revision is insufficient as a clarification and that the scope of UR cannot be clarified without a definition such as ‘less than 10 bar’ or ‘air system other than engine’. Comment that an alternative way is to focus on the purpose of compressed air such as compressed air for control or safety system if a definition of low-pressure cannot be provided.

In response to the comments, it was proposed to delete all references to 'low-pressure' and refer only to 'compressed air' and, as a result, to update the applicability statement in section 1 to clarify that the capacity and availability requirements in section 2 do not apply to compressed air for engine starting.

Comment regarding how to confirm and determine 'sufficient capacity'. Comment that clarification of 'sufficient' is necessary because without specific requirements such as UR M61.1.5, it is impossible to determine whether a ship meets this UR at the time of inspection.

In response to the comments, the word 'sufficient' in the UR clearly indicates that the low pressure compressed air demand for essential services onboard needs to be established and thereafter, the installed capacity needs to be capable of satisfying the demand. As such the compressed air capacity depends upon the overall demand from the individual items of equipment requiring compressed air for operation. Therefore, the demand, and therefore the capacity required to satisfy the demand, can only be determined by the ship designer/shipyard. It is therefore suggested that the ship designer/shipyard submits evidence to demonstrate that the compressed air capacity is sufficient to satisfy the compressed air demand under the conditions mentioned in 2.1 of the requirements of the draft UR.

Comment that the panel could not reach a consensus to define the essential service at the previous meeting (in relation to normal operation of the ship and safe operation of the ship as discussed under task PM23401) and therefore specific uses of compressed air should be identified instead of the expression 'essential services'. Comment that confirmation whether "essential service consumer" includes SCR operation, ventilation of double wall piping for gas fuel lines, etc.

In response to the comments, 'essential service consumers' was changed to read 'essential services' and essential services are considered to be fully addressed by UI SC134. It was intended that the 'essential services' are the same services 'essential for propulsion and steering, and safety of the ship' as currently interpreted by UI SC134. It is acknowledged that the scope of UI SC134 may change in future depending upon the outcome of the discussions within the panel for task PM 23401 however, currently, 'essential services' are as given in UI SC134.

Comment that the task was raised to address the low pressure air supply to SCR system and dual fuel engine although 'essential services' are mentioned in the UR and as such will include a fan or blower as well as a compressor, even though the fan or blower is generally not regarded as discharging compressed air. Comment that the UR may not be effective in addressing the air supply to SCR until the task considering the amendment of essential services (PM23401) is completed.

In response to the comments, the scope of the UR would not include fans or blowers since they are not generally regarded as discharging compressed air as stated and also as stated, at this point in time, the UR will be effective in ensuring the capacity and availability of compressed air for services essential for safety but not for normal operation.

Comment that it is allowed either to fit single LP air compressor continuously supplied from starting air system or to equip redundant LP air compressors with periodical supply from starting air system during maintenance or in the failure of dedicated LP air system and it is unlikely that Shipbuilders go with the latter case and therefore questions the effectiveness of a new UR. Comment regarding clarification of when redundant arrangements are required.

In response to the comments, the UR does not intend to prescribe how redundancy is to be achieved allowing the designer flexibility e.g. the redundancy may be provided by additional air compressors, air receivers or cross connection to the engine starting air system. The wording proposed in the draft UR is deliberately 'goal based' and therefore allows the yard to propose different arrangements to meet the goal e.g. the installation of a single compressor with cross connection to the starting air system would be acceptable or the installation of redundant compressors with or without cross connection to the starting air system would be acceptable.

Comment that 'main' should be deleted from 'main engine starting air system' and UR M61.1.5 should be updated to reference the UR. Comment suggesting that air quality is addressed in the UR.

In response to comments, 'main deleted'. Consideration to given to setting up a new task or tasks to update UR M61.1.5 and to address compressed air quality following publication of the UR.

UR M85 "Type approval testing of synthetic materials for aftmost propeller shaft bearings"

Summary

A new UR is developed to specify the technical requirements for type approval of synthetic materials for aftmost propeller shaft bearings.

Part A. Revision History

None.

5 History of Decisions Made:

1. The UR outlines the requirements for type approval testing of synthetic materials used in aftmost propeller shaft bearings. It does not, however, cover the design and operational requirements for these bearings, which are the responsibility of the manufacturer to provide and guarantee.

2. The wear testing procedure for synthetic materials used in aftmost propeller shaft bearings is specified in accordance with DNV CP-0081_2021.

6 Other Resolutions Changes:

UR M52.

7 Any hinderance to MASS, including any other new technologies:

None.

8 Dates:

Original Proposal:	(Date: July 2020)	Made by: (PM20101_IMa)
Panel Approval:	(Date: 21 Oct 2024)	Made by: (PM20101_IMzd)
GPG Approval:	(Date: 05 Nov 2024)	Made by: (24007_IGi)

Part B. Technical Background

Annex 1. **TB for NEW (November 2024)**

See separate TB document in Annex 1.

Technical Background (TB) document for UR M85 (New Nov 2024)

1. Scope and objectives

This UR gives a description of the procedures and requirements related to documentation, testing and certification of synthetic materials for aftmost propeller shaft bearings.

2. Engineering background for technical basis and rationale

In recent years, in addition to the wood bearings and white metal bearings, synthetic materials have been used to aftmost propeller shaft bearings.
Some classification societies have their own guidelines for materials used for propeller shaft bearings and several synthetic materials are already used for aftmost propeller shaft bearings in ships.

IACS recognized that it is necessary to develop the unified requirements (UR) on the synthetic materials for aftmost propeller shaft bearings.

The UR describes the minimum requirements for documentation, testing and certification of synthetic materials for aftmost propeller shaft bearings, based on the existing guidelines of some classification society specifications and industrial product data.

2a. Specification of the data utilised in the development/revision of the proposed IACS Resolution, if any

None

3. Source/derivation of the proposed IACS Resolution

ISO 604: 2002
ASTM D695- 2015
ISO 175: 2010
ISO 37: 2017
ISO 48-4: 2018
ISO 1817: 2022
ASTM D1141
ISO 813: 2019
ISO 7743: 2017
CCS Guideline No. A-03(202204) "Polymer Bearing Materials"
DNV CP-0081_2021 "Synthetic bearing bushing materials"
LR "Rules for the Manufacture testing and Certification of Materials"

4. Summary of Changes intended for the revised Resolution:

Not applicable – new document

5. Points of discussions or possible discussions

During the development the main discussion points were

- The UR specifies the requirements for type approval testing of synthetic materials used in aftmost propeller shaft bearings. However, the design and application requirements for these bearings are to be provided and guaranteed by the manufacturer.

- There are many types of synthetic materials such as, but not limited to, fiber-reinforced phenolic resins, nylon, polyurethane, and rubber. Tables 1 and table 2 give the test requirements for different types of materials, respectively. A description of elastomeric materials and examples of elastomeric materials and non-elastomeric materials are given. The type of product (elastomeric or non-elastomeric type) is proposed by the manufacturer.

- Some members of the Panel confirm that minimum 0.6 MPa criterion could be applicable to bearings with length less than the required, as referred in 2.1 of UR M52.

- Draft of the UR has been reviewed by Survey Panel and confirmed that majority of Survey Panel members have no comments.

- Specimen number and test loading direction are specified with reference to ISO 604: 2002 and ASTM D695- 2015 and different acceptance criteria are given for different test loading directions.

- The wear test in this UR was prepared with reference to the DNV CP-0081_2021 “Synthetic bearing bushing materials”, including mating material, diameter of shaft, motion of shaft, circumferential velocity, lubrication, surface roughness, interface pressure, duration of test, etc. The wear test in DNV CP-0081_2021 was based on ASTM G77, so the body of this UR is written with reference to DNV CP-0081_2021 and states that unless otherwise specified in this UR, the requirements for the wear test should refer to ASTM G77-17 or other national equivalent standards.

- No clear acceptance criteria of wear test were found in recognized standards and Rules of individual Classification Society. Currently a unified acceptance criteria of wear rate cannot be provided. Consider the possibility of giving an acceptance criteria of wear rate after more data have been collected and analyzed.

- Material of the shaft used in the wear test should be equivalent to typical mating material e.g. alloyed steel or stainless steel or copper alloy to obtain bearing material test results as close as technically possible to real operational conditions of the propulsion shafting with shaft bearing made of synthetic material.

- The draft UR was subjected to the industry hearing, and after discussion within the Panel, the responses to the industry's main comments are as follows,

    a) One manufacturer commented that the definitions of elastomeric and non-elastomeric type are unclear, and the definitions of both types should be clarified with specific examples. However, Panel members believed that the term “elastomeric or non-elastomeric type” is sufficiently clear. Elastomeric materials are a type of polymer that exhibits elastic behavior, meaning they can return to their original shape after being stretched or deformed. For example, rubber is one of the typical elastomeric materials. Fiber reinforced phenolic resin composite is one of the typical non-elastomeric materials.

b) One manufacturer commented that since stern tube bearings are molded products, safety data sheet (SDS) may not be required. Panel members prefer to keep SDS requirement.

c) One manufacturer considered that it is unnecessary to test with minimum and maximum clearance, since the bearing clearance of the wear testing will change during the test, the test should be started with a bearing clearance based on the bearing design. The panel member's understanding is that the running clearance is an important operating parameter of the shaft + bearing assembly as it influences the lubrication pattern. Accordingly, it should be considered.

d) One manufacturer commented that the circumferential velocity should not be predetermined for wear test. Panel member's understanding is that the circumferential speed is an important parameter influencing the lubrication and wear of the bearing. Accordingly, the requirement for the circumferential velocity in wear test should be kept.
